User Guide

AWS Systems Manager

AWS Systems Manager: User Guide

Table of Contents

What is AWS Systems Manager?

AWS Systems Manager helps you centrally view, manage, and operate nodes at scale in AWS, on-premises, and multicloud environments. With the launch of a unified console experience, Systems Manager consolidates various tools to help you complete common node tasks across AWS accounts and AWS Regions.

To use Systems Manager, nodes must be managed, which means SSM Agent is installed on the machine and the agent can communicate with the Systems Manager service. To help you identify why nodes aren't reporting as *managed*, Systems Manager offers a one-click agent issue diagnosis and remediation runbook that you can configure to run automatically according to a schedule you define. This feature helps identify why nodes can't connect to Systems Manager, including networking misconfigurations. This feature also provides recommended runbooks for remediating networking issues and other problems preventing nodes from being configured as managed nodes.

The unified console experience also includes a dashboard that provides a high-level overview of your nodes. You can drill down for more specific node insights such as which nodes are running outdated operating system (OS) software. You can also use filters for granular views based on instance metadata like OSs and OS versions, AWS Regions, AWS accounts, and SSM Agent versions. These filters help you retrieve relevant information at a specific account level or application level across your entire organization.

Topics

How can Systems Manager benefit my operations?

Benefits of Systems Manager include the following:

- **Enhance visibility across your entire infrastructure**

  Systems Manager provides a centralized view of nodes across your organization's accounts and Regions. Quickly access instance information such as ID, name, OS details, and installed agents. Use Amazon Q Developer to query instance metadata using natural language, helping you identify issues and take action faster.

- **Boost operational efficiency with automation**

  Automate common operational tasks and reduce time and effort required to maintain your systems. Systems Manager provides safe and secure remote management of your nodes at scale without logging into your servers. You no longer need to use bastion hosts, SSH, or remote PowerShell. Systems Manager also provides a simple way of automating common administrative tasks across groups of nodes such as registry edits, user management, and software and patch installations.

- **Simplify node management at scale in any environment**

  Systems Manager helps you manage nodes across AWS, on-premises, and multicloud environments. Schedule automated diagnoses to identify SSM Agent issues and remediate them with one-click runbooks. After your nodes are configured as *managed* nodes, you can execute critical operational tasks such as applying security patches, initiating logged sessions, and running commands remotely.

Who should use Systems Manager?

Systems Manager is used by IT operations managers and operators, DevOps engineers, security and compliance managers, and IT directors and CIOs. Broadly speaking, Systems Manager is appropriate for the following:

- Organizations that want to improve the management and security of their nodes at scale.
- Organizations that want to increase visibility and operational agility when managing their infrastructure.
- Organizations that want to increase operational efficiency at scale.

What are the main features of Systems Manager?

The primary features of Systems Manager are shared between the unified console and the individual tools Systems Manager provides to help you manage nodes at scale.

Unified console

The unified console provides a centralized experience to view and manage your nodes. This console leverages several Systems Manager tools and more to provide you with the following:

- Centralized views of your nodes
- Detailed node insights
- Automated diagnosis and remediation of common node issues

For more information about the unified console, see What is the unified console?.

Tools

Tools consist of the individual capabilities of Systems Manager and their features such as Run Command, Session Manager, Automation, and Parameter Store. With Systems Manager tools you can do the following:

- Just-in-time access node access
- Patch nodes at scale
- Securely connect to nodes without opening inbound ports
- Run commands remotely on nodes
- Securely store data referenced by applications
- Automate common systems administration tasks

For more information about Systems Manager tools, see Using AWS Systems Manager tools.

Supported AWS Regions

For a list of AWS Regions that support Systems Manager tools, see Systems Manager service endpoints in the *Amazon Web Services General Reference*.

The unified Systems Manager console, released on November 21, 2024, is available in the following AWS Regions:

- US East (N. Virginia) Region
- US East (Ohio) Region
- US West (N. California) Region
- US West (Oregon) Region
- Canada (Central) Region
- South America (São Paulo) Region
- Asia Pacific (Mumbai) Region
- Asia Pacific (Tokyo) Region
- Asia Pacific (Seoul) Region
- Asia Pacific (Singapore) Region
- Asia Pacific (Sydney) Region
- Europe (Frankfurt) Region
- Europe (Stockholm) Region
- Europe (Ireland) Region
- Europe (London) Region
- Europe (Paris) Region

Accessing Systems Manager

You can work with Systems Manager in any of the following ways:

Systems Manager console

The Systems Manager console is a browser-based interface to access and use Systems Manager.

AWS IoT Greengrass V2 console

You can view and manage edge devices that are configured for AWS IoT Greengrass in the Greengrass console.

AWS command line tools

By using the AWS command line tools, you can issue commands at your system's command line to perform Systems Manager and other AWS tasks. The tools are supported on Linux, macOS, and Windows. Using the AWS Command Line Interface (AWS CLI) can be faster and

more convenient than using the console. The command line tools also are useful if you want to build scripts that perform AWS tasks.

AWS provides two sets of command line tools: the AWS Command Line Interface and the AWS Tools for Windows PowerShell. For information about installing and using the AWS CLI, see the AWS Command Line Interface User Guide. For information about installing and using the Tools for Windows PowerShell, see the AWS Tools for PowerShell User Guide.

> **Note**
>
> On your Windows Server instances, Windows PowerShell 3.0 or later is required to run certain SSM documents (for example, the legacy `AWS-ApplyPatchBaseline` document). Verify that your Windows Server instances are running Windows Management Framework 3.0 or later. The framework includes Windows PowerShell.

AWS SDKs

AWS provides software development kits (SDKs) that consist of libraries and sample code for various programming languages and platforms (for example, Java, Python, Ruby, .NET, iOS and Android, and others). The SDKs provide a convenient way to grant programmatic access to Systems Manager. For information about the AWS SDKs, including how to download and install them, see Tools for Amazon Web Services.

Systems Manager service name history

AWS Systems Manager (Systems Manager) was formerly known as "Amazon Simple Systems Manager (SSM)" and "Amazon EC2 Systems Manager (SSM)". The original abbreviated name of the service, "SSM", is still reflected in various AWS resources, including a few other service consoles. Some examples:

- **Systems Manager Agent**: SSM Agent
- **Systems Manager parameters**: SSM parameters
- **Systems Manager service endpoints**: `ssm.region.amazonaws.com`
- **AWS CloudFormation resource types**: `AWS::SSM::Document`
- **AWS Config rule identifier**: `EC2_INSTANCE_MANAGED_BY_SSM`
- **AWS Command Line Interface (AWS CLI) commands**: `aws ssm describe-patch-baselines`

- **AWS Identity and Access Management (IAM) managed policy names**: `AmazonSSMReadOnlyAccess`
- **Systems Manager resource ARNs**: `arn:aws:ssm:region:account-id:patchbaseline/pb-07d8884178EXAMPLE`

Supported operating systems and machine types

Before working with Systems Manager, verify that your operating system (OS), OS version, and machine type are supported as managed nodes.

Topics

Supported operating systems for Systems Manager

The following sections list the OSs and OS versions supported by Systems Manager.

> **Note**
>
> If you plan to manage and configure AWS IoT Greengrass core devices by using Systems Manager, those devices must meet the requirements for AWS IoT Greengrass. For more information, see Setting up AWS IoT Greengrass core devices in the *AWS IoT Greengrass Version 2 Developer Guide*.
>
> If you plan to manage and configure AWS IoT and non-AWS edge devices, those devices must meet the requirements listed here and be configured as on-premises managed nodes for Systems Manager. For more information, see Managing edge devices with Systems Manager.

> **Important**
>
> Patch Manager, a tool in Systems Manager, might not support all the OS versions listed in this topic. For a list of OS versions supported by Patch Manager, see Patch Manager prerequisites.

Operating system types

- Linux
- macOS (Amazon EC2 instances only)
- Windows Server

Select an OS platform to see the supported major and minor versions.

Linux

AlmaLinux

Versions	x86	x86_64	ARM64
8.3–8.10		✓	✓
9.*x*		✓	✓

Amazon Linux 2

Versions	x86	x86_64	ARM64
2.0 and all later versions		✓	✓

Amazon Linux 2023

Versions	x86	x86_64	ARM64
2023.0.20230315.0 and all later versions		✓	✓

Bottlerocket

Versions	x86_64	ARM64
1.0.0 and all later versions	✓	✓

Debian Server

Versions	x86	x86_64	ARM64
Bullseye (11)		✓	✓
Bookworm (12)		✓	✓

Oracle Linux

Versions	x86	x86_64	ARM64
7.5–7.8		✓	
8.*x*		✓	
9.*x*		✓	

Red Hat Enterprise Linux (RHEL)

Versions	x86	x86_64	ARM64
7.0–7.5		✓	
7.6–8.*x*		✓	✓
9.*x*		✓	✓
10.*x*		✓	✓

Rocky Linux

Versions	x86	x86_64	ARM64
8.*x*		✓	✓
9.*x*		✓	✓

Ubuntu Server

Versions	x86	x86_64	ARM64
16.04 LTS and 18.04 LTS		✓	✓
20.04 LTS		✓	✓
22.04 LTS		✓	✓
24.04 LTS		✓	✓
25.04		✓	✓

macOS (Amazon EC2 instances only)

Version	x86	x86_64	Mac with Apple silicon
13.*x* (Ventura)		✓	✓
14.*x* (Sonoma)		✓	✓
15.*x* (Sequoia)		✓	✓

Note

macOS is not supported in all AWS Regions. For more information about Amazon EC2 support for macOS, see Amazon EC2 Mac instances in the *Amazon EC2 User Guide*.

Windows Server

SSM Agent requires Windows PowerShell 3.0 or later to run certain AWS Systems Manager documents (SSM documents) on Windows Server instances (for example, the legacy `AWS-ApplyPatchBaseline` document). Verify that your Windows Server instances are running

Windows Management Framework 3.0 or later. This framework includes Windows PowerShell. For more information, see Windows Management Framework 3.0.

Version	x86	x86_64	ARM64
2012 and 2012 R2[2]		✓	
2016		✓	
2019		✓	
2022		✓	
2025		✓	

[1] **Windows Server 2012 and 2012 R2 support**: Windows Server 2012 and 2012 R2 reached end of support on October 10, 2023. To use SSM Agent with these versions, we recommend using Extended Security Updates (ESUs) from Microsoft. For more information, see Windows Server 2012 and 2012 R2 reaching end of support on the Microsoft website.

Supported machine types in hybrid and multicloud environments

Systems Manager supports a number of machine types as *managed nodes*. A managed node is any machine configured to work with Systems Manager.

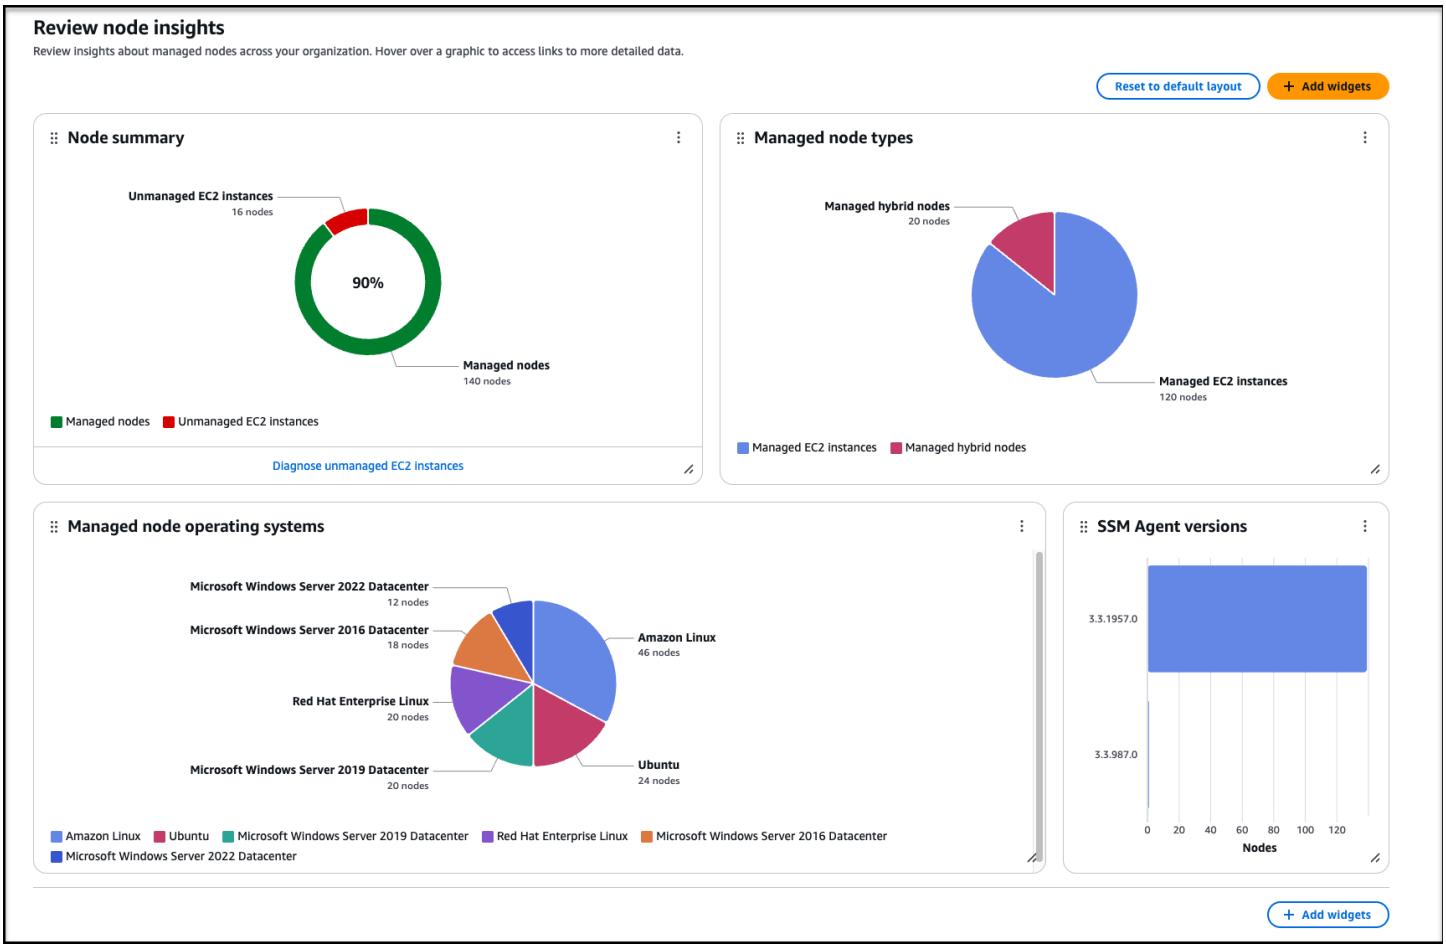
This user guide uses the term *hybrid and multicloud* to refer to an environment that contains any combination of the following machine types:

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Servers on your own premises (on-premises servers)
- AWS IoT Greengrass core devices
- AWS IoT and non-AWS edge devices
- Virtual machines (VMs), including VMs in other cloud environments

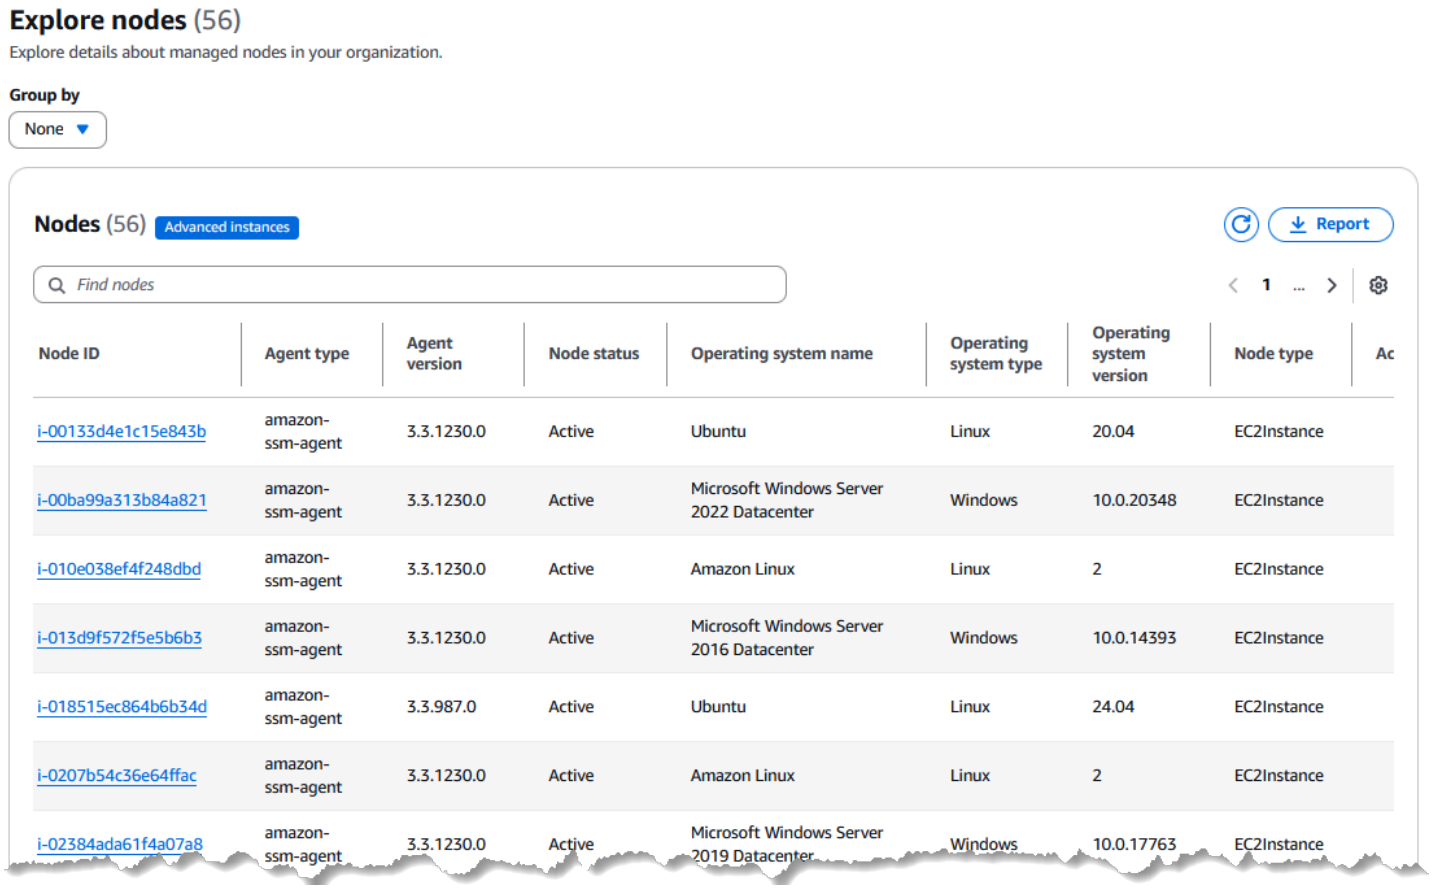
For information about AWS support for hybrid and multicloud environments, see AWS Solutions for Hybrid and Multicloud.

What is the unified console?

The unified Systems Manager console is a consolidated experience that combines various tools to help you complete common node tasks across multiple AWS accounts and AWS Regions in an AWS Organizations organization, or a single account and Region. Nodes can be EC2 instances, hybrid servers, or servers running in a multicloud environment. In the unified console, you're provided with detailed insights to your nodes. You can generate reports for your nodes, diagnose and remediate common issues that prevent nodes from reporting as managed by Systems Manager, like connectivity issues.

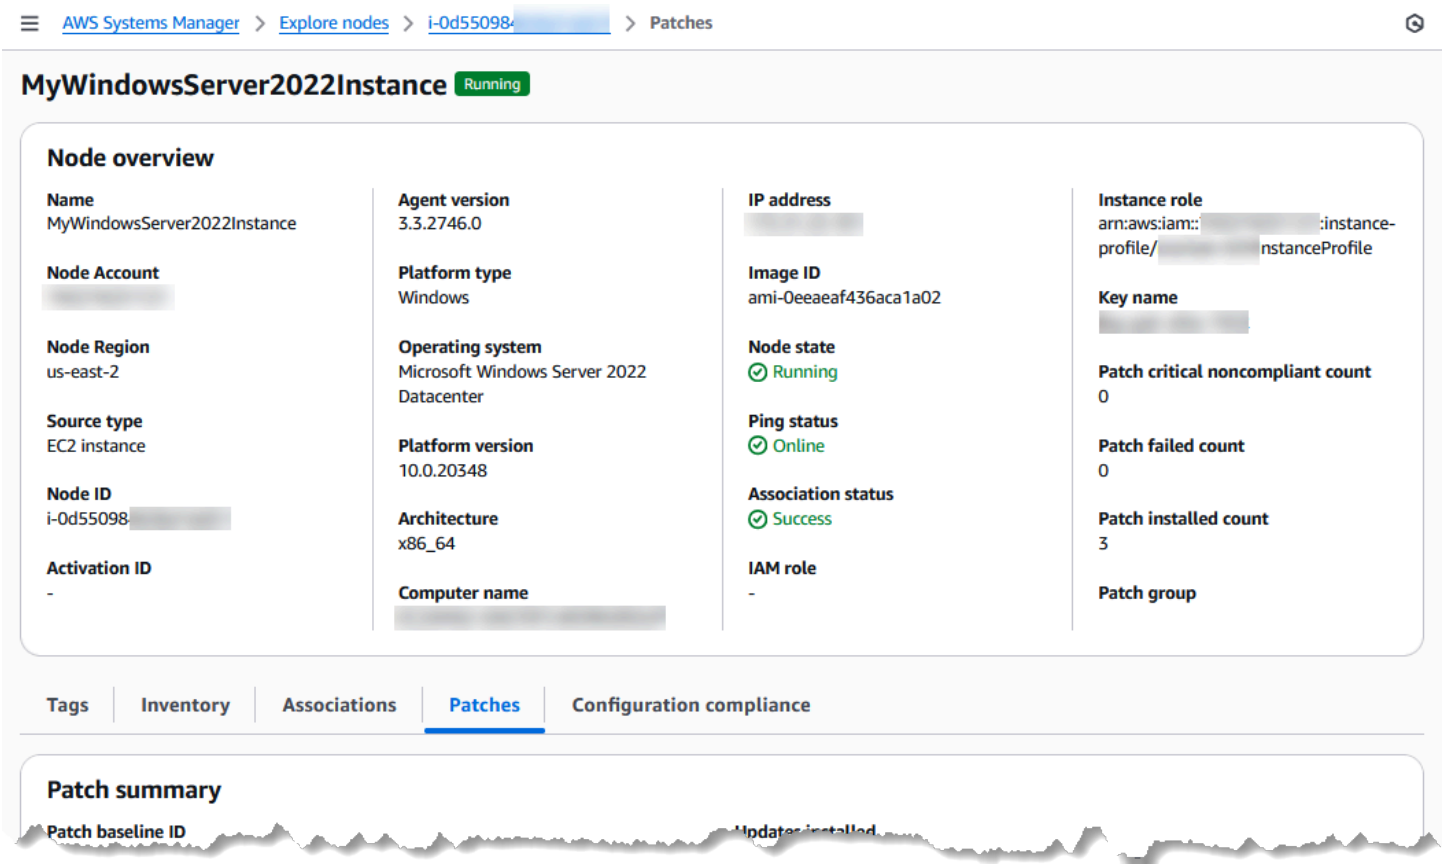


In addition to summaries about your nodes on the **Review node insights** page, you can view specific details about a node from the **Explore nodes** page.



Node details tabs

When you select a node on the **Explore nodes** page, the node detail page provides a comprehensive overview of node details and additional information on a series of tabs:



Tags

(Optional) Manage resource tags to group and filter the managed node with other resources. Tags consist of a case-senstive key-value pair and are used to categorize resources in different ways, such as by purpose, owner, or environment.

Inventory

Displays metadata about the managed node, which you can view according to over 10 different inventory types. For example, when you select the type `AWS:Application`, the inventory filter results provide details about applications installed on the node, such as **Name**, **Version**, **Architecture**, and more. For more information about Inventory, see the section called "Inventory".

Associations

An association is a resource type in State Manager that defines the target state for a managed node and maintains all managed nodes in your account in a consistent state. The association can define the commands, scripts, or policies to apply to which managed instances, and how often the association should run to ensure the nodes are match the defined configuration for

the node. An association can drive compliance reporting of required states for resources in your account. For more information about State Manager and assocations, see the section called "State Manager".

Patches

Displays metadata about the managed node, such as which patch baseline is assigned to the node and the total number of updates for packages that have been updated successfully, failed, or still required for installation. The **Patches** tab also reports details about patches available for the node based on the configuration requirements in the patch baseline, including the package **Name**, such as `libblockdev-crypto.x86_64`; **Classification** (such as `Bugfix` or `Security`); **Description** (showing the full patch title, such as `coreutils.x86_64:0:8.32-36.el9` and `java-11-amazon-corretto-headless-1:11.0.15+9-1.amzn2.x86_64`; and **Patch State**, such as `Installed`, `Installed_Pending_Reboot`, `Missing`, and `Failed`.

> **Note**
>
> Patch *states* do not indicate whether or not a managed node is *compliant*. Patch compliance is not innately tied to patch states, nor is it defined by AWS, by operating system (OS) vendors, or by third parties such as security consulting firms. Instead, you define what patch compliance means for managed nodes in your organization or account in a *patch baseline*. For more information, see the section called "What is compliance in Patch Manager?" and the section called "Predefined and custom patch baselines".

Configuration compliance

Reports patch compliance and configuration inconsistencies on the node (whether the state of a package on the managed node is `Compliant` or `Non-compliant` according to the definition of Compliant as defined in either a State Manager association or a Patch Manager patch baseline). You can filter configuration compliance results according to a package **ID**, **Compliance status**, **Compliance type** (`Association` or `Patch`), `Severity`, and different execution details. For related information, see the section called "Compliance".

Whether you have nodes in multiple accounts and Regions in an organization, or nodes in a single account and Region, we recommend using the unified console. To learn about the node tasks you

can perform now using the unified console, see Performing node management tasks with AWS Systems Manager.

For more information about setting up your nodes for Systems Manager, see Setting up managed nodes for AWS Systems Manager. After you've set up your nodes, you can set up Systems Manager and the unified console. To learn more about setting up Systems Manager, see Setting up AWS Systems Manager.

Setting up managed nodes for AWS Systems Manager

Complete the tasks in this section to set up and configure roles, user accounts, permissions, and initial resources for using AWS Systems Manager tools. The tasks described in this section are typically performed by AWS account and systems administrators. After these steps are complete, users in your organization can use Systems Manager to configure, manage, and access your *managed nodes*. A managed node is any machine configured for use with Systems Manager in a hybrid and multicloud environment.

> **Note**
>
> If you plan to use Amazon EC2 instances *and* your own computing resources in a hybrid and multicloud environment, follow the steps in Managing EC2 instances with Systems Manager. That topic presents steps in the best order for completing Systems Manager setup for EC2 instances and non-EC2 machines.

If you already use other AWS services, you have completed some of these steps. However, other steps are specific to Systems Manager. Therefore, we recommend reviewing this entire section to ensure that you're ready to use all Systems Manager tools.

Topics

- Managing EC2 instances with Systems Manager
- Managing nodes in hybrid and multicloud environments with Systems Manager
- Managing edge devices with Systems Manager
- Creating an AWS Organizations delegated administrator for Systems Manager
- General setup for AWS Systems Manager

Managing EC2 instances with Systems Manager

Complete the tasks in this section to set up and configure roles, permissions, and initial resources for AWS Systems Manager. The tasks described in this section are typically performed by AWS account and systems administrators. After these steps are complete, users in your organization can use Systems Manager to configure, manage, and access Amazon Elastic Compute Cloud (Amazon EC2) instances.

> **Note**
>
> If you plan to use Systems Manager to manage and configure on-premises machines, follow the setup steps in Managing nodes in hybrid and multicloud environments with Systems Manager. If you plan to use both Amazon EC2 instances *and* non-EC2 machines in a hybrid and multicloud environment, follow the steps here first. This section presents steps in the recommended order for configuring the roles, users, permissions, and initial resources to use in your Systems Manager operations.

If you already use other AWS services, you have completed some of these steps. However, other steps are specific to Systems Manager. Therefore, we recommend reviewing this entire section to ensure that you're ready to use all Systems Manager tools.

Contents

Configure instance permissions required for Systems Manager

By default, AWS Systems Manager doesn't have permission to perform actions on your instances. You can provide instance permissions at the account level using an AWS Identity and Access Management (IAM) role, or at the instance level using an instance profile. If your use case allows, we recommend granting access at the account level using the Default Host Management Configuration.

> **Note**
>
> You can skip this step and allow Systems Manager to apply the required permissions to your instances for you when setting up the unified console. For more information, see Setting up AWS Systems Manager.

Recommended configuration for EC2 instance permissions

Default Host Management Configuration allows Systems Manager to manage your Amazon EC2 instances automatically. After you've turned on this setting, all instances using Instance

Metadata Service Version 2 (IMDSv2) in the AWS Region and AWS account with SSM Agent version 3.2.582.0 or later installed automatically become managed instances. Default Host Management Configuration doesn't support Instance Metadata Service Version 1. For information about transitioning to IMDSv2, see Transition to using Instance Metadata Service Version 2 in the *Amazon EC2 User Guide*. For information about checking the version of the SSM Agent installed on your instance, see Checking the SSM Agent version number. For information about updating the SSM Agent, see Automatically updating SSM Agent. Benefits of managed instances include the following:

- Connect to your instances securely using Session Manager.
- Perform automated patch scans using Patch Manager.
- View detailed information about your instances using Systems Manager Inventory.
- Track and manage instances using Fleet Manager.
- Keep the SSM Agent up to date automatically.

Fleet Manager, Inventory, Patch Manager, and Session Manager are tools in AWS Systems Manager.

Default Host Management Configuration allows instance management without the use of instance profiles and ensures that Systems Manager has permissions to manage all instances in the Region and account. If the permissions provided aren't sufficient for your use case, you can also add policies to the default IAM role created by the Default Host Management Configuration. Alternatively, if you don't need permissions for all of the capabilities provided by the default IAM role, you can create your own custom role and policies. Any changes made to the IAM role you choose for Default Host Management Configuration applies to all managed Amazon EC2 instances in the Region and account. For more information about the policy used by Default Host Management Configuration, see AWS managed policy: AmazonSSMManagedEC2InstanceDefaultPolicy. For more information about the Default Host Management Configuration, see Managing EC2 instances automatically with Default Host Management Configuration.

Important

Instances registered using Default Host Management Configuration store registration information locally in the `/lib/amazon/ssm` or `C:\ProgramData\Amazon` directories. Removing these directories or their files will prevent the instance from acquiring the necessary credentials to connect to Systems Manager using Default Host Management

Configuration. In these cases, you must use an instance profile to provide the required permissions to your instance, or recreate the instance.

Note

This procedure is intended to be performed only by administrators. Implement least privilege access when allowing individuals to configure or modify the Default Host Management Configuration. You must turn on the Default Host Management Configuration in each AWS Region you wish to automatically manage your Amazon EC2 instances.

To turn on the Default Host Management Configuration setting

You can turn on the Default Host Management Configuration from the Fleet Manager console. To successfully complete this procedure using either the AWS Management Console or your preferred command line tool, you must have permissions for the GetServiceSetting, ResetServiceSetting, and UpdateServiceSetting API operations. Additionally, you must have permissions for the `iam:PassRole` permission for the `AWSSystemsManagerDefaultEC2InstanceManagementRole` IAM role. The following is an example policy. Replace each *`example resource placeholder`* with your own information.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetServiceSetting",
                "ssm:ResetServiceSetting",
                "ssm:UpdateServiceSetting"
            ],
            "Resource": "arn:aws:ssm:us-east-1:111122223333:servicesetting/ssm/
managed-instance/default-ec2-instance-management-role"
        },
        {
            "Effect": "Allow",
            "Action": [
```

```
                "iam:PassRole"
            ],
            "Resource": "arn:aws:iam::111122223333:role/service-role/
AWSSystemsManagerDefaultEC2InstanceManagementRole",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "ssm.amazonaws.com"
                    ]
                }
            }
        }
    ]
}
```

Before you begin, if you have instance profiles attached to your Amazon EC2 instances, remove any permissions that allow the `ssm:UpdateInstanceInformation` operation. The SSM Agent attempts to use instance profile permissions before using the Default Host Management Configuration permissions. If you allow the `ssm:UpdateInstanceInformation` operation in your instance profiles, the instance will not use the Default Host Management Configuration permissions.

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Configure Default Host Management Configuration** under the **Account management** dropdown.
4. Turn on **Enable Default Host Management Configuration**.
5. Choose the IAM role used to enable Systems Manager tools for your instances. We recommend using the default role provided by Default Host Management Configuration. It contains the minimum set of permissions necessary to manage your Amazon EC2 instances using Systems Manager. If you prefer to use a custom role, the role's trust policy must allow Systems Manager as a trusted entity.
6. Choose **Configure** to complete setup.

After turning on the Default Host Management Configuration, it might take up 30 minutes for your instances to use the credentials of the role you chose. You must turn on the Default Host

Management Configuration in each Region you wish to automatically manage your Amazon EC2 instances.

Alternative configuration for EC2 instance permissions

You can grant access at the individual instance level by using an AWS Identity and Access Management (IAM) instance profile. An instance profile is a container that passes IAM role information to an Amazon Elastic Compute Cloud (Amazon EC2) instance at launch. You can create an instance profile for Systems Manager by attaching one or more IAM policies that define the necessary permissions to a new role or to a role you already created.

> **Note**
>
> You can use Quick Setup, a tool in AWS Systems Manager, to quickly configure an instance profile on all instances in your AWS account. Quick Setup also creates an IAM service role (or *assume* role), which allows Systems Manager to securely run commands on your instances on your behalf. By using Quick Setup, you can skip this step (Step 3) and Step 4. For more information, see AWS Systems Manager Quick Setup.

Note the following details about creating an IAM instance profile:

- If you're configuring non-EC2 machines in a hybrid and multicloud environment for Systems Manager, you don't need to create an instance profile for them. Instead, configure your servers and VMs to use an IAM service role. For more information, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.
- If you change the IAM instance profile, it might take some time for the instance credentials to refresh. SSM Agent won't process requests until this happens. To speed up the refresh process, you can restart SSM Agent or restart the instance.

Depending on whether you're creating a new role for your instance profile or adding the necessary permissions to an existing role, use one of the following procedures.

To create an instance profile for Systems Manager managed instances (console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.

4. Immediately under **Use case**, choose **EC2**, and then choose **Next**.
5. On the **Add permissions** page, do the following:

   - Use the **Search** field to locate the **AmazonSSMManagedInstanceCore** policy. Select the check box next to its name, as shown in the following illustration.

     The console retains your selection even if you search for other policies.

   - If you created a custom S3 bucket policy in the previous procedure, [(Optional) Create a custom policy for S3 bucket access](), search for it and select the check box next to its name.
   - If you plan to join instances to an Active Directory managed by AWS Directory Service, search for **AmazonSSMDirectoryServiceAccess** and select the check box next to its name.
   - If you plan to use EventBridge or CloudWatch Logs to manage or monitor your instance, search for **CloudWatchAgentServerPolicy** and select the check box next to its name.
6. Choose **Next**.
7. For **Role name**, enter a name for your new instance profile, such as **`SSMInstanceProfile`**.

   > **Note**
   >
   > Make a note of the role name. You will choose this role when you create new instances that you want to manage by using Systems Manager.

8. (Optional) For **Description**, update the description for this instance profile.
9. (Optional) For **Tags**, add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Create role**. The system returns you to the **Roles** page.

To add instance profile permissions for Systems Manager to an existing role (console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**, and then choose the existing role you want to associate with an instance profile for Systems Manager operations.

3. On the **Permissions** tab, choose **Add permissions, Attach policies**.
4. On the **Attach policy** page, do the following:
   - Use the **Search** field to locate the **AmazonSSMManagedInstanceCore** policy. Select the check box next to its name.
   - If you have created a custom S3 bucket policy, search for it and select the check box next to its name. For information about custom S3 bucket policies for an instance profile, see (Optional) Create a custom policy for S3 bucket access.
   - If you plan to join instances to an Active Directory managed by AWS Directory Service, search for **AmazonSSMDirectoryServiceAccess** and select the check box next to its name.
   - If you plan to use EventBridge or CloudWatch Logs to manage or monitor your instance, search for **CloudWatchAgentServerPolicy** and select the check box next to its name.
5. Choose **Attach policies**.

For information about how to update a role to include a trusted entity or further restrict access, see Modifying a role in the *IAM User Guide*.

(Optional) Create a custom policy for S3 bucket access

Creating a custom policy for Amazon S3 access is required only if you're using a VPC endpoint or using an S3 bucket of your own in your Systems Manager operations. You can attach this policy to the default IAM role created by the Default Host Management Configuration, or an instance profile you created in the previous procedure.

For information about the AWS managed S3 buckets you provide access to in the following policy, see SSM Agent communications with AWS managed S3 buckets.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**.
3. Choose the **JSON** tab, and replace the default text with the following.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": [
                "arn:aws:s3:::aws-ssm-us-east-2/*",
                "arn:aws:s3:::aws-windows-downloads-us-east-2/*",
                "arn:aws:s3:::amazon-ssm-us-east-2/*",
                "arn:aws:s3:::amazon-ssm-packages-us-east-2/*",

                "arn:aws:s3:::aws-ssm-document-attachments-us-east-2/*",
                "arn:aws:s3:::patch-baseline-snapshot-us-east-2/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:PutObjectAcl",
                "s3:GetEncryptionConfiguration"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket/*",
                "arn:aws:s3:::amzn-s3-demo-bucket"
            ]
        }
    ]
}
```

Note

The first `Statement` element is required only if you're using a VPC endpoint.
The second `Statement` element is required only if you're using an S3 bucket that you created to use in your Systems Manager operations.
The `PutObjectAcl` access control list permission is required only if you plan to support cross-account access to S3 buckets in other accounts.
The `GetEncryptionConfiguration` element is required if your S3 bucket is configured to use encryption.

If your S3 bucket is configured to use encryption, then the S3 bucket root (for example, `arn:aws:s3:::amzn-s3-demo-bucket`) must be listed in the **Resource** section. Your user, group, or role must be configured with access to the root bucket.

4. If you're using a VPC endpoint in your operations, do the following:

   In the first `Statement` element, replace each *`region`* placeholder with the identifier of the AWS Region this policy will be used in. For example, use `us-east-2` for the US East (Ohio) Region. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

   Important

   We recommend that you avoid using wildcard characters (*) in place of specific Regions in this policy. For example, use `arn:aws:s3:::aws-ssm-us-east-2/*` and do not use `arn:aws:s3:::aws-ssm-*/*`. Using wildcards could provide access to S3 buckets that you don't intend to grant access to. If you want to use the instance profile for more than one Region, we recommend repeating the first `Statement` element for each Region.

   -or-

   If you aren't using a VPC endpoint in your operations, you can delete the first `Statement` element.

5. If you're using an S3 bucket of your own in your Systems Manager operations, do the following:

   In the second `Statement` element, replace *`amzn-s3-demo-bucket`* with the name of an S3 bucket in your account. You will use this bucket for your Systems Manager operations. It provides permission for objects in the bucket, using `"arn:aws:s3:::my-bucket-name/*"` as the resource. For more information about providing permissions for buckets or objects in buckets, see the topic Amazon S3 actions in the *Amazon Simple Storage Service User Guide* and the AWS blog post IAM Policies and Bucket Policies and ACLs! Oh, My! (Controlling Access to S3 Resources).

> **Note**
>
> If you use more than one bucket, provide the ARN for each one. See the following example for permissions on buckets.
>
> ```
> "Resource": [
> "arn:aws:s3:::amzn-s3-demo-bucket1/*",
> "arn:aws:s3:::amzn-s3-demo-bucket2/*"
>              ]
> ```

-or-

If you aren't using an S3 bucket of your own in your Systems Manager operations, you can delete the second `Statement` element.

6. Choose **Next: Tags**.
7. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the policy.
8. Choose **Next: Review**.
9. For **Name**, enter a name to identify this policy, such as **`SSMInstanceProfileS3Policy`**.
10. Choose **Create policy**.

Additional policy considerations for managed instances

This section describes some of the policies you can add to the default IAM role created by the Default Host Management Configuration, or your instance profiles for AWS Systems Manager. To provide permissions for communication between instances and the Systems Manager API, we recommend creating custom policies that reflect your system needs and security requirements. Depending on your operations plan, you might need permissions represented in one or more of the other policies.

Policy: `AmazonSSMDirectoryServiceAccess`

Required only if you plan to join Amazon EC2 instances for Windows Server to a Microsoft AD directory.

This AWS managed policy allows SSM Agent to access AWS Directory Service on your behalf for requests to join the domain by the managed instance. For more information, see Seamlessly join a Windows EC2 Instance in the *AWS Directory Service Administration Guide*.

Policy: `CloudWatchAgentServerPolicy`

Required only if you plan to install and run the CloudWatch agent on your instances to read metric and log data on an instance and write it to Amazon CloudWatch. These help you monitor, analyze, and quickly respond to issues or changes to your AWS resources.

Your default IAM role created by the Default Host Management Configuration or instance profile needs this policy only if you will use features such as Amazon EventBridge or Amazon CloudWatch Logs. (You can also create a more restrictive policy that, for example, limits writing access to a specific CloudWatch Logs log stream.)

> **Note**
>
> Using EventBridge and CloudWatch Logs features is optional. However, we recommend setting them up at the beginning of your Systems Manager configuration process if you have decided to use them. For more information, see the *Amazon EventBridge User Guide* and the *Amazon CloudWatch Logs User Guide*.

To create IAM policies with permissions for additional Systems Manager tools, see the following resources:

- Restricting access to Parameter Store parameters using IAM policies
- Setting up Automation
- Step 2: Verify or add instance permissions for Session Manager

Attach the Systems Manager instance profile to an instance (console)

The following procedure describes how to attach an IAM instance profile to an Amazon EC2 instance using the Amazon EC2 console.

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under **Instances**, choose **Instances**.

3. Navigate to and choose your EC2 instance from the list.
4. In the **Actions** menu, choose **Security**, **Modify IAM role**.
5. For **IAM role**, select the instance profile you created using the procedure in Alternative configuration for EC2 instance permissions.
6. Choose **Update IAM role**.

For more information about attaching IAM roles to instances, choose one of the following, depending on your selected operating system type:

- Attach an IAM role to an instance in the *Amazon EC2 User Guide*
- Attach an IAM role to an instance in the *Amazon EC2 User Guide*

Continue to Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

Improve the security of EC2 instances by using VPC endpoints for Systems Manager

You can improve the security posture of your managed nodes (including non-EC2 machines in a hybrid and multicloud environment) by configuring AWS Systems Manager to use an interface VPC endpoint in Amazon Virtual Private Cloud (Amazon VPC). By using an interface VPC endpoint (interface endpoint), you can connect to services powered by AWS PrivateLink. AWS PrivateLink is a technology that allows you to privately access Amazon Elastic Compute Cloud (Amazon EC2) and Systems Manager APIs by using private IP addresses.

AWS PrivateLink restricts all network traffic between your managed instances, Systems Manager, and Amazon EC2 to the Amazon network. This means that your managed instances don't have access to the Internet. If you use AWS PrivateLink, you don't need an internet gateway, a NAT device, or a virtual private gateway.

You aren't required to configure AWS PrivateLink, but it's recommended. For more information about AWS PrivateLink and VPC endpoints, see AWS PrivateLink and VPC endpoints.

> **Note**
>
> The alternative to using a VPC endpoint is to allow outbound internet access on your managed instances. In this case, the managed instances must also allow HTTPS (port 443) outbound traffic to the following endpoints:

- ssm.*region*.amazonaws.com
- ssmmessages.*region*.amazonaws.com
- ec2messages.*region*.amazonaws.com

SSM Agent initiates all connections to the Systems Manager service in the cloud. For this reason, you don't need to configure your firewall to allow inbound traffic to your instances for Systems Manager.
For more information about calls to these endpoints, see Reference: ec2messages, ssmmessages, and other API operations.

About Amazon VPC

You can use Amazon Virtual Private Cloud (Amazon VPC) to define a virtual network in your own logically isolated area within the AWS Cloud, known as a *virtual private cloud (VPC)*. You can launch your AWS resources, such as instances, into your VPC. Your VPC closely resembles a traditional network that you might operate in your own data center, with the benefits of using the scalable infrastructure of AWS. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can connect instances in your VPC to the internet. You can connect your VPC to your own corporate data center, making the AWS Cloud an extension of your data center. To protect the resources in each subnet, you can use multiple layers of security, including security groups and network access control lists. For more information, see the Amazon VPC User Guide.

Topics

- VPC endpoint restrictions and limitations
- Creating VPC endpoints for Systems Manager
- Create an interface VPC endpoint policy

VPC endpoint restrictions and limitations

Before you configure VPC endpoints for Systems Manager, be aware of the following restrictions and limitations.

VPC peering connections

VPC interface endpoints can be accessed through both *intra-Region* and *inter-Region* VPC peering connections. For more information about VPC peering connection requests for VPC interface endpoints, see VPC peering connections (Quotas) in the *Amazon Virtual Private Cloud User Guide*.

VPC gateway endpoint connections can't be extended out of a VPC. Resources on the other side of a VPC peering connection in your VPC can't use the gateway endpoint to communicate with resources in the gateway endpoint service. For more information about VPC peering connection requests for VPC gateway endpoints, see VPC endpoints (Quotas) in the *Amazon Virtual Private Cloud User Guide*

Incoming connections

The security group attached to the VPC endpoint must allow incoming connections on port 443 from the private subnet of the managed instance. If incoming connections aren't allowed, then the managed instance can't connect to the SSM and EC2 endpoints.

DNS resolution

If you use a custom DNS server, you must add a conditional forwarder for any queries to the `amazonaws.com` domain to the Amazon DNS server for your VPC.

S3 buckets

Your VPC endpoint policy must allow access to at least the Amazon S3 buckets listed in SSM Agent communications with AWS managed S3 buckets.

> **Note**
>
> If you use an on-premises firewall and plan to use Patch Manager, that firewall must also allow access to the appropriate patch baseline endpoint.

Amazon CloudWatch Logs

If you don't allow your instances to access the internet, create a VPC endpoint for CloudWatch Logs to use features that send logs to CloudWatch Logs. For more information about creating an endpoint for CloudWatch Logs, see Creating a VPC endpoint for CloudWatch Logs in the *Amazon CloudWatch Logs User Guide*.

DNS in hybrid and multicloud environment

For information about configuring DNS to work with AWS PrivateLink endpoints in hybrid and multicloud environments, see Private DNS for interface endpoints in the *Amazon VPC User Guide*. If you want to use your own DNS, you can use Route 53 Resolver. For more information, see Resolving DNS queries between VPCs and your network in the *Amazon Route 53 Developer Guide*.

Creating VPC endpoints for Systems Manager

Use the following information to create VPC interface endpoints for AWS Systems Manager. This topic links to procedures in the *Amazon VPC User Guide*.

> **Note**
>
> *region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

Follow the steps in Create an interface endpoint to create the following interface endpoints:

- **com.amazonaws.*region*.ssm** – The endpoint for the Systems Manager service.
- **com.amazonaws.*region*.ec2messages** – Systems Manager uses this endpoint to make calls from SSM Agent to the Systems Manager service. Beginning with version 3.3.40.0 of SSM Agent, Systems Manager began using the `ssmmessages:*` endpoint (Amazon Message Gateway Service) whenever available instead of the `ec2messages:*` endpoint (Amazon Message Delivery Service).
- **com.amazonaws.*region*.ec2** – If you're using Systems Manager to create VSS-enabled snapshots, you need to ensure that you have an endpoint to the EC2 service. Without the EC2 endpoint defined, a call to enumerate attached Amazon EBS volumes fails, which causes the Systems Manager command to fail.
- **com.amazonaws.*region*.s3** – Systems Manager uses this endpoint to update SSM Agent. Systems Manager also uses this endpoint if, optionally, you choose to retrieve scripts or other files stored in buckets or upload output logs to a bucket. If the security group associated with your instances restricts outbound traffic, you must add a rule to allow traffic to the prefix list for Amazon S3. For more information, see Modify your security group in the *AWS PrivateLink Guide*.
- **com.amazonaws.*region*.ssmmessages** – This endpoint is required for SSM Agent to communicate with the Systems Manager service, for Run Command, and if you're connecting to

your instances through a secure data channel using Session Manager. For more information, see AWS Systems Manager Session Manager and Reference: ec2messages, ssmmessages, and other API operations.

- (Optional) **com.amazonaws.*region*.kms** – Create this endpoint if you want to use AWS Key Management Service (AWS KMS) encryption for Session Manager or Parameter Store parameters.
- (Optional) **com.amazonaws.*region*.logs** – Create this endpoint if you want to use Amazon CloudWatch Logs (CloudWatch Logs) for Session Manager, Run Command, or SSM Agent logs.

For information about the AWS managed S3 buckets that SSM Agent must be able to access, see SSM Agent communications with AWS managed S3 buckets. If you're using a virtual private cloud (VPC) endpoint in your Systems Manager operations, you must provide explicit permission in an EC2 instance profile for Systems Manager, or in a service role for non-EC2 managed nodes in a hybrid and multicloud environment.

Create an interface VPC endpoint policy

You can create policies for VPC interface endpoints for AWS Systems Manager in which you can specify:

- The principal that can perform actions
- The actions that can be performed
- The resources that can have actions performed on them

For more information, see Control access to services with VPC endpoints in the *Amazon VPC User Guide*.

Managing nodes in hybrid and multicloud environments with Systems Manager

You can use AWS Systems Manager to manage both Amazon Elastic Compute Cloud (EC2) instances and a number of non-EC2 machine types. This section describes the setup tasks that account and system administrators perform to manage non-EC2 machines using Systems Manager in a *hybrid and multicloud environment*. After these steps are complete, users who have been granted permissions by the AWS account administrator can use Systems Manager to configure and manage their organization's non-EC2 machines.

Any machine that has been configured for use with Systems Manager is called a *managed node*.

Note

- You can register edge devices as managed nodes using the same hybrid-activation steps used for other non-EC2 machines. These types of edge devices include both AWS IoT devices and devices other than AWS IoT devices. Use the process described in this section to set up these types of edge devices.

  Systems Manager also supports edge devices that use AWS IoT Greengrass Core software. The setup process and requirements for AWS IoT Greengrass core devices are different from those for AWS IoT and edge devices other than AWS edge devices. For information about registering AWS IoT Greengrass devices for use with Systems Manager, see Managing edge devices with Systems Manager.
- Non-EC2 macOS machines aren't supported for Systems Manager hybrid and multicloud environments.

If you plan to use Systems Manager to manage Amazon Elastic Compute Cloud (Amazon EC2) instances, or to use both Amazon EC2 instances and non-EC2 machines in hybrid and multicloud environment, follow the steps in Managing EC2 instances with Systems Manager first.

After configuring your hybrid and multicloud environment for Systems Manager, you can do the following:

- Create a consistent and secure way to remotely manage your hybrid and multicloud workloads from one location using the same tools or scripts.
- Centralize access control for actions that can be performed on your machines by using AWS Identity and Access Management (IAM).
- Centralize auditing of the operations performed on your machines by viewing the API activity recorded in AWS CloudTrail.

  For information about using CloudTrail to monitor Systems Manager actions, see Logging AWS Systems Manager API calls with AWS CloudTrail.
- Centralize monitoring by configuring Amazon EventBridge and Amazon Simple Notification Service (Amazon SNS) to send notifications about service execution success.

For information about using EventBridge to monitor Systems Manager events, see Monitoring Systems Manager events with Amazon EventBridge.

About managed nodes

After you finish configuring your non-EC2 machines for Systems Manager as described in this section, your hybrid-activated machines are listed in the AWS Management Console and described as *managed nodes*. In the console, the IDs of your hybrid-activated managed nodes are distinguished from Amazon EC2 instances with the prefix "mi-". Amazon EC2 instance IDs use the prefix "i-".

A managed node is any machine configured for Systems Manager. Previously, managed nodes were all referred to as managed instances. The term *instance* now refers to EC2 instances only. The deregister-managed-instance command was named before this terminology change.

For more information, see Working with managed nodes.

About instance tiers

Systems Manager offers a standard-instances tier and an advanced-instances tier for non-EC2 managed nodes in your hybrid and multicloud environment. The standard-instances tier allows you to register a maximum of 1,000 hybrid-activated machines per AWS account per AWS Region. If you need to register more than 1,000 non-EC2 machines in a single account and Region, then use the advanced-instances tier. Advanced instances also allow you to connect to your non-EC2 machines by using AWS Systems Manager Session Manager. Session Manager provides interactive shell access to your managed nodes.

For more information, see Configuring instance tiers.

- Create the IAM service role required for Systems Manager in hybrid and multicloud environments
- Create a hybrid activation to register nodes with Systems Manager
- Install SSM Agent on hybrid Linux nodes
- Install SSM Agent on hybrid Windows Server nodes

Create the IAM service role required for Systems Manager in hybrid and multicloud environments

Non-EC2 (Amazon Elastic Compute Cloud) machines in a hybrid and multicloud environment require an AWS Identity and Access Management (IAM) service role to communicate with the AWS Systems Manager service. The role grants AWS Security Token Service (AWS STS) `AssumeRole` trust to the Systems Manager service. You only need to create a service role for a hybrid and multicloud environment once for each AWS account. However, you might choose to create multiple service roles for different hybrid activations if machines in your hybrid and multicloud environment require different permissions.

The following procedures describe how to create the required service role using the Systems Manager console or your preferred command line tool.

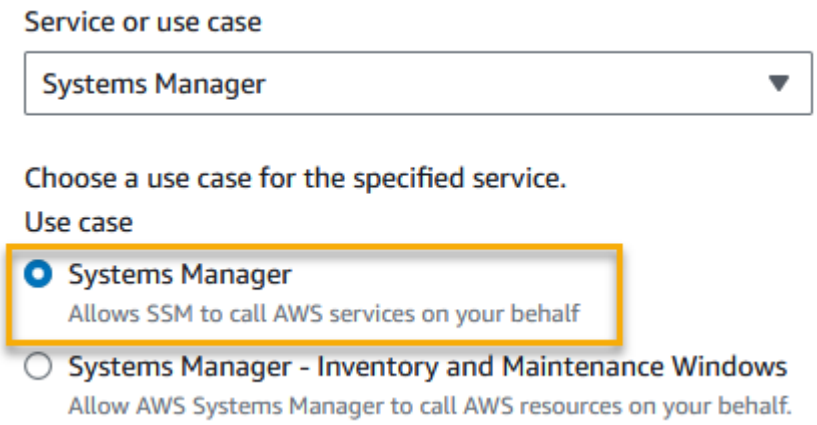
Using the AWS Management Console to create an IAM service role for Systems Manager hybrid activations

Use the following procedure to create a service role for hybrid activation. This procedure uses the `AmazonSSMManagedInstanceCore` policy for Systems Manager core functionality. Depending on your use case, you might need to add additional policies to your service role for your on-premises machines to be able to access other Systems Manager tools or AWS services. For example, without access to the required AWS managed Amazon Simple Storage Service (Amazon S3) buckets, Patch Manager patching operations fail.

To create a service role (console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Select trusted entity**, make the following choices:
    1. For **Trusted entity type**, choose **AWS service**.
    2. For **Use cases for other AWS services**, choose **Systems Manager**.
    3. Choose **Systems Manager**.

    The following image highlights the location of the Systems Manager option.



4. Choose **Next**.
5. On the **Add permissions** page, do the following:

   - Use the **Search** field to locate the **AmazonSSMManagedInstanceCore** policy. Select the check box next to its name, as shown in the following illustration.

   > **Note**
   >
   > The console retains your selection even if you search for other policies.

   - If you created a custom S3 bucket policy in the procedure [(Optional) Create a custom policy for S3 bucket access](), search for it and select the check box next to its name.
   - If you plan to join non-EC2 machines to an Active Directory managed by AWS Directory Service, search for **AmazonSSMDirectoryServiceAccess** and select the check box next to its name.
   - If you plan to use EventBridge or CloudWatch Logs to manage or monitor your managed node, search for **CloudWatchAgentServerPolicy** and select the check box next to its name.

6. Choose **Next**.
7. For **Role name**, enter a name for your new IAM server role, such as **`SSMServerRole`**.

> **Note**
>
> Make a note of the role name. You will choose this role when you register new machines that you want to manage by using Systems Manager.

8. (Optional) For **Description**, update the description for this IAM server role.
9. (Optional) For **Tags**, add one or more tag-key value pairs to organize, track, or control access for this role.
10. Choose **Create role**. The system returns you to the **Roles** page.

Using the AWS CLI to create an IAM service role for Systems Manager hybrid activations

Use the following procedure to create a service role for hybrid activation. This procedure uses the `AmazonSSMManagedInstanceCore` policy Systems Manager core functionality. Depending on your use case, you might need to add additional policies to your service role for your non-EC2 machines in a hybrid and multicloud environment to be able to access other tools or AWS services.

S3 bucket policy requirement

If either of the following cases are true, you must create a custom IAM permission policy for Amazon Simple Storage Service (Amazon S3) buckets before completing this procedure:

- **Case 1** – You're using a VPC endpoint to privately connect your VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink.
- **Case 2** – You plan to use an Amazon S3 bucket that you create as part of your Systems Manager operations, such as for storing output for Run Command commands or Session Manager sessions to an S3 bucket. Before proceeding, follow the steps in Create a custom S3 bucket policy for an instance profile. The information about S3 bucket policies in that topic also applies to your service role.

AWS CLI

To create an IAM service role for a hybrid and multicloud environment (AWS CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see Installing or updating the latest version of the AWS CLI.

2. On your local machine, create a text file with a name such as `SSMService-Trust.json` with the following trust policy. Make sure to save the file with the `.json` file extension. Be sure to specify your AWS account and the AWS Region in the ARN where you created your hybrid activation. Replace the *`placeholder values`* for account ID and Region with your own information.

   JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"",
         "Effect":"Allow",
         "Principal":{
            "Service":"ssm.amazonaws.com"
         },
         "Action":"sts:AssumeRole",
         "Condition":{
            "StringEquals":{
               "aws:SourceAccount":"123456789012"
            },
            "ArnEquals":{
               "aws:SourceArn":"arn:aws:ssm:us-east-1:111122223333:*"
            }
         }
      }
   ]
}
```

3. Open the AWS CLI, and in the directory where you created the JSON file, run the create-role command to create the service role. This example creates a role named `SSMServiceRole`. You can choose another name if you prefer.

   Linux & macOS

```
aws iam create-role \
    --role-name SSMServiceRole \
```

```
    --assume-role-policy-document file://SSMService-Trust.json
```

Windows

```
aws iam create-role ^
    --role-name SSMServiceRole ^
    --assume-role-policy-document file://SSMService-Trust.json
```

4. Run the attach-role-policy command as follows to allow the service role you just created to create a session token. The session token gives your managed node permission to run commands using Systems Manager.

> **Note**
>
> The policies you add for a service profile for managed nodes in a hybrid and multicloud environment are the same policies used to create an instance profile for Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information about the AWS policies used in the following commands, see Configure instance permissions required for Systems Manager.

(Required) Run the following command to allow a managed node to use AWS Systems Manager service core functionality.

Linux & macOS

```
aws iam attach-role-policy \
    --role-name SSMServiceRole \
    --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

Windows

```
aws iam attach-role-policy ^
    --role-name SSMServiceRole ^
    --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

If you created a custom S3 bucket policy for your service role, run the following command to allow AWS Systems Manager Agent (SSM Agent) to access the buckets you specified in

the policy. Replace *account-id* and *amzn-s3-demo-bucket* with your AWS account ID and your bucket name.

Linux & macOS

```
aws iam attach-role-policy \
    --role-name SSMServiceRole \
    --policy-arn arn:aws:iam::account-id:policy/amzn-s3-demo-bucket
```

Windows

```
aws iam attach-role-policy ^
    --role-name SSMServiceRole ^
    --policy-arn arn:aws:iam::account-id:policy/amzn-s3-demo-bucket
```

(Optional) Run the following command to allow SSM Agent to access AWS Directory Service on your behalf for requests to join the domain by the managed node. Your service role needs this policy only if you join your nodes to a Microsoft AD directory.

Linux & macOS

```
aws iam attach-role-policy \
    --role-name SSMServiceRole \
    --policy-arn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

Windows

```
aws iam attach-role-policy ^
    --role-name SSMServiceRole ^
    --policy-arn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

(Optional) Run the following command to allow the CloudWatch agent to run on your managed nodes. This command makes it possible to read information on a node and write it to CloudWatch. Your service profile needs this policy only if you will use services such as Amazon EventBridge or Amazon CloudWatch Logs.

```
aws iam attach-role-policy \
    --role-name SSMServiceRole \
```

```
    --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Tools for PowerShell

To create an IAM service role for a hybrid and multicloud environment (AWS Tools for Windows PowerShell)

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

   For information, see Installing the AWS Tools for PowerShell.

2. On your local machine, create a text file with a name such as `SSMService-Trust.json` with the following trust policy. Make sure to save the file with the `.json` file extension. Be sure to specify your AWS account and the AWS Region in the ARN where you created your hybrid activation.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                },
                "ArnEquals": {
                    "aws:SourceArn": "arn:aws:ssm:us-
east-1:123456789012:*"
                }
            }
        }
    ]
```

```
}
```

3. Open PowerShell in administrative mode, and in the directory where you created the JSON file, run New-IAMRole as follows to create a service role. This example creates a role named `SSMServiceRole`. You can choose another name if you prefer.

```
New-IAMRole `
    -RoleName SSMServiceRole `
    -AssumeRolePolicyDocument (Get-Content -raw SSMService-Trust.json)
```

4. Use Register-IAMRolePolicy as follows to allow the service role you created to create a session token. The session token gives your managed node permission to run commands using Systems Manager.

> **Note**
>
> The policies you add for a service profile for managed nodes in a hybrid and multicloud environment are the same policies used to create an instance profile for EC2 instances. For more information about the AWS policies used in the following commands, see Configure instance permissions required for Systems Manager.

(Required) Run the following command to allow a managed node to use AWS Systems Manager service core functionality.

```
Register-IAMRolePolicy `
    -RoleName SSMServiceRole `
    -PolicyArn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

If you created a custom S3 bucket policy for your service role, run the following command to allow SSM Agent to access the buckets you specified in the policy. Replace *account-id* and *my-bucket-policy-name* with your AWS account ID and your bucket name.

```
Register-IAMRolePolicy `
    -RoleName SSMServiceRole `
    -PolicyArn arn:aws:iam::account-id:policy/my-bucket-policy-name
```

(Optional) Run the following command to allow SSM Agent to access AWS Directory Service on your behalf for requests to join the domain by the managed node. Your server role needs this policy only if you join your nodes to a Microsoft AD directory.

```
Register-IAMRolePolicy `
    -RoleName SSMServiceRole `
    -PolicyArn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

(Optional) Run the following command to allow the CloudWatch agent to run on your managed nodes. This command makes it possible to read information on a node and write it to CloudWatch. Your service profile needs this policy only if you will use services such as Amazon EventBridge or Amazon CloudWatch Logs.

```
Register-IAMRolePolicy `
    -RoleName SSMServiceRole `
    -PolicyArn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Continue to Create a hybrid activation to register nodes with Systems Manager.

Create a hybrid activation to register nodes with Systems Manager

To set up machines other than Amazon Elastic Compute Cloud (EC2) instances as managed nodes for a hybrid and multicloud environment, you create and apply a *hybrid activation*. After you successfully complete the activation, you *immediately* receive an Activation Code and Activation ID at the top of the console page. You specify this Code and ID combination when you install AWS Systems Manager SSM Agent on non-EC2 machines for your hybrid and multicloud environment. The Code and ID provide secure access to the Systems Manager service from your managed nodes.

Important

Systems Manager immediately returns the Activation Code and ID to the console or the command window, depending on how you created the activation. Copy this information and store it in a safe place. If you navigate away from the console or close the command window, you might lose this information. If you lose it, you must create a new activation.

About activation expirations

An *activation expiration* is a window of time when you can register on-premises machines with Systems Manager. An expired activation has no impact on your servers or VMs that you previously registered with Systems Manager. If an activation expires then you can't register more servers or VMs with Systems Manager by using that specific activation. You simply need to create a new one.

Every on-premises server and VM you previously registered remains registered as a Systems Manager managed node until you explicitly deregister it. You can deregister a non-EC2 managed node in the following ways:

- Use the **Managed nodes** tab in Fleet Manager in the Systems Manager console
- Use the AWS CLI command deregister-managed-instance
- Use the API action DeregisterManagedInstance.

For more information, see the following topics

- Deregister and reregister a managed node (Linux)
- Deregister and reregister a managed node (Windows Server)

About managed nodes

A managed node is any machine configured for AWS Systems Manager. AWS Systems Manager supports Amazon Elastic Compute Cloud (Amazon EC2) instances, edge devices, and on-premises servers or VMs, including VMs in other cloud environments. Previously, managed nodes were all referred to as managed instances. The term *instance* now refers to EC2 instances only. The deregister-managed-instance command was named before this terminology change.

About activation tags

If you create an activation by using either the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell, you can specify tags. Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. Here is an AWS CLI sample command to run in the US East (Ohio) Region on a local Linux machine that includes optional tags.

```
aws ssm create-activation \
  --default-instance-name MyWebServers \
  --description "Activation for Finance department webservers" \
  --iam-role service-role/AmazonEC2RunCommandRoleForManagedInstances \
  --registration-limit 10 \
```

```
  --region us-east-2 \
  --tags "Key=Department,Value=Finance"
```

If you specify tags when you create an activation, then those tags are automatically assigned to your managed nodes when you activate them.

You can't add tags to or delete tags from an existing activation. If you don't want to automatically assign tags to your on-premises servers and VMs using an activation, then you can add tags to them later. More specifically, you can tag your on-premises servers and VMs after they connect to Systems Manager for the first time. After they connect, they're assigned a managed node ID and listed in the Systems Manager console with an ID that is prefixed with "mi-".

> **Note**
>
> You can't assign tags to an activation if you create it by using the Systems Manager console. You must create it by using either the AWS CLI or Tools for Windows PowerShell.

If you no longer want to manage an on-premises server or virtual machine (VM) by using Systems Manager, you can deregister it. For information, see Deregistering managed nodes in a hybrid and multicloud environment.

Topics

- Using the AWS Management Console to create an activation for registering managed nodes with Systems Manager
- Using the command line to create an activation for registering managed nodes with Systems Manager

Using the AWS Management Console to create an activation for registering managed nodes with Systems Manager

To create a managed-node activation

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Hybrid Activations**.
3. Choose **Create activation**.

-or-

If you are accessing **Hybrid Activations** for the first time in the current AWS Region, choose **Create an Activation**.

4. (Optional) For **Activation description**, enter a description for this activation. We recommend entering a description if you plan to activate large numbers of servers and VMs.
5. For **Instance limit**, specify the total number of nodes that you want to register with AWS as part of this activation. The default value is 1 instance.
6. For **IAM role**, choose a service role option that allows your servers and VMs to communicate with AWS Systems Manager in the cloud:

   - **Option 1**: Choose **Use the default role created by the system** to use a role and managed policy provided by AWS.
   - **Option 2**: Choose **Select an existing custom IAM role that has the required permissions** to use the optional custom role you created earlier. This role must have a trust relationship policy that specifies `"Service": "ssm.amazonaws.com"`. If your IAM role doesn't specify this principle in a trust relationship policy, you receive the following error:

     ```
     An error occurred (ValidationException) when calling the CreateActivation
                                         operation: Not existing role:
      arn:aws:iam::<accountid>:role/SSMRole
     ```

     For more information about creating this role, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.
7. For **Activation expiry date**, specify an expiration date for the activation. The expiry date must be in the future, and not more than 30 days into the future. The default value is 24 hours.

   > **Note**
   >
   > If you want to register additional managed nodes after the expiry date, you must create a new activation. The expiry date has no impact on registered and running nodes.

8. (Optional) For **Default instance name** field, specify an identifying name value to be displayed for all managed nodes associated with this activation.

9. Choose **Create activation**. Systems Manager immediately returns the Activation Code and ID to the console.

Using the command line to create an activation for registering managed nodes with Systems Manager

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) (on Linux or Windows Server) or AWS Tools for PowerShell to create a managed node activation.

To create an activation

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Run the following command to create an activation.

> **Note**
>
> - In the following command, replace *`region`* with your own information. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.
> - The role you specify for the *`iam-role`* parameter must have a trust relationship policy that specifies `"Service": "ssm.amazonaws.com"`. If your AWS Identity and Access Management (IAM) role doesn't specify this principle in a trust relationship policy, you receive the following error:
>
>   ```
>   An error occurred (ValidationException) when calling the CreateActivation
>                                           operation: Not existing role:
>    arn:aws:iam::<accountid>:role/SSMRole
>   ```
>
>   For more information about creating this role, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.
> - For `--expiration-date`, provide a date in timestamp format, such as `"2021-07-07T00:00:00"`, for when the activation code expires. You can specify a

date up to 30 days in advance. If you don't provide an expiration date, the activation code expires in 24 hours.

Linux & macOS

```
aws ssm create-activation \
    --default-instance-name name \
    --iam-role iam-service-role-name \
    --registration-limit number-of-managed-instances \
    --region region \
    --expiration-date "timestamp" \\
    --tags "Key=key-name-1,Value=key-value-1" "Key=key-name-2,Value=key-value-2"
```

Windows

```
aws ssm create-activation ^
    --default-instance-name name ^
    --iam-role iam-service-role-name ^
    --registration-limit number-of-managed-instances ^
    --region region ^
    --expiration-date "timestamp" ^
    --tags "Key=key-name-1,Value=key-value-1" "Key=key-name-2,Value=key-value-2"
```

PowerShell

```
New-SSMActivation -DefaultInstanceName name `
    -IamRole iam-service-role-name `
    -RegistrationLimit number-of-managed-instances `
    -Region region `
    -ExpirationDate "timestamp" `
    -Tag @{"Key"="key-name-1";"Value"="key-value-1"},@{"Key"="key-
name-2";"Value"="key-value-2"}
```

Here is an example.

Linux & macOS

```
aws ssm create-activation \
    --default-instance-name MyWebServers \
```

```
    --iam-role service-role/AmazonEC2RunCommandRoleForManagedInstances \
    --registration-limit 10 \
    --region us-east-2 \
    --expiration-date "2021-07-07T00:00:00" \
    --tags "Key=Environment,Value=Production" "Key=Department,Value=Finance"
```

Windows

```
aws ssm create-activation ^
    --default-instance-name MyWebServers ^
    --iam-role service-role/AmazonEC2RunCommandRoleForManagedInstances ^
    --registration-limit 10 ^
    --region us-east-2 ^
    --expiration-date "2021-07-07T00:00:00" ^
    --tags "Key=Environment,Value=Production" "Key=Department,Value=Finance"
```

PowerShell

```
New-SSMActivation -DefaultInstanceName MyWebServers `
    -IamRole service-role/AmazonEC2RunCommandRoleForManagedInstances `
    -RegistrationLimit 10 `
    -Region us-east-2 `
    -ExpirationDate "2021-07-07T00:00:00" `
    -Tag
 @{"Key"="Environment";"Value"="Production"},@{"Key"="Department";"Value"="Finance"}
```

If the activation is created successfully, the system immediately returns an Activation Code and ID.

Install SSM Agent on hybrid Linux nodes

This topic describes how to install AWS Systems Manager SSM Agent on non-EC2 (Amazon Elastic Compute Cloud) Linux machines in a hybrid and multicloud environment. For information about installing SSM Agent on EC2 instances for Linux, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.

Before you begin, locate the Activation Code and Activation ID that were generated during the hybrid activation process, as described in Create a hybrid activation to register nodes with Systems Manager. You specify the Code and ID in the following procedure.

To install SSM Agent on non-EC2 machines in a hybrid and multicloud environment

1. Log on to a server or VM in your hybrid and multicloud environment.
2. If you use an HTTP or HTTPS proxy, you must set the `http_proxy` or `https_proxy` environment variables in the current shell session. If you aren't using a proxy, you can skip this step.

   For an HTTP proxy server, enter the following commands at the command line:

   ```
   export http_proxy=http://hostname:port
   export https_proxy=http://hostname:port
   ```

   For an HTTPS proxy server, enter the following commands at the command line:

   ```
   export http_proxy=http://hostname:port
   export https_proxy=https://hostname:port
   ```

3. Copy and paste one of the following command blocks into SSH. Replace the placeholder values with the Activation Code and Activation ID generated during the hybrid activation process and with the identifier of the AWS Region you want to download SSM Agent from, then press `Enter`.

   Important

   Note the following important details:

   - Using `ssm-setup-cli` for non-EC2 installations maximizes the security of your Systems Manager installation and configuration.
   - `sudo` isn't necessary if you're a root user.
   - Download `ssm-setup-cli` from the same AWS Region as where your hybrid activation was created.
   - `ssm-setup-cli` supports a `manifest-url` option that determines the source where the agent is downloaded from. Don't specify a value for this option unless required by your organization.
   - When registering instances, only use the provided download link provided for `ssm-setup-cli`. `ssm-setup-cli` shouldn't be stored separately for future use.
   - You can use the script provided here to validate the signature of `ssm-setup-cli`.

region represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

Additionally, `ssm-setup-cli` includes the following options:

- `version` - Valid values are `latest` and `stable`.
- `downgrade` - Allows the SSM Agent to be downgraded to an earlier version. Specify `true` to install an earlier version of the agent.
- `skip-signature-validation` - Skips the signature validation during the download and installation of the agent.

Amazon Linux 2, RHEL 7.x, and Oracle Linux

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/linux_amd64/ssm-setup-cli
 -o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id
 "activation-id" -region "region"
```

RHEL 8.x

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/linux_amd64/ssm-setup-cli
 -o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id
 "activation-id" -region "region"
```

Debian Server

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/debian_amd64/ssm-setup-
cli -o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
```

```
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id
 "activation-id" -region "region"
```

Ubuntu Server

- **Using .deb packages**

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/debian_amd64/ssm-setup-
cli -o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-
id "activation-id" -region "region"
```

- **Using Snap packages**

  You don't need to specify a URL for the download, because the `snap` command automatically downloads the agent from the Snap app store at https://snapcraft.io.

  On Ubuntu Server 20.04, 18.04, and 16.04 LTS, SSM Agent installer files, including agent binaries and config files, are stored in the following directory: `/snap/amazon-ssm-agent/current/`. If you make changes to any configuration files in this directory, then you must copy these files from the `/snap` directory to the `/etc/amazon/ssm/` directory. Log and library files haven't changed (`/var/lib/amazon/ssm`, `/var/log/amazon/ssm`).

```
sudo snap install amazon-ssm-agent --classic
sudo systemctl stop snap.amazon-ssm-agent.amazon-ssm-agent.service
sudo /snap/amazon-ssm-agent/current/amazon-ssm-agent -register -code "activation-
code" -id "activation-id" -region "region"
sudo systemctl start snap.amazon-ssm-agent.amazon-ssm-agent.service
```

  Important

  The *candidate* channel in the Snap store contains the latest version of SSM Agent; not the stable channel. If you want to track SSM Agent version information on the candidate channel, run the following command on your Ubuntu Server 18.04 and 16.04 LTS 64-bit managed nodes.

```
sudo snap switch --channel=candidate amazon-ssm-agent
```

The command downloads and installs SSM Agent onto the hybrid-activated machine in your hybrid and multicloud environment. The command stops SSM Agent, and then registers the machine with the Systems Manager service. The machine is now a managed node. Amazon EC2 instances configured for Systems Manager are also managed nodes. In the Systems Manager console, however, your hybrid-activated nodes are distinguished from Amazon EC2 instances with the prefix "mi-".

Continue to Install SSM Agent on hybrid Windows Server nodes.

Setting up private key auto rotation

To strengthen your security posture, you can configure AWS Systems Manager Agent (SSM Agent) to automatically rotate the private key for your hybrid and multicloud environment. You can access this feature using SSM Agent version 3.0.1031.0 or later. Turn on this feature using the following procedure.

To configure SSM Agent to rotate the private key for a hybrid and multicloud environment

1. Navigate to `/etc/amazon/ssm/` on a Linux machine or `C:\Program Files\Amazon\SSM` for a Windows machine.
2. Copy the contents of `amazon-ssm-agent.json.template` to a new file named `amazon-ssm-agent.json`. Save `amazon-ssm-agent.json` in the same directory where `amazon-ssm-agent.json.template` is located.
3. Find `Profile`, `KeyAutoRotateDays`. Enter the number of days that you want between automatic private key rotations.
4. Restart SSM Agent.

Every time you change the configuration, restart SSM Agent.

You can customize other features of SSM Agent using the same procedure. For an up-to-date list of the available configuration properties and their default values, see Config Property Definitions.

Deregister and reregister a managed node (Linux)

You can deregister a hybrid-activated managed node by calling the DeregisterManagedInstance API operation from either the AWS CLI or Tools for Windows PowerShell. Here's an example CLI command:

```
aws ssm deregister-managed-instance --instance-id "mi-1234567890"
```

To remove the remaining registration information for the agent, remove the `IdentityConsumptionOrder` key in the `amazon-ssm-agent.json` file. Then, depending on your installation type, run one of the following commands.

On Ubuntu Server nodes where SSM Agent was installed using Snap packages:

```
sudo /snap/amazon-ssm-agent/current/amazon-ssm-agent -register -clear
```

On all other Linux installations:

```
amazon-ssm-agent -register -clear
```

> **Note**
>
> You can reregister an on-premises server, edge device, or VM using the same activation code and ID as long as you haven't reached the instance limit for the designated activation code and ID. You can verify the instance limit for an activation code and ID by calling the describe-activations API using the AWS CLI. After you run the command, verify that the value of `RegistrationCount` doesn't exceed `RegistrationLimit`. If it does, you must use a different activation code and ID.

To reregister a managed node on a non-EC2 Linux machine

1. Connect to your machine.
2. Run the following command. Be sure to replace the placeholder values with the Activation Code and Activation ID generated when you created a managed-node activation, and with the identifier of the Region you want to download the SSM Agent from.

   ```
   echo "yes" | sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id "activation-id" -region "region
   ```

Troubleshooting SSM Agent installation on non-EC2 Linux machines

Use the following information to help you troubleshoot problems installing SSM Agent on hybrid-activated Linux machines in a hybrid and multicloud environment.

You receive DeliveryTimedOut error

Problem: While configuring a machine in one AWS account as a managed node for a separate AWS account, you receive `DeliveryTimedOut` after running the commands to install SSM Agent on the target machine.

Solution: `DeliveryTimedOut` is the expected response code for this scenario. The command to install SSM Agent on the target node changes the node ID of the source node. Because the node ID has changed, the source node isn't able to reply to the target node that the command failed, completed, or timed out while executing.

Unable to load node associations

Problem: After running the install commands, you see the following error in the SSM Agent error logs:

```
Unable to load instance associations, unable to retrieve
associations unable to retrieve associations error occurred in
RequestManagedInstanceRoleToken: MachineFingerprintDoesNotMatch:
Fingerprint doesn't match
```

You see this error when the machine ID doesn't persist after a reboot.

Solution: To solve this problem, run the following command. This command forces the machine ID to persist after a reboot.

```
umount /etc/machine-id
systemd-machine-id-setup
```

Install SSM Agent on hybrid Windows Server nodes

This topic describes how to install AWS Systems Manager SSM Agent on Windows Server machines in a hybrid and multicloud environment. For information about installing SSM Agent on EC2 instances for Windows Server, see Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server.

Before you begin, locate the Activation Code and Activation ID that were generated during the hybrid activation process, as described in Create a hybrid activation to register nodes with Systems Manager. You specify the Code and ID in the following procedure.

To install SSM Agent on non-EC2 Windows Server machines in a hybrid and multicloud environment

1. Log on to a server or VM in your hybrid and multicloud environment.
2. If you use an HTTP or HTTPS proxy, you must set the `http_proxy` or `https_proxy` environment variables in the current shell session. If you aren't using a proxy, you can skip this step.

   For an HTTP proxy server, set this variable:

   ```
   http_proxy=http://hostname:port
   https_proxy=http://hostname:port
   ```

   For an HTTPS proxy server, set this variable:

   ```
   http_proxy=http://hostname:port
   https_proxy=https://hostname:port
   ```
3. Open Windows PowerShell in elevated (administrative) mode.
4. Copy and paste the following command block into Windows PowerShell. Replace each *`example resource placeholder`* with your own information. For example, the Activation Code and Activation ID generated when you create a hybrid activation, and with the identifier of the AWS Region you want to download SSM Agent from.

   Important

   Note the following important details:

   - Using `ssm-setup-cli` for non-EC2 installations maximizes the security of your Systems Manager installation and configuration.
   - `ssm-setup-cli` supports a `manifest-url` option that determines the source where the agent is downloaded from. Don't specify a value for this option unless required by your organization.
   - You can use the script provided here to validate the signature of `ssm-setup-cli`.
   - When registering instances, only use the provided download link provided for `ssm-setup-cli`. `ssm-setup-cli` shouldn't be stored separately for future use.

region represents the identifier for an AWS Region supported by AWS Systems Manager, such as us-east-2 for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

Additionally, ssm-setup-cli includes the following options:

- version - Valid values are latest and stable.
- downgrade - Reverts the agent to an earlier version.
- skip-signature-validation - Skips the signature validation during the download and installation of the agent.

64-bit

```
[System.Net.ServicePointManager]::SecurityProtocol = 'TLS12'
$code = "activation-code"
$id = "activation-id"
$region = "us-east-1"
$dir = $env:TEMP + "\ssm"
New-Item -ItemType directory -Path $dir -Force
cd $dir
(New-Object System.Net.WebClient).DownloadFile("https://amazon-ssm-$region.s3.
$region.amazonaws.com/latest/windows_amd64/ssm-setup-cli.exe", $dir + "\ssm-
setup-cli.exe")
./ssm-setup-cli.exe -register -activation-code="$code" -activation-id="$id" -
region="$region"
Get-Content ($env:ProgramData + "\Amazon\SSM\InstanceData\registration")
Get-Service -Name "AmazonSSMAgent"
```

5. Press Enter.

> **Note**
>
> If the command fails, verify that you are running the latest version of AWS Tools for PowerShell.

The command does the following:

- Downloads and installs SSM Agent onto the machine.
- Registers the machine with the Systems Manager service.
- Returns a response to the request similar to the following:

```
    Directory: C:\Users\ADMINI~1\AppData\Local\Temp\2

Mode                 LastWriteTime         Length Name
----                 -------------         ------ ----
d-----       07/07/2018   8:07 PM                ssm
{"ManagedInstanceID":"mi-008d36be46EXAMPLE","Region":"us-east-2"}

Status      : Running
Name        : AmazonSSMAgent
DisplayName : Amazon SSM Agent
```

The machine is now a *managed node*. These managed nodes are now identified with the prefix "mi-". You can view managed nodes on the **Managed node** page in Fleet Manager, by using the AWS CLI command describe-instance-information, or by using the API command DescribeInstanceInformation.

Setting up private key auto rotation

To strengthen your security posture, you can configure AWS Systems Manager Agent (SSM Agent) to automatically rotate the private key for a hybrid and multicloud environment. You can access this feature using SSM Agent version 3.0.1031.0 or later. Turn on this feature using the following procedure.

To configure SSM Agent to rotate the private key for a hybrid and multicloud environment

1. Navigate to `/etc/amazon/ssm/` on a Linux machine or `C:\Program Files\Amazon\SSM` for a Windows Server machine.
2. Copy the contents of `amazon-ssm-agent.json.template` to a new file named `amazon-ssm-agent.json`. Save `amazon-ssm-agent.json` in the same directory where `amazon-ssm-agent.json.template` is located.

3. Find `Profile`, `KeyAutoRotateDays`. Enter the number of days that you want between automatic private key rotations.
4. Restart SSM Agent.

Every time you change the configuration, restart SSM Agent.

You can customize other features of SSM Agent using the same procedure. For an up-to-date list of the available configuration properties and their default values, see Config Property Definitions.

Deregister and reregister a managed node (Windows Server)

You can deregister a managed node by calling the DeregisterManagedInstance API operation from either the AWS CLI or Tools for Windows PowerShell. Here's an example CLI command:

```
aws ssm deregister-managed-instance --instance-id "mi-1234567890"
```

To remove the remaining registration information for the agent, remove the `IdentityConsumptionOrder` key in the `amazon-ssm-agent.json` file. Then run the following command:

```
amazon-ssm-agent -register -clear
```

> **Note**
>
> You can reregister an on-premises server, edge device, or VM using the same activation code and ID as long as you haven't reached the instance limit for the designated activation code and ID. You can verify the instance limit for an activation code and ID by calling the describe-activations API using the AWS CLI. After you run the command, verify that the value of `RegistrationCount` doesn't exceed `RegistrationLimit`. If it does, you must use a different activation code and ID.

To reregister a managed node on a Windows Server hybrid machine

1. Connect to your machine.
2. Run the following command. Be sure to replace the placeholder values with the Activation Code and Activation ID generated when you created a hybrid activation, and with the identifier of the Region you want to download the SSM Agent from.

```
$dir = $env:TEMP + "\ssm"
cd $dir
Start-Process ./ssm-setup-cli.exe -ArgumentList @(
    "-register",
    "-activation-code=$code",
    "-activation-id=$id",
    "-region=$region"
) -Wait -NoNewWindow
```

Managing edge devices with Systems Manager

This section describes the setup tasks that account and system administrators perform to enable configuration and management of AWS IoT Greengrass core devices. After you complete these tasks, users who have been granted permissions by the AWS account administrator can use AWS Systems Manager to configure and manage their organization's AWS IoT Greengrass core devices.

Note

- SSM Agent for AWS IoT Greengrass isn't supported on macOS and Windows 10. You can't use Systems Manager tools to manage and configure edge devices that use these operating systems.
- Systems Manager also supports edge devices that aren't configured as AWS IoT Greengrass core devices. To use Systems Manager to manage AWS IoT Core devices and non-AWS edge devices, you must configure them using a hybrid activation. For more information, see Managing nodes in hybrid and multicloud environments with Systems Manager.
- To use Session Manager and Microsoft application patching with your edge devices, you must enable the advanced-instances tier. For more information, see Turning on the advanced-instances tier.

Before you begin

Verify that your edge devices meet the following requirements.

- Your edge devices must meet the requirements to be configured as AWS IoT Greengrass core devices. For more information, see Setting up AWS IoT Greengrass core devices in the *AWS IoT Greengrass Version 2 Developer Guide*.
- Your edge devices must be compatible with AWS Systems Manager Agent (SSM Agent). For more information, see Supported operating systems for Systems Manager.
- Your edge devices must be able to communicate with the Systems Manager service in the cloud. Systems Manager doesn't support disconnected edge devices.

About setting up edge devices

Setting up AWS IoT Greengrass devices for Systems Manager involves the following processes.

> **Note**
>
> For information about uninstalling SSM Agent from an edge device, see Uninstall the AWS Systems Manager Agent in the *AWS IoT Greengrass Version 2 Developer Guide*.

Create an IAM service role for your edge devices

AWS IoT Greengrass core devices require an AWS Identity and Access Management (IAM) service role to communicate with AWS Systems Manager. The role grants AWS Security Token Service (AWS STS) AssumeRole trust to the Systems Manager service. You only need to create the service role once for each AWS account. You will specify this role for the `RegistrationRole` parameter when you configure and deploy the SSM Agent component to your AWS IoT Greengrass devices. If you already created this role while setting up non-EC2 nodes for a hybrid and multicloud environment, you can skip this step.

> **Note**
>
> Users in your company or organization who will use Systems Manager on your edge devices must be granted permission in IAM to call the Systems Manager API.

S3 bucket policy requirement

If either of the following cases are true, you must create a custom IAM permission policy for Amazon Simple Storage Service (Amazon S3) buckets before completing this procedure:

- **Case 1**: You're using a VPC endpoint to privately connect your VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink.
- **Case 2**: You plan to use an S3 bucket that you create as part of your Systems Manager operations, such as for storing output for Run Command commands or Session Manager sessions to an S3 bucket. Before proceeding, follow the steps in Create a custom S3 bucket policy for an instance profile. The information about S3 bucket policies in that topic also applies to your service role.

> **Note**
>
> If your devices are protected by a firewall and you plan to use Patch Manager, the firewall must allow access to the patch baseline endpoint `arn:aws:s3:::patch-baseline-snapshot-`*`region`*`/*`.
> *`region`* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

AWS CLI

To create an IAM service role for an AWS IoT Greengrass environment (AWS CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. On your local machine, create a text file with a name such as `SSMService-Trust.json` with the following trust policy. Make sure to save the file with the `.json` file extension.

   > **Note**
   >
   > Make a note of the name. You will specify it when you deploy SSM Agent to your AWS IoT Greengrass core devices.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": {
            "Service": "ssm.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }
}
```

3. Open the AWS CLI, and in the directory where you created the JSON file, run the create-role command to create the service role. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws iam create-role \
    --role-name SSMServiceRole \
    --assume-role-policy-document file://SSMService-Trust.json
```

Windows

```
aws iam create-role ^
    --role-name SSMServiceRole ^
    --assume-role-policy-document file://SSMService-Trust.json
```

4. Run the attach-role-policy command as follows to allow the service role you just created to create a session token. The session token gives your edge devices permission to run commands using Systems Manager.

> **Note**
>
> The policies you add for a service profile for edge devices are the same policies used to create an instance profile for Amazon Elastic Compute Cloud (Amazon

EC2) instances. For more information about the IAM policies used in the following commands, see Configure instance permissions required for Systems Manager.

(Required) Run the following command to allow an edge device to use AWS Systems Manager service core functionality.

Linux & macOS

```
aws iam attach-role-policy \
    --role-name SSMServiceRole \
    --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

Windows

```
aws iam attach-role-policy ^
    --role-name SSMServiceRole ^
    --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

If you created a custom S3 bucket policy for your service role, run the following command to allow AWS Systems Manager Agent (SSM Agent) to access the buckets you specified in the policy. Replace *account_ID* and *my_bucket_policy_name* with your AWS account ID and your bucket name.

Linux & macOS

```
aws iam attach-role-policy \
    --role-name SSMServiceRole \
    --policy-arn arn:aws:iam::account_ID:policy/my_bucket_policy_name
```

Windows

```
aws iam attach-role-policy ^
    --role-name SSMServiceRole ^
    --policy-arn arn:aws:iam::account_id:policy/my_bucket_policy_name
```

(Optional) Run the following command to allow SSM Agent to access AWS Directory Service on your behalf for requests to join the domain from edge devices. The service role needs this policy only if you join your edge devices to a Microsoft AD directory.

Linux & macOS

```
aws iam attach-role-policy \
    --role-name SSMServiceRole \
    --policy-arn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

Windows

```
aws iam attach-role-policy ^
    --role-name SSMServiceRole ^
    --policy-arn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

(Optional) Run the following command to allow the CloudWatch agent to run on your edge devices. This command makes it possible to read information on a device and write it to CloudWatch. Your service role needs this policy only if you will use services such as Amazon EventBridge or Amazon CloudWatch Logs.

```
aws iam attach-role-policy \
    --role-name SSMServiceRole \
    --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Tools for PowerShell

To create an IAM service role for an AWS IoT Greengrass environment (AWS Tools for Windows PowerShell)

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

   For information, see Installing the AWS Tools for PowerShell.

2. On your local machine, create a text file with a name such as `SSMService-Trust.json` with the following trust policy. Make sure to save the file with the `.json` file extension.

> **Note**
>
> Make a note of the name. You will specify it when you deploy SSM Agent to your AWS IoT Greengrass core devices.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": {
            "Service": "ssm.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }
}
```

3. Open PowerShell in administrative mode, and in the directory where you created the JSON file, run New-IAMRole as follows to create a service role.

```
New-IAMRole `
    -RoleName SSMServiceRole `
    -AssumeRolePolicyDocument (Get-Content -raw SSMService-Trust.json)
```

4. Use Register-IAMRolePolicy as follows to allow the service role you created to create a session token. The session token gives your edge devices permission to run commands using Systems Manager.

> **Note**
>
> The policies you add for a service role for edge devices in an AWS IoT Greengrass environment are the same policies used to create an instance profile for EC2 instances. For more information about the AWS policies used in the following commands, see Configure instance permissions required for Systems Manager.

(Required) Run the following command to allow an edge device to use AWS Systems Manager service core functionality.

```
Register-IAMRolePolicy `
    -RoleName SSMServiceRole `
    -PolicyArn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

If you created a custom S3 bucket policy for your service role, run the following command to allow SSM Agent to access the buckets you specified in the policy. Replace *account_ID* and *my_bucket_policy_name* with your AWS account ID and your bucket name.

```
Register-IAMRolePolicy `
    -RoleName SSMServiceRole `
    -PolicyArn arn:aws:iam::account_ID:policy/my_bucket_policy_name
```

(Optional) Run the following command to allow SSM Agent to access AWS Directory Service on your behalf for requests to join the domain from edge devices. The service role needs this policy only if you join your edge devices to a Microsoft AD directory.

```
Register-IAMRolePolicy `
    -RoleName SSMServiceRole `
    -PolicyArn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

(Optional) Run the following command to allow the CloudWatch agent to run on your edge devices. This command makes it possible to read information on a device and write it to CloudWatch. Your service role needs this policy only if you will use services such as Amazon EventBridge or Amazon CloudWatch Logs.

```
Register-IAMRolePolicy `
    -RoleName SSMServiceRole `
    -PolicyArn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Configure your edge devices for AWS IoT Greengrass

Set up your edge devices as AWS IoT Greengrass core devices. The setup process involves verifying supported operating systems and system requirements, as well as installing and configuring the AWS IoT Greengrass Core software on your devices. For more information, see Setting up AWS IoT Greengrass core devices in the *AWS IoT Greengrass Version 2 Developer Guide*.

Update the AWS IoT Greengrass token exchange role and install SSM Agent on your edge devices

The final step for setting up and configuring your AWS IoT Greengrass core devices for Systems Manager requires you to update the AWS IoT Greengrass AWS Identity and Access Management

(IAM) device service role, also called the *token exchange role*, and deploy AWS Systems Manager Agent (SSM Agent) to your AWS IoT Greengrass devices. For information about these processes, see Install the AWS Systems Manager Agent in the *AWS IoT Greengrass Version 2 Developer Guide*.

After you deploy SSM Agent to your devices, AWS IoT Greengrass automatically registers your devices with Systems Manager. No additional registration is necessary. You can begin using Systems Manager tools to access, manage, and configure your AWS IoT Greengrass devices.

> **Note**
>
> Your edge devices must be able to communicate with the Systems Manager service in the cloud. Systems Manager doesn't support disconnected edge devices.

Creating an AWS Organizations delegated administrator for Systems Manager

When you set up an organization in AWS Organizations, you assign a management account to perform all administrative tasks for all AWS services. The management account user can assign a *delegated administrator account* only for Systems Manager to perform administrative tasks for Change Manager, Explorer, and OpsCenter. AWS Organizations is an account management service that you can use to create an organization and assign AWS accounts to manage these accounts centrally. For information about AWS Organizations, see AWS Organizations in the *AWS Organizations User Guide*.

Change Manager, Explorer, and OpsCenter, tools in AWS Systems Manager, work with AWS Organizations to perform tasks on all member accounts of your organization. You can assign only one delegated administrator for all Systems Manager tools. The delegated administrator account must be a member of the organization to which it's assigned.

Topics

Using a delegated administrator with Change Manager

Change Manager is an enterprise change management framework for requesting, approving, implementing, and reporting on operational changes to your application configuration and infrastructure.

If you use Change Manager across an organization, assign a delegated administrator account to manage change templates, approvals, and reporting for all member accounts. Using Quick Setup, you can set up Change Manager to use with an organization and select the delegated administrator account. If you use Change Manager with a single AWS account, the delegated administrator account isn't required.

By default, Change Manager displays all change-related tasks in the delegated administrator account. For instructions on configuring a delegated administrator while setting up Change Manager for an organization, see Setting up Change Manager for an organization (management account).

> **Important**
>
> If you use Change Manager across an organization, we recommend always making changes from the delegated administrator account. Although you can make changes from other accounts in the organization, those changes won't be reported in or viewable from the delegated administrator account.

Using a delegated administrator with Explorer

Explorer is a customizable operations dashboard that reports aggregated view of operations data (OpsData) for your AWS accounts, across AWS Regions.

You can configure a delegated administrator account for Systems Manager to aggregate Explorer data from multiple Regions and accounts by using resource data sync with AWS Organizations. A delegated administrator can search, filter, and aggregate Explorer data using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell.

When you use a delegated administrator account for Explorer, you limit the number of administrators who can create or delete multi-account and Region resource data syncs to an individual AWS account.

You can synchronize operations data across all AWS accounts in your organization by using Explorer. For information on how to assign a delegated administrator from Explorer, see Configuring a delegated administrator for Explorer.

Using a delegated administrator with OpsCenter

OpsCenter provides a central location where operations engineers and IT professionals can manage operational work items (OpsItems) related to AWS resources. If you want to use OpsCenter to manage OpsItems centrally across accounts, you must set up the organization in AWS Organizations.

Using Quick Setup for OpsCenter, you can assign a delegated administrator account and configure OpsCenter to manage OpsItems centrally. For more information, see (Optional) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup.

Using a delegated administrator with Quick Setup

Quick Setup is a tool in Systems Manager that helps you to quickly configure frequently used AWS services and features with recommended best practices. You can configure a delegated administrator account for Quick Setup to help you deploy and manage configurations across accounts and Regions using AWS Organizations. A delegated administrator for Quick Setup can create, update, view, and delete configuration manager resources in your organization. Systems Manager registers a delegated administrator for Quick Setup as part of the setup process for the integrated console experience. For more information, see Setting up Systems Manager unified console for an organization.

General setup for AWS Systems Manager

If you haven't already done so, sign up for an AWS account and create an administrative user.

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

1. Open https://portal.aws.amazon.com/billing/signup.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call or text message and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to a user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing **My Account**.

Create a user with administrative access

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the AWS Management Console as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

   For help signing in by using root user, see Signing in as the root user in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

   For instructions, see Enable a virtual MFA device for your AWS account root user (console) in the *IAM User Guide*.

Create a user with administrative access

1. Enable IAM Identity Center.

   For instructions, see Enabling AWS IAM Identity Center in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to a user.

For a tutorial about using the IAM Identity Center directory as your identity source, see Configure user access with the default IAM Identity Center directory in the *AWS IAM Identity Center User Guide*.

Sign in as the user with administrative access

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

  For help signing in using an IAM Identity Center user, see Signing in to the AWS access portal in the *AWS Sign-In User Guide*.

Assign access to additional users

1. In IAM Identity Center, create a permission set that follows the best practice of applying least-privilege permissions.

   For instructions, see Create a permission set in the *AWS IAM Identity Center User Guide*.
2. Assign users to a group, and then assign single sign-on access to the group.

   For instructions, see Add groups in the *AWS IAM Identity Center User Guide*.

Setting up AWS Systems Manager

The following topics describe how to set up the unified AWS Systems Manager console for AWS Organizations organizations and single AWS accounts.

Topics

Setting up Systems Manager console access

To use AWS Systems Manager in the AWS Management Console, you must have the correct permissions configured.

For more information about how to create AWS Identity and Access Management policies and attach them to IAM identities, see Create IAM policies in the *IAM User Guide*

Systems Manager onboarding policy

You can create an IAM policy like the one shown in the following example, and attach the policy to your IAM identities. This policy grants full access to onboard to and configure Systems Manager.

Permissions details

This policy includes the following permissions.

- `ssm-quicksetup` – Allows principals to access all AWS Systems Manager Quick Setup actions.
- `ssm` – Allows principals access to Systems Manager Automation and Resource Explorer.
- `organizations` – Allows principals to read an organization's structure in AWS Organizations, and manage delegated administrators when they are onboarding to Systems Manager as an organization.
- `cloudformation` – Allows principals to manage their Quick Setup stacks.
- `iam` – Allows principals to manage IAM roles and policies that are required for Systems Manager onboarding.

AWSServiceRoleForResourceExplorer"
      ]
    }
  ]
}
```

AWS Systems Manager console operator policy

You can create an IAM policy like the one shown in the following example, and attach the policy to your IAM identities. This policy grants full access to operate Systems Manager, and allow Systems Manager to run Automation documents for diagnosis and remediation.

Permissions details

This policy includes the following permissions.

- `ssm` – Allows principals to access all Systems Manager APIs.
- `ssm-quicksetup` – Allows principals to manage their Quick Setup configurations.

- `ec2` – Allows Systems Manager to determine your enabled AWS Regions and Amazon EC2 instance status.
- `cloudformation` – Allows principals to read their Quick Setup stacks.
- `organizations` – Allows principals to read an organization's structure in AWS Organizations, and manage delegated administrators when they are onboarding to Systems Manager as an organization.
- `s3` – Allows principals to list and get objects in an Amazon S3 bucket for diagnosis, which is created during the Systems Manager onboarding process.
- `iam:PassRole` – Allows principals to pass roles to be assumed to Systems Manager when they run automations for diagnosis and remediation of unmanaged nodes.
- `iam:GetRole` – Allows principals to get specific role information for Quick Setup roles when they are working in Systems Manager.

AWS Systems Manager console operator read-only policy

You can create an IAM policy like the one shown in the following example, and attach the policy to your IAM identities. This policy grants read-only access to use Systems Manager.

- `ssm` – Allows principals access to Systems Manager read-only APIs.
- `ssm-quicksetup` – Allows principals to read their Quick Setup configurations.
- `cloudformation` – Allows principals to read their Quick Setup stacks.
- `iam:GetRole` – Allows principals to get specific role information for Quick Setup roles when they are using Systems Manager.
- `ec2:DescribeRegions` – Allows Systems Manager to determine your enabled AWS Regions.
- `organizations` – Allows principals to read an organization's structure in AWS Organizations when they are onboarding to Systems Manager as an organization.
- `s3` – Allows principals to list and get objects in an Amazon S3 bucket that is created during the Systems Manager onboarding process.

Permissions details

This policy includes the following permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",

    }
  ]
}
```

Setting up Systems Manager unified console for an organization

The setup process for the Systems Manager unified console experience is completed from the AWS Management Console with just a few clicks. To set up Systems Manager for an AWS Organizations

organization, you must have access to the management account for your organization and another account in your organization to use as a delegated administrator. Access to the management account is only required to enable or disable Systems Manager. To manage your nodes, you'll use the delegated administrator account.

Prerequisites

When managing nodes across an organization, Systems Manager uses various dependent services to set up and enhance the functionality of the unified console. As a result, Systems Manager must enable trusted access and register a delegated administrator account for the following services:

- AWS CloudFormation - Deploys resources required for Systems Manager to your accounts.
- AWS Resource Explorer - Searching and filtering EC2 instances in your accounts.
- AWS Systems Manager Explorer - Monitoring and troubleshooting the health of resources deployed for Systems Manager in your accounts.
- AWS Systems Manager Quick Setup - Deploys Quick Setup configurations required for Systems Manager to your accounts.

Before you begin, make sure you're not already over the quota for delegated administrators for any of these dependent services. Otherwise, you won't be able to register the delegated administrator accounts necessary to enable Systems Manager. When you enable Systems Manager for an organization, every account in your organization is included. At this time, there is no provision for excluding accounts from the setting up process. When you enable Systems Manager, you can choose the AWS Regions you want to include. Only Regions that currently support the Systems Manager unified console can be selected. To learn more about the Regions where the console experience is available, see Supported AWS Regions.

Unified console resources

The setup process for the Systems Manager unified console completes many prerequisite tasks for you. Depending on the features you choose to configure, this includes enabling Default Host Management Configuration to provide the required IAM permissions to your nodes and more. The following is a detailed list of the resources created by Systems Manager for the unified console. Depending on the features you choose to configure, some resources might not be created.

AWS Resource Explorer managed views

- `AWSManagedViewForSSM` – Allows Systems Manager to access resource information indexed by Resource Explorer for your organization. These managed views can only be updated or deleted by Systems Manager. This means that if you want to delete the managed views, or turn off Resource Explorer, you must disable the unified console. For more information about disabling the unified console, see Disabling the Systems Manager unified console. For more information about managed views, see AWS Managed Views in the *Resource Explorer User Guide*.

> **Note**
>
> If you've created an aggregator index for Resource Explorer in a Region different than your home Region, Systems Manager demotes the current index. Then, Systems Manager promotes the local index in your home Region as the new aggregator index. During this time, only nodes for your home Region are displayed. This process can take up to 24 hours to complete.

IAM roles

- `RoleForOnboardingAutomation` – Allows Systems Manager to manage resources during the setting up process. For more information about the policy, see AWSQuickSetupSSMManageResourcesExecutionPolicy.
- `RoleForLifecycleManagement` – Allows Lambda to manage the lifecycle of resources created by the setting up process. For more information about the policy, see AWSQuickSetupSSMLifecycleManagementExecutionPolicy.
- `RoleForAutomation` – A service role for Systems Manager Automation to assume to execute runbooks. For more information, see Create the service roles for Automation using the console.
- `AWSSSMDiagnosisAdminRole` – An adminsitrative role used to start automations that use diagnosis runbooks. For more information about the policies, see AWS-SSM-DiagnosisAutomation-AdministrationRolePolicy, AWS-SSM-Automation-DiagnosisBucketPolicy, and AWS-SSM-DiagnosisAutomation-OperationalAccountAdministrationRolePolicy.
- `AWSSSMDiagnosisExecutionRole` – An automation execution role for the diagnosis runbook. For more information about the policies, see AWS-SSM-DiagnosisAutomation-ExecutionRolePolicy and AWS-SSM-Automation-DiagnosisBucketPolicy.
- `AWSSSMRemediationAdminRole` – An adminsitrative role used to start automations that use remediation runbooks. For more information about the policies, see AWS-SSM-RemediationAutomation-AdministrationRolePolicy, AWS-SSM-

Automation-DiagnosisBucketPolicy, and AWS-SSM-RemediationAutomation-OperationalAccountAdministrationRolePolicy.

- `AWSSSMRemediationExecutionRole` – An automation execution role for the remediation runbook. For more information about the policies, see AWS-SSM-RemediationAutomation-ExecutionRolePolicy and AWS-SSM-Automation-DiagnosisBucketPolicy.
- `ManagedInstanceCrossAccountManagementRole` – Allows Systems Manager to gather managed node information across accounts.

State Manager associations

- `EnableDHMCAssociation` – Runs daily and ensures Default Host Management Configuration is enabled.
- `SystemAssociationForEnablingExplorer` – Runs daily and ensures Explorer is enabled. Explorer is used to sync data from your managed nodes.
- `EnableAREXAssociation` – Runs daily and ensures AWS Resource Explorer is enabled. Resource Explorer is used to determine which Amazon EC2 instances in your organization aren't managed by Systems Manager.
- `SSMAgentUpdateAssociation` – Runs every 14 days and ensures the latest available version of SSM Agent is installed on your managed nodes.
- `SystemAssociationForInventoryCollection` – Runs every 12 hours and collects inventory data from your managed nodes.

S3 buckets

- `DiagnosisBucket` – Stores data collected from the diagnosis runbook execution.

Lambda functions

- `SSMLifecycleOperatorLambda` – Allows principals to access all AWS Systems Manager Quick Setup actions.
- `SSMLifecycleResource` – Custom resource to help manage the lifecycle of resources created by the setting up process.

Additionally, after the setup process completes you can select the **Diagnose and remediate** node task to automatically apply fixes to nodes that aren't reporting as managed by Systems Manager.

This can include identifying issues such as network connectivity issues to the Systems Manager endpoints, and more. For more information, see Diagnosing and remediating.

Set up the unified console

To set up Systems Manager for an organization

1. Log in to the management account for your organization.
2. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
3. Enter the ID of the account you want to register as a delegated administrator.
4. After the delegated administrator account is successfully registered, log in to the delegated administrator account you just registered and return to the Systems Manager console to finish setting up Systems Manager.
5. Select **Enable Systems Manager**.
6. In the **Home Region** section, you determine a Region where you want Systems Manager to aggregate your node data. By default, Systems Manager selects the Region you're currently using. To choose a different home Region, change the console to the Region you want to use before you set up Systems Manager. Node data is replicated across accounts and Regions for your organization and stored in the home Region. The Region you choose can't be changed after Systems Manager is set up. To use a different Region as the home Region for your organization, you must disable the unified console and complete the setup process again. If your organization uses IAM Identity Center, you must select the same Region where you set up IAM Identity Center as your home Region.
7. In the **Regions** section, select the Regions where you want to enable Systems Manager.
8. In the **Feature configurations** section, choose the options that you want to enable for your configuration:

   Enable Default Host Management Configuration (DHMC)

   Allows Systems Manager to configure DHMC. This feature allows Systems Manager to use an IAM role to ensure that all Amazon EC2 instances in the account and Region have the permissions necessary to be managed by Systems Manager. You can also specify the frequency of drift remediation. Configuration drift occurs whenever a user makes any change to a service or feature that conflicts with the selections made through your configuration. Systems Manager checks for configuration drift and attempts to remediate it based on the frequency you specify. You must specify a value between 1 and 31 days. If

you've already configured DHMC in a Region, Systems Manager doesn't change the IAM role you previously selected. For more information about DHMC, see Managing EC2 instances automatically with Default Host Management Configuration.

DHMC makes it possible to manage Amazon EC2 instances without your having to manually create an AWS Identity and Access Management (IAM) instance profile. We encourage you to choose this option to ensure that your EC2 instances have the permissions necessary to be managed by Systems Manager.

Enable inventory metadata collection

Enables Systems Manager to configure collection of the following types of metadata from your nodes:

- **AWS components** – EC2 driver, agents, versions, and more.
- **Applications** – Application names, publishers, versions, and more.
- **Node details** – System name, operating system (OS) name, OS version, last boot, DNS, domain, work group, OS architecture, and more.
- **Network configuration** – IP address, MAC address, DNS, gateway, subnet mask, and more.
- **Services** – Name, display name, status, dependent services, service type, start type, and more (Windows Server nodes only).
- **Windows roles** – Name, display name, path, feature type, installed state, and more (Windows Server nodes only).
- **Windows updates** – Hotfix ID, installed by, installed date, and more (Windows Server nodes only).

Specify the frequency at which inventory is collected. You must specify a value between 1 and 744 hours. For more information about Inventory, a tool in AWS Systems Manager, see AWS Systems Manager Inventory.

Enable automatic Systems Manager (SSM) Agent updates

Enables Systems Manager to check for a new version of the agent at the frequency you specify. The value for the frequency must be between 1 and 31 days. If there is a new version, then Systems Manager automatically updates the agent on your managed node to the latest released version. Systems Manager doesn't install the agent on instances where it's not already present. For information about which AMIs have SSM Agent preinstalled, see Find AMIs with the SSM Agent preinstalled.

We encourage you to choose this option to ensure that your nodes are always running the most up-to-date version of SSM Agent. For more information about SSM Agent, including information about how to manually install the agent, see Working with SSM Agent.

9. Choose **Submit**.

Depending on the size of your organization, it can take an extended amount of time to set up the Systems Manager unified console experience.

Setting up Systems Manager unified console for a single account and Region

To set up the Systems Manager unified console experience for a single AWS account and AWS Region you don't need to use Organizations or register a delegated administrator account. The setup process for the Systems Manager console experience completes many prerequisite tasks for you. Depending on the features you choose to configure, this includes enabling Default Host Management Configuration to provide the required IAM permissions to your nodes and more. The following is a detailed list of the resources created by Systems Manager for the unified console.

Unified console resources

Depending on the features you choose to configure, some resources might not be created.

IAM roles

- `RoleForOnboardingAutomation` – Allows Systems Manager to manage resources during the setting up process. For more information about the policy, see AWSQuickSetupSSMManageResourcesExecutionPolicy.
- `RoleForLifecycleManagement` – Allows Lambda to manage the lifecycle of resources created by the setting up process. For more information about the policy, see AWSQuickSetupSSMLifecycleManagementExecutionPolicy.
- `RoleForAutomation` – A service role for Systems Manager Automation to assume to execute runbooks. For more information, see Create the service roles for Automation using the console.
- `AWSSSMDiagnosisAdminRole` – An automation execution role for the diagnosis runbook. For more information about the policies, see AWS-SSM-DiagnosisAutomation-AdministrationRolePolicy, AWS-SSM-Automation-DiagnosisBucketPolicy, and AWS-SSM-DiagnosisAutomation-OperationalAccountAdministrationRolePolicy.

- `AWSSSMRemediationAdminRole` – An automation execution role for the remediation runbook. For more information about the policies, see AWS-SSM-RemediationAutomation-AdministrationRolePolicy, AWS-SSM-Automation-DiagnosisBucketPolicy, and AWS-SSM-RemediationAutomation-OperationalAccountAdministrationRolePolicy.
- `ManagedInstanceCrossAccountManagementRole` – Allows Systems Manager to gather managed node information across accounts.

State Manager associations

- `EnableDHMCAssociation` – Runs daily and ensures Default Host Management Configuration is enabled.
- `SystemAssociationForEnablingExplorer` – Runs daily and ensures Explorer is enabled. Explorer is used to sync data from your managed nodes.
- `EnableAREXAssociation` – Runs daily and ensures AWS Resource Explorer is enabled. Resource Explorer is used to determine which Amazon EC2 instances in your organization aren't managed by Systems Manager.
- `SSMAgentUpdateAssociation` – Runs every 14 days and ensures the latest available version of SSM Agent is installed on your managed nodes.
- `SystemAssociationForInventoryCollection` – Runs every 12 hours and collects inventory data from your managed nodes.

S3 buckets

- `DiagnosisBucket` – Stores data collected from the diagnosis runbook execution.

Lambda functions

- `SSMLifecycleOperatorLambda` – Allows principals to access all AWS Systems Manager Quick Setup actions.
- `SSMLifecycleResource` – Custom resource to help manage the lifecycle of resources created by the setting up process.

Additionally, after the setup process completes you can select the **Diagnose and remediate** node task to automatically apply fixes to nodes that aren't reporting as managed by Systems Manager.

This can include identifying issues such as network connectivity issues to the Systems Manager endpoints, and more.

Set up the unified console

To set up Systems Manager for a single account and Region

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Enable Systems Manager**.
3. In the **Feature configurations** section, choose the options that you want to enable for your configuration:

Enable Default Host Management Configuration (DHMC)

Allows Systems Manager to configure DHMC. This feature allows Systems Manager to use an IAM role to ensure that all Amazon EC2 instances in the account and Region have the permissions necessary to be managed by Systems Manager. You can also specify the frequency of drift remediation. Configuration drift occurs whenever a user makes any change to a service or feature that conflicts with the selections made through your configuration. Systems Manager checks for configuration drift and attempts to remediate it based on the frequency you specify. You must specify a value between 1 and 31 days. If you've already configured DHMC in a Region, Systems Manager doesn't change the IAM role you previously selected. For more information about DHMC, see Managing EC2 instances automatically with Default Host Management Configuration.

DHMC makes it possible to manage Amazon EC2 instances without your having to manually create an AWS Identity and Access Management (IAM) instance profile. We encourage you to choose this option to ensure that your EC2 instances have the permissions necessary to be managed by Systems Manager.

Enable inventory metadata collection

Enables Systems Manager to configure collection of the following types of metadata from your nodes:

- **AWS components** – EC2 driver, agents, versions, and more.
- **Applications** – Application names, publishers, versions, and more.

- **Node details** – System name, operating system (OS) name, OS version, last boot, DNS, domain, work group, OS architecture, and more.
- **Network configuration** – IP address, MAC address, DNS, gateway, subnet mask, and more.
- **Services** – Name, display name, status, dependent services, service type, start type, and more (Windows Server nodes only).
- **Windows roles** – Name, display name, path, feature type, installed state, and more (Windows Server nodes only).
- **Windows updates** – Hotfix ID, installed by, installed date, and more (Windows Server nodes only).

Specify the frequency at which inventory is collected. You must specify a value between 1 and 744 hours. For more information about Inventory, a tool in AWS Systems Manager, see AWS Systems Manager Inventory.

Enable automatic Systems Manager (SSM) Agent updates

Enables Systems Manager to check for a new version of the agent at the frequency you specify. The value for the frequency must be between 1 and 31 days. If there is a new version, then Systems Manager automatically updates the agent on your managed node to the latest released version. Systems Manager doesn't install the agent on instances where it's not already present. For information about which AMIs have SSM Agent preinstalled, see Find AMIs with the SSM Agent preinstalled.

We encourage you to choose this option to ensure that your nodes are always running the most up-to-date version of SSM Agent. For more information about SSM Agent, including information about how to manually install the agent, see Working with SSM Agent.

4. Choose **Submit**.

Disabling the Systems Manager unified console

To disable the Systems Manager unified console for an organization, you'll need access to the account you registered as a delegated administrator for Systems Manager. After logging in to the delegated administrator account for your organization, you can disable the setup for your organization in the **Settings** section of the unified console. When you disable the unified console setup for your organization, Systems Manager deletes the resources created, including Resource Explorer managed views, during the setting up process. Disabling the setup for your organization

doesn't revoke trusted access or deregister the delegated administrator accounts for dependent services. The following procedure describes how to disable the setup for the unified console.

To disable the setup for the Systems Manager unified console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Settings** in the navigation pane.
3. Select **Disable**. You must confirm that you want to disable the setup for your organization. This action deletes the resources created for the unified console and can't be undone.

If you're unable to access the delegated administrator account for Systems Manager and want to disable the setup for the unified console, you can also do so from the management account for your organization. Using the AWS CLI or SDK, call the `DeleteConfigurationManager` API operation and pass the `ManagerArn` value for the organization setup in your account. The format for the manager ARN used to set up the unified console is as follows:

`arn:aws:ssm-quicksetup:`*`account-id`*`:configuration-manager/`*`configuration-manager-id`*.

> **Note**
>
> If you don't know the value for *`configuration-manager-id`*, call the `ListConfigurationManagers` API action and filter the results using the `AWSQuickSetupType-SSM` type.

Performing node management tasks with AWS Systems Manager

The following topics describe how to complete common node tasks using the unified AWS Systems Manager console for an AWS Organizations organization and single AWS accounts.

Topics

Reviewing node insights

You can gain insights into the overall status of managed nodes and unmanaged EC2 instances in your organization or account by using the unified Systems Manager console.

Systems Manager provides a visual overview into your managed nodes and EC2 instances that are not yet managed by Systems Manager. (A managed node is any machine configured for use with Systems Manager in hybrid and multicloud environments. For information about supported machine types, see Supported machine types in hybrid and multicloud environments.)

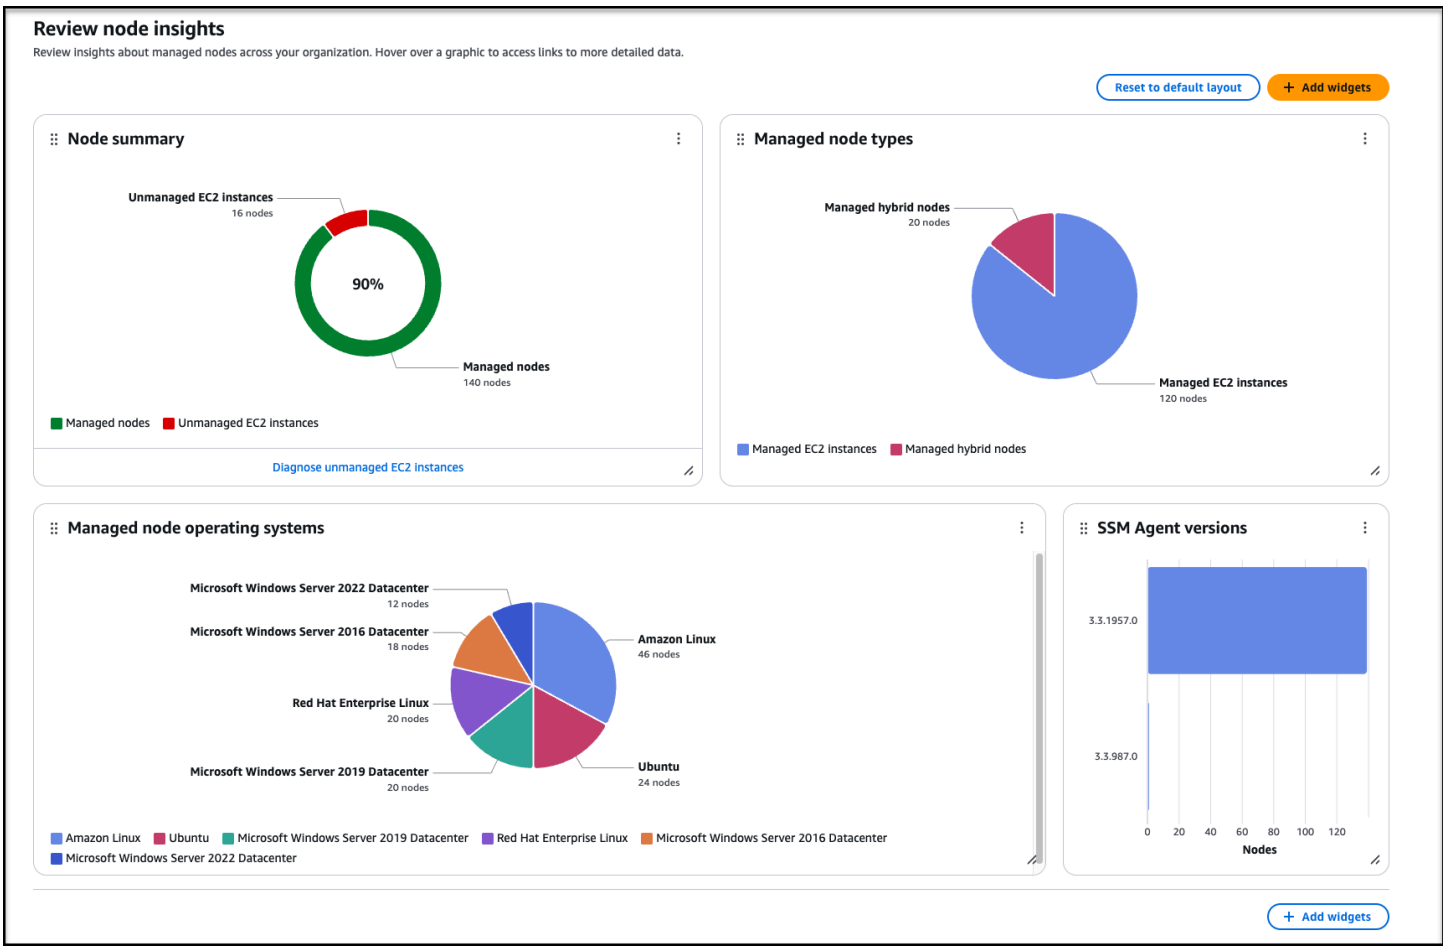
This overview is provided through individual report boxes, called *widgets*, which feature interactive pie charts and other graphics.

Before you begin

In order to review node insights, you must first onboard your organization or account to the unified Systems Manager console. For more information, see Setting up AWS Systems Manager.

After onboarding, open the Systems Manager console and choose **Review node insights**.

The following image shows the individual report boxes, called *widgets*, which are available on the **Review node insights** page.



The display supports widgets that provide you with the following information.

Node summary

Indicates how many EC2 instances in your organization or account aren't currently managed nodes, and how many managed nodes are in your organization's or account's fleet.

What is an unmanaged instance?

When you stop a managed EC2 instance, it is reported as "Unmanaged" in the Systems Manager console. This is expected behavior because SSM Agent doesn't have an active connection to the service.

> **Note**
>
> This is different from how AWS Config defines an instance as unmanaged. If an instance is currently stopped, AWS Config reports what the status of the instance was the last

time a "heartbeat" connection was made between SSM Agent on the instance and the Systems Manager service.

When the instance restarts, it automatically reconnects to the Systems Manager service, and its status in the unified console is restored to "Managed" within five minutes. No manual intervention is required, and all Systems Manager configurations for the instance are preserved during the Stop/Start cycle.

However, if the instance is still not reported as "Managed" several minutes after starting, the instance is likely not properly configured for Systems Manager management. In this case, we recommend running a diagnosis to identify why the instance remains in an unmanaged state. For more information, see Diagnosing and remediating unmanaged Amazon EC2 instances in Systems Manager.

If the diagnostic scan is not able to determine the issue, refer to the following topics to verify that the requirements for SSM Agent, AWS Identity and Access Management (IAM) roles, and Systems Manager prerequisites have all been met:

- Troubleshooting SSM Agent
- Configure instance permissions required for Systems Manager
- Troubleshooting managed node availability

Managed node types

Indicates how many managed nodes in your fleet are EC2 instances and how many are other server types, including servers on your own premises (on-premises servers), AWS IoT Greengrass core devices, AWS IoT and non-AWS edge devices, and virtual machines (VMs), including VMs in other cloud environments. You can hover over the **Node types** graphic to access links to more details in the **Explore nodes** page.

For more information about AWS support for hybrid and multicloud environments, see AWS Solutions for Hybrid and Multicloud.

SSM Agent versions

Provides information about installations of AWS Systems Manager Agent (SSM Agent) in your fleet. SSM Agent is Amazon software that runs on your managed nodes. SSM Agent makes it possible for Systems Manager to update, manage, and configure these resources. The agent processes requests from the Systems Manager service in the AWS Cloud, and then runs them as specified in the request.

For managed nodes in your fleet, this widget reports on the SSM Agent versions in your fleet, from newest to oldest. You can hover over the **SSM Agent versions** graphic to access links to more details in the **Explore nodes** page.

For more information about SSM Agent, see Working with SSM Agent.

Managed node operating systems

Provides a breakdown of the percentage of each operating system on managed nodes in your fleet. You can hover over the **Managed nodes by operating systems** graphic to access links to more details in the **Explore nodes** page.

You can customize widget layout on the **Review node insights** page by using a drag-and-drop capability, and by removing and adding widgets to the display.

Use information in the following topics to help you work with the Systems Manager node insights widgets.

Topics

- Adding or removing widgets from the Review node insights page
- Rearranging widgets in the Review node insights page

Adding or removing widgets from the Review node insights page

You can customize the layout in the Systems Manager **Review node insights** page by adding and removing widgets.

> **Note**
>
> By default, the page displays all available widgets.

To add or remove widgets from the Review node insights page

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the left navigation, choose **Review node insights**.
3. To remove a widget from the display, do the following:

a. Choose the More options menu
()
for the widget.

b. Choose **Remove widget**.

4. To add a widget to the display, do the following:

a. Choose **Add widgets**.

b. In the **Add widgets** pane, click and hold the drag handle
()
of the widget to add to the display.

c. Drag the widget and drop it into the main pane.

Rearranging widgets in the Review node insights page

You can customize the layout in the **Review node insights** page by rearranging widgets.

To rearrange widgets in the Review node insights page

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Review node insights**.
3. To customize the widget layout, choose a widget that you want to move. Click and hold the drag handle
()
of the widget and then drag it to its new location.
4. Repeat this process for each widget that you want to reposition.

If you decide that you don't like the new layout, choose **Reset to default layout** to move all widgets back to their original location.

Exploring nodes

You can use the **Explore nodes** page in Systems Manager to review details of managed nodes in your organization or account according to the criteria you specify in filters. You can also use

Systems Manager integration with Amazon Q Developer (Amazon Q), an AWS generative AI solution, to search using text prompts.

Before you begin

In order to use the **Explore nodes** feature, you must first onboard your organization or account to the unified Systems Manager console. For more information, see Setting up Systems Manager unified console for an organization.

After onboarding, open the Systems Manager console and choose **Explore nodes**.

> **Note**
>
> If you've created an aggregator index for Resource Explorer in a Region different than your home Region, Systems Manager demotes the current index. Then, Systems Manager promotes the local index in your home Region as the new aggregator index. During this time, only nodes for your home Region are displayed. This process can take up to 24 hours to complete.

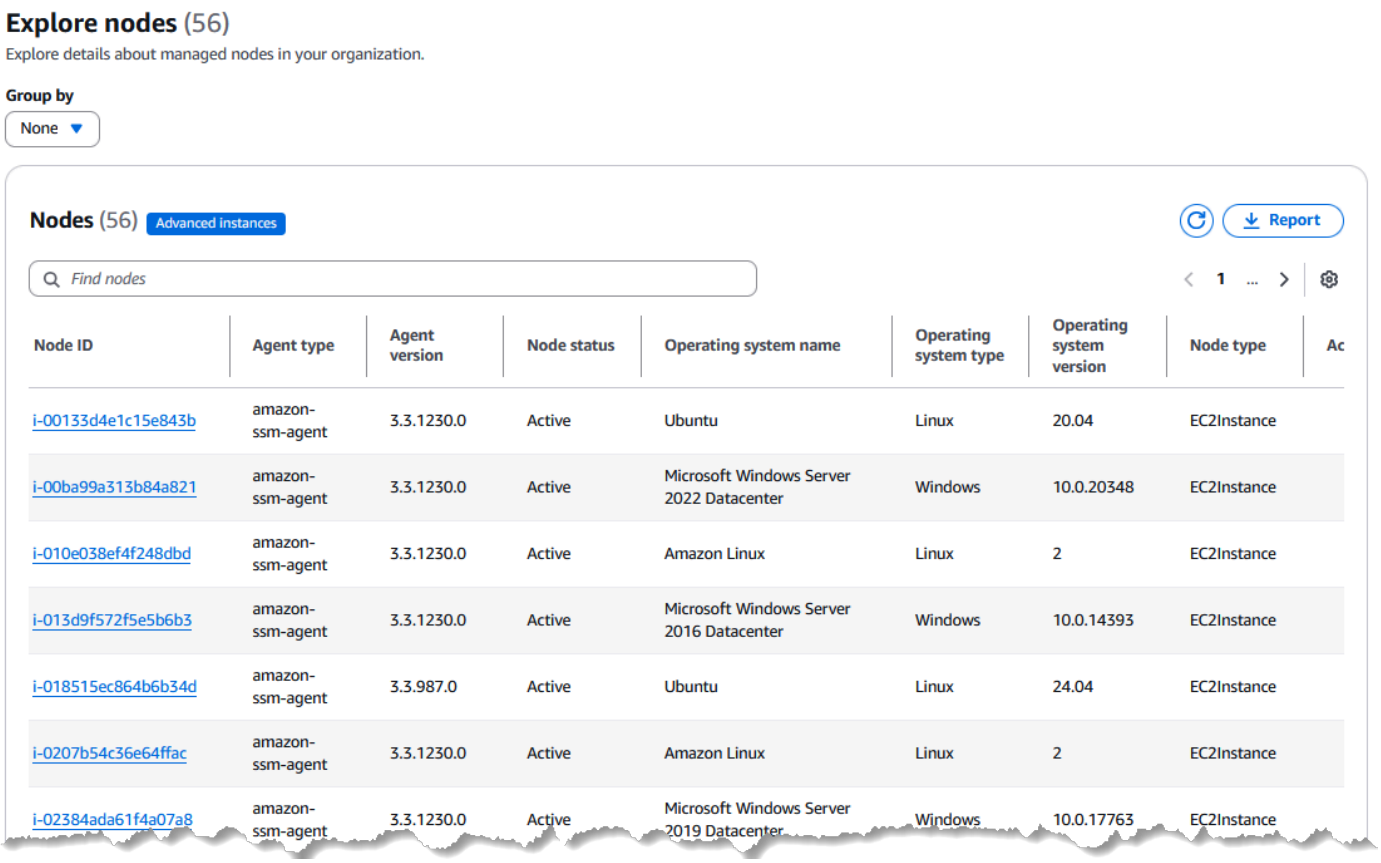
Topics

Exploring nodes using console filters

In the Systems Manager console, you can then group your managed nodes according to the following views:

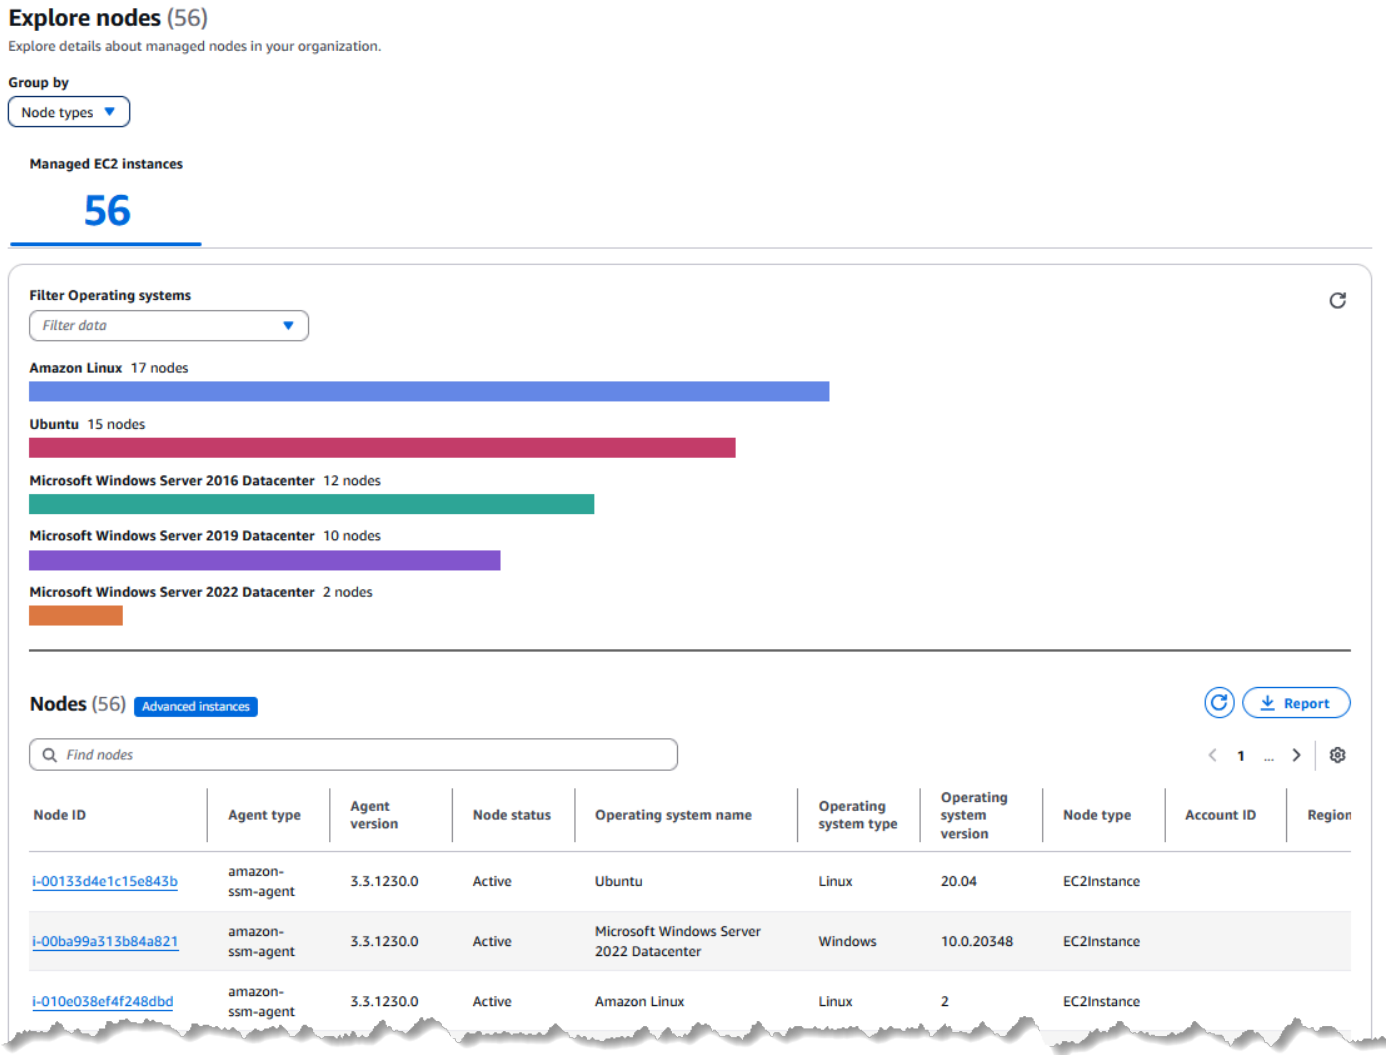
All nodes (No filter)

Lists all managed nodes in your organization or account.



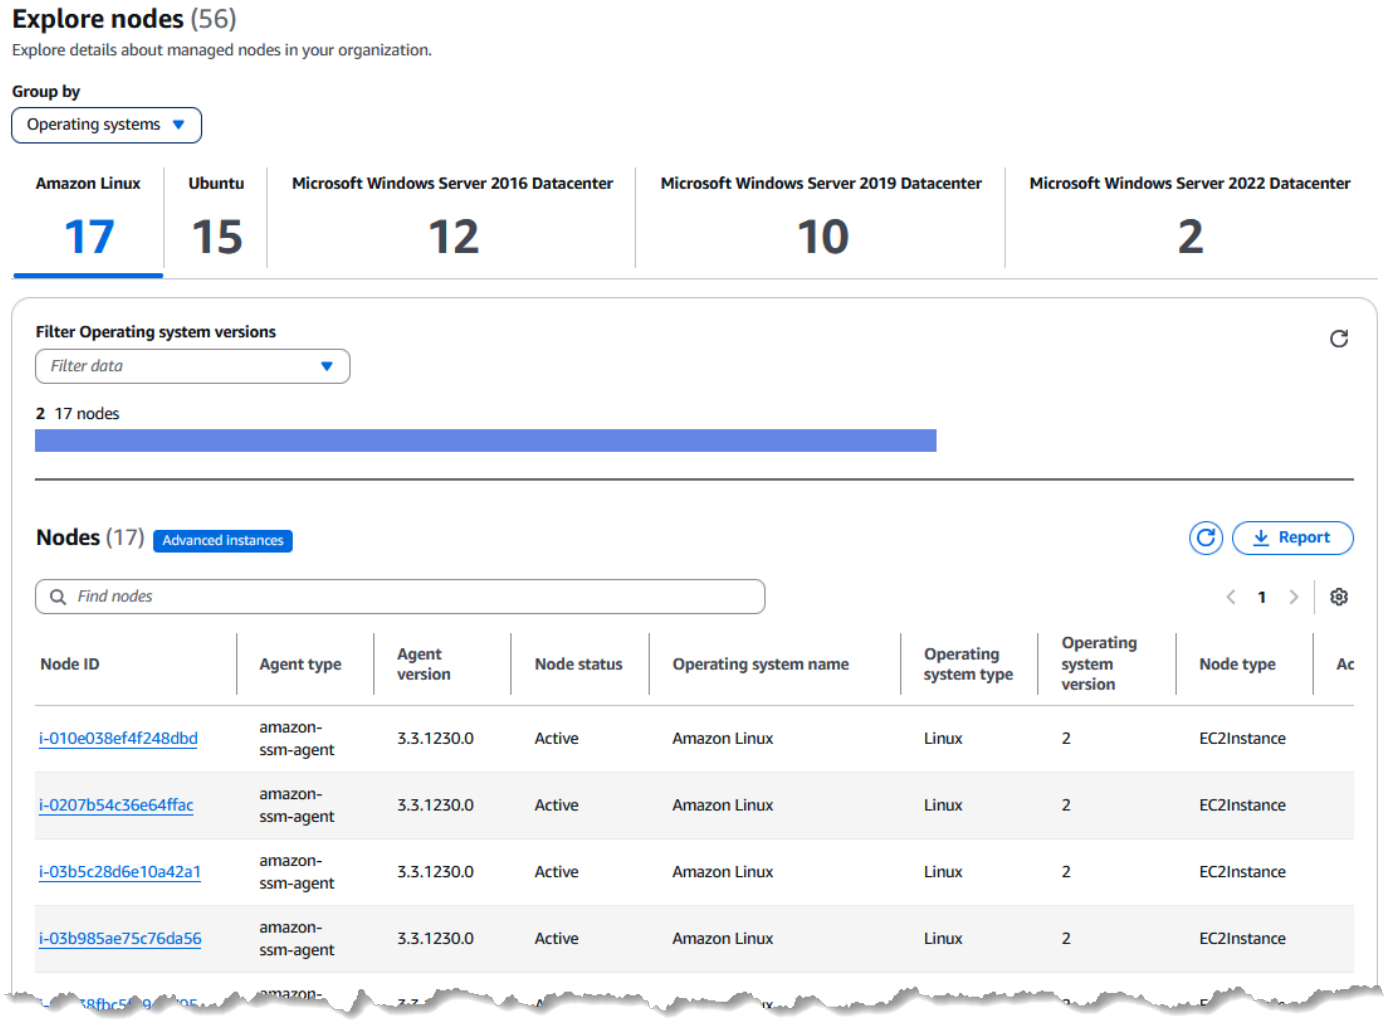
Node types

Provides tabs for viewing data separately for Amazon Elastic Compute Cloud (Amazon EC2) instances and other machine types, including servers on your own premises (on-premises servers), AWS IoT Greengrass core devices, AWS IoT and non-AWS edge devices, and virtual machines (VMs), including VMs in other cloud environments.



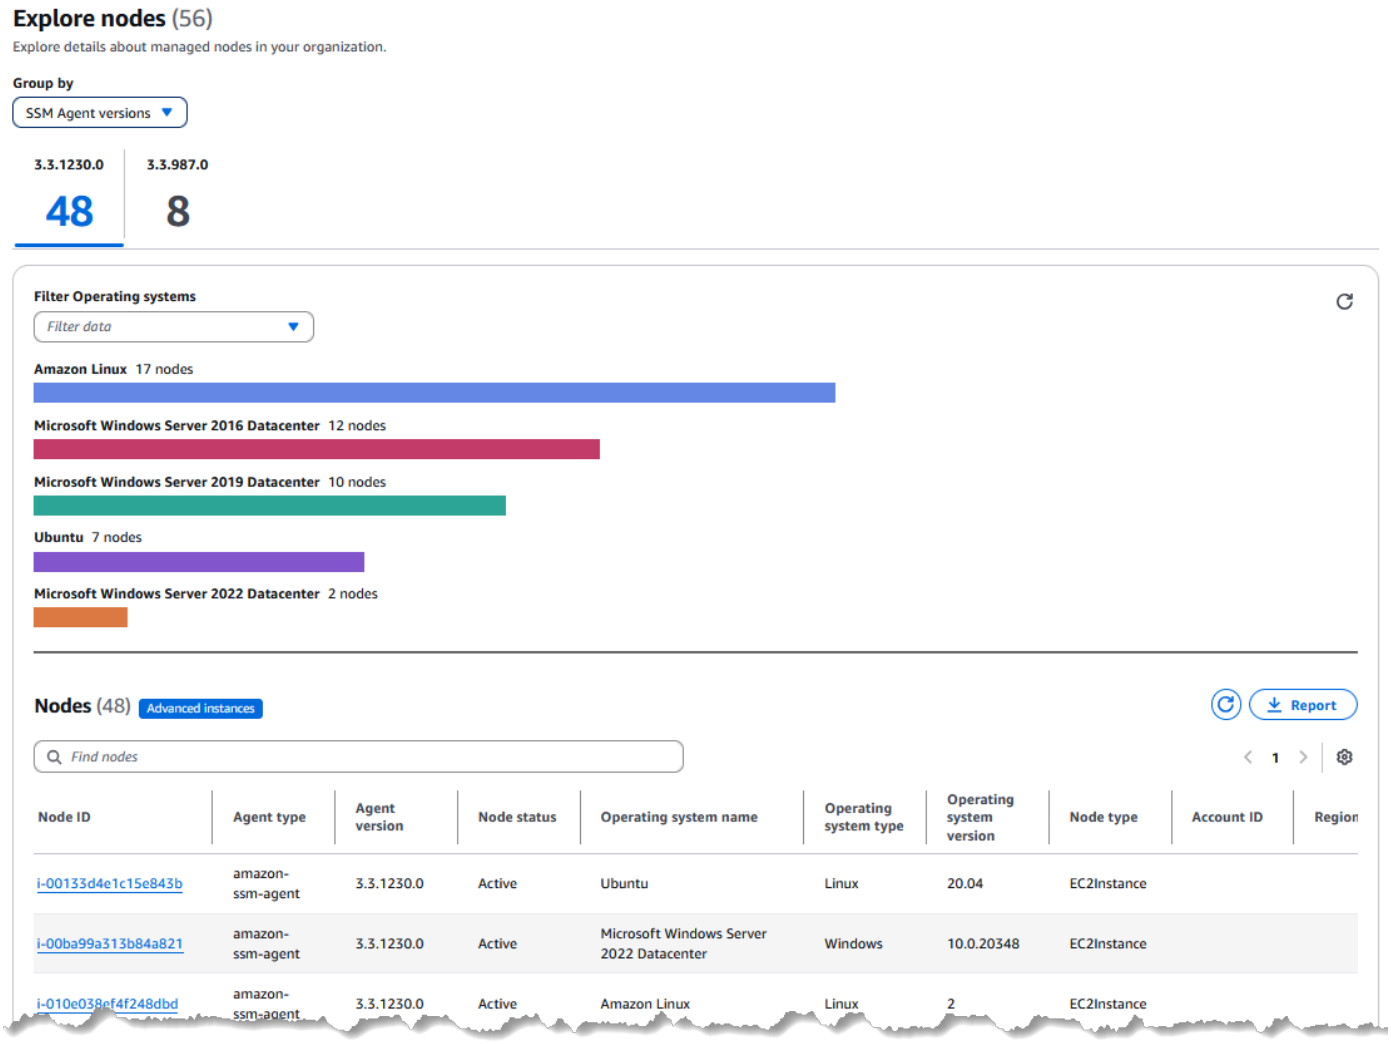
Operating systems

Provides a tab for each operating system type in your organization or account, such as **Amazon Linux** and **Microsoft Windows Server 2022 Datacenter**. On each tab, you can further filter the list by selecting only specific versions of the operating systems, such as *Amazon Linux 2* and *Amazon Linux 2023*.



SSM Agent versions

Provides a tab for each version of SSM Agent installed on managed nodes in your fleet. On each tab, you can further filter the list by selecting only specific operating systems, such as **Amazon Linux** and **Microsoft Windows Server 2022 Datacenter**.



In addition, for each of these views, you can further refine the list of nodes reported by choosing to view only nodes for a certain property, such as node status, AWS account ID, organization unit ID, and more.

You can customize the report display by choosing which of the available data columns are displayed in the **Explore nodes** page. You can also download reports in CSV or JSON formats, or export reports to Amazon S3 in CSV format.

Topics

- Choosing a filter view for managed node summaries

Choosing a filter view for managed node summaries

The **Explore nodes** page in Systems Manager lets you view aggregated data about your fleet according to a number of available filter views.

To choose a filter view for managed node summaries

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Explore nodes**.
3. For **Filter view**, select one of the filter options and optionally further refine the report:

   - **Managed nodes** – In the search () box, you can select a property and delimiter, such as `Node type = Managed EC2 instances`.
   - **Operating systems** – In the **Filter Operating system versions** list, you can select an OS version number. In the search () box, you can select a property and delimiter, such as `Node type = Managed EC2 instances`.
   - **SSM Agent versions** – In the **Filter Operating systems** list, you can select an OS name. In the search () box, you can select a property and delimiter, such as `Node type = Managed EC2 instances`.
   - **Node types** – In the **Filter Operating systems** list, you can select an OS name. In the search () box, you can select a property and delimiter, such as `Node type = Managed EC2 instances`.

After optionally filtering the list, you can view details about a specific managed node by choosing its ID in the **Node ID** column. From that detailed view, you can perform a number of actions on the node.

Exploring nodes using text prompts in Amazon Q

Using Systems Manager integration with Amazon Q Developer, you can use text prompts to view information created by generative AI about your managed nodes.

Amazon Q Developer is a generative AI-powered conversational assistant that can help you to understand, build, extend, and operate AWS applications. To accelerate your building on AWS, the model that powers Amazon Q is augmented with high-quality AWS content to produce more complete, actionable, and referenced answers. For more information, see What is Amazon Q Developer? in the *Amazon Q Developer User Guide*.

The integration between Systems Manager and Amazon Q lets you quickly get visibility and control over large, distributed environments across multiple AWS accounts and Regions. You can use natural language querying to quickly search node data, and then identify issues and take action faster.

When you ask a natural language question about managed nodes or managed instances, Amazon Q uses the Systems Manager `ListNodes` action and creates filters based on your textual input to retrieve results.

For example, say that you give Amazon Q the following prompt:

`List my managed nodes running Red Hat Enterprise Linux 9.2`

Amazon Q determines what filters to include in a request, and then runs a query similar to the following:

```
aws ssm list-nodes \
    --filters Key=PlatformName,Values='Red Hat Enterprise Linux',Type=Equal
 Key=PlatformVersion,Values=9.2,Type=Equal
```

Amazon Q then generates a report about Red Hat Enterprise Linux instances in your account, listing information such as the number of instances, their IDs, and their Regions.

You can also view a JSON summary of each instance's details, as well open a link to view the entire lists of EC2 instances or managed nodes in the Systems Manager **Explore nodes** page. The **Explore nodes** displays results that match the filter criteria you included in your prompt. From there, you can change or refine the filters for your request, as described in Exploring nodes.

Learning to craft effective prompts to ask Amazon Q about your fleet

The better quality of the question, or the prompt, that you give to Amazon Q, the better the result it provides you with.

Tips for query prompts

Keep in mind the following tips when querying Amazon Q about your fleet:

1. To help improve the accuracy of your results, use the terms "managed nodes" and "managed instances" in your prompts instead of just "nodes" and "instances".
2. To query for results across multiple accounts that are part of an *organization*, as configured in AWS Organizations, you must be logged into the delegated administrator account in the designated home Region.
3. In the delegated administrator account, use terms to help Amazon Q understand that you are asking about nodes and instances across the organization by specifically using terms such as "in my organization" or "in my account 123456789012".

Topics

- Sample questions for Amazon Q
- Supported operating system names and versions for prompts

Sample questions for Amazon Q

In the following table, we provide sample questions demonstrate some ways you can create queries of Amazon Q that lead to better results.

We also provide examples of the filters Amazon Q will apply when running the ListNodes command, which are generated from the content of your prompt.

Sample natural language question	Amazon Q applied filters
`Show me my Windows managed nodes.`	`PlatformType = Windows`

Sample natural language question	Amazon Q applied filters
List my managed instances in account 123456789012.	`AccountId = 123456789012`
Show me all managed nodes running Amazon Linux 2 across my organization.	`PlatformName = Amazon Linux` `PlatformVersion = 2`
Show me all managed instances running Microsoft Windows Server 2019 Datacenter in my organization.	`PlatformName = Microsoft Windows Server 2019 Datacenter`
Can you show me all managed nodes with SSM Agent version 3.3.1142.0?	`AgentType = amazon-ssm-agent` `AgentVersion = 3.3.1142.0`

List all Amazon Linux 2 managed instances in account 123456789012 that have SSM Agent version 3.3.1230.0.	`PlatformName = Amazon Linux`
	`PlatformVersion = 2`
	`AccountId = 123456789012`
	`AgentType = amazon-ssm-agent`
	`AgentVersion = 3.3.1230.0`

What Microsoft Windows Server 2012 R2 Enterprise managed nodes are running in the eu-central-1 region across my entire organization?	`PlatformName = Microsoft Windows Server 2012 R2 Enterprise` `Region = eu-central-1`

Show me all managed instances running Red Hat Linux 7 in ou-d6ty-gxdma6vm.	`PlatformName = RHEL Linux`
	`PlatformVersion = 7`
	`OrganizationalUnitId = ou-d6ty-gxdma6vm`

What Ubuntu managed instances are in account 123456789012?	`PlatformName = Ubuntu` `AccountId = 123456789012`

Sample natural language question	Amazon Q applied filters
List my Linux managed instances.	`PlatformType = Linux`
Find my macOS managed nodes.	`PlatformType = macOS`
Show me all versions of Amazon Linux managed nodes in my org.	`PlatformName = Amazon Linux`
List managed nodes running Amazon Linux 2.	`PlatformName = Amazon Linux` `PlatformVersion = 2`

List the managed nodes with Ubuntu 16.04 in account 123456789012.	`PlatformName = Ubuntu`
	`PlatformVersion = 16.04`
	`AccountId = 123456789012`

Find all managed nodes that have an SSM Agent version that is not 3.3.987.0.	`AgentType = amazon-ssm-agent` `AgentVersion != 3.3.987.0`
List all managed instances that are not running a Linux operating system.	`PlatformType != Linux`

Supported operating system names and versions for prompts

When you are asking Amazon Q about the managed nodes in your account, it's helpful to provide the name of an operating system as its labeled in Systems Manager. You can also provide version numbers to further narrow down your results. For example, as represented in the following tables, you could ask for results specifically about **`macOS 14.5`**, **`Microsoft Windows Server 2019 Datacenter`**, and **`AlmaLinux 9.2 through 9.4`**, to name just a few examples.

These lists might not be exhaustive and are offered as examples only.

macOS

Platform name	Version numbers
macOS	13.2, 13.4, 13.7, 14.1, 14.5, 14.6.1, 15.0

Windows

Releases	Version numbers
Microsoft Windows Server 2012 R2 Datacenter	6.3.9600
Microsoft Windows Server 2012 R2 Standard	6.3.9600
Microsoft Windows Server 2012 Standard	6.2.9200
Microsoft Windows Server 2016 Datacenter	*N/A*
Microsoft Windows Server 2016 Standard	10.0.14393
Microsoft Windows Server 2019 Datacenter	*N/A*
Microsoft Windows Server 2019 Standard	*N/A*
Microsoft Windows Server 2022 Datacenter	*N/A*
Microsoft Windows Server 2022 Standard	10.0.20348

Linux

Platform names	Version numbers
AlmaLinux	8.10, 9.2, 9.3, 9.4
Amazon Linux 2	2.0 and greater
Amazon Linux 2023	2023.0.20230315.0 and greater

Platform names	Version numbers
BottleRocket	1.14.3, 1.16.1, 1.18.0, 1.19.1, 1.19.2, 1.19.5, 1.20.0, 1.20.1, 1.20.2, 1.20.3, 1.20.5, 1.21.1, 1.23.0, 1.24.0, 1.24.1, 1.25.0, 1.26.1,
Debian GNU/Linux	11-12
Oracle Linux Server	7.8, 8.2, 8.3, 8.8, 8.9, 8.10, 9.4
Red Hat Enterprise Linux	8.2, 8.3, 8.4, 8.5, 8.6, 8.7, 8.8, 8.9, 8.10, 9.2, 9.3, 9.4
Red Hat Enterprise Linux Server	17.3, 7.6, 7.7, 7.8,7.9
Rocky Linux	8.6, 8.7, 8.8, 8.9, 8.10, 9.1, 9.2, 9.3, 9.4
Ubuntu Server	16.04, 18.04, 20.04, 22.04, 24.04

Exploring managed nodes using Amazon Q

Systems Manager integration with Amazon Q Developer lets you ask questions about managed nodes in your fleet from anywhere in the AWS Management Console where the Amazon Q interface is available.

For more information about interacting with Amazon Q, see Chatting with Amazon Q Developer about AWS in the *Amazon Q Developer User Guide*.

To explore managed nodes using Amazon Q

1. From anywhere in the AWS Management Console, choose the Amazon Q icon ().
2. In the prompt field at the bottom of the Amazon Q pane, ask a question about managed nodes in your account or organization.

> **Tip**
>
> For tips on creating effective prompts, review the information in Learning to craft effective prompts to ask Amazon Q about your fleet .

3. Examine information about specific nodes, or choose **Open AWS Systems Manager console** to continue exploring.

Viewing individual node details and taking action on a node

From a list in the **Explore nodes** page in Systems Manager, you can select an individual node in order to view comprehensive details about the machine or perform a variety of actions on the node. The **General** page in the detail page presents comprehensive information about the node.

To view individual node details and take action on a node

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Explore nodes**.
3. (Optional) Follow the steps in Choosing a filter view for managed node summaries to refine the list of managed nodes displayed for your organization or account.
4. In the **Node ID** column, choose the linked ID of a node.
5. To view more details about the node, in the left navigation, in the **Properties** list, choose a property to view more information about:

   - **Tags** – View a list of tags applied to the node. You can also add or remove tags.
   - **Inventory** – Choose an inventory type, such as **AWS:Application** or **AWS:Network**, to view inventory details for the node.
   - **Associations** – View details about all State Manager associations applied to the node, including details such as status and associated SSM document name.
   - **Patches** – View summary information about patches and patch status for the node.
   - **Configuration compliance** – View compliance details for the node, such as compliance status and compliance issue severity.

For more information about details on the tabs, see the section called "What is the unified console?".

6. To take actions on the node, use the following options in the **Node actions** menu:

> **Note**
>
> These actions are available only for managed nodes in the AWS account and Region you are currently working in. For managed nodes you might have access to in other accounts or Regions, you can instead access a **Properties** list.

- **Connect, Start terminal session** – Connect to the node using AWS Systems Manager Session Manager.
- **Tools**
  - **View file system** – Browse the contents of the node's directory structure. Add, rename, and remove directories. Cut or copy and paste files.
  - **View performance counters** – View performance information about the node such as CPU utilization, network traffic, and other utilization types.
  - **Managed processes** – View information about resource usage on the node. Start or stop processes on the node.
  - **Manage users and groups** – View, add, or delete user accounts and user groups on the node.
  - **Execute run command** – Use AWS Systems Manager Run Command to manage the configuration of the node. Run Command uses Systems Manager documents to perform on-demand changes such as updating applications or running Linux shell scripts and Windows PowerShell commands.
  - **Patch nodes** – Use the **Patch now** feature in AWS Systems Manager Patch Manager to run an on-demand patching operation on the node from the console.

  > **Note**
  >
  > The preceding tasks can also be initiated from the **Tools** menu in the left navigation.

- **Node settings**

- **Add tags** – Apply additional tag key-value pairs to the node.
- **Reset node user password** – Set a new password for a specified user on the node.
- **Modify IAM role** – Change the IAM role that's associated with the node. Create a new IAM role to attach to the node.

Downloading or exporting a managed node report

You can use the Systems Manager **Explore nodes** feature to view filtered or unfiltered lists of managed nodes for your AWS organization or account in the Systems Manager console. For cases where you want to view the data offline or process it in another application, you can save the report as a `CSV` or `JSON` file.

Depending on the size of the report, you're prompted to download the report to your local machine or export it to an Amazon S3 bucket. Reports are saved to S3 buckets in `CSV` format only.

To download or export a managed node report

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Explore nodes**.
3. (Optional) Follow the steps in Choosing a filter view for managed node summaries to refine the list of managed nodes displayed for your organization or account.
4. Choose **Report** ().
5. If the **Download report** dialog box is displayed, do the following:

   a. For **File name**, enter a name for the file. We recommend specifying a name that represents the scope of the report, such as `all-organization-nodes` or `ec2-instances-out-of-date-agent`.

   b. For **Included columns**, specify whether to include columns for all available node details, or only those you've selected for your current display.

   > **Tip**
   >
   > For information about managing the columns in your report display, see Managing node report content and appearance.

c. For **File format**, select **CSV** or **JSON**, depending on how you will use the file.

d. For **Spreadsheet heading**, to include a column headings row in a CSV file, select **Include row of column names**.

e. Choose **Download**.

The report is saved to the default download location according to your browser's settings.

6. If the **Export to Amazon S3** dialog box is displayed, do the following:

a. For **S3 URI**, enter the URI for the bucket to export the report to.

> **Tip**
>
> To view a list of your buckets in the Amazon S3 console, choose **View**. To select from a list of buckets in your account, choose **Browse S3**.

b. For **Authorization method**, specify the service role to use to provide permissions for exporting the report to the bucket.

If you choose to let Systems Manager create the role for you, it provides all needed permissions and trust statements for the operation.

If you want to use or create your own role, the role must include the required permissions and trust statements. For information about creating this role, see Creating a custom service role to export diagnosis reports to S3.

c. Choose **Submit**.

Creating a custom service role to export diagnosis reports to S3

When you are viewing filtered or unfiltered lists of managed nodes for your AWS organization or account in the Systems Manager **Explore nodes** page, you can export the list as a report to an Amazon S3 bucket as a CSV file.

To do so, you must specify a service role with the necessary permissions and trust policy for the operation. You can choose for Systems Manager to create the role for you during the process of downloading the report. Optionally, you can create the role and its required policy yourself.

To create a custom service role to export diagnosis reports to S3

1. Follow the steps in Creating policies using the JSON editor in the *IAM User Guide*.

   - Use the following for the policy content, making sure to replace the *placeholder values* with your own information.

     JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceAccount": "111122223333"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketAcl",
        "s3:ListBucket",
        "s3:PutLifecycleConfiguration",
        "s3:GetLifecycleConfiguration"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
      "Condition": {
        "StringEquals": {
          "aws:ResourceAccount": "111122223333"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:ListNodes"
```

```
      ],
      "Resource": "*"
    }
  ]
}
```

- Give the policy a name to help you recognize it easily in the next step.

2. Follow the steps in Creating an IAM role using a custom trust policy (console) in the *IAM User Guide*.

   - For step 4, enter the following trust policy, making sure to replace the *placeholder values* with your own information.

     JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SSMAssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333"
        }
      }
    }
  ]
}
```

3. For step 10, choose **Step 2: Add permissions** and select the name of the policy you created in the previous step.

After you create the role, you can select it when following the steps in Downloading or exporting a managed node report.

Managing node report content and appearance

You can use the Systems Manager **Explore nodes** feature to view filtered or unfiltered lists of managed nodes for your AWS organization or account in the Systems Manager console. You can choose from over a dozen fields to include in your lists of nodes, such as **Node ID**, **Operating system name**, **Region**, and more. You can also reorder the columns for your lists and reports and change how the list is displayed in the console.

To manage node report content and appearance

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Explore nodes**.
3. In the **Nodes** area, choose the preferences gear icon ().
4. In the **Preferences** dialog box, do the following:
   a. For **Page size**, choose how many rows are included in each console view display, **10**, **25**, or **50**.
   b. For **Wrap lines**, select the box to display all content of a cell in the available column width.
   c. For **Striped rows**, select the box to display alternating rows of clear and shaded backgrounds.
   d. For **Select visible content**, do the following:
      - Turn on or off individual columns for your list display and reports.
      - To change the order of columns, click and hold the drag handle () of a column name and drag it up or down in the list.
5. Choose **Confirm**.

Just-in-time node access using Systems Manager

Systems Manager helps you to improve the security of your nodes by supporting *just-in-time* access. Just-in-time node access allows users to request temporary, time-bound access to nodes that you can approve only when access is truly needed. This removes the need to provide long

standing access to nodes managed by IAM policies. Additionally, Systems Manager provides session recording for RDP sessions to Windows Server nodes to help you meet compliance requirements, perform root cause analysis, and more. To use just-in-time node access, you must set up the unified Systems Manager console.

With just-in-time node access, you create granular IAM policies to ensure only the users you permit can submit access requests to your nodes. Then you create *approval policies* which define the approvals required to connect to your nodes. For just-in-time node access, there are *auto-approval* policies and *manual approval* policies. An auto-approval policy defines which nodes users can connect to automatically. Manual approval policies define the number and levels of manual approvals that must be provided to access the nodes you specify. Also, you can create a *deny-access* policy. A deny-access policy explicitly prevents the auto-approval of access requests to the nodes you specify. A deny-access policy applies to all accounts in an AWS Organizations organization. Auto-approval and manual approval policies apply only to the AWS accounts and AWS Regions where they're created.

When a user attempts to connect to a node, they're prompted to enter a reason for accessing the node. Then your approval policies are evaluated. Depending on your policies, users either connect automatically to the target node or Systems Manager automatically creates a manual approval request on the requester's behalf. The approvers specified in the manual approval policy that applies to the node are then notified of the access request, and can approve or deny the request. Approvers and requesters can be notified by email, or through Amazon Q Developer in chat applications integration with Slack or Microsoft Teams. Systems Manager only grants access to requested nodes when the specified approvers provide all required approvals. Once all of the required approvals are received, the user can start as many sessions to the node as needed for the duration of the access window specified in the approval policy. Systems Manager doesn't automatically terminate just-in-time node access sessions. As a best practice, specify values for the *maximum session duration* and *idle session timeout* session preferences. These preferences prevent users from staying connected to nodes beyond their approved access window.

We recommend using a combination of approval policies to help you secure nodes with more critical data while allowing users to connect to less critical nodes without intervention. For example, you can require manual approvals for access requests to database nodes, and auto-approve sessions to non-persistent presentation tier nodes.

Systems Manager supports just-in-time node access for users federated with IAM Identity Center or IAM. When a federated user submits an access request, they specify the target node, and the reason for needing to connect to the node. Systems Manager compares the user's identity to

the parameters defined in your organization's approval policies. When the auto-approval policy conditions are met, or approvers manually provide approvals, the requester is able to connect to the target node. When a user attempts to connect to an approved node, Systems Manager creates and uses a temporary token to establish the session.

Since the Systems Manager service handles the authentication for access requests and establishing sessions, you don't have to use IAM policies to manage access to your nodes. By using just-in-time node access, Systems Manager helps your organization move closer to zero standing privileges since you only need to allow users to create access requests instead of allowing them to start sessions with persistent permissions to your nodes. To help you meet compliance requirements, Systems Manager retains all access requests for 1 year. Systems Manager also emits EventBridge events for just-in-time node access for failed access requests and status updates to access requests for manual approvals. For more information see, Monitoring Systems Manager events with Amazon EventBridge.

Topics

Setting up just-in-time access with Systems Manager

Setting up just-in-time node access with Systems Manager involved multiple steps. First, you choose the *targets* where you want to set up just-in-time node access. Targets consist of AWS Organizations organizational units (OUs) and AWS Regions. By default, the same targets you chose when setting up the unified Systems Manager console are selected for just-in-time node access. You can choose to set up just-in-time node access for all of the same targets, or a subset of the targets you specified when setting up the unified Systems Manager console. Adding new targets that weren't selected when you set up the unified Systems Manager console isn't supported.

Next you'll create *approval policies* to determine when node connections require manual approval and are automatically approved. Approval policies are managed by each account in your

organization. You can also share a policy from the delegated administrator account to explicitly deny the automatic approval of connections to specific nodes.

> **Note**
>
> Setting up just-in-time node access doesn't affect existing IAM policies or preferences you've configured for Session Manager. You must remove permission to the `StartSession` API action from your IAM policies to ensure that only just-in-time node access is used when users attempt to connect to your nodes. After you set up just-in-time node access, we recommend testing your approval policies with a subset of users and nodes to verify your policies are working as desired before removing permissions to Session Manager.

Authentication support

Note the following details about authentication support used for just-in-time node access:

- Just-in-time node access doesn't support the Single Sign-On authentication type when connecting to Windows Server instances with Remote Desktop.
- Only AWS Security Token Service (AWS STS) `AssumeRole` temporary security credentials are supported. For more information, see the following topics in the *IAM User Guide*:
- • Temporary security credentials in IAM
  - Comparing AWS STS credentials
  - Requesting temporary security credentials

The following IAM policies outline the permissions needed to administer and allow users to create just-in-time node access requests to nodes with Systems Manager. After verifying you have the required permissions to use just-in-time node access with Systems Manager, you can continue the setting up process. Replace each *`example resource placeholder`* with your own information.

IAM policy for enabling just-in-time node access

                "identitystore:DescribeUser",
                "identitystore:DescribeGroup"
            ],
            "Resource": "*"
        }
    ]
}
```

Note

To restrict access to API operations that create, update, or delete approval policies, use the `ssm:DocumentType` condition key for the `AutoApprovalPolicy` and `ManualApprovalPolicy` document types. The `StartAccessRequest` and `GetAccessToken` API operations don't support the following global context keys:

- aws:ViaAwsService
- aws:MultiFactorAuthPresent
- aws:SourceVpce
- aws:UserAgent

For more information about condition context keys for Systems Manager, see Condition keys for AWS Systems Manager in the *Service Authorization Reference*.

The following procedure describes how to complete the first set up step for just-in-time node access.

To set up just-in-time node access

1. Log in to the Systems Manager delegated administrator account for your organization.
2. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
3. Select **Just-in-time node access** in the navigation pane.
4. Select **Enable the new experience**.
5. Choose the Regions where you want to enable just-in-time node access. By default, the same Regions you chose when setting up the unified Systems Manager console are selected for just-in-time node access. Choosing new Regions that weren't selected when you set up the unified Systems Manager console isn't supported.
6. Select **Enable just-in-time node access**.

There is no charge to use just-in-time node access for 30 days after enabling the feature. After the 30 day trial period, there is a charge to use just-in-time node access. For more information, see AWS Systems Manager Pricing.

Create approval policies for your nodes

Approval policies define what approvals users need to access a node. Since just-in-time node access removes the need for long standing permissions to nodes through IAM policies, you must create approval policies to allow access to your nodes. If there are no approval policies that apply to a node, users are unable to request access to the node.

In just-in-time node access, there are three types of policies. The policy types are *auto-approval*, *deny-access*, and *manual approval*.

Just-in-time node access policy types

- An auto-approval policy defines which nodes users can connect to automatically.
- Manual approval policies define the number and levels of manual approvals that must be provided to access the nodes you specify.

- A deny-access policy explicitly prevents the auto-approval of access requests to the nodes you specify.

A deny-access policy applies to all accounts in an AWS Organizations organization. For example, you could explicitly deny auto-approvals for the `Intern` group to nodes tagged with the `Production` key. Auto-approval and manual approval policies apply only to the AWS accounts and AWS Regions where they're created. Each member account in your organization manages their own approval policies. Approval policies are evaluated in the following order:

1. Deny-access
2. Auto-approval
3. Manual

While you can only have one deny-access policy per organization, and one auto-approval policy per account and Region, you'll likely have several manual approval policies in an account. When evaluating manual approval policies, just-in-time node access always favors the more specific policy for a node. Manual approval policies are evaluated in the following order:

1. Tag specific target
2. All nodes target

For example, you have a node tagged with the `Demo` key. In the same account, you have a manual approval policy that targets all nodes and requires one approval from one level. You also have a manual approval policy that requires two approvals from two levels for nodes tagged with the `Demo` key. Systems Manager applies the policy that targets the `Demo` tag to the node since it's more specific than the policy that targets all nodes. This allows you to create a general policy for all nodes in your account, ensuring users can submit access requests while enabling you to create more granular policies as needed.

Depending on your organization, there might be multiple tags applied to your nodes. In this scenario, if multiple manual approval policies apply to a node, access requests fail. For example, a node is tagged with the `Production` and `Database` keys. In the same account, you have a manual approval policy that applies to nodes tagged with the `Production` key and another manual approval policy that applies to nodes tagged with the `Database` key. This results in a conflict for the node tagged with both keys and access requests fail. Systems Manager redirects the user to the failed request. There, they can view details about the conflicting policies and tags so they can make

the necessary adjustments if they have the required permissions. Otherwise, they can notify a colleague in their organization with the required permissions to modify the policies. Policy conflicts resulting in failed access requests emit EventBridge events allowing you flexibility in building your own response workflows. Additionally, Systems Manager sends email notifications for policy conflicts resulting in failed access requests to the recipients you specify. For more information about configuring email notifications for policy conflicts, see Configure notifications for just-in-time access requests.

In a *deny-access* policy, you use the Cedar policy language to define which nodes users explicitly can't automatically connect to in your organization. This policy is created and shared from the delegated administrator account for your organization. The deny-access policy supercedes all auto-approval policies. You can only have one deny-access policy per organization.

In an *auto-approval* policy, you use the Cedar policy language to define which users can automatically connect to the specified nodes without manual approval. The access duration for an access request that is automatically approved is 1 hour. This value can't be changed. You can only have one auto-approval policy per account and Region.

In a *manual* approval policy, you specify the access duration, how many levels of approvals are required, the number of approvers required per level, and the nodes they can approve just-in-time access requests to. The access duration for a manual approval policy must be between 1 and 336 hours. If you specify multiple levels of approvals, the approvals for the access request process one level at a time. This means all approvals you require for one level must be provided before the approval process moves to subsequent levels. If you specify multiple tags in a manual approval policy, they are evaluated as `or` statements not `and` statements. For example, if you create a manual approval policy that includes the tags `Application`, `Web`, and `Test`, the policy applies to any node that is tagged with one of those keys. The policy doesn't apply only to nodes that are tagged with all three keys.

We recommend using a combination of manual policies with your auto-approval policy to help you secure nodes with more critical data while allowing users to connect to less critical nodes without intervention. For example, you can require manual approvals for access requests to database nodes, and auto-approve sessions to non-persistent presentation tier nodes.

The following procedures describe how to create approval policies for just-in-time node access.

Topics

- Create manual approval policies for just-in-time node access
- Statement structure and built-in operators for auto-approval and deny-access policies

- Create an auto-approval policy for just-in-time node access
- Create a deny-access policy for just-in-time node access
- Create approval policies for just-in-time node access with Amazon Q

Create manual approval policies for just-in-time node access

The following procedure describes how to create manual approval policies. Systems Manager allows you to create up to 50 manual approval policies per AWS account and AWS Region.

To create a manual approval policy

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Manage node access** in the navigation pane.
3. In the **Policy details** section of the **Create manual approval policy** step, enter a name and description for the approval policy.
4. Enter a value for the **Access duration**. This is the maximum amount of time a user can start sessions to a node after an access request is approved. The value must be between 1 and 336 hours.
5. In the **Node targets** section, enter tag key-value pairs associated with the nodes you want the policy to apply to. If none of the tags specified in the policy are associated with a node, the policy isn't applied to the node.
6. In the **Access request approvers** section, enter the users or groups you want to be able to approve access requests to the node targets in the policy. Access request approvers can be IAM Identity Center users and groups or IAM roles. You can specify up to 5 approvers per level, and up to 5 levels of approvers.
7. Select **Create manual approval policy**.

Statement structure and built-in operators for auto-approval and deny-access policies

The following table shows the structure of auto-approval and deny-access policies.

Component	Syntax
effect	`permit | forbid`

Component	Syntax
scope	`(principal, action, resource)`
condition clause	`when { principal or resource has attribute name };`

Policy components

An auto-approval or deny-access policy contains the following components:

- **Effect** – Either `permit` (allow) or `forbid` (deny) access.
- **Scope** – The principals, actions, and resources to which the effect applies. You can leave the scope in Cedar undefined by not identifying specific principals, actions, or resources. In this case, the policy applies to all possible principals, actions, and resources. For just-in-time node access, the `action` is always `AWS::SSM::Action::"getTokenForInstanceAccess"`.
- **Condition clause** – The context in which the effect applies.

Comments

You can include comments in your policies. Comments are defined as a line starting with `//` and ending with a newline character.

The following example shows comments in a policy.

```
// Allows users in the Engineering group from the Platform org to automatically connect
 to nodes tagged with Engineering and Production keys.
permit (
    principal in AWS::IdentityStore::Group::"d4q81745-r081-7079-d789-14da1EXAMPLE",
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    principal has organization && resource.hasTag("Engineering") &&
 resource.hasTag("Production") && principal.organization == "Platform"
};
```

Multiple clauses

You can use more than one condition clause in a policy statement using the && operator.

```
// Allow access if node has tag where the tag key is Environment
// & tag value is Development

permit(principal, action == AWS::SSM::getTokenForInstanceAccess, resource)
when {
    resource.hasTag("Environment") &&
    resource.getTag("Environment") == "Development"
};
```

Reserved characters

The following example shows how to write a policy if a context property uses a : (semicolon), which is a reserved character in the policy language.

```
permit (
    principal,
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    principal has employeeNumber && principal.employeeNumber like "E-1*" &&
 resource.hasTag("Purpose") && resource.getTag("Purpose") == "Testing"
}
```

For additional examples, see Example policy statements.

Just-in-time node access schema

The following is the Cedar schema for just-in-time node access.

```
namespace AWS::EC2 {
    entity Instance tags String;
}

namespace AWS::IdentityStore {
    entity Group;
```

```
    entity User in [Group] {
    employeeNumber?: String,
    costCenter?: String,
    organization?: String,
    division?: String,
    };

}

namespace AWS::IAM {

    entity Role;

    type AuthorizationContext = {
        principalTags: PrincipalTags,
    };

    entity PrincipalTags tags String;
}

namespace AWS::SSM {

    entity ManagedInstance tags String;

    action "getTokenForInstanceAccess" appliesTo {
    principal: [AWS::IdentityStore::User],
    resource: [AWS::EC2::Instance, AWS::SSM::ManagedInstance],
    context: {
        "iam": AWS::IAM::AuthorizationContext
        }
    };
}
```

Built-in operators

When creating the context of an auto-approval or deny-access policy using various conditions, you can use the && operator to add additional conditions. There are also many other built-in operators that you can use to add additional expressive power to your policy conditions. The following table contains all the built-in operators for reference.

Operator	Types and overloads	Description
!	Boolean → Boolean	Logical not.
==	any → any	Equality. Works on arguments of any type, even if the types don't match. Values of different types are never equal to each other.
!=	any → any	Inequality; the exact inverse of equality (see above).
<	(long, long) → Boolean	Long integer less-than.
<=	(long, long) → Boolean	Long integer less-than-or-equal-to.
>	(long, long) → Boolean	Long integer greater-than.
>=	(long, long) → Boolean	Long integer greater-than-or-equal-to.
in	(entity, entity) → Boolean	Hierarchy membership (reflexive: A in A is always true).
	(entity, set(entity)) → Boolean	Hierarchy membership: A in [B, C, ...] is true if (A and B) || (A in C) || … error if the set contains a non-entity.
&&	(Boolean, Boolean) → Boolean	Logical and (short-circuiting).
||	(Boolean, Boolean) → Boolean	Logical or (short-circuiting).
.exists()	entity → Boolean	Entity existence.
has	(entity, attribute) → Boolean	Infix operator. `e has f` tests if the record or entity e has

Operator	Types and overloads	Description
		a binding for the attribute `f`. Returns `false` if `e` does not exist or if `e` does exist but doesn't have the attribute `f`. Attributes can be expressed as identifiers or string literals.
like	(string, string) → Boolean	Infix operator. `t like p` checks if the text `t` matches the pattern `p`, which may include wildcard characters * that match 0 or more of any character. In order to match a literal star character in `t`, you can use the special escaped character sequence `\*` in `p`.
.hasTag()	(entity, string) → Boolean	Checks if entity has the specified tag applied.
.getTag()	(entity, string) → Boolean	Returns the value of the specified tag key.
.contains()	(set, any) → Boolean	Set membership (is B an element of A).
.containsAll()	(set, set) → Boolean	Tests if set A contains all of the elements in set B.
.containsAny()	(set, set) → Boolean	Tests if set A contains any of the elements in set B.

Example policy statements

The following are policy statement examples.

```
// Users assuming IAM roles with a principal tag of "Elevated" can automatically access
 nodes tagged with the "Environment" key when the value equals "prod"
permit(principal, action == AWS::SSM::getTokenForInstanceAccess, resource)
when {
    // Verify IAM role principal tag
    context.iam.principalTags.getTag("AccessLevel") == "Elevated" &&

    // Verify the node has a tag with "Environment" tag key and a tag value of "prod"
    resource.hasTag("Environment") &&
    resource.getTag("Environment") == "prod"
};
```

```
// Identity Center users in the "Contractor" division can automatically access nodes
 tagged with the "Environment" key when the value equals "dev"
permit(principal, action == AWS::SSM::getTokenForInstanceAccess, resource)
when {
    // Verify that the user is part of the "Contractor" division
    principal.division == "Contractor" &&

    // Verify the node has a tag with "Environment" tag key and a tag value of "dev"
    resource.hasTag("Environment") &&
    resource.getTag("Environment") == "dev"
};
```

```
// Identity Center users in a specified group can automatically access nodes tagged
 with the "Environment" key when the value equals "Production"
permit(principal in AWS::IdentityStore::Group::"d4q81745-r081-7079-d789-14da1EXAMPLE",
    action == AWS::SSM::getTokenForInstanceAccess,
    resource)
when {
    resource.hasTag("Environment") &&
    resource.getTag("Environment") == "Production"
};
```

Create an auto-approval policy for just-in-time node access

Auto-approval policies use the Cedar policy language to define which users can automatically connect to the specified nodes without manual approval. An auto-approval policy contains multiple `permit` statements specifying the `principal` and `resource`. Each statement includes a `when` clause defining the conditions for automatic approval.

The following is an example auto-approval policy.

```
permit (
    principal in AWS::IdentityStore::Group::"e8c17310-e011-7089-d989-10da1EXAMPLE",
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    principal has costCenter && resource.hasTag("CostCenter") && principal.costCenter
 == resource.getTag("CostCenter")
};

permit (
    principal in AWS::IdentityStore::Group::"d4q81745-r081-7079-d789-14da1EXAMPLE",
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    principal has organization && resource.hasTag("Engineering") &&
 resource.hasTag("Production") && principal.organization == "Platform"
};

permit (
    principal,
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    principal has employeeNumber && principal.employeeNumber like "E-1*" &&
 resource.hasTag("Purpose") && resource.getTag("Purpose") == "Testing"
};
```

The following procedure describes how to create an auto-approval policy for just-in-time node acces. The access duration for an access request that is automatically approved is 1 hour. This value can't be changed. You can only have one auto-approval policy per AWS account and AWS Region. For more information about how to construct policy statements, see Statement structure and built-in operators for auto-approval and deny-access policies.

To create an auto-approval policy

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.

2. Select **Manage node access** in the navigation pane.
3. In the **Approval policies** tab, select **Create an auto-approval policy**.
4. Enter your policy statement for the auto-approval policy in the **Policy statement** section. You can use the **Sample statements** provided to help you create your policy.
5. Select **Create auto-approval policy**.

Create a deny-access policy for just-in-time node access

Deny-access policies use the Cedar policy language to define which nodes users can't automatically connect to without manual approval. A deny-access policy contains multiple `forbid` statements specifying the `principal` and `resource`. Each statement includes a `when` clause defining the conditions for explicitly denying automatic approval.

The following is an example deny-access policy.

```
forbid (
    principal in AWS::IdentityStore::Group::"e8c17310-e011-7089-d989-10da1EXAMPLE",
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    resource.hasTag("Environment") && resource.getTag("Environment") == "Production"
};

forbid (
    principal,
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    principal has division && principal.division != "Finance" &&
 resource.hasTag("DataClassification") && resource.getTag("DataClassification") ==
 "Financial"
};

forbid (
    principal,
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
```

```
when {

    principal has employeeNumber && principal.employeeNumber like "TEMP-*" &&
 resource.hasTag("Criticality") && resource.getTag("Criticality") == "High"
};
```

The following procedure describes how to create a deny-access policy for just-in-time node access. For more information about how to construct policy statements, see Statement structure and built-in operators for auto-approval and deny-access policies.

Note

Note the following information.

- You can create deny-access policies while logged into the AWS Management account or the delegated administrator account. Your AWS Organizations organization can have only one deny-access policy.
- Just-in-time node access uses AWS Resource Access Manager (AWS RAM) to share your deny-access policy with member accounts in your organization. If you would like to share your deny-access policy with the member accounts in your organization, resource sharing must be enabled from the management account of your organization. For more information, see Enable resource sharing within AWS Organizations in the *AWS RAM User Guide*.

To create a deny-access policy

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Manage node access** in the navigation pane.
3. In the **Approval policies** tab, select **Create a deny-access policy**.
4. Enter your policy statement for the deny-access policy in the **Policy statement** section. You can use the **Sample statements** provided to help you create your policy.
5. Select **Create deny-access policy**.

Create approval policies for just-in-time node access with Amazon Q

Using Amazon Q Developer for command line provides guidance and support across various aspects of software development. For just-in-time node access, Amazon Q helps you create approval policies by generating and updating the code for the policies, analyzing policy statements, and more. The following information describes how to create approval policies using Amazon Q for command line.

Identify your use case

The first step in creating approval policies is clearly defining your use case. For example, in your organization you might want to automatically approve access requests to nodes with an `Environment:Testing` tag. You might also want to explicitly deny auto-approvals to nodes with an `Environment:Production` tag if an employee ID begins with `TEMP`. For nodes with a `Tier:Database` tag, you might want to require two levels of manual approvals.

In any given scenario, you might prefer one policy or condition, over another. Therefore, we recommend that you clearly define the policy behaviors you want to determine which statements best fit your use case and preferences.

Set up your development environment

Install Amazon Q for command line where you want to develop your approval policies. For information about installing Amazon Q for the command line, see Installing Amazon Q for command line in the *Amazon Q Developer User Guide*.

We also recommend installing the MCP server for AWS documentation. This MCP server connects Amazon Q for command line to the most current documentation resources. For information about using MCP with Amazon Q for the command line, see Using MCP with Amazon Q Developer in the *Amazon Q Developer User Guide*.

For more information about the AWS Documentation MCP server see AWS Documentation MCP Server.

Install and configure the AWS CLI, if you have not already. For information, see Installing or updating the latest version of the AWS CLI.

Develop approval policy content

With your use case identified and environment set up, you're ready to develop the content for your policies. Your use case and preferences will largely dictate the types of approval policies and statements you use.

If you're unsure how to use a particular policy or need more information about the schema for a policy, see Create approval policies for your nodes and the subsequent topics. These topics explain in detail how policies are evaluated and provide working example statements.

The following procedure describes how to create approval policies with Amazon Q for command line.

> **Note**
>
> Amazon Q Developer uses generative AI. You may need to verify responses. See the AWS Responsible AI Policy.

To create a approval policies using Amazon Q for command line

1. Open your terminal and start a session with Amazon Q.

```
$ q chat
```

2. Enter a prompt and describe what kind of policy statement you want to create. For example, using the earlier scenario for an approval policy, you could enter the following prompt:

```
Create a Cedar policy statement that allows a principal to use the
 “getTokenForInstanceAccess" action for a resource
that has a tag key “Environment” and tag value of “Testing”. Use the following
 example statement for reference to verify the syntax.

permit (
    principal in AWS::IdentityStore::Group::"e8c17310-e011-7089-d989-10da1EXAMPLE",
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    principal has organization && resource.hasTag("Engineering") &&
 resource.hasTag("Production") && principal.organization == "Platform"
};

The Cedar policy statement you create must be valid. Validate the Cedar statement
 using the AWS documentation provided for just-in-time node access policy statement
 structure and make sure you abide by the schema.
```

3. Entering this example prompt resulted in the following output:

```
Based on the AWS documentation for Cedar policy statements and the examples
 provided, I'll create a valid Cedar policy
statement that allows a principal to use the "getTokenForInstanceAccess" action for
 resources with the tag key "Environment" and tag value "Testing".

Here's the Cedar policy statement:

permit (
    principal,
    action == AWS::SSM::Action::"getTokenForInstanceAccess",
    resource
)
when {
    resource.hasTag("Environment") &&
    resource.getTag("Environment") == "Testing"
};

This policy statement:
1. Uses the permit effect to allow access
2. Applies to any principal (since no specific principal is defined)
3. Specifically targets the "getTokenForInstanceAccess" action
4. Applies to resources that have a tag with key "Environment" and value "Testing"
5. Uses the proper syntax for the condition clause with the hasTag() and getTag()
 operators

The statement follows the Cedar policy language structure as documented in the AWS
 Systems Manager documentation for just-in-time node access policies.
```

4. Paste the policy statement into a new Cedar file to validate the syntax. You can also validate the statement using the Cedar playground.
5. After validating the statement, save the Cedar file.
6. From your terminal, run the following AWS CLI command to create an SSM document using your policy content. Before using approval policies in a production environment, test your approval policies with a subset of identities and nodes in an AWS account and AWS Region.

> **Note**
>
> For an auto-approval policy, the document name must be `SSM-JustInTimeAccessAutoApprovalPolicy`. There can only be one auto-approval

policy per AWS account and AWS Region. For a deny-access policy, the document name must be `SSM-JustInTimeAccessDenyAccessOrgPolicy`. There can only be one deny-access policy per AWS Organizations organization, and the policy must be created in the delegated administrator account for Systems Manager. The naming constraints for manual approval policies are the same as other SSM documents. For more information, see CreateDocument.

Linux & macOS

```
aws ssm create-document \
    --content file://path/to/file/policyContent.cedar \
    --name "SSM-JustInTimeAccessAutoApprovalPolicy" \
    --document-type "AutoApproval"
```

Windows

```
aws ssm create-document ^
    --content file://C:\path\to\file\policyContent.cedar ^
    --name "SSM-JustInTimeAccessAutoApprovalPolicy" ^
    --document-type "AutoApproval"
```

PowerShell

```
$cedar = Get-Content -Path "C:\path\to\file\policyContent.cedar" | Out-String
New-SSMDocument `
    -Content $cedar `
    -Name "SSM-JustInTimeAccessAutoApprovalPolicy" `
    -DocumentType "AutoApproval"
```

Update just-in-time node access session preferences

With just-in-time node access, you can specify general session and logging preferences in each AWS account and AWS Region in your organization. Alternatively, you can use AWS CloudFormation StackSets to create a session preferences document in multiple accounts and Regions to help you have consistent session preferences. For information about the schema for session preferences documents, see Session document schema.

For logging purposes, we recommend using the streaming option with Amazon CloudWatch Logs. This feature allows you to send a continual stream of session data logs to CloudWatch Logs. Essential details, such as the commands a user has run in a session, the ID of the user who ran the commands, and timestamps for when the session data is streamed to CloudWatch Logs, are included when streaming session data. When streaming session data, the logs are JSON-formatted to help you integrate with your existing logging solutions.

Systems Manager doesn't automatically terminate just-in-time node access sessions. As a best practice, specify values for the *maximum session duration* and *idle session timeout* settings. Using these settings helps you to prevent a user from remaining connected to a node longer than the window of time approved in an access request. The following procedure describes how to update session preferences for just-in-time node access.

> **⚠ Important**
>
> You must tag the AWS KMS keys used for Session Manager encryption and RDP recording in just-in-time node access with the tag key `SystemsManagerJustInTimeNodeAccessManaged` and tag value `true`. For information about tagging KMS keys, see Tags in AWS KMS in the *AWS Key Management Service Developer Guide*.

To update session preferences

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Settings** in the navigation pane.
3. Select the **Just-in-time node access** tab.
4. In the **Session preferences** section, select **Edit**.
5. Update your general and logging preferences as needed and select **Save**.

Configure notifications for just-in-time access requests

You can configure Systems Manager to send notifications when a user creates a just-in-time node access request to the email addresses, or chat client, for approvers and the requester. The notification contains the reason for the access request provided by the requester, the AWS

account, AWS Region, status of the request, and ID of the target node. Currently, Systems Manager supports Slack and Microsoft Teams clients through integration with Amazon Q Developer in chat applications. When using notifications through chat clients, access request approvers can interact directly with access requests. This eliminates the need to log in to the console to take action on access requests.

Before you begin

Before you configure a chat client for just-in-time node access notifications, note the following requirement:

- If you're using IAM roles to manage user identities in your account, you must manually associate the email addresses of the approvers or requesters you want to send notifications to with the associated role. Otherwise the intended recipients can't be notified by email.

The following procedures describe how to configure notifications for just-in-time node access requests.

To configure a chat client for just-in-time node access notifications

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Settings** in the navigation pane.
3. Select the **Just-in-time node access** tab.
4. In the **Chat** section, select **Configure new client**.
5. In the **Select client type** dropdown, choose the type of chat client you want to configure and select **Next**.
6. You're prompted to allow Amazon Q Developer in chat applications to access your chat client. Select **Allow**.
7. In the **Configure channel** section, enter the information for your chat client channel and select the types of notifications you want to receive.
8. If you're configuring Slack notifications, invite "@Amazon Q" to every Slack channel that notifications are being configured in.
9. Select **Configure channel**.

Note

To allow approving/rejecting access requests directly from a Slack channel, make sure the IAM role that is configured with the Slack channel has `ssm:SendAutomationSignal` permissions and has a trust policy that includes chatbot:

```
{
            "Effect": "Allow",
            "Principal": {
                "Service": "chatbot.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
}
```

To configure email notifications for just-in-time node access notifications

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Settings** in the navigation pane.
3. Select the **Just-in-time node access** tab.
4. In the **Email** section, select **Edit**.
5. Select **Add emails**, choose the **IAM role** you want to manually associate email addresses with.
6. Enter an email address in the **Email address** field. Whenever an access request is created that requires approval from the IAM role you specified, the email addresses you associate with the role are notified.
7. Select **Add email address**.

Recording RDP connections

Just-in-time node access includes the ability to record RDP connections made to your Windows Server nodes. Recording RDP connections require an S3 bucket and an AWS Key Management Service (AWS KMS) customer managed key. The AWS KMS key is used to temporarily encrypt the recording data while it's generated and stored on Systems Manager resources. The customer managed key must be a symmetric key with a key usage of encrypt and decrypt. You can either

use a multi-Region key for your organization, or you must create a customer managed key in each Region where you've enabled just-in-time node access.

If you have enabled KMS encryption on the S3 bucket where you store recordings, you must provide access to the customer managed key used for bucket encryption to the `ssm-guiconnect` service principal. This customer managed key can be a different one than you specify in the recording settings, which must include for which the `kms:CreateGrant` permission is required for establishing connections.

Configuring S3 bucket encryption for RDP recordings

Your connection recordings are stored in the S3 bucket that you specify when you enable RDP recording.

If you use a KMS key as the default encryption mechanism for the S3 bucket (SSE-KMS), you must allow the `ssm-guiconnect` service principal access to `kms:GenerateDataKey` action on the key. We recommend using a customer managed key when using SSE-KMS encryption with S3 bucket. This is because you can update the associated key policy for a customer managed key. You can't update the key policies for AWS managed keys.

> **Important**
>
> You must tag the AWS KMS keys used for Session Manager encryption and RDP recording in just-in-time node access with the tag key `SystemsManagerJustInTimeNodeAccessManaged` and tag value `true`. For information about tagging KMS keys, see Tags in AWS KMS in the *AWS Key Management Service Developer Guide*.

Use the following customer managed key policy to allow the `ssm-guiconnect` service access to the KMS key for S3 storage. For information about updating a customer managed key, see Change a key policy in the *AWS Key Management Service Developer Guide*.

Replace each *`example resource placeholder`* with your own information:

- *`account-id`* represents the ID of the AWS account that initiates the connection.
- *`region`* represents the AWS Region where the S3 bucket is located . (You can use `*` if the bucket will receive recordings from multiple Regions. Example: `s3.*.amazonaws.com`.)

> **Note**
>
> You can use `aws:SourceOrgID` in the policy instead of `aws:SourceAccount` if the account belongs to an organization in AWS Organizations.

```
{
    "Sid": "Allow the GUI Connect service principal to access S3",
    "Effect": "Allow",
    "Principal": {
        "Service": "ssm-guiconnect.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey*"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "account-id"
        },
        "StringLike": {
            "kms:ViaService": "s3.region.amazonaws.com"
        }
    }
}
```

Configuring IAM permissions for recording RDP connections

In addition to the required IAM permissions for just-in-time node access, the user or role you use must be allowed the following permissions based on the task you need to perform.

Permissions for configuring connection recording

To configure RDP connection recording, the following permissions are required:

- `ssm-guiconnect:UpdateConnectionRecordingPreferences`
- `ssm-guiconnect:GetConnectionRecordingPreferences`
- `ssm-guiconnect:DeleteConnectionRecordingPreferences`
- `kms:CreateGrant`

Permissions for initiating connections

To make RDP connections with just-in-time node access, the following permissions are required:

- `ssm-guiconnect:CancelConnection`
- `ssm-guiconnect:GetConnection`
- `ssm-guiconnect:StartConnection`
- `kms:CreateGrant`

Before you begin

To store your connection recordings, you must first create an S3 bucket and add the following bucket policy. Replace each *`example resource placeholder`* with your own information.

(For information about adding a bucket policy, see Adding a bucket policy by using the Amazon S3 console in the *Amazon Simple Storage Service User Guide*.)

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ConnectionRecording",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "ssm-guiconnect.amazonaws.com"
                ]
            },
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ],
            "Condition":{
            "StringEquals":{
                "aws:SourceAccount":"111122223333"
                }
            }
```

```
        }
    ]
}
```

Enabling and configuring RDP connection recording

The following procedure describes how to enable and configure RDP connection recording.

To enable and configure RDP connection recording

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Settings** in the navigation pane.
3. Select the **Just-in-time node access** tab.
4. In the **RDP recording** section, select **Enable RDP recording**.
5. Choose the S3 bucket you want to upload session recordings to.
6. Choose the customer managed key you want to use to temporarily encrypt the recording data while it's generated and stored on Systems Manager resources. (This can be a different customer managed key than you use to encrypt the bucket.)
7. Select **Save**.

RDP connection recording status values

Valid status values for RPD connection recordings include the following:

- `Recording` - The connection is in the process of being recorded
- `Processing` - The video is being processed after the connection is terminated.
- `Finished` - Successful terminal state:The connection recording video processed successfully and uploaded to the specified bucket.
- `Failed` - Failed terminal state. The connection wasn't recorded successfully.
- `ProcessingError` - One or more intermediate failures/errors occurred during video processing. Potential causes include service dependency failures or missing permissions due to a misconfiguration on the S3 bucket specified for storing recordings. The service continues to attempt processing when the recording is in this state.

> **Note**
>
> `ProcessingError` can be the result of the `ssm-guiconnect` service principal not having permission to upload objects to the S3 bucket after the connection has been established. Another potential cause is missing KMS permissions on the KMS key used for S3 bucket encryption.

Modifying targets

When you set up just-in-time node access, you choose the *targets* where you want to set up just-in-time node access. Targets consist of AWS Organizations organizational units (OUs) and AWS Regions. By default, the same targets you chose when setting up the unified Systems Manager console are selected for just-in-time node access. You can choose to set up just-in-time node access for all of the same targets, or a subset of the targets you specified when setting up the unified Systems Manager console. Adding new targets that weren't selected when you set up the unified Systems Manager console isn't supported. You can change the targets you selected after setting up just-in-time node access.

The following procedure describes how to modify the targets for just-in-time node access.

To modify targets

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Settings** in the navigation pane.
3. Select the **Just-in-time node access** tab.
4. In the **Targets** section, select **Edit**.
5. Select the **Organizational units** and **Regions** where you want to use just-in-time node access.
6. Select **Save**.

Changing identity providers

By default, just-in-time node access uses IAM for an identity provider. After enabling just-in-time node access, customers using the unified console with an organization can modify this setting to use IAM Identity Center. Just-in-time node access doesn't support IAM Identity Center as an identity provider when set up for a single account and Region.

The following procedure describes how to modify the identity provider for just-in-time node access.

To modify identity providers

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Settings** in the navigation pane.
3. Select the **Just-in-time node access** tab.
4. In the **User identity** section, select **Edit**.
5. Choose **AWS IAM Identity Center**.
6. Select **Save**.

Start a just-in-time node access session

After enabling and setting up just-in-time node access, and configuring session and notification preferences, users are ready to start just-in-time node access sessions. You can start sessions using just-in-time node access from the Systems Manager console or from the AWS Command Line Interface using the Session Manager plugin. Just-in-time node access sessions can be started on nodes in the same account and Region. The following procedures describe how to start sessions with just-in-time node access.

> **Note**
>
> If your users previously used Session Manager to connect to nodes, you must remove the Session Manager permissions, for example `ssm:StartSession`, from their IAM policies to start sessions using just-in-time node access. Otherwise, when connecting to nodes they'll continue to use Session Manager.

To start a session with just-in-time node access using the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Explore nodes** in the navigation pane.
3. Select the node you want to connect to.

4. In the **Actions** dropdown, select **Connect**.

If your organization's approval policies don't allow you to automatically connect to the node, you're prompted to submit an access request. After you fill out the information requested and submit the acccess request, you'll be able to start sessions to the node once all of the required approvals are received.

To start a session with just-in-time node access using the AWS CLI

1. Run the following command to start the access request workflow, making sure to replace the *placeholder values* with your own information.

   ```
   aws ssm start-access-request \
       --targets  Key=InstanceIds,Values=i-02573cafcfEXAMPLE
       --reason "Troubleshooting networking performance issue"
   ```

   Depending on your organization's approval policies, you'll either be automatically connected to the node or the manual approval process is started. For requests that require manual approvals, note the ID of the access request that is returned in the response.
2. Wait for all of the required approvals to be provided.
3. After all required approvals have been provided, run the following command to get an access token containing temporary credentials. Replace the *placeholder values* with your own information.

   ```
   aws ssm get-access-token \
       --access-request-id oi-12345abcdef
   ```

   Note the access token returned in the response.
4. Run the following command to use the temporary credential in the AWS CLI, making sure to replace the *placeholder values* with your own information.

   ```
   export AWS_SESSION_TOKEN=AQoDYXdzEJr...<remainder of session token>
   ```
5. Run the following command to start a session to the node, making sure to replace the *placeholder values* with your own information.

   ```
   aws ssm start-session \
   ```

```
    --target i-02573cafcfEXAMPLE
```

Managing just-in-time access requests

For increased visibility across your organization, Systems Manager replicates access requests to the delegated administrator account for your organization. To help you meet compliance requirements, Systems Manager retains all access requests for 1 year. The following topics describe how to manage just-in-time node access requests. This information is intended for access request approvers. Before you begin, we commend reviewing your IAM policies and making sure you have the required permissions for administering just-in-time node access. For more information see, Setting up just-in-time access with Systems Manager.

Topics

Approving and denying just-in-time node access requests

Access request approvers can approve or deny just-in-time node access requests from the unified Systems Manager console or using your preferred command line tool. This information is intended for access request approvers. If you don't have the permissions required to approve or reject access requests, contact your administrator. The following procedures describe how to approve or deny just-in-time node access requests.

To approve or deny just-in-time node access requests using the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Select **Manage node access** in the navigation pane.
3. Select the **Access requests** tab.
4. Select the **Requests for me** toggle.
5. Select the checkbox next to the access request you want to approve or deny.
6. Select **Approve** or **Reject**.

After approving an access request you can revoke your approval at any time by selecting **Revoke**.

To approve or deny just-in-time node access requests using the command line

1. Note the access request ID from the notification. For example, *oi-12345abcdef*.
2. Run the following command to return details about the access request approval workflow, making sure to replace the *placeholder values* with your own information.

   ```
   aws ssm get-ops-item \
       --ops-item-id oi-12345abcdef
   ```

   Note the `automationExecutionId` value in the `/aws/accessrequest` field for the `OperationalData`. For example, *9231944f-61c6-40be-8bce-8ee2bEXAMPLE*.
3. Run the following command to approve or deny the access request. Use the `Approve` signal type to approve the request, and `Deny` to deny the request. Make sure to replace the *placeholder values* with your own information.

   ```
   aws ssm send-automation-signal \
       --automation-execution-id 9231944f-61c6-40be-8bce-8ee2bEXAMPLE \
       --signal-type "Approve"
   ```

Moving to just-in-time node access from Session Manager

When you enable just-in-time node access, Systems Manager doesn't make any changes to your existing resources for Session Manager. This ensures there's no disruption to your existing environment and users can continue to start sessions while you create and validate approval policies. Once you're ready to test your approval policies, you must modify your existing IAM policies to complete the transition to just-in-time node access. This includes adding the required permissions for just-in-time node access to identities, and removing permission for the `StartSession` API operation for Session Manager. We recommend testing approval policies with a subset of identities and nodes in an AWS account and AWS Region.

For more information about the permissions required for just-in-time node access, see Setting up just-in-time access with Systems Manager.

For more information about modifying and identity's IAM permissions, see Adding and removing IAM identity permissions in the *IAM User Guide*.

The following describes a detailed method of how you can move to just-in-time node access from Session Manager.

Moving from Session Manager to just-in-time node access requires careful planning and testing to ensure a smooth transition without disrupting your operations. The following sections describe how you can complete this process.

Prerequisites

Before you begin, ensure that you have completed the following tasks:

- Set up the Systems Manager unified console.
- Verified you have permissions to modify IAM policies in your account.
- Identified all IAM policies and roles that currently grant Session Manager permissions.
- Documented your current Session Manager configuration, including session preferences and logging settings.

Assessment

Assess your current environment and outline desired approval behaviors by completing the following tasks:

1. **Inventory your nodes** - Identify all nodes that users currently access through Session Manager.
2. **Identify user access patterns** - Document which users or roles need access to which nodes, and under what circumstances.
3. **Map approval workflows** - Determine who should approve access requests for different types of nodes.
4. **Review tagging strategy** - Ensure your nodes are properly tagged to support your planned approval policies.
5. **Audit existing IAM policies** - Identify all policies that include Session Manager permissions.

Planning

Phased strategy

When moving from Session Manager to just-in-time node access, we recommend using a phased approach like the following:

1. **Phase 1: Setup and configuration** - Enable just-in-time node access without modifying existing Session Manager permissions.

2. **Phase 2: Policy development** - Create and test approval policies for your nodes.
3. **Phase 3: Pilot migration** - Modify a small group of non-critical nodes and users or roles from Session Manager to just-in-time node access.
4. **Phase 4: Full migration** - Gradually migrate all remaining nodes and users or roles.

Timeline considerations

Consider the following factors when creating your timeline to move from Session Manager to just-in-time node access:

- Allow time for user training and adjustment to the new approval workflow.
- Schedule migrations during periods of lower operational activity.
- Include buffer time for troubleshooting and adjustments.
- Plan for a period of parallel operation where both systems are available.

Implementation steps

Phase 1: Setup and configuration

1. Enable just-in-time node access in the Systems Manager console. For detailed steps, see Setting up just-in-time access with Systems Manager.
2. Configure session preferences for just-in-time node access to match your current Session Manager settings. For more information, see Update just-in-time node access session preferences.
3. Set up notification preferences for access requests. For more information, see Configure notifications for just-in-time access requests.
4. If you use RDP connections to Windows Server nodes, configure RDP recording. For more information, see Recording RDP connections.

Phase 2: Policy development

1. Create IAM policies for just-in-time node access administrators and users.
2. Develop approval policies based on your security requirements and use case.
3. Test your policies in a non-production environment to ensure they work as expected.

Phase 3: Pilot migration

1. Select a small group of users and non-critical nodes for the pilot.
2. Create new IAM policies for pilot users that include just-in-time node access permissions.
3. Remove Session Manager permissions (`ssm:StartSession`) from the pilot users' IAM policies.
4. Train pilot users on the new access request workflow.
5. Monitor the pilot for issues and gather feedback.
6. Adjust policies and procedures based on pilot results.

Example IAM policy modification for pilot users

Original policy with Session Manager permissions:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:StartSession",
        "ssm:ResumeSession",
        "ssm:TerminateSession"
      ],
      "Resource": "*"
    }
  ]
}
```

Modified policy for just-in-time node access:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
      "Effect": "Allow",
      "Action": [
        "ssm:StartAccessRequest",
        "ssm:GetAccessToken",
        "ssm:ResumeSession",
        "ssm:TerminateSession"
      ],
      "Resource": "*"
    }
  ]
}
```

Phase 4: Full migration

Develop a schedule for migrating remaining users and nodes in batches.

Testing methodology

Throughout the migration process, conduct the following tests:

- **Policy validation** - Verify that approval policies correctly apply to the intended nodes and users.
- **Access request workflow** - Test the complete workflow from access request to session establishment for both auto-approval and manual approval scenarios.
- **Notifications** - Verify that approvers receive notifications through configured channels (email, Slack, Microsoft Teams).
- **Logging and monitoring** - Verify that session logs and access requests are properly captured and stored.

Best practices for a successful migration

- **Communicate early and often** - Inform users about the migration timeline and benefits of just-in-time node access.
- **Start with non-critical systems** - Begin migration with development or test environments before moving to production.
- **Document everything** - Maintain detailed records of your approval policies, IAM policy changes, and configuration settings.
- **Monitor and adjust** - Continuously monitor access requests and approval workflows, adjusting policies as needed.

- **Establish governance** - Create a process for regularly reviewing and updating approval policies as your environment changes.

Disabling just-in-time access with Systems Manager

The following procedure describes how to disable just-in-time node access. After disabling just-in-time node access, users in your organization might be unable to connect to your nodes unless you've already implemented other connection methods.

To disable just-in-time node access

1. Log in to the Systems Manager delegated administrator account for your organization.
2. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
3. Select **Settings** in the navigation pane.
4. In the **Just-in-time node access** tab, select **Disable**.

Just-in-time node access frequently asked questions

How do I move from Session Manager to just-in-time node access?

After setting up the unified console and enabling just-in-time node access, you must modify your existing IAM policies to complete the move to just-in-time node access. This includes adding the required permissions for just-in-time node access and removing permission for the `StartSession` API operation for Session Manager. For more information about IAM policies for just-in-time node access see Setting up just-in-time access with Systems Manager.

Do I have to set up the unified console to use just-in-time node access?

Yes, setting up the unified console is a prerequisite for just-in-time node access. However, after you set up the unified console and enable just-in-time node access, there are several methods for connecting to your nodes. For example, you can start just-in-time node access sessions from the Amazon EC2 console and the AWS CLI. For more information about setting up the unified console, see Setting up Systems Manager unified console for an organization.

Is there cost associated with just-in-time node access?

Systems Manager provides a 30 day free trial for just-in-time node access. After the trial, just-in-time node access incurs costs. For more information, see AWS Systems Manager Pricing.

What is the precedence for just-in-time node access approval policies?

Approval policies are evaluated in the following order:

1. Deny-access
2. Auto-approval
3. Manual

How are manual approval policies evaluated?

Just-in-time node access always favors the more specific policy for a node. Manual approval policies are evaluated in the following order:

1. Tag specific target
2. All nodes target

What happens if there isn't an approval policy that applies to a node?

To connect to a node using just-in-time node access, an approval policy must apply to the node. If there are no approval policies that apply to a node, users are unable to request access to the node.

Can multiple approval policies target a tag?

A tag can only be targeted once in your approval policies.

What happens if multiple manual approval policies apply to a node as a result of overlapping tags?

When multiple manual approval policies apply to a node, this results in a conflict and users are unable to request access to the node. Keep this in mind when creating your manual approval policies since some instances might have multiple tags depending on your case.

Can I use just-in-time node access to request access and start sessions on nodes across accounts and Regions?

Just-in-time node access supports requesting access to and starting sessions on nodes in the same account and Region as the requester.

Can I use just-in-time node access to request access and start sessions on nodes registered with a hybrid activation?

Yes, just-in-time node access supports requesting access to and starting sessions on nodes registered with a hybrid activation. The node must be registered in the same account and Region as the requester.

Diagnosing and remediating

Using the unified Systems Manager console, you can identify problems across your fleet in a single diagnosis operation. For organizations, you can then attempt remediation on all or only select targets using a single Automation operation. For an organization, as a delegated account administrator, you can select targets across all accounts and Regions. If you are working in a single account, you can select targets in a single Region at a time.

Systems Manager can diagnose and help you remediate several types of deployment failures, as well as drifted configurations. Systems Manager can also identify Amazon Elastic Compute Cloud (Amazon EC2) instances in your account or organization that Systems Manager isn't able to treat as a *managed node*. The EC2 instance diagnosis process can identify issues related to misconfigurations for a virtual private cloud (VPC), in a Domain Name Service (DNS) setting, or in an Amazon Elastic Compute Cloud (Amazon EC2) security group.

> **Note**
>
> Systems Manager supports both EC2 instances and other machine types in a hybrid and multicloud environment as *managed nodes*. To be a managed node, AWS Systems Manager Agent (SSM Agent) must be installed on the machine, and Systems Manager must have permission to perform actions on the machine.
> For EC2 instances, this permission can be provided at the account level using an AWS Identity and Access Management (IAM) role, or at the instance level using an instance profile. For more information, see Configure instance permissions required for Systems Manager.

For non-EC2 machines, this permission is provided using an IAM service role. For more information, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.

Before you begin

In order to use the **Diagnose and remediate** feature to detect unmanaged EC2 instances, you must first onboard your organization or account to the unified Systems Manager console. During this process, you must choose the option to create IAM roles and managed policies required for these operations. For more information, see Setting up Systems Manager unified console for an organization.

Use the following topics to help you identify and fix certain common types of failed deployments, drifted configurations, and unmanaged EC2 instances.

Topics

- Diagnosing and remediating failed deployments
- Diagnosing and remediating drifted configurations
- Diagnosing and remediating unmanaged Amazon EC2 instances in Systems Manager
- Remediation impact types of runbook actions
- Viewing execution progress and history for remediations in Systems Manager

Diagnosing and remediating failed deployments

Systems Manager can diagnose and then help you remediate the following types of failed deployments:

- Core setup for organization member accounts
- Core setup for delegated administrator account
- Core setup for your account

Use the following procedure to attempt to remediate these types of issues.

To diagnose and remediate failed deployments

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose the **Deployment issues** tab.
4. In the **Failed deployments** section, review the list of findings for failed deployments.
5. In the **Setup step** column, choose the name of a finding to review additional details about the issue. For example: **Core setup for organization member accounts**.
6. In the detail page for that failed deployment, you can view a list of accounts and how many Regions in each have experienced deployment failures.
7. Select an account ID to view information about the reason for failures in that account.
8. In the **Failed Regions** area, examine the information provided for **Status reason**. This information can indicate a reason for the failed deployment, which might provide insight into configuration changes that need to be made.
9. If you want to retry the deployment without making configuration changes, choose **Redeploy**.

Diagnosing and remediating drifted configurations

Systems Manager can diagnose and then help you remediate the following types of drifted configurations:

- Core setup for organization member accounts
- Core setup for delegated administrator account
- Core setup for your account

Use the following procedure to attempt to remediate these types of drifted configurations.

To diagnose and remediate drifted configurations

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose the **Deployment issues** tab.
4. In the **Drifted deployments** section, review the list of finding for failed deployments.

-or-

To run a new diagnosis, choose **Detect drift**.

5. In the **Setup step** column, choose the name of a finding to review additional details about the issue. For example: **Core setup for organization member accounts**.
6. In the detail page for that failed deployment, you can view a list of accounts and how many Regions in each have experienced configuration drifts.
7. Select an account ID to view information about the reason for configuration drifts in that account.
8. In the **Drifted resources** area, the **Resource** column reports names of resources that have experienced drift. The **Drift type** column reports whether the resource was modified or deleted..
9. To redeploy the intended configuration, choose **Redeploy**.

Diagnosing and remediating unmanaged Amazon EC2 instances in Systems Manager

To help you manage your Amazon Elastic Compute Cloud (Amazon EC2) instances with Systems Manager, you can use the unified Systems Manager console to do the following:

1. Run a manual or scheduled diagnosis process to identify which EC2 instances in your account or organization aren't currently managed by Systems Manager.
2. Identify network or other issues that are preventing Systems Manager from taking over management of the instances.
3. Run an Automation execution to automatically remediate the problem, or access information to help you manually address the issue.

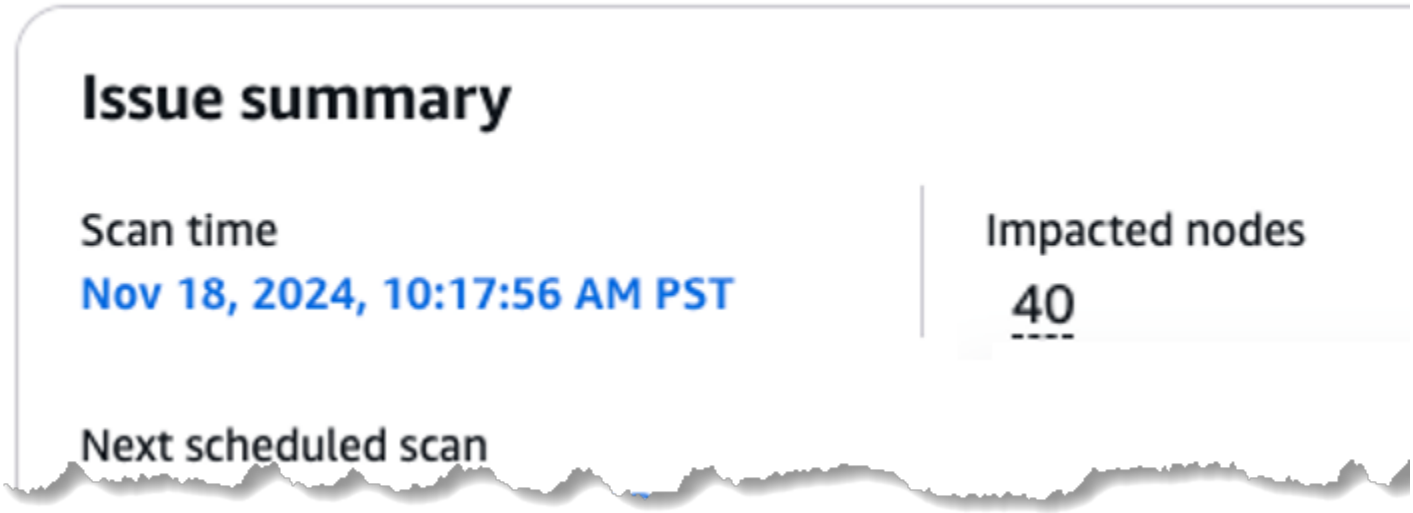
Use the information in the following topics to help you diagnose and remediate issues that are preventing Systems Manager from managing your EC2 instances.

How Systems Manager counts impacted nodes for the 'Unmanaged EC2 instance issues' list

The number of nodes reported as unmanaged on the **Unmanaged EC2 instances issues** tab represents to the total number of instances with any of the follow status values at the diagnosis scan time:

- `Running`
- `Stopped`
- `Stopping`

This number is reported as **Impacted nodes** in the **Issue summary** area. In the following image, this number of impacted nodes not currently managed by Systems Manager is `40`.



Unlike the report of unmanaged EC2 instances on the **Review node insights** page, this count of EC2 instances is not dynamic. It represents findings made during the last reported diagnostic scan, shown as the **Scan time** value. We therefore recommend running a diagnostic scan for unmanaged EC2 instances on a regular schedule to keep this reported number of impacted nodes up to date.

For information about unmanaged instance counts on the **Review node insights** page, see What is an unmanaged instance? in the topic Reviewing node insights.

Topics

- Categories of diagnosable unmanaged EC2 instance issues
- Running a diagnosis and optional remediation for unmanaged EC2 instances

- Scheduling a recurring scan for unmanaged EC2 instances

Categories of diagnosable unmanaged EC2 instance issues

This topic lists the major categories of EC2 management issues, and the specific issues in each category, that Systems Manager can help you diagnose and remediate. Note that for some of the issues, Systems Manager can identify the issue, but not provide automatic remediation. In those cases, the Systems Manager console directs you to information to help you manually resolve an issue.

The diagnosis process examines each group of EC2 instances at once according to the virtual private cloud (VPC) they belong to.

Issue types

- Problem category: Security group configuration and HTTPS communications
- Problem category: DNS or DNS host name configuration
- Problem category: VPC endpoint configuration

Problem category: Security group configuration and HTTPS communications

A diagnosis operation might find that SSM Agent isn't able to communicate with the Systems Manager service over HTTPS. In those cases, you can choose to execute an Automation runbook that attempts to update security groups that are attached to the instances.

> **Note**
>
> Occasionally, Systems Manager might not be able to automatically remediate these issues, but you can manually edit the affected security groups.

Supported issue types

- **Instance security group**: Outbound traffic is not allowed on port 443
- **`ssm` VPC endpoint's security group**: Inbound traffic is not allowed on port 443
- **`ssmmessages` VPC endpoint's security group**: Inbound traffic not allowed on port 443
- **`ec2messages` VPC endpoint's security group**: Inbound traffic not allowed on port 443

For more information, see Verify ingress rules on endpoint security groups in the topic Troubleshooting SSM Agent.

Problem category: DNS or DNS host name configuration

A diagnosis operation might find that Doman Name System (DNS) or DNS host names aren't properly configured for the VPC. In those cases, you can choose to execute an Automation runbook that attempts to enable the `enableDnsSupport` and `enableDnsHostnames` attributes of the affected VPC.

Supported issue types

- DNS support is disabled in a VPC.
- A DNS hostname is disabled in a VPC.

For more information, see Verify your VPC DNS-related attributes in the topic Troubleshooting SSM Agent.

Problem category: VPC endpoint configuration

A diagnosis operation might find that VPC endpoints aren't properly configured for the VPC.

If VPC endpoints required by SSM Agent don't exist, Systems Manager attempts to execute an Automation runbook to create the VPC endpoints and associates them with one subnet in each relevant regional availability zone (AZ). If VPC the required endpoints exist but aren't associated with a subnet in which the issue is found, the runbook associates the VPC endpoints to the affected subnet.

> **Note**
>
> Systems Manager doesn't support remediating all misconfigured VPC endpoint issues. In those cases, Systems Manager directs you to manual remedy instructions instead of running an Automation runbook.

Supported issue types

- No `ssm.region.amazonaws.com` endpoint for PrivateLink was found.
- No `ssmmessages.region.amazonaws.com` endpoint for PrivateLink was found.

- No `ec2messages.region.amazonaws.com` endpoint for PrivateLink was found.

Diagnosable issue types

Systems Manager can diagnose the following issue types, but currently no runbook is available for remediating their issues. You can edit your configuration manually for these issues.

- An instance's subnet is not attached to an `ssm.region.amazonaws.com` endpoint.
- An instance's subnet is not attached to an `ssmmessages.region.amazonaws.com` endpoint.
- An instance's subnet not attached to an `ec2messages.region.amazonaws.com` endpoint.

For more information, see Verify your VPC configuration in the topic Troubleshooting SSM Agent.

Running a diagnosis and optional remediation for unmanaged EC2 instances

Use the following procedure to diagnose the network-related and VPC-related issues that might be preventing Systems Manager from managing your EC2 instances.

The diagnosis operation can detect and group together issues of the following types:

- **Network configurations issues** – Types of networking issues that might be preventing EC2 instances from communicating with the Systems Manager service in the cloud. Remediation operations might be available for these issues. For more information about the network configuration issues, see Categories of diagnosable unmanaged EC2 instance issues.
- **Unidentified issues** – A list of findings for cases where the diagnostic operation was unable to determine why EC2 instances are not able to communicate with the Systems Manager service in the cloud.

To run a diagnosis and remediation for unmanaged EC2 instances

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose the **Unmanaged EC2 instances issue** tab.
4. In the **Issue summary** section, choose **Run new diagnosis**.

   -or-

If this is your first time to diagnose unmanaged EC2 issues, in the **Diagnose unmanaged EC2 instances** section, choose **Execute**.

> **Tip**
>
> While the diagnosis is running, choose **View progress** or **View executions** to monitor the current state of the execution. For more information, see Viewing execution progress and history for remediations in Systems Manager.

5. After the diagnosis completes, do the following:

   - For any issues reported in the **Unidentified issues** section, choose the **Learn more** link for information about resolving the problem.
   - For issues reported in the **Network configurations issues** section, continue with the next step.

6. In the list of finding types, in the **Recommendations** column, for a particular issue, choose the link, such as **2 recommendations**.
7. In the **Recommendations** pane that opens, choose from the available mitigations:

   - **Learn more** – Open a topic with information about how to resolve an issue manually.
   - **View runbook** – Open a pane with information about the Automation runbook you can execute to resolve the issue with your EC2 instances, as well as options for generating a *preview* of the actions that runbook would take. Continue with the next step.

8. In the runbook pane, do the following:

   a. For **Document description**, review the content, which provides an overview of the actions the runbook can take to remediate your unmanaged EC2 instance issues. Choose **View steps** to preview the individual actions the runbook would take.

   b. For **Targets**, do the following:

      - If you are managing remediations for an organization, for **Accounts**, specify whether this runbook would target all accounts, or only a subset of accounts you choose.
      - For **Regions**, specify whether this runbook would target all AWS Regions in your account or organization, or only a subset of Regions you choose.

   c. For **Runbook preview**, carefully review the information. This information explains what the scope and impact would be if you choose to execute the runbook.

> **Note**
>
> Choosing to execute the runbook would incur charges. Review the preview information carefully before deciding whether to proceed.

The **Runbook preview** content provides the following information:

- How many Regions the runbook operation would occur in.
- (Organizations only) How many organizational units (OUs) the operation would run in.
- The types of actions that would be taken, and how many of each.

  Action types include the following:

  - **Mutating**: The runbook step would make changes to the targets through actions that create, modify, or delete resources.
  - **Non-mutating**: The runbook step would retrieve data about resources but not make changes to them. This category generally includes `Describe*`, `List*`, `Get*`, and similar read-only API actions.
  - **Undetermined**: An undetermined step invokes executions performed by another orchestration service like AWS Lambda, AWS Step Functions, or AWS Systems Manager Run Command. An undetermined step might also call a third-party API. Systems Manager Automation doesn't know the outcome of the orchestration processes or third-party API executions, so the results of the steps are undetermined.

d. At this point, you can choose one of the following actions:

- Stop and do not execute the runbook.
- Choose **Execute** to run the runbook with the options you have already selected.

If you choose to run the operation, choose **View progress** or **View executions** to monitor the current state of the execution. For more information, see Viewing execution progress and history for remediations in Systems Manager.

Scheduling a recurring scan for unmanaged EC2 instances

You can run an on-demand scan for Amazon EC2 instances in your account or organization that Systems Manager isn't able to manage due to various configuration issues. You can also schedule this scan to occur automatically on a regular schedule.

To schedule a recurring scan for unmanaged EC2 instances

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose the **Unmanaged EC2 instances issue** tab.
4. In the **Diagnose unmanaged EC2 instances** section, turn on **Schedule recurring diagnosis**.
5. For **Diagnostic frequency**, select whether to run the diagnosis once a day or once a week.
6. (Optional) For **Start time**, enter a time, in 24-hour format, for the diagnosis to begin. For example, for 8:15 PM, enter **`20:15`**.

   The time you enter is for your current local time zone.

   If you don't specify a time, the diagnostic scan runs immediately. Systems Manager also schedules the scan to run in the future at the current time. If you specify a time, Systems Manager waits to run the diagnostic scan at the specified time.
7. Choose **Execute**. The diagnosis runs immediately, but will also run on the schedule you have specified.

Remediation impact types of runbook actions

Systems Manager can run diagnosis operations that discover certain types of failed deployments and drifted configurations, as well as certain types of configuration issues that are preventing Systems Manager from managing EC2 instances. The results of the diagnosis might include recommendations for Automation runbooks that you can execute to attempt to remedy a problem. For more information about these diagnosis operations, see the following topics:

- Diagnosing and remediating failed deployments
- Diagnosing and remediating drifted configurations
- Diagnosing and remediating unmanaged Amazon EC2 instances in Systems Manager

When Systems Manager identifies an issue that might be fixed by running an Automation runbook on the affected resources, it provides you with an *execution preview*. The execution preview provides information about the *types* of changes the runbook execution would make to your targets. This information includes how many of each of three types of changes the diagnosis identified.

These change types are as follows:

- `Mutating`: A runbook step would make changes to the targets through actions that create, modify, or delete resources.
- `Non-Mutating`: A runbook step would retrieve data about resources but not make changes to them. This category generally includes `Describe*`, `List*`, `Get*`, and similar read-only API actions.
- `Undetermined`: An undetermined step invokes executions performed by another orchestration service like AWS Lambda, AWS Step Functions, or Run Command, a tool in AWS Systems Manager. An undetermined step might also call a third-party API or run a Python or PowerShell script. Systems Manager Automation can't detect what the outcome would be of the orchestration processes or third-party API executions, and therefore can't evaluate them. The results of those steps would have to be manually reviewed to determine their impact.

  See the following table for information about the impact type of supported Automation actions.

Impact types of supported remediation actions

The table presents the impact type—Mutating, Non-mutating, and Undetermined—of various actions that can be included in a remediation runbook.

Action[1]	Impact type
aws:approve	Non-mutating
aws:assertAwsResourceProperty	Non-mutating
aws:branch	Non-mutating
aws:changeInstanceState	Mutating
aws:copyImage	Mutating

Action[1]	Impact type
aws:createImage	Mutating
aws:createStack	Mutating
aws:createTags	Mutating
aws:deleteImage	Mutating
aws:deleteStack	Mutating
aws:executeAutomation	Undetermined
aws:executeAwsApi	Undetermined
aws:executeScript	Undetermined
aws:executeStateMachine	Undetermined
aws:invokeLambdaFunction	Undetermined
aws:invokeWebhook	Undetermined
aws:loop	Varies. Depends on the actions in the loop.
aws:pause	Non-mutating
aws:runCommand	Undetermined
aws:runInstances	Mutating
aws:sleep	Non-mutating
aws:updateVariable	Mutating
aws:waitForAwsResourceProperty	Non-mutating

[1] For more information about Automation actions, see Systems Manager Automation actions reference.

Viewing execution progress and history for remediations in Systems Manager

You can view a list of all in-progress and completed remediation operations made using the **Diagnose and remediate** feature in Systems Manager.

Data in the execution history list reports the following types of information:

- The type of execution, `Diagnosis` or `Remediation`.
- The execution status, such as `Success` or `Failed`.
- The times that the execution started and ended.

To view execution progress and history for remediations

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose **View executions**.

   > **Tip**
   >
   > When an execution is running, you can also choose **View progress** to open the **Execution history** page.

4. (Optional) In the search
   ()
   box, enter a phrase to help narrow down the execution list, such as **EC2** or **VPC**.
5. (Optional) To view additional details about an execution, in the **Execution name** column, choose an operation name, such as **AWS-DiagnoseUnmanagedEC2NetworkIssues**.

   In the details pane, you can review information about all the steps attempted during the operation, and about all the inputs and outputs for the execution.

Adjusting Systems Manager settings

The options on the **Settings** pages enable and configure features in the Systems Manager unified console. The options displayed depend on the account you are logged into and whether or not you have already set up Systems Manager.

> **Note**
>
> The options on the **Settings** page don't affect Systems Manager tools (formerly called capabilities).

Account setup settings

If Systems Manager is enabled, and if you are logged into an account that is not a member of Organizations or if the delegated administrator has not added your Organizations account to Systems Manager, the **Account setup** page shows the option to **Disable Systems Manager**. Disabling Systems Manager means Systems Manager doesn't display the unified console. All Systems Manager tools still function.

Organizational setup settings

On the **Organizational setup** tab, the **Home Region** section displays the AWS Region chosen as the home Region during setup. In multi-account and multi-Region environments that use AWS Organizations, Systems Manager automatically aggregates node data from all accounts and Regions to the home Region. Aggregating data in this way enables you to view node data across accounts and Regions in a single location.

> **Note**
>
> If you want to change the home Region, you must disable Systems Manager and enable it again. To disable Systems Manager, choose **Disable**.

The **Organizational setup** section displays the AWS organizational units and AWS Regions chosen during setup. To change which organizational units and Regions display node data in Systems Manager, choose **Edit**. For more information about setting up Systems Manager for Organizations, see Setting up AWS Systems Manager.

Feature configurations

The **Feature configurations** section allows you to enable and configure key Systems Manager capabilities that enhance node management across your organization. These features work together to provide automated management, compliance monitoring, and maintenance of your managed nodes.

You can configure these features during initial Systems Manager setup or modify them later through the Settings page. Each feature can be enabled or disabled independently based on your organization's requirements.

Default Host Management Configuration

Default Host Management Configuration (DHMC) automatically configures Amazon Elastic Compute Cloud (Amazon EC2) instances in your organization to be managed by Systems Manager. When enabled, DHMC ensures that new and existing EC2 instances have the necessary AWS Identity and Access Management (IAM) permissions and configurations to communicate with Systems Manager services.

DHMC provides the following benefits:

- **Automatic IAM role assignment** - Ensures EC2 instances have the required IAM roles and policies to function as managed nodes
- **Drift remediation** - Automatically corrects configuration drift when instances lose their managed node status
- **Simplified onboarding** - Reduces manual configuration steps for new instances
- **Consistent configuration** - Maintains uniform settings across your EC2 fleet

Configuring drift remediation frequency

Drift remediation automatically detects and corrects when EC2 instances lose their managed node configuration. You can configure how frequently Systems Manager checks for and remediates configuration drift.

To configure Default Host Management Configuration

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Settings**.

3. In the **Feature configurations** section, locate **Default Host Management Configuration**.
4. To enable DHMC, turn on the toggle switch.
5. For **Drift remediation frequency**, choose how often you want Systems Manager to check for and remediate configuration drift:
   - **Daily** - Checks and remediates drift once per day
   - **Weekly** - Checks and remediates drift once per week
   - **Monthly** - Checks and remediates drift once per month
6. Choose **Save**.

> **Note**
>
> When you enable DHMC, Systems Manager creates the necessary IAM roles and policies in your account. These roles allow EC2 instances to communicate with Systems Manager services. For more information about the IAM roles created by DHMC, see Managing EC2 instances with Systems Manager.

Inventory metadata collection

Inventory metadata collection automatically gathers detailed information about your managed nodes, including installed applications, network configurations, system updates, and other system metadata. This information helps you maintain compliance, perform security analysis, and understand your infrastructure composition.

Inventory collection provides the following benefits:

- **Compliance monitoring** - Track installed software and configurations for compliance reporting
- **Security analysis** - Identify outdated software and potential security vulnerabilities
- **Asset management** - Maintain an up-to-date inventory of your infrastructure
- **Query capabilities** - Use collected data with Amazon Q Developer for natural language queries

Types of inventory data collected

When inventory metadata collection is enabled, Systems Manager collects the following types of information from your managed nodes:

- **Applications** - Installed software packages and applications
- **Network configurations** - Network interfaces, IP addresses, and network settings
- **System updates** - Installed patches and available updates
- **System properties** - Hardware specifications, operating system details, and system configurations
- **Services** - Running services and their configurations

Configuring inventory collection frequency

You can configure how frequently Systems Manager collects inventory metadata from your managed nodes. More frequent collection provides more up-to-date information but may increase AWS service usage.

To configure inventory metadata collection

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Settings**.
3. In the **Feature configurations** section, locate **Inventory metadata collection**.
4. To enable inventory collection, turn on the toggle switch.
5. For **Collection frequency**, choose how often you want Systems Manager to collect inventory data:
   - **Daily** - Collects inventory data once per day
   - **Weekly** - Collects inventory data once per week
   - **Monthly** - Collects inventory data once per month
6. Choose **Save**.

> **Important**
>
> Inventory collection requires managed nodes to have the necessary permissions to gather system information. Ensure your managed nodes have the appropriate IAM roles and policies. For more information about required permissions, see AWS Systems Manager Inventory.

SSM Agent updates

Automatic SSM Agent updates ensure that your managed nodes are running the latest version of the SSM Agent. Keeping the agent up-to-date provides access to the latest features, security improvements, and bug fixes.

SSM Agent automatic updates provide the following benefits:

- **Latest features** - Access to new Systems Manager capabilities and improvements
- **Security updates** - Automatic installation of security patches and fixes
- **Improved reliability** - Bug fixes and stability improvements
- **Reduced maintenance** - Eliminates the need for manual agent updates

Configuring automatic agent updates

You can configure how frequently Systems Manager checks for and installs SSM Agent updates on your managed nodes. Regular updates help ensure optimal performance and security.

To configure SSM Agent updates

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Settings**.
3. In the **Feature configurations** section, locate **SSM Agent updates**.
4. To enable automatic updates, turn on the toggle switch.
5. For **Update frequency**, choose how often you want Systems Manager to check for and install agent updates:
   - **Daily** - Checks for updates once per day
   - **Weekly** - Checks for updates once per week
   - **Monthly** - Checks for updates once per month
6. Choose **Save**.

Diagnose and remediate settings

The **Diagnose and remediate** settings determine whether or not Systems Manager automatically scans your nodes to ensure they can communicate with Systems Manager. If enabled, the feature

runs automatically according to a schedule you define. The feature identifies which nodes can't connect to Systems Manager and why. This feature also provides recommended runbooks for remediating networking issues and other problems preventing nodes from being configured as managed nodes.

Scheduling a recurring diagnostic scan

Systems Manager can diagnose and help you remediate several types of deployment failures, as well as drifted configurations. Systems Manager can also identify Amazon Elastic Compute Cloud (Amazon EC2) instances in your account or organization that Systems Manager isn't able to treat as a *managed node*. The EC2 instance diagnosis process can identify issues related to misconfigurations for a virtual private cloud (VPC), in a Domain Name Service (DNS) setting, or in an Amazon Elastic Compute Cloud (Amazon EC2) security group.

To simply the task of identifying nodes that can't connect to Systems Manager, the **Schedule recurring diagnosis** feature enables you to automate a recurring diagnostic scan. The scans help identify which nodes can't connect to Systems Manager and why. Use the following procedure to enable and configure a recurring diagnostic scan of your nodes.

To schedule a recurring diagnostic scan

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Settings**, and then choose the **Diagnose and remediate** tab.
3. Turn on the **Schedule recurring diagnosis** option.
4. For **Scanning period**, choose how often you want the scan to run.
5. (Optional) For **Start time**, enter a time, in 24-hour format, for the diagnosis to begin. For example, for 8:15 PM, enter **`20:15`**.

   The time you enter is for your current local time zone.

   If you don't specify a time, the diagnostic scan runs immediately. Systems Manager also schedules the scan to run in the future at the current time. If you specify a time, Systems Manager waits to run the diagnostic scan at the specified time.
6. Choose **Save**.
7. After the scan completes, view the details by choosing **Diagnose and remediate** in the left navigation.

For more information about the **Diagnose and remediate** feature, see Diagnosing and remediating.

Updating S3 bucket encryption

When you onboard Systems Manager, Quick Setup creates an Amazon Simple Storage Service (Amazon S3) bucket in the delegated administrator account for AWS Organizations setups. For single-account setups, the bucket is stored in the account being set up. This bucket is used to store the metadata generated during diagnostic scans.

For more information about setting up the unified Systems Manager console, see Setting up AWS Systems Manager.

By default, your data in the bucket is encrypted using a AWS Key Management Service (AWS KMS) key that AWS owns and manages for you.

You can choose to use a different AWS KMS key for your bucket encryption. As another alternative, you can use server-side encryption with AWS KMS keys (SSE-KMS) using a customer managed key (CMK). For information, see Working with Amazon S3 buckets and bucket policies for Systems Manager.

To use a different AWS KMS key for S3 bucket encryption

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Settings**, and then choose the **Diagnose and remediate** tab.
3. In the **Update S3 bucket encryption** area, choose **Edit**.
4. Select the **Customize encryption settings (advanced)** check box.
5. For **Choose an AWS KMS key**, choose or enter the Amazon Resource Name (ARN) of the key.

   > **Tip**
   >
   > To create a new key, choose **Create an AWS KMS key**.

6. Choose **Save**.

Working with Amazon S3 buckets and bucket policies for Systems Manager

During the onboarding process for AWS Systems Manager, Quick Setup creates an Amazon Simple Storage Service (Amazon S3) bucket in the delegated administrator account for organization setups. For single-account setups, the bucket is stored in the account being set up.

You can use Systems Manager to run diagnostic operations on your fleet to identify cases of failed deployments and drifted configurations. Systems Manager can also detect cases where configuration issues are preventing Systems Manager from managing EC2 instances in your account or organization. The results of these diagnostic operations are stored in this Amazon S3 bucket, which is protected by both an encryption method and an S3 bucket policy. For information about the diagnostic operations that output data to this bucket, see Diagnosing and remediating.

Changing the bucket encryption method

By default, the S3 bucket uses server-side encryption with Amazon S3 managed keys (SSE-S3).

You can instead use server-side encryption with AWS KMS keys (SSE-KMS) using a customer managed key (CMK) as an alternative to Amazon S3 managed keys, as explained in Changing to an AWS KMS customer managed key to encrypt S3 resources.

Contents of the bucket policy

The bucket policy prevents member accounts in an organization from discovering one another. Read and write permissions to the bucket are allowed only for the diagnosis and remediation roles created for Systems Manager. The contents of these system-generated policies are presented in S3 bucket policies for the unified Systems Manager console.

> **Warning**
>
> Modifying the default bucket policy might allow member accounts in an organization to discover one another, or read diagnosis outputs for instances in another account. We recommend using extreme caution if you choose to modify this policy.

Topics

- S3 bucket policies for the unified Systems Manager console

Changing to an AWS KMS customer managed key to encrypt S3 resources

During the onboarding process for the unified Systems Manager console, Quick Setup creates an Amazon Simple Storage Service (Amazon S3) bucket in the delegated administrator account. This bucket is used to store the diagnosis output data generated during remediation runbook executions. By default, the bucket uses server-side encryption with Amazon S3 managed keys (SSE-S3).

You can review the content of these policies in S3 bucket policies for the unified Systems Manager console.

However, you can instead use server-side encryption with AWS KMS keys (SSE-KMS) using a customer managed key (CMK) as an alternative to an AWS KMS key.

Complete the following tasks in order to configure Systems Manager to use your CMK.

Task 1: Add a tag to an existing CMK

AWS Systems Manager uses your CMK only if it is tagged with the following key-value pair:

- Key: `SystemsManagerManaged`
- Value: `true`

Use the following procedure to provide access for encrypting the S3 bucket with your CMK.

To add a tag to your existing CMK

1. Open the AWS KMS console at https://console.aws.amazon.com/kms.
2. In the left navigation, choose **Customer managed keys**.
3. Select the AWS KMS key to use with AWS Systems Manager.
4. Choose the **Tags** tab, and then choose **Edit**.
5. Choose **Add tag**.
6. Do the following:

    a. For **Tag key**, enter **`SystemsManagerManaged`**.

b. For **Tag value**, enter **`true`**.

7. Choose **Save**.

Task 2: Modify an existing CMK key policy

Use the following procedure to update the KMS key policy of your CMK to allow AWS Systems Manager roles to encrypt the S3 bucket on your behalf.

To modify an existing CMK key policy

1. Open the AWS KMS console at https://console.aws.amazon.com/kms.
2. In the left navigation, choose **Customer managed keys**.
3. Select the AWS KMS key to use with AWS Systems Manager.
4. On the **Key policy** tab, choose **Edit**.
5. Add the following JSON statement to the `Statement` field, and replace the *`placeholder values`* with your own information.

   Ensure that you add all AWS account IDs that are onboarded in your organization to AWS Systems Manager in the `Principal` field.

   To locate the correct bucket name in the Amazon S3 console, in the delegated administrator account, locate the bucket in the format `do-not-delete-ssm-`*`operational-account-id`*`-`*`home-region`*`-`*`disambiguator`*.

```
{
     "Sid": "EncryptionForSystemsManagerS3Bucket",
     "Effect": "Allow",
     "Principal": {
         "AWS": [
             "account-id-1",
             "account-id-2",
             ...
         ]
     },
     "Action": ["kms:Decrypt", "kms:GenerateDataKey"],
     "Resource": "*",
     "Condition": {
         "StringEquals": {
             "kms:EncryptionContext:aws:s3:arn": "arn:aws:s3:::amzn-s3-demo-bucket"
```

```
            },
            "StringLike": {
                "kms:ViaService": "s3.*.amazonaws.com"
            },
            "ArnLike": {
                "aws:PrincipalArn": "arn:aws:iam::*:role/AWS-SSM-*"
            }
        }
    }
```

Tip

Alternatively, you can update the CMK key policy using the aws:PrincipalOrgID condition key to grant AWS Systems Manager access to your CMK.

Task 3: Specify the CMK in Systems Manager settings

After completing the previous two tasks, use the following procedure to change the S3 bucket encryption. This change ensures that the associated Quick Setup configuration process can add permissions for Systems Manager to accept your CMK.

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Settings**.
3. On the **Diagnose and remediate** tab, in the **Update S3 bucket encryption** section, choose **Edit**.
4. Select the **Customize encryption settings (advanced)** check box.
5. In the search (🔍) box, choose the ID of an existing key, or paste the ARN of an existing key.
6. Choose **Save**.

S3 bucket policies for the unified Systems Manager console

This topic includes the Amazon S3 bucket policies created by Systems Manager when you onboard an organization or single account to the unified Systems Manager console.

Warning

Modifying the default bucket policy might allow member accounts in an organization to discover one another, or read diagnosis outputs for instances in another account. We recommend using extreme caution if you choose to modify this policy.

Amazon S3 bucket policy for an organization

The diagnosis bucket is created with the following default bucket policy when onboarding an organization to Systems Manager.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyHTTPRequests",

                    "aws:PrincipalOrgID": "organization-id"
                },
                "ArnLike": {
                    "aws:PrincipalArn": [
                        "arn:aws:iam::*:role/AWS-SSM-
DiagnosisExecutionRole-operational-account-id-home-region",
                        "arn:aws:iam::*:role/AWS-SSM-
DiagnosisAdminRole-operational-account-id-home-region",
                        "arn:aws:iam::*:role/AWS-SSM-
RemediationExecutionRole-operational-account-id-home-region",
                        "arn:aws:iam::*:role/AWS-SSM-
RemediationAdminRole-operational-account-id-home-region"
                    ]
                }
            }
        },
        {
            "Sid": "AllowCrossAccountListUnderAccountOwnPrefix",
            "Effect": "Allow",
            "Principal": "*",
            "Action": "s3:ListBucket",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
            "Condition": {
                "StringEquals": {
                    "aws:PrincipalOrgID": "organization-id"
                },
                "StringLike": {
                    "s3:prefix": "*/${aws:PrincipalAccount}/*"
                }
            }
        },
        {
            "Sid": "AllowCrossAccountGetConfigWithinOrganization",
            "Effect": "Allow",
            "Principal": "*",
            "Action": "s3:GetEncryptionConfiguration",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
            "Condition": {
                "StringEquals": {
                    "aws:PrincipalOrgID": "organization-id"
```

```
                }
            }
        }
    ]
}
```

Amazon S3 bucket policy for a single account

The diagnosis bucket is created with the following default bucket policy when onboarding a single account to Systems Manager.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyHTTPRequests",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
      ],
      "Condition": {
        "Bool": {
          "aws:SecureTransport": "false"
        }
      }
    },
    {
      "Sid": "DenyNonSigV4Requests",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
      ],
      "Condition": {
        "StringNotEquals": {
```

```
          "s3:SignatureVersion": "AWS4-HMAC-SHA256"
        }
      }
    }
  ]
}
```

Using AWS Systems Manager tools

Systems Manager groups tools into four categories. The following documentation describes the various tools of AWS Systems Manager and how to set up and use these tools. Choose the tabs under each category to learn more about each tool.

Node tools

A *managed node* is any machine configured for use with Systems Manager in hybrid and multicloud environments.

Compliance

Use Compliance to scan your fleet of managed nodes for patch compliance and configuration inconsistencies. You can collect and aggregate data from multiple AWS accounts and AWS Regions, and then drill down into specific resources that aren't compliant. By default, Compliance displays compliance data about Patch Manager patching and State Manager associations. You can also customize the service and create your own compliance types based on your IT or business requirements.

Distributor

Use Distributor to create and deploy packages to managed nodes. With Distributor, you can package your own software—or find AWS-provided agent software packages, such as **AmazonCloudWatchAgent**—to install on Systems Manager managed nodes. After you install a package for the first time, you can use Distributor to uninstall and reinstall a new package version, or perform an in-place update that adds new or changed files. Distributor publishes resources, such as software packages, to Systems Manager managed nodes.

Fleet Manager

Fleet Manager is a unified user interface (UI) experience that helps you remotely manage your nodes. With Fleet Manager, you can view the health and performance status of your entire fleet from one console. You can also gather data from individual devices and instances to perform common troubleshooting and management tasks from the console. This includes viewing directory and file contents, Windows registry management, operating system user management, and more.

Hybrid Activations

To set up non-EC2 machines in your hybrid and multicloud environment as managed nodes, create a hybrid activation. After you complete the activation, you receive an activation code and ID. This code and ID combination functions like an Amazon Elastic Compute Cloud (Amazon EC2) access ID and secret key to provide secure access to the Systems Manager service from your managed instances.

You can also create an activation for edge devices if you want to manage them by using Systems Manager.

Inventory

Inventory automates the process of collecting software inventory from your managed nodes. You can use Inventory to gather metadata about applications, files, components, patches, and more.

Patch Manager

Use Patch Manager to automate the process of patching your managed nodes with both security related and other types of updates. You can use Patch Manager to apply patches for both operating systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.)

This tool allows you to scan managed nodes for missing patches and apply missing patches individually or to large groups of managed nodes by using tags. Patch Manager uses *patch baselines*, which can include rules for auto-approving patches within days of their release, and a list of approved and rejected patches. You can install security patches on a regular basis by scheduling patching to run as a Systems Manager maintenance window task, or you can patch your managed nodes on demand at any time.

For Linux operating systems, you can define the repositories that should be used for patching operations as part of your patch baseline. This allows you to ensure that updates are installed only from trusted repositories regardless of what repositories are configured on the managed node. For Linux, you also have the ability to update any package on the managed node, not just those that are classified as operating system security updates. You can also generate patch reports that are sent to an S3 bucket of your choice. For a single managed node, reports include details of all patches for the machine. For a report on all managed nodes, only a summary of how many patches are missing is provided.

Run Command

Use Run Command to remotely and securely manage the configuration of your managed nodes at scale. Use Run Command to perform on-demand changes such as updating applications or running Linux shell scripts and Windows PowerShell commands on a target set of dozens or hundreds of managed nodes.

Session Manager

Use Session Manager to manage your edge devices and Amazon Elastic Compute Cloud (Amazon EC2) instances through an interactive one-click browser-based shell or through the AWS CLI. Session Manager provides secure and auditable edge device and instance management without needing to open inbound ports, maintain bastion hosts, or manage SSH keys. Session Manager also allows you to comply with corporate policies that require controlled access to edge devices and instances, strict security practices, and fully auditable logs with edge device and instance access details, while still providing end users with simple one-click cross-platform access to your edge devices and EC2 instances. To use Session Manager, you must enable the advanced-instances tier. For more information, see Turning on the advanced-instances tier.

State Manager

Use State Manager to automate the process of keeping your managed nodes in a defined state. You can use State Manager to guarantee that your managed nodes are bootstrapped with specific software at startup, joined to a Windows domain (Windows Server nodes only), or patched with specific software updates.

Change Management tools

Automation

Use Automation to automate common maintenance and deployment tasks. You can use Automation to create and update Amazon Machine Images (AMIs), apply driver and agent updates, reset passwords on Windows Server instance, reset SSH keys on Linux instances, and apply OS patches or application updates.

Change Calendar

Change Calendar helps you set up date and time ranges when actions you specify (for example, in Systems Manager Automation runbooks) can or can't be performed in your AWS account.

In Change Calendar, these ranges are called *events*. When you create a Change Calendar entry, you're creating a Systems Manager document of the type `ChangeCalendar`. In Change Calendar, the document stores iCalendar 2.0 data in plaintext format. Events that you add to the Change Calendar entry become part of the document. You can add events manually in the Change Calendar interface or import events from a supported third-party calendar using an `.ics` file.

Change Manager

Change Manager is an enterprise change management framework for requesting, approving, implementing, and reporting on operational changes to your application configuration and infrastructure. From a single *delegated administrator account*, if you use AWS Organizations, you can manage changes across multiple AWS accounts in multiple AWS Regions. Alternatively, using a *local account*, you can manage changes for a single AWS account. Use Change Manager for managing changes to both AWS resources and on-premises resources.

Documents

A Systems Manager document (SSM document) defines the actions that Systems Manager performs. SSM document types include *Command* documents, which are used by State Manager and Run Command, and Automation runbooks, which are used by Systems Manager Automation. Systems Manager includes dozens of pre-configured documents that you can use by specifying parameters at runtime. Documents can be expressed in JSON or YAML, and include steps and parameters that you specify.

Maintenance Windows

Use Maintenance Windows to set up recurring schedules for managed instances to run administrative tasks such as installing patches and updates without interrupting business-critical operations.

Quick Setup

Use Quick Setup to configure frequently used AWS services and features with recommended best practices. You can use Quick Setup in an individual AWS account or across multiple AWS accounts and AWS Regions by integrating with AWS Organizations. Quick Setup simplifies setting up services, including Systems Manager, by automating common or recommended tasks. These tasks include, for example, creating required AWS Identity and Access Management (IAM) instance profile roles and setting up operational best practices, such as periodic patch scans and inventory collection.

Application tools

AppConfig

AppConfig helps you create, manage, and deploy application configurations and feature flags. AppConfig supports controlled deployments to applications of any size. You can use AppConfig with applications hosted on Amazon EC2 instances, AWS Lambda containers, mobile applications, or edge devices. To prevent errors when deploying application configurations, AppConfig includes validators. A validator provides a syntactic or semantic check to verify that the configuration you want to deploy works as intended. During a configuration deployment, AppConfig monitors the application to verify that the deployment is successful. If the system encounters an error or if the deployment invokes an alarm, AppConfig rolls back the change to minimize impact for your application users.

Application Manager

Application Manager helps DevOps engineers investigate and remediate issues with their AWS resources in the context of their applications and clusters. In Application Manager, an *application* is a logical group of AWS resources that you want to operate as a unit. This logical group can represent different versions of an application, ownership boundaries for operators, or developer environments, to name a few. Application Manager support for container clusters includes both Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon Elastic Container Service (Amazon ECS) clusters. Application Manager aggregates operations information from multiple AWS services and Systems Manager tools to a single AWS Management Console.

Parameter Store

Parameter Store provides secure, hierarchical storage for configuration data and secrets management. You can store data such as passwords, database strings, Amazon Elastic Compute Cloud (Amazon EC2) instance IDs and Amazon Machine Image (AMI) IDs, and license codes as parameter values. You can store values as plain text or encrypted data. You can then reference values by using the unique name you specified when you created the parameter.

Operations tools

CloudWatch Dashboards

Amazon CloudWatch Dashboards are customizable pages in the CloudWatch console that you can use to monitor your resources in a single view, even those resources that are spread

across different regions. You can use CloudWatch dashboards to create customized views of the metrics and alarms for your AWS resources.

Explorer

Explorer is a customizable operations dashboard that reports information about your AWS resources. Explorer displays an aggregated view of operations data (OpsData) for your AWS accounts and across AWS Regions. In Explorer, OpsData includes metadata about your Amazon EC2 instances, patch compliance details, and operational work items (OpsItems). Explorer provides context about how OpsItems are distributed across your business units or applications, how they trend over time, and how they vary by category. You can group and filter information in Explorer to focus on items that are relevant to you and that require action. When you identify high priority issues, you can use OpsCenter, a tool in Systems Manager, to run Automation runbooks and resolve those issues.

Incident Manager

Incident Manager is an incident management console that helps users mitigate and recover from incidents affecting their AWS hosted applications.

Incident Manager increases incident resolution by notifying responders of impact, highlighting relevant troubleshooting data, and providing collaboration tools to get services back up and running. Incident Manager also automates response plans and allows responder team escalation.

OpsCenter

OpsCenter provides a central location where operations engineers and IT professionals can view, investigate, and resolve operational work items (OpsItems) related to AWS resources. OpsCenter is designed to reduce mean time to resolution for issues impacting AWS resources. This Systems Manager tool aggregates and standardizes OpsItems across services while providing contextual investigation data about each OpsItem, related OpsItems, and related resources. OpsCenter also provides Systems Manager Automation runbooks that you can use to resolve issues. You can specify searchable, custom data for each OpsItem. You can also view automatically generated summary reports about OpsItems by status and source.

Perform a node task with Systems Manager

Use this tutorial to get started with AWS Systems Manager. You'll learn how to launch an Amazon Elastic Compute Cloud (Amazon EC2) instance that is managed by Systems Manager, and how to connect to the managed instance.

Because Systems Manager is a collection of multiple tools, no single walkthrough or tutorial can introduce the entire service. This tutorial provides an introduction to some of the tools.

Prerequisites

Before you begin, be sure that you've completed the steps in Managing EC2 instances with Systems Manager.

Launch an instance using an AMI with SSM Agent preinstalled

You can launch an Amazon EC2 instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you launch your first managed instance quickly, so it doesn't cover all possible options.

To launch an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the EC2 console dashboard, in the **Launch instance** box, choose **Launch instance**, and then choose **Launch instance** from the options that appear.
3. For **Name and tags**, for **Name**, enter a descriptive name for your instance.
4. For **Application and OS Images (Amazon Machine Image)**, do the following:
   a. Choose the **Quick Start** tab, and then choose Amazon Linux. This is the operating system (OS) for your instance.
   b. For **Amazon Machine Image (AMI)**, choose an HVM version of Amazon Linux 2.
5. For **Instance type**, from the **Instance type** list, choose the hardware configuration for your instance. Choose the `t2.micro` instance type, which is selected by default. The `t2.micro` instance type is eligible for the AWS Free Tier. In AWS Regions where `t2.micro` is unavailable, you can use a `t3.micro` instance under the Free Tier. For more information, see AWS Free Tier.
6. For **Key pair (login)**, for **Key pair name**, choose a key pair.

7. For **Network settings**, choose **Edit**. For **Security group name**, notice that the wizard created and selected a security group for you. You can use this security group, or alternatively you can select a security group that you created previously using the following steps:

   a. Choose **Select existing security group**.

   b. From **Common security groups**, choose your security group from the list of existing security groups.

8. If you aren't using Default Host Management Configuration, expand the **Advanced details** section, and for **IAM instance profile**, choose the instance profile that you created when getting set up in Configure instance permissions required for Systems Manager.

9. Keep the default selections for the other configuration settings for your instance.

10. Review a summary of your instance configuration in the **Summary** pane. When you're ready, choose **Launch instance**.

11. A confirmation page informs you that your instance is launching. Choose **View all instances** to close the confirmation page and return to the console.

12. On the **Instances** screen, you can view the status of the launch. It takes a short time for an instance to launch.

13. It can take a few minutes for the instance to show as managed and be ready for you to connect to it. To check that your instance passed its status checks, view this information in the **Status check** column.

Connect to your managed instance using Systems Manager

To connect to your managed instance

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.

2. In the navigation pane, choose **Fleet Manager**.

3. Choose the button next to the instance that you want to connect to.

4. In the **Node actions** menu, choose **Start terminal session**.

5. Select **Connect**.

Clean up your instance

If you're done working with the managed instance that you created for this tutorial, terminate it. Terminating an instance effectively deletes it.

To terminate your instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**. In the list of instances, select the instance.
3. Choose **Instance state**, **Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

   Amazon EC2 shuts down and terminates your instance. After your instance is terminated, it remains visible on the console briefly, and then the entry is deleted automatically. You can't remove the terminated instance from the console display yourself.

AWS Systems Manager Node tools

AWS Systems Manager provides the following tools for accessing, managing, and configuring your *managed nodes*. A managed node is any machine configured for use with Systems Manager in a hybrid and multicloud environment.

Topics

- AWS Systems Manager Compliance
- AWS Systems Manager Distributor
- AWS Systems Manager Fleet Manager
- AWS Systems Manager Hybrid Activations
- AWS Systems Manager Inventory
- AWS Systems Manager Patch Manager
- AWS Systems Manager Run Command
- AWS Systems Manager Session Manager
- AWS Systems Manager State Manager

AWS Systems Manager Compliance

You can use Compliance, a tool in AWS Systems Manager, to scan your fleet of managed nodes for patch compliance and configuration inconsistencies. You can collect and aggregate data from multiple AWS accounts and Regions, and then drill down into specific resources that aren't compliant. By default, Compliance displays current compliance data about patching in Patch Manager and associations in State Manager. (Patch Manager and State Manager are also both tools in AWS Systems Manager.) To get started with Compliance, open the Systems Manager console. In the navigation pane, choose **Compliance**.

Patch compliance data from Patch Manager can be sent to AWS Security Hub. Security Hub gives you a comprehensive view of your high-priority security alerts and compliance status. It also monitors the patching status of your fleet. For more information, see Integrating Patch Manager with AWS Security Hub.

Compliance offers the following additional benefits and features:

- View compliance history and change tracking for Patch Manager patching data and State Manager associations by using AWS Config.
- Customize Compliance to create your own compliance types based on your IT or business requirements.
- Remediate issues by using Run Command, another tool in AWS Systems Manager, State Manager, or Amazon EventBridge.
- Port data to Amazon Athena and Amazon QuickSight to generate fleet-wide reports.

EventBridge support

This Systems Manager tool is supported as an *event* type in Amazon EventBridge rules. For information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

Chef InSpec integration

Systems Manager integrates with Chef InSpec. InSpec is an open-source, runtime framework that allows you to create human-readable profiles on GitHub or Amazon Simple Storage Service (Amazon S3). You can then use Systems Manager to run compliance scans and view compliant and noncompliant managed nodes. For more information, see Using Chef InSpec profiles with Systems Manager Compliance.

Pricing

Compliance is offered at no additional charge. You only pay for the AWS resources that you use.

Contents

Getting started with Compliance

To get started with Compliance, a tool in AWS Systems Manager, complete the following tasks.

Task	For more information
Compliance works with patch data in Patch Manager and associations in State Manager. (Patch Manager and State Manager are also both tools in AWS Systems Manager.) Compliance also works with custom compliance types on managed nodes that are managed using Systems Manager. Verify that you have completed the setup requirements for your Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 machines in a hybrid and multicloud environment.	Setting up Systems Manager unified console for an organization
Update the AWS Identity and Access Management (IAM) role used by your managed nodes to restrict Compliance permissions.	Configuring permissions for Compliance
If you plan to monitor patch compliance, verify that you've configured Patch Manager.	AWS Systems Manager Patch Manager

Task	For more information
You must perform patching operations by using Patch Manager before Compliance can display patch compliance data.	
If you plan to monitor association compliance, verify that you've created State Manager associations. You must create associations before Compliance can display association compliance data.	AWS Systems Manager State Manager
(Optional) Configure the system to view compliance history and change tracking.	Viewing compliance configuration history and change tracking
(Optional) Create custom compliance types.	Assign custom compliance metadata using the AWS CLI
(Optional) Create a resource data sync to aggregate all compliance data in a target Amazon Simple Storage Service (Amazon S3) bucket.	Creating a resource data sync for Compliance

Configuring permissions for Compliance

As a security best practice, we recommend that you update the AWS Identity and Access Management (IAM) role used by your managed nodes with the following permissions to restrict the node's ability to use the PutComplianceItems API action. This API action registers a compliance type and other compliance details on a designated resource, such as an Amazon EC2 instance or a managed node.

If your node is an Amazon EC2 instance, you must update the IAM instance profile used by the instance with the following permissions. For more information about instance profiles for EC2 instance managed by Systems Manager, see Configure instance permissions required for Systems Manager. For other types of managed nodes, update the IAM role used by the node with the following permissions. For more information, see Update permissions for a role in the *IAM User Guide*.

                "StringEquals": {
                    "ssm:SourceInstanceARN": "${ssm:SourceInstanceARN}"
                }
            }
        }
    ]
}
```

Creating a resource data sync for Compliance

You can use the resource data sync feature in AWS Systems Manager to send compliance data from all of your managed nodes to a target Amazon Simple Storage Service (Amazon S3) bucket. When you create the sync, you can specify managed nodes from multiple AWS accounts, AWS Regions, and your hybrid and multicloud environment. Resource data sync then automatically updates the centralized data when new compliance data is collected. With all compliance data stored in a target

S3 bucket, you can use services like Amazon Athena and Amazon QuickSight to query and analyze the aggregated data. Configuring resource data sync for Compliance is a one-time operation.

Use the following procedure to create a resource data sync for Compliance by using the AWS Management Console.

To create and configure an S3 bucket for resource data sync (console)

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Create a bucket to store your aggregated compliance data. For more information, see Create a Bucket in the *Amazon Simple Storage Service User Guide*. Make a note of the bucket name and the AWS Region where you created it.
3. Open the bucket, choose the **Permissions** tab, and then choose **Bucket Policy**.
4. Copy and paste the following bucket policy into the policy editor. Replace amzn-s3-demo-bucket and *Account-ID* with the name of the S3 bucket you created and a valid AWS account ID. Optionally, replace *Bucket-Prefix* with the name of an Amazon S3 prefix (subdirectory). If you didn't create a prefix, remove *Bucket-Prefix*/ from the ARN in the policy.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SSMBucketPermissionsCheck",
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "s3:GetBucketAcl",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
            "Sid": " SSMBucketDelivery",
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "s3:PutObject",
```

```
            "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/Bucket-Prefix/*/
accountid=111122223333/*"],
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control"
                }
            }
        }
    ]
}
```

To create a resource data sync

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management**, **Resource Data Syncs**, and then choose **Create resource data sync**.
4. In the **Sync name** field, enter a name for the sync configuration.
5. In the **Bucket name** field, enter the name of the Amazon S3 bucket you created at the start of this procedure.
6. (Optional) In the **Bucket prefix** field, enter the name of an S3 bucket prefix (subdirectory).
7. In the **Bucket region** field, choose **This region** if the S3 bucket you created is located in the current AWS Region. If the bucket is located in a different AWS Region, choose **Another region**, and enter the name of the Region.

   > **Note**
   >
   > If the sync and the target S3 bucket are located in different Regions, you might be subject to data transfer pricing. For more information, see Amazon S3 Pricing.

8. Choose **Create**.

Learn details about Compliance

Compliance, a tool in AWS Systems Manager, collects and reports data about the status of patching in Patch Manager patching and associations in State Manager. (Patch Manager and State Manager are also both tools in AWS Systems Manager.) Compliance also reports on custom compliance types you have specified for your managed nodes. This section includes details about each of these compliance types and how to view Systems Manager compliance data. This section also includes information about how to view compliance history and change tracking.

> **Note**
>
> Systems Manager integrates with Chef InSpec. InSpec is an open-source, runtime framework that allows you to create human-readable profiles on GitHub or Amazon Simple Storage Service (Amazon S3). Then you can use Systems Manager to run compliance scans and view compliant and noncompliant instances. For more information, see Using Chef InSpec profiles with Systems Manager Compliance.

About patch compliance

After you use Patch Manager to install patches on your instances, compliance status information is immediately available to you in the console or in response to AWS Command Line Interface (AWS CLI) commands or corresponding Systems Manager API operations.

For information about patch compliance status values, see Patch compliance state values.

About State Manager association compliance

After you create one or more State Manager associations, compliance status information is immediately available to you in the console or in response to AWS CLI commands or corresponding Systems Manager API operations. For associations, Compliance shows statuses of `Compliant` or `Non-compliant` and the severity level assigned to the association, such as `Critical` or `Medium`.

When State Manager executes an association on a managed node, it triggers a compliance aggregation process that updates compliance status for all associations on that node. The `ExecutionTime` value in compliance reports represents when the compliance status was captured by Systems Manager, not when the association was executed on the managed node. This means multiple associations might display identical `ExecutionTime` values even if they were executed at different times. To determine actual association execution times, refer to the association execution

history using the AWS CLI command describe-association-execution-targets or by viewing the execution details in the console.

About custom compliance

You can assign compliance metadata to a managed node. This metadata can then be aggregated with other compliance data for compliance reporting purposes. For example, say that your business runs versions 2.0, 3.0, and 4.0 of software X on your managed nodes. The company wants to standardize on version 4.0, meaning that instances running versions 2.0 and 3.0 are non-compliant. You can use the PutComplianceItems API operation to explicitly note which managed nodes are running older versions of software X. You can only assign compliance metadata by using the AWS CLI, AWS Tools for Windows PowerShell, or the SDKs. The following CLI sample command assigns compliance metadata to a managed instance and specifies the compliance type in the required format `Custom:`. Replace each *`example resource placeholder`* with your own information.

Linux & macOS

```
aws ssm put-compliance-items \
    --resource-id i-1234567890abcdef0 \
    --resource-type ManagedInstance \
    --compliance-type Custom:SoftwareXCheck \
    --execution-summary ExecutionTime=AnyStringToDenoteTimeOrDate \
    --items
 Id=Version2.0,Title=SoftwareXVersion,Severity=CRITICAL,Status=NON_COMPLIANT
```

Windows

```
aws ssm put-compliance-items ^
    --resource-id i-1234567890abcdef0 ^
    --resource-type ManagedInstance ^
    --compliance-type Custom:SoftwareXCheck ^
    --execution-summary ExecutionTime=AnyStringToDenoteTimeOrDate ^
    --items
 Id=Version2.0,Title=SoftwareXVersion,Severity=CRITICAL,Status=NON_COMPLIANT
```

> **Note**
>
> The `ResourceType` parameter only supports `ManagedInstance`. If you add custom compliance to a managed AWS IoT Greengrass core device, you must specify a `ResourceType` of `ManagedInstance`.

Compliance managers can then view summaries or create reports about which managed nodes are or aren't compliant. You can assign a maximum of 10 different custom compliance types to a managed node.

For an example of how to create a custom compliance type and view compliance data, see Assign custom compliance metadata using the AWS CLI.

Viewing current compliance data

This section describes how to view compliance data in the Systems Manager console and by using the AWS CLI. For information about how to view patch and association compliance history and change tracking, see Viewing compliance configuration history and change tracking.

Topics

- Viewing current compliance data (console)
- Viewing current compliance data (AWS CLI)

Viewing current compliance data (console)

Use the following procedure to view compliance data in the Systems Manager console.

To view current compliance reports in the Systems Manager console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Compliance**.
3. In the **Compliance dashboard filtering** section, choose an option to filter compliance data. The **Compliance resources summary** section displays counts of compliance data based on the filter you chose.
4. To drill down into a resource for more information, scroll down to the **Details overview for resources** area and choose the ID of a managed node.

5. On the **Instance ID** or **Name** details page, choose the **Configuration compliance** tab to view a detailed configuration compliance report for the managed node.

> **Note**
>
> For information about fixing compliance issues, see Remediating compliance issues using EventBridge.

Viewing current compliance data (AWS CLI)

You can view summaries of compliance data for patching, associations, and custom compliance types in the in the AWS CLI by using the following AWS CLI commands.

list-compliance-summaries

Returns a summary count of compliant and non-compliant association statuses according to the filter you specify. (API: ListComplianceSummaries)

list-resource-compliance-summaries

Returns a resource-level summary count. The summary includes information about compliant and non-compliant statuses and detailed compliance-item severity counts, according to the filter criteria you specify. (API: ListResourceComplianceSummaries)

You can view additional compliance data for patching by using the following AWS CLI commands.

describe-patch-group-state

Returns high-level aggregated patch compliance state for a patch group. (API: DescribePatchGroupState)

describe-instance-patch-states-for-patch-group

Returns the high-level patch state for the instances in the specified patch group. (API: DescribeInstancePatchStatesForPatchGroup)

> **Note**
>
> For an illustration of how to configure patching and view patch compliance details by using the AWS CLI, see Tutorial: Patch a server environment using the AWS CLI.

Viewing compliance configuration history and change tracking

Systems Manager Compliance displays *current* patching and association compliance data for your managed nodes. You can view patching and association compliance history and change tracking by using AWS Config. AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time. To view patching and association compliance history and change tracking, you must turn on the following resources in AWS Config:

- `SSM:PatchCompliance`
- `SSM:AssociationCompliance`

For information about how to choose and configure these specific resources in AWS Config, see Selecting Which Resources AWS Config Records in the *AWS Config Developer Guide*.

> **Note**
>
> For information about AWS Config pricing, see Pricing.

Deleting a resource data sync for Compliance

If you no longer want to use AWS Systems Manager Compliance to view compliance data, then we also recommend deleting resource data syncs used for Compliance data collection.

To delete a Compliance resource data sync

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management**, **Resource data syncs**.

4. Choose a sync in the list.

> **Important**
>
> Make sure you choose the sync used for Compliance. Systems Manager supports resource data sync for multiple tools. If you choose the wrong sync, you could disrupt data aggregation for Systems Manager Explorer or Systems Manager Inventory.

5. Choose **Delete**.
6. Delete the Amazon Simple Storage Service (Amazon S3) bucket where the data was stored. For information about deleting an S3 bucket, see Deleting a bucket.

Remediating compliance issues using EventBridge

You can quickly remediate patch and association compliance issues by using Run Command, a tool in AWS Systems Manager. You can target instance or AWS IoT Greengrass core device IDs or tags and run the `AWS-RunPatchBaseline` document or the `AWS-RefreshAssociation` document. If refreshing the association or re-running the patch baseline fails to resolve the compliance issue, then you need to investigate your associations, patch baselines, or instance configurations to understand why the Run Command operations didn't resolve the problem.

For more information about patching, see AWS Systems Manager Patch Manager and SSM Command document for patching: `AWS-RunPatchBaseline`.

For more information about associations, see Working with associations in Systems Manager.

For more information about running a command, see AWS Systems Manager Run Command.

Specify Compliance as the target of an EventBridge event

You can also configure Amazon EventBridge to perform an action in response to Systems Manager Compliance events. For example, if one or more managed nodes fail to install Critical patch updates or run an association that installs anti-virus software, then you can configure EventBridge to run the `AWS-RunPatchBaseline` document or the `AWS-RefreshAssocation` document when the Compliance event occurs.

Use the following procedure to configure Compliance as the target of an EventBridge event.

To configure Compliance as the target of a EventBridge event (console)

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule.

   A rule can't have the same name as another rule in the same AWS Region and on the same event bus.
5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own AWS account, select **default**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
6. For **Rule type**, choose **Rule with an event pattern**.
7. Choose **Next**.
8. For **Event source**, choose **AWS events or EventBridge partner events**.
9. In the **Event pattern** section, choose **Event pattern form**.
10. For **Event source**, choose **AWS services**.
11. For **AWS service**, choose **Systems Manager**.
12. For **Event type**, choose **Configuration Compliance**.
13. For **Specific detail type(s)**, choose **Configuration Compliance State Change**.
14. Choose **Next**.
15. For **Target types**, choose **AWS service**.
16. For **Select a target**, choose **Systems Manager Run Command**.
17. In the **Document** list, choose a Systems Manager document (SSM document) to run when your target is invoked. For example, choose `AWS-RunPatchBaseline` for a non-compliant patch event, or choose `AWS-RefreshAssociation` for a non-compliant association event.
18. Specify information for the remaining fields and parameters.

> **Note**
>
> Required fields and parameters have an asterisk (*) next to the name. To create a target, you must specify a value for each required parameter or field. If you don't, the system creates the rule, but the rule won't be run.

19. Choose **Next**.
20. (Optional) Enter one or more tags for the rule. For more information, see Tagging Your Amazon EventBridge Resources in the *Amazon EventBridge User Guide*.
21. Choose **Next**.
22. Review the details of the rule and choose **Create rule**.

Assign custom compliance metadata using the AWS CLI

The following procedure walks you through the process of using the AWS Command Line Interface (AWS CLI) to call the AWS Systems Manager PutComplianceItems API operation to assign custom compliance metadata to a resource. You can also use this API operation to manually assign patch or association compliance metadata to a managed nodes, as shown in the following walkthrough. For more information about custom compliance, see About custom compliance.

To assign custom compliance metadata to a managed instance (AWS CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command to assign custom compliance metadata to a managed node. Replace each *example resource placeholder* with your own information. The `ResourceType` parameter only supports a value of `ManagedInstance`. Specify this value even if you are assigning custom compliance metadata to a managed AWS IoT Greengrass core device.

   Linux & macOS

   ```
   aws ssm put-compliance-items \
       --resource-id instance_ID \
       --resource-type ManagedInstance \
       --compliance-type Custom:user-defined_string \
   ```

```
    --execution-summary ExecutionTime=user-defined_time_and/or_date_value \
    --items Id=user-defined_ID,Title=user-
defined_title,Severity=one_or_more_comma-separated_severities:CRITICAL, MAJOR,
 MINOR,INFORMATIONAL, or UNSPECIFIED,Status=COMPLIANT or NON_COMPLIANT
```

Windows

```
aws ssm put-compliance-items ^
    --resource-id instance_ID ^
    --resource-type ManagedInstance ^
    --compliance-type Custom:user-defined_string ^
    --execution-summary ExecutionTime=user-defined_time_and/or_date_value ^
    --items Id=user-defined_ID,Title=user-
defined_title,Severity=one_or_more_comma-separated_severities:CRITICAL, MAJOR,
 MINOR,INFORMATIONAL, or UNSPECIFIED,Status=COMPLIANT or NON_COMPLIANT
```

3. Repeat the previous step to assign additional custom compliance metadata to one or more nodes. You can also manually assign patch or association compliance metadata to managed nodes by using the following commands:

   Association compliance metadata

   Linux & macOS

```
aws ssm put-compliance-items \
    --resource-id instance_ID \
    --resource-type ManagedInstance \
    --compliance-type Association \
    --execution-summary ExecutionTime=user-defined_time_and/or_date_value \
    --items Id=user-defined_ID,Title=user-
defined_title,Severity=one_or_more_comma-separated_severities:CRITICAL, MAJOR,
 MINOR,INFORMATIONAL, or UNSPECIFIED,Status=COMPLIANT or NON_COMPLIANT
```

   Windows

```
aws ssm put-compliance-items ^
    --resource-id instance_ID ^
    --resource-type ManagedInstance ^
    --compliance-type Association ^
    --execution-summary ExecutionTime=user-defined_time_and/or_date_value ^
```

```
    --items Id=user-defined_ID,Title=user-
defined_title,Severity=one_or_more_comma-separated_severities:CRITICAL, MAJOR,
 MINOR,INFORMATIONAL, or UNSPECIFIED,Status=COMPLIANT or NON_COMPLIANT
```

Patch compliance metadata

Linux & macOS

```
aws ssm put-compliance-items \
    --resource-id instance_ID \
    --resource-type ManagedInstance \
    --compliance-type Patch \
    --execution-summary ExecutionTime=user-defined_time_and/
or_date_value,ExecutionId=user-defined_ID,ExecutionType=Command  \
    --items Id=for_example, KB12345,Title=user-
defined_title,Severity=one_or_more_comma-separated_severities:CRITICAL,
 MAJOR, MINOR,INFORMATIONAL, or UNSPECIFIED,Status=COMPLIANT or
 NON_COMPLIANT,Details="{PatchGroup=name_of_group,PatchSeverity=the_patch_severity,
 for example, CRITICAL}"
```

Windows

```
aws ssm put-compliance-items ^
    --resource-id instance_ID ^
    --resource-type ManagedInstance ^
    --compliance-type Patch ^
    --execution-summary ExecutionTime=user-defined_time_and/
or_date_value,ExecutionId=user-defined_ID,ExecutionType=Command  ^
    --items Id=for_example, KB12345,Title=user-
defined_title,Severity=one_or_more_comma-separated_severities:CRITICAL,
 MAJOR, MINOR,INFORMATIONAL, or UNSPECIFIED,Status=COMPLIANT or
 NON_COMPLIANT,Details="{PatchGroup=name_of_group,PatchSeverity=the_patch_severity,
 for example, CRITICAL}"
```

4. Run the following command to view a list of compliance items for a specific managed node. Use filters to drill down into specific compliance data.

   Linux & macOS

```
aws ssm list-compliance-items \
    --resource-ids instance_ID \
```

```
    --resource-types ManagedInstance \
    --filters one_or_more_filters
```

Windows

```
aws ssm list-compliance-items ^
    --resource-ids instance_ID ^
    --resource-types ManagedInstance ^
    --filters one_or_more_filters
```

The following examples show you how to use this command with filters.

Linux & macOS

```
aws ssm list-compliance-items \
    --resource-ids i-02573cafcfEXAMPLE \
    --resource-type ManagedInstance \
    --filters Key=DocumentName,Values=AWS-RunPowerShellScript
 Key=Status,Values=NON_COMPLIANT,Type=NotEqual
 Key=Id,Values=cee20ae7-6388-488e-8be1-a88ccEXAMPLE
 Key=Severity,Values=UNSPECIFIED
```

Windows

```
aws ssm list-compliance-items ^
    --resource-ids i-02573cafcfEXAMPLE ^
    --resource-type ManagedInstance ^
    --filters Key=DocumentName,Values=AWS-RunPowerShellScript
 Key=Status,Values=NON_COMPLIANT,Type=NotEqual
 Key=Id,Values=cee20ae7-6388-488e-8be1-a88ccEXAMPLE
 Key=Severity,Values=UNSPECIFIED
```

Linux & macOS

```
aws ssm list-resource-compliance-summaries \
    --filters Key=OverallSeverity,Values=UNSPECIFIED
```

Windows

```
aws ssm list-resource-compliance-summaries ^
    --filters Key=OverallSeverity,Values=UNSPECIFIED
```

Linux & macOS

```
aws ssm list-resource-compliance-summaries \
    --filters Key=OverallSeverity,Values=UNSPECIFIED
 Key=ComplianceType,Values=Association Key=InstanceId,Values=i-02573cafcfEXAMPLE
```

Windows

```
aws ssm list-resource-compliance-summaries ^
    --filters Key=OverallSeverity,Values=UNSPECIFIED
 Key=ComplianceType,Values=Association Key=InstanceId,Values=i-02573cafcfEXAMPLE
```

5. Run the following command to view a summary of compliance statuses. Use filters to drill down into specific compliance data.

```
aws ssm list-resource-compliance-summaries --filters One or more filters.
```

The following examples show you how to use this command with filters.

Linux & macOS

```
aws ssm list-resource-compliance-summaries \
    --filters Key=ExecutionType,Values=Command
```

Windows

```
aws ssm list-resource-compliance-summaries ^
    --filters Key=ExecutionType,Values=Command
```

Linux & macOS

```
aws ssm list-resource-compliance-summaries \
```

```
    --filters Key=AWS:InstanceInformation.PlatformType,Values=Windows
 Key=OverallSeverity,Values=CRITICAL
```

Windows

```
aws ssm list-resource-compliance-summaries ^
    --filters Key=AWS:InstanceInformation.PlatformType,Values=Windows
 Key=OverallSeverity,Values=CRITICAL
```

6. Run the following command to view a summary count of compliant and non-compliant resources for a compliance type. Use filters to drill down into specific compliance data.

```
aws ssm list-compliance-summaries --filters One or more filters.
```

The following examples show you how to use this command with filters.

Linux & macOS

```
aws ssm list-compliance-summaries \
    --filters Key=AWS:InstanceInformation.PlatformType,Values=Windows
 Key=PatchGroup,Values=TestGroup
```

Windows

```
aws ssm list-compliance-summaries ^
    --filters Key=AWS:InstanceInformation.PlatformType,Values=Windows
 Key=PatchGroup,Values=TestGroup
```

Linux & macOS

```
aws ssm list-compliance-summaries \
    --filters Key=AWS:InstanceInformation.PlatformType,Values=Windows
 Key=ExecutionId,Values=4adf0526-6aed-4694-97a5-14522EXAMPLE
```

Windows

```
aws ssm list-compliance-summaries ^
    --filters Key=AWS:InstanceInformation.PlatformType,Values=Windows
 Key=ExecutionId,Values=4adf0526-6aed-4694-97a5-14522EXAMPLE
```

AWS Systems Manager Distributor

Distributor, a tool in AWS Systems Manager, helps you package and publish software to AWS Systems Manager managed nodes. You can package and publish your own software or use Distributor to find and publish AWS-provided agent software packages, such as **AmazonCloudWatchAgent**, or third-party packages such as **Trend Micro.** Publishing a package advertises specific versions of the package's document to managed nodes that you identify using node IDs, AWS account IDs, tags, or an AWS Region. To get started with Distributor, open the Systems Manager console. In the navigation pane, choose **Distributor**.

After you create a package in Distributor, you can install the package in one of the following ways:

- One time by using AWS Systems Manager Run Command
- On a schedule by using AWS Systems Manager State Manager

> **Important**
>
> Packages distributed by third-party sellers are not managed by AWS and are published by the vendor of the package. We encourage you to conduct additional due diligence to ensure compliance with your internal security controls. Security is a shared responsibility between AWS and you. This is described as the shared responsibility model. To learn more, see the shared responsibility model.

How can Distributor benefit my organization?

Distributor offers these benefits:

- **One package, many platforms**

  When you create a package in Distributor, the system creates an AWS Systems Manager document (SSM document). You can attach .zip files to this document. When you run Distributor, the system processes the instructions in the SSM document and installs the software package in the .zip file on the specified targets. Distributor supports multiple operating systems, including Windows, Ubuntu Server, Debian Server, and Red Hat Enterprise Linux. For more information about supported platforms, see Supported package platforms and architectures.

- **Control package access across groups of managed instances**

You can use Run Command or State Manager to control which of your managed nodes get a package and which version of that package. Run Command and State Manager are tools in AWS Systems Manager. Managed nodes can be grouped by instance or device IDs, AWS account numbers, tags, or AWS Regions. You can use State Manager associations to deliver different versions of a package to different groups of instances.

- **Many AWS agent packages included and ready to use**

  Distributor includes many AWS agent packages that are ready for you to deploy to managed nodes. Look for packages in the Distributor `Packages` list page that are published by `Amazon`. Examples include `AmazonCloudWatchAgent` and `AWSPVDriver`.

- **Automate deployment**

  To keep your environment current, use State Manager to schedule packages for automatic deployment on target managed nodes when those machines are first launched.

Who should use Distributor?

- Any AWS customer who wants to create new or deploy existing software packages, including AWS published packages, to multiple Systems Manager managed nodes at one time.
- Software developers who create software packages.
- Administrators who are responsible for keeping Systems Manager managed nodes current with the most up-to-date software packages.

What are the features of Distributor?

- **Deployment of packages to both Windows and Linux instances**

  With Distributor, you can deploy software packages to Amazon Elastic Compute Cloud (Amazon EC2) instances and AWS IoT Greengrass core devices for Linux and Windows Server. For a list of supported instance operating system types, see the section called “Supported package platforms and architectures”.

  > **Note**
  >
  > Distributor isn't supported on the macOS operating system.

- **Deploy packages one time, or on an automated schedule**

  You can choose to deploy packages one time, on a regular schedule, or whenever the default package version is changed to a different version.

- **Completely reinstall packages, or perform in-place updates**

  To install a new package version, you can completely uninstall the current version and install a new one in its place, or only update the current version with new and updated components, according to an *update script* that you provide. Your package application is unavailable during a reinstallation, but can remain available during an in-place update. In-place updates are especially useful for security monitoring applications or other scenarios where you need to avoid application downtime.

- **Console, CLI, PowerShell, and SDK access to Distributor capabilities**

  You can work with Distributor by using the Systems Manager console, AWS Command Line Interface (AWS CLI), AWS Tools for PowerShell, or the AWS SDK of your choice.

- **IAM access control**

  By using AWS Identity and Access Management (IAM) policies, you can control which members of your organization can create, update, deploy, or delete packages or package versions. For example, you might want to give an administrator permissions to deploy packages, but not to change packages or create new package versions.

- **Logging and auditing capability support**

  You can audit and log Distributor user actions in your AWS account through integration with other AWS services. For more information, see Auditing and logging Distributor activity.

What is a package in Distributor?

A *package* is a collection of installable software or assets that includes the following.

- A .zip file of software per target operating system platform. Each .zip file must include the following.
  - An **install** and an **uninstall** script. Windows Server-based managed nodes require PowerShell scripts (scripts named `install.ps1` and `uninstall.ps1`). Linux-based managed nodes require shell scripts (scripts named `install.sh` and `uninstall.sh`). AWS Systems Manager SSM Agent reads and carries out the instructions in the **install** and **uninstall** scripts.

- An executable file. SSM Agent must find this executable to install the package on target managed nodes.
- A JSON-formatted manifest file that describes the package contents. The manifest isn't included in the .zip file, but it's stored in the same Amazon Simple Storage Service (Amazon S3) bucket as the .zip files that form the package. The manifest identifies the package version and maps the .zip files in the package to target managed node attributes, such as operating system version or architecture. For information about how to create the manifest, see Step 2: Create the JSON package manifest.

When you choose **Simple** package creation in the Distributor console, Distributor generates the installation and uninstallation scripts, file hashes, and the JSON package manifest for you, based on the software executable file name and target platforms and architectures.

Supported package platforms and architectures

You can use Distributor to publish packages to the following Systems Manager managed node platforms. A version value must match the exact release version of the operating system Amazon Machine Image (AMI) that you're targeting. For more information about determining this version, see step 4 of Step 2: Create the JSON package manifest.

> **Note**
>
> Systems Manager doesn't support all of the following operating systems for AWS IoT Greengrass core devices. For more information, see Setting up AWS IoT Greengrass core devices in the *AWS IoT Greengrass Version 2 Developer Guide*.

Platform	Code value in manifest file	Supported architectures
AlmaLinux	`almalinux`	x86_64 ARM64
Amazon Linux 2 and Amazon Linux 2023	`amazon`	x86_64 or x86 ARM64 (Amazon Linux 2 and AL2023, A1 instance types)

Platform	Code value in manifest file	Supported architectures
CentOS	`centos`	x86_64 or x86
Debian Server	`debian`	x86_64 or x86
openSUSE	`opensuse`	x86_64
openSUSE Leap	`opensuseleap`	x86_64
Oracle Linux	`oracle`	x86_64
Red Hat Enterprise Linux (RHEL)	`redhat`	x86_64 ARM64 (RHEL 7.6 and later, A1 instance types)
Rocky Linux	`rocky`	x86_64 ARM64
SUSE Linux Enterprise Server (SLES)	`suse`	x86_64
Ubuntu Server	`ubuntu`	x86_64 or x86 ARM64 (Ubuntu Server 16 and later, A1 instance types)
Windows Server	`windows`	x86_64

Setting up Distributor

Before you use Distributor, a tool in AWS Systems Manager, to create, manage, and deploy software packages, follow these steps.

Complete Distributor prerequisites

Before you use Distributor, a tool in AWS Systems Manager, be sure your environment meets the following requirements.

Distributor prerequisites

Requirement	Description
SSM Agent	AWS Systems Manager SSM Agent version 2.3.274.0 or later must be installed on the managed nodes on which you want to deploy or from which you want to remove packages. To install or update SSM Agent, see Working with SSM Agent.
AWS CLI	(Optional) To use the AWS Command Line Interface (AWS CLI) instead of the Systems Manager console to create and manage packages, install the newest release of the AWS CLI on your local computer. For more information about how to install or upgrade the CLI, see Installing the AWS Command Line Interface in the *AWS Command Line Interface User Guide*.
AWS Tools for PowerShell	(Optional) To use the Tools for PowerShel l instead of the Systems Manager console to create and manage packages, install the newest release of Tools for PowerShell on your local computer.

Requirement	Description
	For more information about how to install or upgrade the Tools for PowerShell, see Setting up the AWS Tools for Windows PowerShell or AWS Tools for PowerShell Core in the *AWS Tools for PowerShell User Guide*.

> **Note**
>
> Systems Manager doesn't support distributing packages to Oracle Linux managed nodes by using Distributor.

Verify or create an IAM instance profile with Distributor permissions

By default, AWS Systems Manager doesn't have permission to perform actions on your instances. You must grant access by using an AWS Identity and Access Management (IAM) instance profile. An instance profile is a container that passes IAM role information to an Amazon Elastic Compute Cloud (Amazon EC2) instance at launch. This requirement applies to permissions for all Systems Manager tools, not just Distributor.

> **Note**
>
> When you configure your edge devices to run AWS IoT Greengrass Core software and SSM Agent, you specify an IAM service role that enables Systems Manager to peform actions on it. You don't need to configure managed edge devices with an instance profile.

If you already use other Systems Manager tools, such as Run Command and State Manager, an instance profile with the required permissions for Distributor is already attached to your instances. The simplest way to ensure that you have permissions to perform Distributor tasks is to attach the **AmazonSSMManagedInstanceCore** policy to your instance profile. For more information, see Configure instance permissions required for Systems Manager.

Control user access to packages

Using AWS Identity and Access Management (IAM) policies, you can control who can create, deploy, and manage packages. You also control which Run Command and State Manager API operations they can perform on managed nodes. Like Distributor, both Run Command and State Manager, are tools in AWS Systems Manager.

ARN Format

User-defined packages are associated with document Amazon Resource Names (ARNs) and have the following format.

```
arn:aws:ssm:region:account-id:document/document-name
```

The following is an example.

```
arn:aws:ssm:us-west-1:123456789012:document/ExampleDocumentName
```

You can use a pair of AWS supplied default IAM policies, one for end users and one for administrators, to grant permissions for Distributor activities. Or you can create custom IAM policies appropriate for your permissions requirements.

For more information about using variables in IAM policies, see IAM Policy Elements: Variables.

For information about how to create policies and attach them to users or groups, see Creating IAM Policies and Adding and Removing IAM Policies in the *IAM User Guide*.

Create or choose an Amazon S3 bucket to store Distributor packages

When you create a package by using the **Simple** workflow in the AWS Systems Manager console, you choose an existing Amazon Simple Storage Service (Amazon S3) bucket to which Distributor uploads your software. Distributor is a tool in AWS Systems Manager. In the **Advanced** workflow, you must upload .zip files of your software or assets to an Amazon S3 bucket before you begin. Whether you create a package by using the **Simple** or **Advanced** workflows in the console, or by using the API, you must have an Amazon S3 bucket before you start creating your package. As part of the package creation process, Distributor copies your installable software and assets from this bucket to an internal Systems Manager store. Because the assets are copied to an internal store, you can delete or repurpose your Amazon S3 bucket when package creation is finished.

For more information about how to create a bucket, see Create a Bucket in the *Amazon Simple Storage Service Getting Started Guide*. For more information about how to run an AWS CLI command to create a bucket, see **mb** in the *AWS CLI Command Reference*.

Working with Distributor packages

You can use the AWS Systems Manager console, AWS command line tools (AWS CLI and AWS Tools for PowerShell), and AWS SDKs to add, manage, or deploy packages in Distributor. Distributor is a tool in AWS Systems Manager. Before you add a package to Distributor:

- Create and zip installable assets.
- (Optional) Create a JSON manifest file for the package. This isn't required to use the **Simple** package creation process in the Distributor console. Simple package creation generates a JSON manifest file for you.

  You can use the AWS Systems Manager console or a text or JSON editor to create the manifest file.
- Have an Amazon Simple Storage Service (Amazon S3) bucket ready to store your installable assets or software. If you're using the **Advanced** package creation process, upload your assets to the Amazon S3 bucket before you begin.

> **Note**
>
> You can delete or repurpose this bucket after you finish creating your package because Distributor moves the package contents to an internal Systems Manager bucket as part of the package creation process.

AWS published packages are already packaged and ready for deployment. To deploy an AWS-published package to managed nodes, see Install or update Distributor packages.

You can share Distributor packages between AWS accounts. When using a package shared from another account in AWS CLI commands use the package Amazon Resource Name (ARN) instead of the package name.

View packages in Distributor

To view packages that are available for installation, you can use the AWS Systems Manager console or your preferred AWS command line tool. Distributor is a tool in AWS Systems Manager. To access Distributor, open the AWS Systems Manager console and choose **Distributor** in the left navigation pane. You will see all of the packages available to you.

The following section describes how you can view Distributor packages using your preferred command line tool.

View packages using the command line

This section contains information about how you can use your preferred command line tool to view Distributor packages using the provided commands.

Linux & macOS

To view packages using the AWS CLI on Linux

- To view all packages, excluding shared packages, run the following command.

```
aws ssm list-documents \
    --filters Key=DocumentType,Values=Package
```

- To view all packages owned by Amazon, run the following command.

```
aws ssm list-documents \
    --filters Key=DocumentType,Values=Package Key=Owner,Values=Amazon
```

- To view all packages owned by third parties, run the following command.

```
aws ssm list-documents \
```

```
    --filters Key=DocumentType,Values=Package Key=Owner,Values=ThirdParty
```

Windows

To view packages using the AWS CLI on Windows

- To view all packages, excluding shared packages, run the following command.

```
aws ssm list-documents ^
    --filters Key=DocumentType,Values=Package
```

- To view all packages owned by Amazon, run the following command.

```
aws ssm list-documents ^
    --filters Key=DocumentType,Values=Package Key=Owner,Values=Amazon
```

- To view all packages owned by third parties, run the following command.

```
aws ssm list-documents ^
    --filters Key=DocumentType,Values=Package Key=Owner,Values=ThirdParty
```

PowerShell

To view packages using the Tools for PowerShell

- To view all packages, excluding shared packages, run the following command.

```
$filter = New-Object Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$filter.Key = "DocumentType"
$filter.Values = "Package"

Get-SSMDocumentList `
    -Filters @($filter)
```

- To view all packages owned by Amazon, run the following command.

```
$typeFilter = New-Object
 Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$typeFilter.Key = "DocumentType"
$typeFilter.Values = "Package"
```

```
$ownerFilter = New-Object
 Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$ownerFilter.Key = "Owner"
$ownerFilter.Values = "Amazon"

Get-SSMDocumentList `
    -Filters @($typeFilter,$ownerFilter)
```

- To view all packages owned by third parties, run the following command.

```
$typeFilter = New-Object
 Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$typeFilter.Key = "DocumentType"
$typeFilter.Values = "Package"

$ownerFilter = New-Object
 Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$ownerFilter.Key = "Owner"
$ownerFilter.Values = "ThirdParty"

Get-SSMDocumentList `
    -Filters @($typeFilter,$ownerFilter)
```

Create a package in Distributor

To create a package, prepare your installable software or assets, one file per operating system platform. At least one file is required to create a package.

Different platforms might sometimes use the same file, but all files that you attach to your package must be listed in the `Files` section of the manifest. If you're creating a package by using the simple workflow in the console, the manifest is generated for you. The maximum number of files that you can attach to a single document is 20. The maximum size of each file is 1 GB. For more information about supported platforms, see Supported package platforms and architectures.

When you create a package, the system creates a new SSM document. This document allows you to deploy the package to managed nodes.

For demonstration purposes only, an example package, ExamplePackage.zip, is available for you to download from our website. The example package includes a completed JSON manifest and three .zip files containing installers for PowerShell v7.0.0. The installation and uninstallation scripts

don't contain valid commands. Although you must zip each software installable and scripts into a .zip file to create a package in the **Advanced** workflow, you don't zip installable assets in the **Simple** workflow.

Topics

Create a package using the Simple workflow

This section describes how to create a package in Distributor by choosing the **Simple** package creation workflow in the Distributor console. Distributor is a tool in AWS Systems Manager. To create a package, prepare your installable assets, one file per operating system platform. At least one file is required to create a package. The **Simple** package creation process generates installation and uninstallation scripts, file hashes, and a JSON-formatted manifest for you. The **Simple** workflow handles the process of uploading and zipping your installable files, and creating a new package and associated SSM document. For more information about supported platforms, see Supported package platforms and architectures.

When you use the Simple method to create a package, Distributor creates `install` and `uninstall` scripts for you. However, when you create a package for an in-place update, you must provide your own `update` script content on the **Update script** tab. When you add input commands for an `update` script, Distributor includes this script in the .zip package it creates for you, along with the `install` and `uninstall` scripts.

> **Note**
>
> Use the `In-place` update option to add new or updated files to an existing package installation without taking the associated application offline.

To create a package using the Simple workflow

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the Distributor home page, choose **Create package**, and then choose **Simple**.

4. On the **Create package** page, enter a name for your package. Package names can contain letters, numbers, periods, dashes, and underscores. The name should be generic enough to apply to all versions of the package attachments, but specific enough to identify the purpose of the package.
5. (Optional) For **Version name**, enter a version name. Version names can be a maximum of 512 characters, and can't contain special characters.
6. For **Location**, choose a bucket by using the bucket name and prefix or by using the bucket URL.
7. For **Upload software**, choose **Add software**, and then navigate to installable software files with `.rpm`, `.msi`, or `.deb` extensions. If the file name contains spaces, the upload fails. You can upload more than one software file in a single action.
8. For **Target platform**, verify that the target operating system platform shown for each installable file is correct. If the operating system shown isn't correct, choose the correct operating system from the dropdown list.

   For the **Simple** package creation workflow, because you upload each installable file only once, extra steps are required to instruct Distributor to target a single file at multiple operating systems. For example, if you upload an installable software file named `Logtool_v1.1.1.rpm`, you must change some defaults in the **Simple** workflow to target the same software on supported versions of both Amazon Linux and Ubuntu Server operating systems. When targeting multiple platforms, do one of the following.

   - Use the **Advanced** workflow instead, zip each installable file into a .zip file before you begin, and manually author the manifest so that one installable file can be targeted at multiple operating system platforms or versions. For more information, see Create a package using the Advanced workflow.
   - Manually edit the manifest file in the **Simple** workflow so that your .zip file is targeted at multiple operating system platforms or versions. For more information about how to do this, see the end of step 4 in Step 2: Create the JSON package manifest.
9. For **Platform version**, verify that the operating system platform version shown is either **_any**, a major release version followed by a wildcard (7.*), or the exact operating system release version to which you want your software to apply. For more information about specifying an operating system platform version, see step 4 in Step 2: Create the JSON package manifest.
10. For **Architecture**, choose the correct processor architecture for each installable file from the dropdown list. For more information about supported processor architectures, see Supported package platforms and architectures.

11. (Optional) Expand **Scripts**, and review the scripts that Distributor generates for your installable software.
12. (Optional) To provide an update script for use with in-place updates, expand **Scripts**, choose the **Update script** tab, and enter your update script commands.

    Systems Manager doesn't generate update scripts on your behalf.
13. To add more installable software files, choose **Add software**. Otherwise, go to the next step.
14. (Optional) Expand **Manifest**, and review the JSON package manifest that Distributor generates for your installable software. If you changed any information about your software since you began this procedure, such as platform version or target platform, choose **Generate manifest** to show the updated package manifest.

    You can edit the manifest manually if you want to target a software installable at more than one operating system, as described in step 8. For more information about editing the manifest, see Step 2: Create the JSON package manifest.
15. Choose **Create package**.

Wait for Distributor to finish uploading your software and creating your package. Distributor shows upload status for each installable file. Depending on the number and size of packages you're adding, this can take a few minutes. Distributor automatically redirects you to the **Package details** page for the new package, but you can choose to open this page yourself after the software is uploaded. The **Package details** page doesn't show all information about your package until Distributor finishes the package creation process. To stop the upload and package creation process, choose **Cancel**.

If Distributor can't upload any of the software installable files, it displays an **Upload failed** message. To retry the upload, choose **Retry upload**. For more information about how to troubleshoot package creation failures, see Troubleshooting AWS Systems Manager Distributor.

Create a package using the Advanced workflow

In this section, learn about how advanced users can create a package in Distributor after uploading installable assets zipped with installation and uninstallation scripts, and a JSON manifest file, to an Amazon S3 bucket.

To create a package, prepare your .zip files of installable assets, one .zip file per operating system platform. At least one .zip file is required to create a package. Next, create a JSON manifest. The

manifest includes pointers to your package code files. When you have your required code files added to a folder or directory, and the manifest is populated with correct values, upload your package to an S3 bucket.

An example package, ExamplePackage.zip, is available for you to download from our website. The example package includes a completed JSON manifest and three .zip files.

Topics

Step 1: Create the ZIP files

The foundation of your package is at least one .zip file of software or installable assets. A package includes one .zip file per operating system that you want to support, unless one .zip file can be installed on multiple operating systems. For example, supported versions of Red Hat Enterprise Linux and Amazon Linux instances can typically run the same .RPM executable files, so you need to attach only one .zip file to your package to support both operating systems.

Required files

The following items are required in each .zip file:

- An **install** and an **uninstall** script. Windows Server-based managed nodes require PowerShell scripts (scripts named `install.ps1` and `uninstall.ps1`). Linux-based managed nodes require shell scripts (scripts named `install.sh` and `uninstall.sh`). SSM Agent runs the instructions in the **install** and **uninstall** scripts.

  For example, your installation scripts might run an installer (such as .rpm or .msi), they might copy files, or they might set configurations.
- An executable file, installer packages (.rpm, .deb, .msi, etc.), other scripts, or configuration files.

Optional files

The following item is optional in each .zip file:

- An **update** script. Providing an update script makes it possible for you to use the `In-place update` option to install a package. When you want to add new or updated files to an existing package installation, the `In-place update` option doesn't take the package application offline while the update is performed. Windows Server-based managed nodes require a PowerShell script (script named `update.ps1`). Linux-based managed nodes require a shell script (script named `update.sh`). SSM Agent runs the instructions in the **update** script.

For more information about installing or updating packages, see Install or update Distributor packages.

For examples of .zip files, including sample **install** and **uninstall** scripts, download the example package, ExamplePackage.zip.

Step 2: Create the JSON package manifest

After you prepare and zip your installable files, create a JSON manifest. The following is a template. The parts of the manifest template are described in the procedure in this section. You can use a JSON editor to create this manifest in a separate file. Alternatively, you can author the manifest in the AWS Systems Manager console when you create a package.

```
{
  "schemaVersion": "2.0",
  "version": "your-version",
  "publisher": "optional-publisher-name",
  "packages": {
    "platform": {
      "platform-version": {
        "architecture": {
          "file": ".zip-file-name-1.zip"
        }
      }
    },
    "another-platform": {
      "platform-version": {
        "architecture": {
          "file": ".zip-file-name-2.zip"
        }
      }
    },
    "another-platform": {
      "platform-version": {
```

```
        "architecture": {
          "file": ".zip-file-name-3.zip"
        }
      }
    }
  },
  "files": {
    ".zip-file-name-1.zip": {
      "checksums": {
        "sha256": "checksum"
      }
    },
    ".zip-file-name-2.zip": {
      "checksums": {
        "sha256": "checksum"
      }
    }
  }
}
```

To create a JSON package manifest

1. Add the schema version to your manifest. In this release, the schema version is always `2.0`.

   ```
   { "schemaVersion": "2.0",
   ```

2. Add a user-defined package version to your manifest. This is also the value of **Version name** that you specify when you add your package to Distributor. It becomes part of the AWS Systems Manager document that Distributor creates when you add your package. You also provide this value as an input in the `AWS-ConfigureAWSPackage` document to install a version of the package other than the latest. A `version` value can contain letters, numbers, underscores, hyphens, and periods, and be a maximum of 128 characters in length. We recommend that you use a human-readable package version to make it easier for you and other administrators to specify exact package versions when you deploy. The following is an example.

   ```
   "version": "1.0.1",
   ```

3. (Optional) Add a publisher name. The following is an example.

```
"publisher": "MyOrganization",
```

4. Add packages. The `"packages"` section describes the platforms, release versions, and architectures supported by the .zip files in your package. For more information, see Supported package platforms and architectures.

   The *`platform-version`* can be the wildcard value, `_any`. Use it to indicate that a .zip file supports any release of the platform. You can also specify a major release version followed by a wildcard so all minor versions are supported, for example 7.*. If you choose to specify a *`platform-version`* value for a specific operating system version, be sure that it matches the exact release version of the operating system AMI that you're targeting. The following are suggested resources for getting the correct value of the operating system.

   - On a Windows Server-based managed nodes, the release version is available as Windows Management Instrumentation (WMI) data. You can run the following command from a command prompt to get version information, then parse the results for `version`.

     ```
     wmic OS get /format:list
     ```

   - On a Linux-based managed node, get the version by first scanning for operating system release (the following command). Look for the value of `VERSION_ID`.

     ```
     cat /etc/os-release
     ```

     If that doesn't return the results that you need, run the following command to get LSB release information from the `/etc/lsb-release` file, and look for the value of `DISTRIB_RELEASE`.

     ```
     lsb_release -a
     ```

     If these methods fail, you can usually find the release based on the distribution. For example, on Debian Server, you can scan the `/etc/debian_version` file, or on Red Hat Enterprise Linux, the `/etc/redhat-release` file.

     ```
     hostnamectl
     ```

```
"packages": {
    "platform": {
      "platform-version": {
        "architecture": {
          "file": ".zip-file-name-1.zip"
        }
      }
    },
    "another-platform": {
      "platform-version": {
        "architecture": {
          "file": ".zip-file-name-2.zip"
        }
      }
    },
    "another-platform": {
      "platform-version": {
        "architecture": {
          "file": ".zip-file-name-3.zip"
        }
      }
    }
  }
```

The following is an example. In this example, the operating system platform is `amazon`, the supported release version is `2016.09`, the architecture is `x86_64`, and the .zip file that supports this platform is `test.zip`.

```
{
    "amazon": {
        "2016.09": {
            "x86_64": {
                "file": "test.zip"
            }
        }
    }
},
```

You can add the `_any` wildcard value to indicate that the package supports all versions of the parent element. For example, to indicate that the package is supported on any release version

of Amazon Linux, your package statement should be similar to the following. You can use the _any wildcard at the version or architecture levels to support all versions of a platform, or all architectures in a version, or all versions and all architectures of a platform.

```
{
    "amazon": {
        "_any": {
            "x86_64": {
                "file": "test.zip"
            }
        }
    }
},
```

The following example adds _any to show that the first package, data1.zip, is supported for all architectures of Amazon Linux 2016.09. The second package, data2.zip, is supported for all releases of Amazon Linux, but only for managed nodes with x86_64 architecture. Both the 2023.8 and _any versions are entries under amazon. There is one platform (Amazon Linux), but different supported versions, architectures, and associated .zip files.

```
{
    "amazon": {
        "2023.8": {
            "_any": {
                "file": "data1.zip"
            }
        },
        "_any": {
            "x86_64": {
                "file": "data2.zip"
            }
        }
    }
}
```

You can refer to a .zip file more than once in the "packages" section of the manifest, if the .zip file supports more than one platform. For example, if you have a .zip file that supports both Red Hat Enterprise Linux 8.x versions and Amazon Linux, you have two entries in the "packages" section that point to the same .zip file, as shown in the following example.

```
{
    "amazon": {
        "2023.8.20250715 ": {
            "x86_64": {
                "file": "test.zip"
            }
        }
    },
    "redhat": {
        "8.*": {
            "x86_64": {
                "file": "test.zip"
            }
        }
    }
},
```

5. Add the list of .zip files that are part of this package from step 4. Each file entry requires the file name and `sha256` hash value checksum. Checksum values in the manifest must match the `sha256` hash value in the zipped assets to prevent the package installation from failing.

   To get the exact checksum from your installables, you can run the following commands. On Linux, run `shasum -a 256` *`file-name`*`.zip` or `openssl dgst -sha256` *`file-name`*`.zip`. On Windows, run the `Get-FileHash -Path` *`path-to-.zip-file`* cmdlet in PowerShell.

   The `"files"` section of the manifest includes one reference to each of the .zip files in your package.

```
"files": {
        "test-agent-x86.deb.zip": {
            "checksums": {
                "sha256":
 "EXAMPLE2706223c7616ca9fb28863a233b38e5a23a8c326bb4ae241dcEXAMPLE"
            }
        },
        "test-agent-x86_64.deb.zip": {
            "checksums": {
                "sha256":
 "EXAMPLE572a745844618c491045f25ee6aae8a66307ea9bff0e9d1052EXAMPLE"
            }
```

```
        },
        "test-agent-x86_64.nano.zip": {
            "checksums": {
                "sha256":
 "EXAMPLE63ccb86e830b63dfef46995af6b32b3c52ce72241b5e80c995EXAMPLE"
            }
        },
        "test-agent-rhel8-x86.nano.zip": {
            "checksums": {
                "sha256":
 "EXAMPLE13df60aa3219bf117638167e5bae0a55467e947a363fff0a51EXAMPLE"
            }
        },
        "test-agent-x86.msi.zip": {
            "checksums": {
                "sha256":
 "EXAMPLE12a4abb10315aa6b8a7384cc9b5ca8ad8e9ced8ef1bf0e5478EXAMPLE"
            }
        },
        "test-agent-x86_64.msi.zip": {
            "checksums": {
                "sha256":
 "EXAMPLE63ccb86e830b63dfef46995af6b32b3c52ce72241b5e80c995EXAMPLE"
            }
        },
        "test-agent-rhel8-x86.rpm.zip": {
            "checksums": {
                "sha256":
 "EXAMPLE13df60aa3219bf117638167e5bae0a55467e947a363fff0a51EXAMPLE"
            }
        }
    }
```

6. After you add your package information, save and close the manifest file.

The following is an example of a completed manifest. In this example, you have a .zip file, `NewPackage_LINUX.zip`, that supports more than one platform, but is referenced in the `"files"` section only once.

```
{
    "schemaVersion": "2.0",
    "version": "1.7.1",
    "publisher": "Amazon Web Services",
```

```
    "packages": {
        "windows": {
            "_any": {
                "x86_64": {
                    "file": "NewPackage_WINDOWS.zip"
                }
            }
        },
        "amazon": {
            "_any": {
                "x86_64": {
                    "file": "NewPackage_LINUX.zip"
                }
            }
        },
        "ubuntu": {
            "_any": {
                "x86_64": {
                    "file": "NewPackage_LINUX.zip"
                }
            }
        }
    },
    "files": {
        "NewPackage_WINDOWS.zip": {
            "checksums": {
                "sha256":
 "EXAMPLEc2c706013cf8c68163459678f7f6daa9489cd3f91d52799331EXAMPLE"
            }
        },
        "NewPackage_LINUX.zip": {
            "checksums": {
                "sha256":
 "EXAMPLE2b8b9ed71e86f39f5946e837df0d38aacdd38955b4b18ffa6fEXAMPLE"
            }
        }
    }
}
```

Package example

An example package, ExamplePackage.zip, is available for you to download from our website. The example package includes a completed JSON manifest and three .zip files.

Step 3: Upload the package and manifest to an Amazon S3 bucket

Prepare your package by copying or moving all .zip files into a folder or directory. A valid package requires the manifest that you created in Step 2: Create the JSON package manifest and all .zip files identified in the manifest file list.

To upload the package and manifest to Amazon S3

1. Copy or move all .zip archive files that you specified in the manifest to a folder or directory. Don't zip the folder or directory you move your .zip archive files and manifest file to.
2. Create a bucket or choose an existing bucket. For more information, see Create a Bucket in the *Amazon Simple Storage Service Getting Started Guide*. For more information about how to run an AWS CLI command to create a bucket, see **mb** in the *AWS CLI Command Reference*.
3. Upload the folder or directory to the bucket. For more information, see Add an Object to a Bucket in the *Amazon Simple Storage Service Getting Started Guide*. If you plan to paste your JSON manifest into the AWS Systems Manager console, don't upload the manifest. For more information about how to run an AWS CLI command to upload files to a bucket, see **mv** in the *AWS CLI Command Reference*.
4. On the bucket's home page, choose the folder or directory that you uploaded. If you uploaded your files to a subfolder in a bucket, be sure to note the subfolder (also known as a *prefix*). You need the prefix to add your package to Distributor.

Step 4: Add a package to Distributor

You can use the AWS Systems Manager console, AWS command line tools (AWS CLI and AWS Tools for PowerShell), or AWS SDKs to add a new package to Distributor. When you add a package, you're adding a new SSM document. The document allows you to deploy the package to managed nodes.

Topics

- Add a package using the console
- Add a package using the AWS CLI

Add a package using the console

You can use the AWS Systems Manager console to create a package. Have ready the name of the bucket to which you uploaded your package in Step 3: Upload the package and manifest to an Amazon S3 bucket.

To add a package to Distributor (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the Distributor home page, choose **Create package**, and then choose **Advanced**.
4. On the **Create package** page, enter a name for your package. Package names can contain letters, numbers, periods, dashes, and underscores. The name should be generic enough to apply to all versions of the package attachments, but specific enough to identify the purpose of the package.
5. For **Version name**, enter the exact value of the `version` entry in your manifest file.
6. For **S3 bucket name**, choose the name of the bucket to which you uploaded your .zip files and manifest in the section called "Step 3: Upload the package and manifest to an Amazon S3 bucket".
7. For **S3 key prefix**, enter the subfolder of the bucket where your .zip files and manifest are stored.
8. For **Manifest**, choose **Extract from package** to use a manifest that you have uploaded to the Amazon S3 bucket with your .zip files.

   (Optional) If you didn't upload your JSON manifest to the S3 bucket where you stored your .zip files, choose **New manifest**. You can author or paste the entire manifest in the JSON editor field. For more information about how to create the JSON manifest, see Step 2: Create the JSON package manifest.
9. When you're finished with the manifest, choose **Create package**.
10. Wait for Distributor to create your package from your .zip files and manifest. Depending on the number and size of packages you are adding, this can take a few minutes. Distributor automatically redirects you to the **Package details** page for the new package, but you can choose to open this page yourself after the software is uploaded. The **Package details** page doesn't show all information about your package until Distributor finishes the package creation process. To stop the upload and package creation process, choose **Cancel**.

Add a package using the AWS CLI

You can use the AWS CLI to create a package. Have the URL ready from the bucket to which you uploaded your package in Step 3: Upload the package and manifest to an Amazon S3 bucket.

To add a package to Amazon S3 using the AWS CLI

1. To use the AWS CLI to create a package, run the following command, replacing *package-name* with the name of your package and *path-to-manifest-file* with the file path for your JSON manifest file. amzn-s3-demo-bucket is the URL of the Amazon S3 bucket where the entire package is stored. When you run the **create-document** command in Distributor, you specify the `Package` value for `--document-type`.

   If you didn't add your manifest file to the Amazon S3 bucket, the `--content` parameter value is the file path to the JSON manifest file.

   ```
   aws ssm create-document \
       --name "package-name" \
       --content file://path-to-manifest-file \
       --attachments Key="SourceUrl",Values="amzn-s3-demo-bucket" \
       --version-name version-value-from-manifest \
       --document-type Package
   ```

   The following is an example.

   ```
   aws ssm create-document \
       --name "ExamplePackage" \
       --content file://path-to-manifest-file \
       --attachments Key="SourceUrl",Values="https://s3.amazonaws.com/amzn-s3-demo-
   bucket/ExamplePackage" \
       --version-name 1.0.1 \
       --document-type Package
   ```

2. Verify that your package was added and show the package manifest by running the following command, replacing *package-name* with the name of your package. To get a specific version of the document (not the same as the version of a package), you can add the `--document-version` parameter.

   ```
   aws ssm get-document \
       --name "package-name"
   ```

For information about other options you can use with the **create-document** command, see **create-document** in the AWS Systems Manager section of the *AWS CLI Command Reference*.

For information about other options you can use with the **get-document** command, see **get-document**.

Edit Distributor package permissions in the console

After you add a package to Distributor, a tool in AWS Systems Manager, you can edit the package's permissions in the Systems Manager console. You can add other AWS accounts to a package's permissions. Packages can be shared with other accounts in the same AWS Region only. Cross-Region sharing isn't supported. By default, packages are set to **Private**, meaning only those with access to the package creator's AWS account can view package information and update or delete the package. If **Private** permissions are acceptable, you can skip this procedure.

> **Note**
>
> You can update the permissions of packages that are shared with 20 or fewer accounts.

To edit package permissions in the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the **Packages** page, choose the package for which you want to edit permissions.
4. On the **Package details** tab, choose **Edit permissions** to change permissions.
5. For **Edit permissions**, choose **Shared with specific accounts**.
6. Under **Shared with specific accounts**, add AWS account numbers, one at a time. When you're finished, choose **Save**.

Edit Distributor package tags in the console

After you have added a package to Distributor, a tool in AWS Systems Manager, you can edit the package's tags in the Systems Manager console. These tags are applied to the package, and aren't connected to tags on the managed node on which you want to deploy the package. Tags are case sensitive key and value pairs that can help you group and filter your packages by criteria that are relevant to your organization. If you don't want to add tags, you're ready to install your package or add a new version.

To edit package tags in the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the **Packages** page, choose the package for which you want to edit tags.
4. On the **Package details** tab, in **Tags**, choose **Edit**.
5. For **Add tags**, enter a tag key, or a tag key and value pair, and then choose **Add**. Repeat if you want to add more tags. To delete tags, choose **X** on the tag at the bottom of the window.
6. When you're finished adding tags to your package, choose **Save**.

Add a version to a Distributor package

To add a package version, create a package, and then use Distributor to add a package version by adding an entry to the AWS Systems Manager (SSM) document that already exists for older versions. Distributor is a tool in AWS Systems Manager. To save time, update the manifest for an older version of the package, change the value of the `version` entry in the manifest (for example, from `Test_1.0` to `Test_2.0`) and save it as the manifest for the new version. The simple **Add version** workflow in the Distributor console updates the manifest file for you.

A new package version can:

- Replace at least one of the installable files attached to the current version.
- Add new installable files to support additional platforms.
- Delete files to discontinue support for specific platforms.

A newer version can use the same Amazon Simple Storage Service (Amazon S3) bucket, but must have a URL with a different file name shown at the end. You can use the Systems Manager console or the AWS Command Line Interface (AWS CLI) to add the new version. Uploading an installable file with the exact name as an existing installable file in the Amazon S3 bucket overwrites the existing file. No installable files are copied over from the older version to the new version; you must upload installable files from the older version to have them be part of a new version. After Distributor is finished creating your new package version, you can delete or repurpose the Amazon S3 bucket, because Distributor copies your software to an internal Systems Manager bucket as part of the versioning process.

> **Note**
>
> Each package is held to a maximum of 25 versions. You can delete versions that are no longer required.

Topics

Adding a package version using the console

Before you perform these steps, follow the instructions in Create a package in Distributor to create a new package for the version. Then, use the Systems Manager console to add a new package version to Distributor.

Adding a package version using the Simple workflow

To add a package version by using the **Simple** workflow, prepare updated installable files or add installable files to support more platforms and architectures. Then, use Distributor to upload new and updated installable files and add a package version. The simplified **Add version** workflow in the Distributor console updates the manifest file and associated SSM document for you.

To add a package version using the Simple workflow

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the Distributor home page, choose the package to which you want to add another version.
4. On the **Add version** page, choose **Simple**.
5. For **Version name**, enter a version name. The version name for the new version must be different from older version names. Version names can be a maximum of 512 characters, and can't contain special characters.
6. For **S3 bucket name**, choose an existing S3 bucket from the list. This can be the same bucket that you used to store installable files for older versions, but the installable file names must be different to avoid overwriting existing installable files in the bucket.
7. For **S3 key prefix**, enter the subfolder of the bucket where your installable assets are stored.

8. For **Upload software**, navigate to the installable software files that you want to attach to the new version. Installable files from existing versions aren't automatically copied over to a new version; you must upload any installable files from older versions of the package if you want any of the same installable files to be part of the new version. You can upload more than one software file in a single action.
9. For **Target platform**, verify that the target operating system platform shown for each installable file is correct. If the operating system shown isn't correct, choose the correct operating system from the dropdown list.

   In the **Simple** versioning workflow, because you upload each installable file only once, extra steps are required to target a single file at multiple operating systems. For example, if you upload an installable software file named `Logtool_v1.1.1.rpm`, you must change some defaults in the **Simple** workflow to instruct Distributor to target the same software at both Amazon Linux and Ubuntu Server operating systems. You can do one of the following to work around this limitation.

   - Use the **Advanced** versioning workflow instead, zip each installable file into a .zip file before you begin, and manually author the manifest so that one installable file can be targeted at multiple operating system platforms or versions. For more information, see Adding a package version using the Advanced workflow.
   - Manually edit the manifest file in the **Simple** workflow so that your .zip file is targeted at multiple operating system platforms or versions. For more information about how to do this, see the end of step 4 in Step 2: Create the JSON package manifest.
10. For **Platform version**, verify that the operating system platform version shown is either **_any**, a major release version followed by a wildcard (8.*), or the exact operating system release version to which you want your software to apply. For more information about specifying a platform version, see step 4 in Step 2: Create the JSON package manifest.
11. For **Architecture**, choose the correct processor architecture for each installable file from the drop-down list. For more information about supported architectures, see Supported package platforms and architectures.
12. (Optional) Expand **Scripts**, and review the installation and uninstallation scripts that Distributor generates for your installable software.
13. To add more installable software files to the new version, choose **Add software**. Otherwise, go to the next step.
14. (Optional) Expand **Manifest**, and review the JSON package manifest that Distributor generates for your installable software. If you changed any information about your installable software

since you began this procedure, such as platform version or target platform, choose **Generate manifest** to show the updated package manifest.

You can edit the manifest manually if you want to target a software installable at more than one operating system, as described in step 9. For more information about editing the manifest, see Step 2: Create the JSON package manifest.

15. When you finish adding software and reviewing the target platform, version, and architecture data, choose **Add version**.
16. Wait for Distributor to finish uploading your software and creating the new package version. Distributor shows upload status for each installable file. Depending on the number and size of packages you are adding, this can take a few minutes. Distributor automatically redirects you to the **Package details** page for the package, but you can choose to open this page yourself after the software is uploaded. The **Package details** page doesn't show all information about your package until Distributor finishes creating the new package version. To stop the upload and package version creation, choose **Stop upload**.
17. If Distributor can't upload any of the software installable files, it displays an **Upload failed** message. To retry the upload, choose **Retry upload**. For more information about how to troubleshoot package version creation failures, see Troubleshooting AWS Systems Manager Distributor.
18. When Distributor is finished creating the new package version, on the package's **Details** page, on the **Versions** tab, view the new version in the list of available package versions. Set a default version of the package by choosing a version, and then choosing **Set default version**.

    If you don't set a default version, the newest package version is the default version.

Adding a package version using the Advanced workflow

To add a package version, create a package, and then use Distributor to add a package version by adding an entry to the SSM document that exists for older versions. To save time, update the manifest for an older version of the package, change the value of the `version` entry in the manifest (for example, from `Test_1.0` to `Test_2.0`) and save it as the manifest for the new version. You must have an updated manifest to add a new package version by using the **Advanced** workflow.

To add a package version using the Advanced workflow

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the Distributor home page, choose the package to which you want to add another version, and then choose **Add version**.
4. For **Version name**, enter the exact value that is in the `version` entry of your manifest file.
5. For **S3 bucket name**, choose an existing S3 bucket from the list. This can be the same bucket that you used to store installable files for older versions, but the installable file names must be different to avoid overwriting existing installable files in the bucket.
6. For **S3 key prefix**, enter the subfolder of the bucket where your installable assets are stored.
7. For **Manifest**, choose **Extract from package** to use a manifest that you uploaded to the S3 bucket with your .zip files.

   (Optional) If you didn't upload your revised JSON manifest to the Amazon S3 bucket where you stored your .zip files, choose **New manifest**. You can author or paste the entire manifest in the JSON editor field. For more information about how to create the JSON manifest, see Step 2: Create the JSON package manifest.
8. When you're finished with the manifest, choose **Add package version**.
9. On the package's **Details** page, on the **Versions** tab, view the new version in the list of available package versions. Set a default version of the package by choosing a version, and then choosing **Set default version**.

   If you don't set a default version, the newest package version is the default version.

Adding a package version using the AWS CLI

You can use the AWS CLI to add a new package version to Distributor. Before you run these commands, you must create a new package version and upload it to S3, as described at the start of this topic.

To add a package version using the AWS CLI

1. Run the following command to edit the AWS Systems Manager document with an entry for a new package version. Replace *`document-name`* with the name of your document. Replace

amzn-s3-demo-bucket with the URL of the JSON manifest that you copied in Step 3: Upload the package and manifest to an Amazon S3 bucket. *S3-bucket-URL-of-package* is the URL of the Amazon S3 bucket where the entire package is stored. Replace *version-name-from-updated-manifest* with the value of `version` in the manifest. Set the `--document-version` parameter to `$LATEST` to make the document associated with this package version the latest version of the document.

```
aws ssm update-document \
    --name "document-name" \
    --content "S3-bucket-URL-to-manifest-file" \
    --attachments Key="SourceUrl",Values="amzn-s3-demo-bucket" \
    --version-name version-name-from-updated-manifest \
    --document-version $LATEST
```

The following is an example.

```
aws ssm update-document \
    --name ExamplePackage \
    --content "https://s3.amazonaws.com/amzn-s3-demo-bucket/ExamplePackage/
manifest.json" \
    --attachments Key="SourceUrl",Values="https://s3.amazonaws.com/amzn-s3-demo-
bucket/ExamplePackage" \
    --version-name 1.1.1 \
    --document-version $LATEST
```

2. Run the following command to verify that your package was updated and show the package manifest. Replace *package-name* with the name of your package, and optionally, *document-version* with the version number of the document (not the same as the package version) that you updated. If this package version is associated with the latest version of the document, you can specify `$LATEST` for the value of the optional `--document-version` parameter.

```
aws ssm get-document \
    --name "package-name" \
    --document-version "document-version"
```

For information about other options you can use with the **update-document** command, see **update-document** in the AWS Systems Manager section of the *AWS CLI Command Reference*.

Install or update Distributor packages

You can deploy packages to your AWS Systems Manager managed nodes by using Distributor, a tool in AWS Systems Manager. To deploy the packages, use either the AWS Management Console or AWS Command Line Interface (AWS CLI). You can deploy one version of one package per command. You can install new packages or update existing installations in place. You can choose to deploy a specific version or choose to always deploy the latest version of a package for deployment. We recommend using State Manager, a tool in AWS Systems Manager, to install packages. Using State Manager helps ensure that your managed nodes are always running the most up-to-date version of your package.

> **Important**
>
> Packages that you install using Distributor should be uninstalled only by using Distributor. Otherwise, Systems Manager can still register the application as `INSTALLED` and lead to other unintended results.

Preference	AWS Systems Manager action	More info
Install or update a package immediately.	Run Command	• Installing or updating a package one time using the console • Installing a package one time using the AWS CLI • Updating a package one time using the AWS CLI
Install or update a package on a schedule, so that the installation always includes the default version.	State Manager	• Scheduling a package installation or update using the console • Scheduling a package installation using the AWS CLI

Preference	AWS Systems Manager action	More info
		• Scheduling a package update using the AWS CLI
Automatically install a package on new managed nodes that have a specific tag or set of tags. For example, installing the Amazon CloudWatch agent on new instances.	State Manager	One way to do this is to apply tags to new managed nodes, and then specify the tags as targets in your State Manager association. State Manager automatically installs the package in an association on managed nodes that have matching tags. See Understanding targets and rate controls in State Manager associations.

- Scheduling a package update using the AWS CLI

Installing or updating a package one time using the console

You can use the AWS Systems Manager console to install or update a package one time. When you configure a one-time installation, Distributor uses AWS Systems Manager Run Command, a tool in AWS Systems Manager, to perform the installation.

To install or update a package one time using the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.

2. In the navigation pane, choose **Distributor**.
3. On the Distributor home page, choose the package that you want to install.
4. Choose **Install one time**.

   This command opens Run Command with the command document `AWS-ConfigureAWSPackage` and your Distributor package already selected.
5. For **Document version**, select the version of the `AWS-ConfigureAWSPackage` document that you want to run.
6. For **Action**, choose **Install**.
7. For **Installation type**, choose one of the following:

   - **Uninstall and reinstall**: The package is completely uninstalled, and then reinstalled. The application is unavailable until the reinstallation is complete.
   - **In-place update**: Only new or changed files are added to the existing installation according to instructions you provide in an `update` script. The application remains available throughout the update process. This option isn't supported for AWS published packages except the `AWSEC2Launch-Agent` package.
8. For **Name**, verify that the name of the package you selected is entered.
9. (Optional) For **Version**, enter the version name value of the package. If you leave this field blank, Run Command installs the default version that you selected in Distributor.
10. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or devices manually, or by specifying a resource group.

    > **Note**
    >
    > If you don't see a managed node in the list, see Troubleshooting managed node availability.

11. For **Other parameters**:

    - For **Comment**, enter information about this command.
    - For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.
12. For **Rate Control**:

- For **Concurrency**, specify either a number or a percentage of targets on which to run the command at the same time.

  > **Note**
  >
  > If you selected targets by specifying tags or resource groups and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other targets after it fails on either a number or a percentage of managed nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

13. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

    > **Note**
    >
    > The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

14. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

    For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

15. When you're ready to install the package, choose **Run**.

16. The **Command status** area reports the progress of the execution. If the command is still in progress, choose the refresh icon in the top-left corner of the console until the **Overall status** or **Detailed status** column shows **Success** or **Failed**.
17. In the **Targets and outputs** area, choose the button next to a managed node name, and then choose **View output**.

    The command output page shows the results of your command execution.
18. (Optional) If you chose to write command output to an Amazon S3 bucket, choose **Amazon S3** to view the output log data.

Scheduling a package installation or update using the console

You can use the AWS Systems Manager console to schedule the installation or update of a package. When you schedule package installation or update, Distributor uses AWS Systems Manager State Manager to install or update.

To schedule a package installation using the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the Distributor home page, choose the package that you want to install or update.
4. For **Package**, choose **Install on a schedule**.

   This command opens State Manager to a new association that is created for you.
5. For **Name**, enter a name (for example, **`Deploy-test-agent-package`**). This is optional, but recommended. Spaces aren't allowed in the name.
6. In the **Document** list, the document name `AWS-ConfigureAWSPackage` is already selected.
7. For **Action**, verify that **Install** is selected.
8. For **Installation type**, choose one of the following:

   - **Uninstall and reinstall**: The package is completely uninstalled, and then reinstalled. The application is unavailable until the reinstallation is complete.
   - **In-place update**: Only new or changed files are added to the existing installation according to instructions you provide in an `update` script. The application remains available throughout the update process.

9. For **Name**, verify that the name of your package is entered.
10. For **Version**, if you to want to install a package version other than the latest published version, enter the version identifier.
11. For **Targets**, choose **Selecting all managed instances in this account**, **Specifying tags**, or **Manually Selecting Instance**. If you target resources by using tags, enter a tag key and a tag value in the fields provided.

    > **Note**
    >
    > You can choose managed AWS IoT Greengrass core devices by choosing either **Selecting all managed instances in this account** or **Manually Selecting Instance**.

12. For **Specify schedule**, choose **On Schedule** to run the association on a regular schedule, or **No Schedule** to run the association once. For more information about these options, see Working with associations in Systems Manager. Use the controls to create a `cron` or rate schedule for the association.
13. Choose **Create Association**.
14. On the **Association** page, choose the button next to the association you created, and then choose **Apply association now**.

    State Manager creates and immediately runs the association on the specified targets. For more information about the results of running associations, see Working with associations in Systems Manager in this guide.

For more information about working with the options in **Advanced options**, **Rate control**, and **Output options**, see Working with associations in Systems Manager.

Installing a package one time using the AWS CLI

You can run **send-command** in the AWS CLI to install a Distributor package one time. If the package is already installed, the application will be taken offline while the package is uninstalled and the new version installed in its place.

To install a package one time using the AWS CLI

- Run the following command in the AWS CLI.

```
aws ssm send-command \
```

```
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "instance-IDs" \
    --parameters '{"action":["Install"],"installationType":["Uninstall and
 reinstall"],"name":["package-name (in same account) or package-ARN (shared from
 different account)"]}'
```

> **Note**
>
> The default behavior for `installationType` is `Uninstall and reinstall`. You can omit `"installationType":["Uninstall and reinstall"]` from this command when you're installing a complete package.

The following is an example.

```
aws ssm send-command \
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "i-00000000000000" \
    --parameters '{"action":["Install"],"installationType":["Uninstall and
 reinstall"],"name":["ExamplePackage"]}'
```

For information about other options you can use with the **send-command** command, see **send-command** in the AWS Systems Manager section of the *AWS CLI Command Reference*.

Updating a package one time using the AWS CLI

You can run **send-command** in the AWS CLI to update a Distributor package without taking the associated application offline. Only new or updated files in the package are replaced.

To update a package one time using the AWS CLI

- Run the following command in the AWS CLI.

```
aws ssm send-command \
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "instance-IDs" \
    --parameters '{"action":["Install"],"installationType":["In-place
 update"],"name":["package-name (in same account) or package-ARN (shared from
 different account)"]}'
```

> **Note**
>
> When you add new or changed files, you must include `"installationType":["In-place update"]` in the command.

The following is an example.

```
aws ssm send-command \
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "i-02573cafcfEXAMPLE" \
    --parameters '{"action":["Install"],"installationType":["In-place
 update"],"name":["ExamplePackage"]}'
```

For information about other options you can use with the **send-command** command, see **send-command** in the AWS Systems Manager section of the *AWS CLI Command Reference*.

Scheduling a package installation using the AWS CLI

You can run **create-association** in the AWS CLI to install a Distributor package on a schedule. The value of `--name`, the document name, is always `AWS-ConfigureAWSPackage`. The following command uses the key `InstanceIds` to specify target managed nodes. If the package is already installed, the application will be taken offline while the package is uninstalled and the new version installed in its place.

```
aws ssm create-association \
    --name "AWS-ConfigureAWSPackage" \
    --parameters '{"action":["Install"],"installationType":["Uninstall and
 reinstall"],"name":["package-name (in same account) or package-ARN (shared from
 different account)"]}' \
    --targets [{\"Key\":\"InstanceIds\",\"Values\":[\"instance-ID1\",\"instance-
ID2\"]}]
```

> **Note**
>
> The default behavior for `installationType` is `Uninstall and reinstall`. You can omit `"installationType":["Uninstall and reinstall"]` from this command when you're installing a complete package.

The following is an example.

```
aws ssm create-association \
    --name "AWS-ConfigureAWSPackage" \
    --parameters '{"action":["Install"],"installationType":["Uninstall and
 reinstall"],"name":["Test-ConfigureAWSPackage"]}' \
    --targets [{\"Key\":\"InstanceIds\",\"Values\":[\"i-02573cafcfEXAMPLE\",
\"i-0471e04240EXAMPLE\"]}]
```

For information about other options you can use with the **create-association** command, see **create-association** in the AWS Systems Manager section of the *AWS CLI Command Reference*.

Scheduling a package update using the AWS CLI

You can run **create-association** in the AWS CLI to update a Distributor package on a schedule without taking the associated application offline. Only new or updated files in the package are replaced. The value of `--name`, the document name, is always `AWS-ConfigureAWSPackage`. The following command uses the key `InstanceIds` to specify target instances.

```
aws ssm create-association \
    --name "AWS-ConfigureAWSPackage" \
    --parameters '{"action":["Install"],"installationType":["In-place update"],"name":
["package-name (in same account) or package-ARN (shared from different account)"]}' \
    --targets [{\"Key\":\"InstanceIds\",\"Values\":[\"instance-ID1\",\"instance-
ID2\"]}]
```

> **Note**
>
> When you add new or changed files, you must include `"installationType":["In-place update"]` in the command.

The following is an example.

```
aws ssm create-association \
    --name "AWS-ConfigureAWSPackage" \
    --parameters '{"action":["Install"],"installationType":["In-place update"],"name":
["Test-ConfigureAWSPackage"]}' \
    --targets [{\"Key\":\"InstanceIds\",\"Values\":[\"i-02573cafcfEXAMPLE\",
\"i-0471e04240EXAMPLE\"]}]
```

For information about other options you can use with the **create-association** command, see **create-association** in the AWS Systems Manager section of the *AWS CLI Command Reference*.

Uninstall a Distributor package

You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to uninstall Distributor packages from your AWS Systems Manager managed nodes by using Run Command. Distributor and Run Command are tools in AWS Systems Manager. In this release, you can uninstall one version of one package per command. You can uninstall a specific version or the default version.

> **Important**
>
> Packages that you install using Distributor should be uninstalled only by using Distributor. Otherwise, Systems Manager can still register the application as `INSTALLED` and lead to other unintended results.

Topics

Uninstalling a package using the console

You can use Run Command in the Systems Manager console to uninstall a package one time. Distributor uses AWS Systems Manager Run Command to uninstall packages.

To uninstall a package using the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

3. On the Run Command home page, choose **Run command**.
4. Choose the `AWS-ConfigureAWSPackage` command document.
5. From **Action**, choose **Uninstall**
6. For **Name**, enter the name of the package that you want to uninstall.
7. For **Targets**, choose how you want to target your managed nodes. You can specify a tag key and values that are shared by the targets. You can also specify targets by choosing attributes, such as an ID, platform, and SSM Agent version.
8. You can use the advanced options to add comments about the operation, change **Concurrency** and **Error threshold** values in **Rate control**, specify output options, or configure Amazon Simple Notification Service (Amazon SNS) notifications. For more information, see Running Commands from the Console in this guide.
9. When you're ready to uninstall the package, choose **Run**, and then choose **View results**.
10. In the commands list, choose the `AWS-ConfigureAWSPackage` command that you ran. If the command is still in progress, choose the refresh icon in the top-right corner of the console.
11. When the **Status** column shows **Success** or **Failed**, choose the **Output** tab.
12. Choose **View output**. The command output page shows the results of your command execution.

Uninstalling a package using the AWS CLI

You can use the AWS CLI to uninstall a Distributor package from managed nodes by using Run Command.

To uninstall a package using the AWS CLI

- Run the following command in the AWS CLI.

```
aws ssm send-command \
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "instance-IDs" \
    --parameters '{"action":["Uninstall"],"name":["package-name (in same account)
 or package-ARN (shared from different account)"]}'
```

The following is an example.

```
aws ssm send-command \
```

```
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "i-02573cafcfEXAMPLE" \
    --parameters '{"action":["Uninstall"],"name":["Test-ConfigureAWSPackage"]}'
```

For information about other options you can use with the **send-command** command, see **send-command** in the AWS Systems Manager section of the *AWS CLI Command Reference*.

Delete a Distributor package

This section describes how to a delete a package. You can't delete a version of a package, only the entire package.

Deleting a package using the console

You can use the AWS Systems Manager console to delete a package or a package version from Distributor, a tool in AWS Systems Manager. Deleting a package deletes all versions of a package from Distributor.

To delete a package using the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the **Distributor** home page, choose the package that you want to delete.
4. On the package's details page, choose **Delete package**.
5. When you're prompted to confirm the deletion, choose **Delete package**.

Deleting a package version using the console

You can use the Systems Manager console to delete a package version from Distributor.

To delete a package version using the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Distributor**.
3. On the **Distributor** home page, choose the package that you want to delete a version of.
4. On the versions page for the package, choose the version to delete and choose **Delete version**.

5. When you're prompted to confirm the deletion, choose **Delete package version**.

Deleting a package using the command line

You can use your preferred command line tool to delete a package from Distributor.

Linux & macOS

To delete a package using the AWS CLI

1. Run the following command to list documents for specific packages. In the results of this command, look for the package that you want to delete.

```
aws ssm list-documents \
    --filters Key=Name,Values=package-name
```

2. Run the following command to delete a package. Replace *package-name* with the package name.

```
aws ssm delete-document \
    --name "package-name"
```

3. Run the **list-documents** command again to verify that the package was deleted. The package you deleted shouldn't be included in the list.

```
aws ssm list-documents \
    --filters Key=Name,Values=package-name
```

Windows

To delete a package using the AWS CLI

1. Run the following command to list documents for specific packages. In the results of this command, look for the package that you want to delete.

```
aws ssm list-documents ^
    --filters Key=Name,Values=package-name
```

2. Run the following command to delete a package. Replace *package-name* with the package name.

```
aws ssm delete-document ^
    --name "package-name"
```

3. Run the **list-documents** command again to verify that the package was deleted. The package you deleted shouldn't be included in the list.

```
aws ssm list-documents ^
    --filters Key=Name,Values=package-name
```

PowerShell

To delete a package using Tools for PowerShell

1. Run the following command to list documents for specific packages. In the results of this command, look for the package that you want to delete.

```
$filter = New-Object
 Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$filter.Key = "Name"
$filter.Values = "package-name"

Get-SSMDocumentList `
    -Filters @($filter)
```

2. Run the following command to delete a package. Replace *package-name* with the package name.

```
Remove-SSMDocument `
    -Name "package-name"
```

3. Run the **Get-SSMDocumentList** command again to verify that the package was deleted. The package you deleted shouldn't be included in the list.

```
$filter = New-Object
 Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$filter.Key = "Name"
$filter.Values = "package-name"

Get-SSMDocumentList `
```

```
    -Filters @($filter)
```

Deleting a package version using the command line

You can use your preferred command line tool to delete a package version from Distributor.

Linux & macOS

To delete a package version using the AWS CLI

1. Run the following command to list the versions of your package. In the results of this command, look for the package version that you want to delete.

```
aws ssm list-document-versions \
    --name "package-name"
```

2. Run the following command to delete a package version. Replace *package-name* with the package name and *version* with the version number.

```
aws ssm delete-document \
    --name "package-name" \
    --document-version version
```

3. Run the **list-document-versions** command to verify that the version of the package was deleted. The package version that you deleted shouldn't be found.

```
aws ssm list-document-versions \
    --name "package-name"
```

Windows

To delete a package version using the AWS CLI

1. Run the following command to list the versions of your package. In the results of this command, look for the package version that you want to delete.

```
aws ssm list-document-versions ^
    --name "package-name"
```

2. Run the following command to delete a package version. Replace *package-name* with the package name and *version* with the version number.

```
aws ssm delete-document ^
    --name "package-name" ^
    --document-version version
```

3. Run the **list-document-versions** command to verify that the version of the package was deleted. The package version that you deleted shouldn't be found.

```
aws ssm list-document-versions ^
    --name "package-name"
```

PowerShell

To delete a package version using Tools for PowerShell

1. Run the following command to list the versions of your package. In the results of this command, look for the package version that you want to delete.

```
Get-SSMDocumentVersionList `
    -Name "package-name"
```

2. Run the following command to delete a package version. Replace *package-name* with the package name and *version* with the version number.

```
Remove-SSMDocument `
    -Name "package-name" `
    -DocumentVersion version
```

3. Run the **Get-SSMDocumentVersionList** command to verify that the version of the package was deleted. The package version that you deleted shouldn't be found.

```
Get-SSMDocumentVersionList `
    -Name "package-name"
```

For information about other options you can use with the **list-documents** command, see **list-documents** in the AWS Systems Manager section of the *AWS CLI Command Reference*. For

information about other options you can use with the **delete-document** command, see **delete-document**.

Auditing and logging Distributor activity

You can use AWS CloudTrail to audit activity related to Distributor, a tool in AWS Systems Manager. For more information about auditing and logging options for Systems Manager, see Logging and monitoring in AWS Systems Manager.

Audit Distributor activity using CloudTrail

CloudTrail captures API calls made in the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), and the Systems Manager SDK. The information can be viewed in the CloudTrail console or stored in an Amazon Simple Storage Service (Amazon S3) bucket. One bucket is used for all CloudTrail logs for your account.

Logs of Run Command and State Manager actions show document creation, package installation, and package uninstallation activity. Run Command and State Manager are tools in AWS Systems Manager. For more information about viewing and using CloudTrail logs of Systems Manager activity, see Logging AWS Systems Manager API calls with AWS CloudTrail.

Troubleshooting AWS Systems Manager Distributor

The following information can help you troubleshoot problems that might occur when you use Distributor, a tool in AWS Systems Manager.

Topics

Wrong package with the same name is installed

Problem: You've installed a package, but Distributor installed a different package instead.

Cause: During installation, Systems Manager finds AWS published packages as results before user-defined external packages. If your user-defined package name is the same as an AWS published package name, the AWS package is installed instead of your package.

Solution: To avoid this problem, name your package something different from the name for an AWS published package.

Error: Failed to retrieve manifest: Could not find latest version of package

Problem: You received an error like the following.

```
Failed to retrieve manifest: ResourceNotFoundException: Could not find the latest
 version of package
arn:aws:ssm:::package/package-name status code: 400, request id: guid
```

Cause: You're using a version of SSM Agent with Distributor that is earlier than version 2.3.274.0.

Solution: Update the version of SSM Agent to version 2.3.274.0 or later. For more information, see Updating the SSM Agent using Run Command or Walkthrough: Automatically update SSM Agent with the AWS CLI.

Error: Failed to retrieve manifest: Validation exception

Problem: You received an error like the following.

```
Failed to retrieve manifest: ValidationException: 1 validation error detected: Value
 'documentArn'
at 'packageName' failed to satisfy constraint: Member must satisfy regular expression
 pattern:
arn:aws:ssm:region-id:account-id:package/package-name
```

Cause: You're using a version of SSM Agent with Distributor that is earlier than version 2.3.274.0.

Solution: Update the version of SSM Agent to version 2.3.274.0 or later. For more information, see Updating the SSM Agent using Run Command or Walkthrough: Automatically update SSM Agent with the AWS CLI.

Package isn't supported (package is missing install action)

Problem: You received an error like the following.

```
Package is not supported (package is missing install action)
```

Cause: The package directory structure is incorrect.

Solution: Don't zip a parent directory containing the software and required scripts. Instead, create a `.zip` file of all the required contents directly in the absolute path. To verify the `.zip` file was created correctly, unzip the target platform directory and review the directory structure. For example, the install script absolute path should be */ExamplePackage_targetPlatform/install.sh*.

Error: Failed to download manifest : Document with name does not exist

Problem: You received an error like the following.

```
Failed to download manifest - failed to retrieve package document description:
 InvalidDocument: Document with name filename does not exist.
```

Cause 1: Distributor can't find the package by the package name when sharing a Distributor package from another account.

Solution 1: When sharing a package from another account, use the full Amazon Resource Name (ARN) for the package and not just its name.

Cause 2: When using a VPC, you haven't provided your IAM instance profile with access to the AWS managed S3 bucket that contains the document `AWS-ConfigureAWSPackage` for the AWS Region you are targeting.

Solution 2: Ensure that your IAM instance profile provides SSM Agent with access to the AWS managed S3 bucket that contains the document `AWS-ConfigureAWSPackage` for the AWS Region you are targeting, as explained in SSM Agent communications with AWS managed S3 buckets.

Upload failed.

Problem: You received an error like the following.

```
Upload failed. At least one of your files was not successfully uploaded to your S3
 bucket.
```

Cause: The name of your software package includes a space. For example, `Hello World.msi` would fail to upload.

Error: Failed to find platform: no manifest found for platform: oracle, version 8.9, architecture x86_64

Problem: You received an error like the following.

```
Failed to find platform: no manifest found for platform: oracle, version 8.9,
 architecture x86_64
```

Cause: The error means that the JSON package manifest does not have any definition for that platform, in this case, Oracle Linux..

Solution: Download the package you want to distribute from the Trend Micro Deep Security Software site. Create an `.rpm` software package using the Distributor Simple workflow process. Set the following values for the package and complete the upload software package using Distributor:

```
Platform version: _any
Target platform: oracle
Architecture: x86_64
```

AWS Systems Manager Fleet Manager

Fleet Manager, a tool in AWS Systems Manager, is a unified user interface (UI) experience that helps you remotely manage your nodes running on AWS or on premises. With Fleet Manager, you can view the health and performance status of your entire server fleet from one console. You can also gather data from individual nodes to perform common troubleshooting and management tasks from the console. This includes connecting to Windows instances using the Remote Desktop Protocol (RDP), viewing folder and file contents, Windows registry management, operating system user management, and more.

To get started with Fleet Manager, open the Systems Manager console. In the navigation pane, choose **Fleet Manager**.

Who should use Fleet Manager?

Any AWS customer who wants a centralized way to manage their node fleet should use Fleet Manager.

How can Fleet Manager benefit my organization?

Fleet Manager offers these benefits:

- Perform a variety of common systems administration tasks without having to manually connect to your managed nodes.
- Manage nodes running on multiple platforms from a single unified console.
- Manage nodes running different operating systems from a single unified console.
- Improve the efficiency of your systems administration.

What are the features of Fleet Manager?

Key features of Fleet Manager include the following:

- **Access the Red Hat Knowledgebase Portal**

  Access binaries, knowledge-shares, and discussion forums on the Red Hat Knowledgebase Portal through your Red Hat Enterprise Linux (RHEL) instances.

- **Managed node status**

  View which managed instances are `running` and which are `stopped`. For more information about stopped instances, see Stop and start your instance in the *Amazon EC2 User Guide*. For AWS IoT Greengrass core devices, you can view which are `online`, `offline`, or show a status of `Connection lost`.

  > **Note**
  >
  > If you stopped your managed instance before July 12, 2021, it won't display the `stopped` marker. To show the marker, start and stop the instance.

- **View instance information**

  View information about the folder and file data stored on the volumes attached to your managed instances, performance data about your instances in real-time, and log data stored on your instances.

- **View edge device information**

View the AWS IoT Greengrass Thing name for the device, SSM Agent ping status and version, and more.

- **Manage accounts and registry**

  Manage operating system (OS) user accounts on your instances and registry on your Windows instances.

- **Control access to features**

  Control access to Fleet Manager features using AWS Identity and Access Management (IAM) policies. With these policies, you can control which individual users or groups in your organization can use various Fleet Manager features, and which managed nodes they can manage.

Topics

Setting up Fleet Manager

Before users in your AWS account can use Fleet Manager, a tool in AWS Systems Manager, to monitor and manage your managed nodes, they must be granted the necessary permissions. In addition, any Amazon Elastic Compute Cloud (Amazon EC2) instances; AWS IoT Greengrass core devices; and on-premises servers, edge devices, and virtual machines (VMs) to be monitored and managed using Fleet Manager must be Systems Manager *managed nodes*. A managed node is any machine configured for use with Systems Manager in hybrid and multicloud environments.

This means your nodes must meet certain prerequisites and be configured with the AWS Systems Manager Agent (SSM Agent).

Depending on the machine type, refer to one of the following topics to ensure your machines meet the requirements for managed nodes.

- Amazon EC2 instances: Managing EC2 instances with Systems Manager

> **Tip**
>
> You can also use Quick Setup, a tool in AWS Systems Manager, to help you quickly configure your Amazon EC2 instances as managed instances in an individual account. If your business or organization uses AWS Organizations, you can also configure instances across multiple organizational units (OUs) and AWS Regions. For more information about using Quick Setup to configure managed instances, see Set up Amazon EC2 host management using Quick Setup.

- On-premises and other server types in the cloud: Managing nodes in hybrid and multicloud environments with Systems Manager
- AWS IoT Greengrass (edge) devices: Managing edge devices with Systems Manager

Sample policies

- Controlling access to Fleet Manager

Controlling access to Fleet Manager

To use Fleet Manager, a tool in AWS Systems Manager, your AWS Identity and Access Management (IAM) user or role must have the required permissions. You can create an IAM policy that provides access to all Fleet Manager features, or modify your policy to grant access to the features you choose. You then grant these permissions to users, or identities, in your account.

Task 1: Create IAM policies to define access permissions

Follow one of the methods provided in the followig topic in the *IAM User Guide* to create an IAM to provide identities (users, roles, or user groupss) with access to Fleet Manager:

- Define custom IAM permissions with customer managed policies

You can use one of the sample policies we provide below, or modify them according to the permissions you want to grant. We provide sample policies for full Fleet Manager access and read-only access.

Task 2: Attach the IAM policies to users to grant permissions

After you have created the IAM policy or policies that define access permissions to Fleet Manager, use one of the following procedures in the *IAM User Guide* to grant these permissions to identities in your account:

- Adding IAM identity permissions (console)
- Adding IAM identity permissions (AWS CLI)
- Adding IAM identity permissions (AWS API)

Topics

Sample policy for Fleet Manager administrator access

The following policy provides permissions to all Fleet Manager features. This means a user can create and delete local users and groups, modify group membership for any local group, and modify Windows Server registry keys or values. Replace each *example resource placeholder* with your own information.

                }
            }
        }
    ]
}
```

Working with managed nodes

A *managed node* is any machine configured for AWS Systems Manager. You can configure the following machine types as managed nodes:

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Servers on your own premises (on-premises servers)
- AWS IoT Greengrass core devices
- AWS IoT and non-AWS edge devices
- Virtual machines (VMs), including VMs in other cloud environments

In the Systems Manager console, any machine prefixed with "mi-" has been configured as a managed node using a *hybrid activation*. Edge devices display their AWS IoT Thing name.

> **Note**
>
> The only supported feature for macOS instances is viewing the file system.

About Systems Manager instances tiers

AWS Systems Manager offers a standard-instances tier and an advanced-instances tier. Both support managed nodes in your hybrid and multicloud environment. The standard-instances tier allows you to register a maximum of 1,000 machines per AWS account per AWS Region. If you need to register more than 1,000 machines in a single account and Region, then use the advanced-instances tier. You can create as many managed nodes as you like in the advanced-instances tier. All managed nodes configured for Systems Manager are priced on a pay-per-use basis. For more information about enabling the advanced instances tier, see Turning on the advanced-instances tier. For more information about pricing, see AWS Systems Manager Pricing.

Note the following additional information about the standard-instances tier and advanced-instances tier:

- Advanced instances also allow you to connect to your non-EC2 nodes in a hybrid and multicloud environment by using AWS Systems Manager Session Manager. Session Manager provides interactive shell access to your instances. For more information, see AWS Systems Manager Session Manager.
- The standard-instances quota also applies to EC2 instances that use a Systems Manager on-premises activation (which isn't a common scenario).
- To patch applications released by Microsoft on virtual machines (VMs) on-premises instances, activate the advanced-instances tier. There is a charge to use the advanced-instances tier. There is no additional charge to patch applications released by Microsoft on Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information, see Patching applications released by Microsoft on Windows Server.

Display managed nodes

If you don't see your managed nodes listed in the console, then do the following:

1. Verify that the console is open in the AWS Region where you created your managed nodes. You can switch Regions by using the list in the top, right corner of the console.
2. Verify that the setup steps for your managed nodes meet Systems Manager requirements. For information, see Setting up managed nodes for AWS Systems Manager.
3. For non-EC2 machines, verify that you completed the hybrid activation process. For more information, see Managing nodes in hybrid and multicloud environments with Systems Manager.

Note the following additional information:

- The Fleet Manager console does not display Amazon EC2 nodes that have been terminated.
- Systems Manager requires accurate time references in order to perform operations on your machines. If the date and time aren't set correctly on your managed nodes, the machines might not match the signature date of your API requests. For more information, see Use cases and best practices.
- When you create or edit tags, the system can take up to one hour to display changes in the table filter.
- After the status of a managed node has been `Connection Lost` for at least 30 days, the node might no longer be listed in the Fleet Manager console. To restore it to the list, the issue that caused the lost connection must be resolved. For troubleshooting tips, see Troubleshooting managed node availability.

Verify Systems Manager support on a managed node

AWS Config provides AWS Managed Rules, which are predefined, customizable rules that AWS Config uses to evaluate whether your AWS resource configurations comply with common best practices. AWS Config Managed Rules include the ec2-instance-managed-by-systems-manager rule. This rule checks whether the Amazon EC2 instances in your account are managed by Systems Manager. For more information, see AWS Config Managed Rules.

Increase security posture on managed nodes

For information about increasing your security posture against unauthorized root-level commands on your managed nodes, see Restricting access to root-level commands through SSM Agent.

Deregister managed nodes

You can deregister managed nodes at any time. For example, if you're managing multiple nodes with the same AWS Identity and Access Management (IAM) role and you notice any kind of malicious behavior, you can deregister any number of machines at any point. (In order to re-register the same machine, you must use a different hybrid Activation Code and Activation ID than previously used to register it.) For information about deregistering managed nodes, see Deregistering managed nodes in a hybrid and multicloud environment.

Configuring instance tiers

This topic describes the scenarios when you must activate the advanced-instanced tier.

AWS Systems Manager offers a standard-instances tier and an advanced-instances tier for non-EC2 machines in a hybrid and multicloud environment.

You can register up to 1,000 standard hybrid-activated nodes per account per AWS Region at no additional cost. However, registering more than 1,000 hybrid nodes requires that you activate the advanced-instances tier. There is a charge to use the advanced-instances tier. For more information, see AWS Systems Manager Pricing.

Even with fewer than 1,000 registered hybrid-activated nodes, two other scenarios require the advanced-instances tier:

- You want to use Session Manager to connect to non-EC2 nodes.
- You want to patch applications (not operating systems) released by Microsoft on non-EC2 nodes.

> **Note**
>
> There is no charge to patch applications released by Microsoft on Amazon EC2 instances.

Advanced-instances tier detailed scenarios

The following information provides details on the three scenarios for which you must activate the advanced-instances tier.

Scenario 1: You want to register more than 1,000 hybrid-activated nodes

Using the standard-instances tier, you can register a maximum of 1,000 non-EC2 nodes in a hybrid and multicloud environment per AWS Region in a specific account without additional

charge. If you need to register more than 1,000 non-EC2 nodes in a Region, you must use the advanced-instances tier. You can then activate as many machines for your hybrid and multicloud environment as you want. Charges for the advanced-instances tier are based on the number of advanced nodes activated as Systems Manager managed nodes and the hours those nodes are running.

All Systems Manager managed nodes that use the activation process described in Create a hybrid activation to register nodes with Systems Manager are then subject to charge if you exceed 1,000 on-premises nodes in a Region in a specific account .

> **Note**
>
> You can also activate existing Amazon Elastic Compute Cloud (Amazon EC2) instances using Systems Manager hybrid activations and work with them as non-EC2 instances, such as for testing. These also qualify as hybrid nodes. This isn't a common scenario.

Scenario 2: Patching Microsoft-released applications on hybrid-activated nodes

The advanced-instances tier is also required if you want to patch Microsoft-released applications on non-EC2 nodes in a hybrid and multicloud environment. If you activate the advanced-instances tier to patch Microsoft applications on non-EC2 nodes, charges are then incurred for all on-premises nodes, even if you have fewer than 1,000.

There is no additional charge to patch applications released by Microsoft on Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information, see Patching applications released by Microsoft on Windows Server.

Scenario 3: Connecting to hybrid-activated nodes using Session Manager

Session Manager provides interactive shell access to your instances. To connect to hybrid-activated managed nodes using Session Manager, you must activate the advanced-instances tier. Charges are then incurred for all hybrid-activated nodes, even if you have fewer than 1,000.

Summary: When do I need the advanced-instances tier?

Use the following table to review when you must use the advanced-instances tier, and for which scenarios additional charges apply.

Scenario	Advanced-instances tier required?	Additional charges apply?
The number of hybrid-activated nodes in my Region in a specific account is more than 1,000.	Yes	Yes
I want to use Patch Manager to patch Microsoft-released applications on any number of hybrid-activated nodes, even less than 1,000.	Yes	Yes
I want to use Session Manager to connect to any number of hybrid-activated nodes, even less than 1,000.	Yes	Yes
1. The number of hybrid-activated nodes in a Region in a specific account is 1,000 or less; and 2. I am not patching Microsoft applications on any hybrid-activated nodes; and 3. I am not connecting to any hybrid-activated nodes using Session Manager.	No	No

- Reverting from the advanced-instances tier to the standard-instances tier

Turning on the advanced-instances tier

AWS Systems Manager offers a standard-instances tier and an advanced-instances tier for non-EC2 machines in a hybrid and multicloud environment. The standard-instances tier lets you register a maximum of 1,000 hybrid-activated machines per AWS account per AWS Region. The advanced-instances tier is also required to use Patch Manager to patch Microsoft-released applications on non-EC2 nodes, and to connect to non-EC2 nodes using Session Manager. For more information, see Turning on the advanced-instances tier.

This section describes how to configure your hybrid and multicloud environment to use the advanced-instances tier.

Before you begin

Review pricing details for advanced instances. Advanced instances are available on a per-use-basis. For more information see, AWS Systems Manager Pricing.

Configuring permissions to turn on the advanced-instances tier

Verify that you have permission in AWS Identity and Access Management (IAM) to change your environment from the standard-instances tier to the advanced-instances tier. You must either have the `AdministratorAccess` IAM policy attached to your user, group, or role, or you must have permission to change the Systems Manager activation-tier service setting. The activation-tier setting uses the following API operations:

- GetServiceSetting
- UpdateServiceSetting
- ResetServiceSetting

Use the following procedure to add an inline IAM policy to a user account. This policy allows a user to view the current managed-instance tier setting. This policy also allows the user to change or reset the current setting in the specified AWS account and AWS Region.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Users**.
3. In the list, choose the name of the user to embed a policy in.
4. Choose the **Permissions** tab.

5. On the right side of the page, under **Permission policies**, choose **Add inline policy**.
6. Choose the **JSON** tab.
7. Replace the default content with the following:

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetServiceSetting"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:ResetServiceSetting",
                "ssm:UpdateServiceSetting"
            ],
            "Resource": "arn:aws:ssm:us-east-1:111122223333:servicesetting/
ssm/managed-instance/activation-tier"
        }
    ]
}
```

8. Choose **Review policy**.
9. On the **Review policy** page, for **Name**, enter a name for the inline policy. For example: **`Managed-Instances-Tier`**.
10. Choose **Create policy**.

Administrators can specify read-only permission by assigning the following inline policy to the user.

JSON

```
{
```

```

```

For more information about creating and editing IAM policies, see Creating IAM Policies in the *IAM User Guide*.

Turning on the advanced-instances tier (console)

The following procedure shows you how to use the Systems Manager console to change *all* non-EC2 nodes that were added using managed-instance activation, in the specified AWS account and AWS Region, to use the advanced-instances tier.

Before you begin

Verify that the console is open in the AWS Region where you created your managed instances. You can switch Regions by using the list in the top, right corner of the console.

Verify that you have completed the setup requirements for your Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 machines in a hybrid and multicloud environment. For information, see Setting up managed nodes for AWS Systems Manager.

> **Important**
>
> The following procedure describes how to change an account-level setting. This change results in charges being billed to your account.

To turn on the advanced-instances tier (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Settings**, and then choose **Change instance tier settings**.
4. Review the information in the dialog box about changing account settings.
5. If you approve, choose the option to accept, and then choose **Change setting**.

The system can take several minutes to complete the process of moving all instances from the standard-instances tier to the advanced-instances tier.

> **Note**
>
> For information about changing back to the standard-instances tier, see Reverting from the advanced-instances tier to the standard-instances tier.

Turning on the advanced-instances tier (AWS CLI)

The following procedure shows you how to use the AWS Command Line Interface to change *all* on-premises servers and VMs that were added using managed-instance activation, in the specified AWS account and AWS Region, to use the advanced-instances tier.

> **Important**
>
> The following procedure describes how to change an account-level setting. This change results in charges being billed to your account.

To turn on the advanced-instances tier using the AWS CLI

1. Open the AWS CLI and run the following command. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm update-service-setting \
       --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier \
       --setting-value advanced
   ```

   Windows

   ```
   aws ssm update-service-setting ^
       --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier ^
       --setting-value advanced
   ```

   There is no output if the command succeeds.

2. Run the following command to view the current service settings for managed nodes in the current AWS account and AWS Region.

   Linux & macOS

   ```
   aws ssm get-service-setting \
       --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier
   ```

   Windows

   ```
   aws ssm get-service-setting ^
       --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier
   ```

   The command returns information like the following.

   ```
   {
   ```

```
    "ServiceSetting": {
        "SettingId": "/ssm/managed-instance/activation-tier",
        "SettingValue": "advanced",
        "LastModifiedDate": 1555603376.138,
        "LastModifiedUser": "arn:aws:sts::123456789012:assumed-role/
Administrator/User_1",
        "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/managed-
instance/activation-tier",
        "Status": "PendingUpdate"
    }
}
```

Turning on the advanced-instances tier (PowerShell)

The following procedure shows you how to use the AWS Tools for Windows PowerShell to change *all* on-premises servers and VMs that were added using managed-instance activation, in the specified AWS account and AWS Region, to use the advanced-instances tier.

> **Important**
>
> The following procedure describes how to change an account-level setting. This change results in charges being billed to your account.

To turn on the advanced-instances tier using PowerShell

1. Open AWS Tools for Windows PowerShell and run the following command. Replace each *example resource placeholder* with your own information.

   ```
   Update-SSMServiceSetting `
       -SettingId "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-
   instance/activation-tier" `
       -SettingValue "advanced"
   ```

   There is no output if the command succeeds.

2. Run the following command to view the current service settings for managed nodes in the current AWS account and AWS Region.

   ```
   Get-SSMServiceSetting `
   ```

```
    -SettingId "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-
instance/activation-tier"
```

The command returns information like the following.

```
ARN:arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/managed-instance/
activation-tier
LastModifiedDate : 4/18/2019 4:02:56 PM
LastModifiedUser : arn:aws:sts::123456789012:assumed-role/Administrator/User_1
SettingId        : /ssm/managed-instance/activation-tier
SettingValue     : advanced
Status           : PendingUpdate
```

The system can take several minutes to complete the process of moving all nodes from the standard-instances tier to the advanced-instances tier.

> **Note**
>
> For information about changing back to the standard-instances tier, see Reverting from the advanced-instances tier to the standard-instances tier.

Reverting from the advanced-instances tier to the standard-instances tier

This section describes how to change hybrid-activated nodes running in the advanced-instances tier back to the standard-instances tier. This configuration applies to all hybrid-activated nodes in an AWS account and a single AWS Region.

Before you begin

Review the following important details.

> **Note**
>
> - You can't revert back to the standard-instance tier if you're running more than 1,000 hybrid-activated nodes in the account and Region. You must first deregister nodes until you have 1,000 or fewer. This also applies to Amazon Elastic Compute Cloud (Amazon EC2) instances that use a Systems Manager hybrid activation (which isn't a common

scenario). For more information, see Deregistering managed nodes in a hybrid and multicloud environment.

- After you revert, you won't be able to use Session Manager, a tool in AWS Systems Manager, to interactively access your hybrid-activated nodes.
- After you revert, you won't be able to use Patch Manager, a tool in AWS Systems Manager, to patch applications released by Microsoft on hybrid-activated nodes.
- The process of reverting all hybrid-activated nodes back to the standard-instance tier can take 30 minutes or more to complete.

This section describes how to revert all hybrid-activated nodes in an AWS account and AWS Region from the advanced-instances tier to the standard-instances tier.

Reverting to the standard-instances tier (console)

The following procedure shows you how to use the Systems Manager console to change all hybrid-activated nodes in your hybrid and multicloud environment to use the standard-instances tier in the specified AWS account and AWS Region.

To revert to the standard-instances tier (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the **Account settings** dropdown and choose **Instance tier settings**.
4. Choose **Change account setting**.
5. Review the information in the pop-up about changing account settings, and then if you approve, choose the option to accept and continue.

Reverting to the standard-instances tier (AWS CLI)

The following procedure shows you how to use the AWS Command Line Interface to change all hybrid-activated nodes in your hybrid and multicloud environment to use the standard-instances tier in the specified AWS account and AWS Region.

To revert to the standard-instances tier using the AWS CLI

1. Open the AWS CLI and run the following command. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm update-service-setting \
       --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier \
       --setting-value standard
   ```

   Windows

   ```
   aws ssm update-service-setting ^
       --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier ^
       --setting-value standard
   ```

   There is no output if the command succeeds.

2. Run the following command 30 minutes later to view the settings for managed instances in the current AWS account and AWS Region.

   Linux & macOS

   ```
   aws ssm get-service-setting \
       --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier
   ```

   Windows

   ```
   aws ssm get-service-setting ^
       --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier
   ```

   The command returns information like the following.

   ```
   {
   ```

```
    "ServiceSetting": {
        "SettingId": "/ssm/managed-instance/activation-tier",
        "SettingValue": "standard",
        "LastModifiedDate": 1555603376.138,
        "LastModifiedUser": "System",
        "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/managed-
instance/activation-tier",
        "Status": "Default"
    }
}
```

The status changes to *Default* after the request has been approved.

Reverting to the standard-instances tier (PowerShell)

The following procedure shows you how to use AWS Tools for Windows PowerShell to change hybrid-activated nodes in your hybrid and multicloud environment to use the standard-instances tier in the specified AWS account and AWS Region.

To revert to the standard-instances tier using PowerShell

1. Open AWS Tools for Windows PowerShell and run the following command.

```
Update-SSMServiceSetting `
    -SettingId "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-
instance/activation-tier" `
    -SettingValue "standard"
```

There is no output if the command succeeds.

2. Run the following command 30 minutes later to view the settings for managed instances in the current AWS account and AWS Region.

```
Get-SSMServiceSetting `
    -SettingId "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-
instance/activation-tier"
```

The command returns information like the following.

```
ARN: arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/managed-instance/
activation-tier
```

```
LastModifiedDate : 4/18/2019 4:02:56 PM
LastModifiedUser : System
SettingId        : /ssm/managed-instance/activation-tier
SettingValue     : standard
Status           : Default
```

The status changes to *Default* after the request has been approved.

Resetting passwords on managed nodes

You can reset the password for any user on a managed node. This includes Amazon Elastic Compute Cloud (Amazon EC2) instances; AWS IoT Greengrass core devices; and on-premises servers, edge devices, and virtual machines (VMs) that are managed by AWS Systems Manager. The password reset functionality is built on Session Manager, a tool in AWS Systems Manager. You can use this functionality to connect to managed nodes without opening inbound ports, maintaining bastion hosts, or managing SSH keys.

Password reset is useful when a user has forgotten a password, or when you want to quickly update a password without making an RDP or SSH connection to a managed node.

Prerequisites

Before you can reset the password on a managed node, the following requirements must be met:

- The managed node on which you want to change a password must be a Systems Manager managed node. Also, SSM Agent version 2.3.668.0 or later must be installed on the managed node.) For information about installing or updating SSM Agent, see Working with SSM Agent.
- The password reset functionality uses the Session Manager configuration that is set up for your account to connect to the managed node. Therefore, the prerequisites for using Session Manager must have been completed for your account in the current AWS Region. For more information, see Setting up Session Manager.

  > **Note**
  >
  > Session Manager support for on-premises nodes is provided for the advanced-instances tier only. For more information, see Turning on the advanced-instances tier.

- The AWS user who is changing the password must have the `ssm:SendCommand` permission for the managed node. For more information, see Restricting Run Command access based on tags.

Restricting access

You can limit a user's ability to reset passwords to specific managed nodes. This is done by using identity-based policies for the Session Manager `ssm:StartSession` operation with the `AWS-PasswordReset` SSM document. For more information, see Control user session access to instances.

Encrypting data

Turn on AWS Key Management Service (AWS KMS) complete encryption for Session Manager data to use the password reset option for managed nodes. For more information, see Turn on KMS key encryption of session data (console).

Reset a password on a managed node

You can reset a password on a Systems Manager managed node using the Systems Manager **Fleet Manager** console or the AWS Command Line Interface (AWS CLI).

To change the password on a managed node (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the node that needs a new password.
4. Choose **Instance actions, Reset password**.
5. For **User name**, enter the name of the user for which you're changing the password. This can be any user name that has an account on the node.
6. Choose **Submit**.
7. Follow the prompts in the **Enter new password** command window to specify the new password.

> **Note**
>
> If the version of SSM Agent on the managed node doesn't support password resets, you're prompted to install a supported version using Run Command, a tool in AWS Systems Manager.

To reset the password on a managed node (AWS CLI)

1. To reset the password for a user on a managed node, run the following command. Replace each *example resource placeholder* with your own information.

   > **Note**
   >
   > To use the AWS CLI to reset a password, the Session Manager plugin must be installed on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.

   Linux & macOS

   ```
   aws ssm start-session \
       --target instance-id \
       --document-name "AWS-PasswordReset" \
       --parameters '{"username": ["user-name"]}'
   ```

   Windows

   ```
   aws ssm start-session ^
       --target instance-id ^
       --document-name "AWS-PasswordReset" ^
       --parameters username="user-name"
   ```

2. Follow the prompts in the **Enter new password** command window to specify the new password.

Troubleshoot password resets on managed nodes

Many password reset issues can be resolved by ensuring that you have completed the password reset prerequisites. For other problems, use the following information to help you troubleshoot password reset issues.

Topics

- Managed node not available
- SSM Agent not up-to-date (console)
- Password reset options aren't provided (AWS CLI)

- No authorization to run ssm:SendCommand
- Session Manager error message

Managed node not available

Problem: You want to reset the password for a managed node on the **Managed instances** console page, but the node isn't in the list.

- **Solution**: The managed node you want to connect to might not be configured for Systems Manager. To use an EC2 instance with Systems Manager, an AWS Identity and Access Management (IAM) instance profile that gives Systems Manager permission to perform actions on your instances must be attached to the instance. For information, see Configure instance permissions required for Systems Manager.

  To use a non-EC2 machine with Systems Manager, create an IAM service role that gives Systems Manager permission to perform actions on your managed nodes. For more information, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments. (Session Manager support for on-premises servers and VMs is provided for the advanced-instances tier only. For more information, see Turning on the advanced-instances tier.)

SSM Agent not up-to-date (console)

Problem: A message reports that the version of SSM Agent doesn't support password reset functionality.

- **Solution**: Version 2.3.668.0 or later of SSM Agent is required to perform password resets. In the console, you can update the agent on the managed node by choosing **Update SSM Agent**.

  An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Password reset options aren't provided (AWS CLI)

Problem: You connect successfully to a managed node using the AWS CLI `start-session` command. You specified the SSM Document `AWS-PasswordReset` and provided a valid user name, but prompts to change the password aren't displayed.

- **Solution**: The version of SSM Agent on the managed node isn't up-to-date. Version 2.3.668.0 or later is required to perform password resets.

  An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

No authorization to run `ssm:SendCommand`

Problem: You attempt to connect to a managed node to change the password but receive an error message saying that you aren't authorized to run `ssm:SendCommand` on the managed node.

- **Solution**: Your IAM policy must include permission to run the `ssm:SendCommand` command. For information, see Restricting Run Command access based on tags.

Session Manager error message

Problem: You receive an error message related to Session Manager.

- **Solution**: Password reset support requires that Session Manager is configured correctly. For information, see Setting up Session Manager and Troubleshooting Session Manager.

Deregistering managed nodes in a hybrid and multicloud environment

If you no longer want to manage an on-premises server, edge device, or virtual machine (VM) by using AWS Systems Manager, then you can deregister it. Deregistering a hybrid-activated node removes it from the list of managed nodes in Systems Manager. AWS Systems Manager Agent (SSM Agent) running on the hybrid-activated node won't be able to refresh its authorization token because it's no longer registered. SSM Agent hibernates and reduce its ping frequency to

Systems Manager in the cloud to once per hour. Systems Manager stores the command history for a deregistered managed node for 30 days.

> **Note**
>
> You can reregister an on-premises server, edge device, or VM using the same activation code and ID as long as you haven't reached the instance limit for the designated activation code and ID. You can verify the instance limit in the console by choosing **Node tools**, and then choose **Hybrid activations**. If the value of **Registered instances** is less than **Registration limit**, you can reregister a machine using the same activation code and ID. If it's greater, you must use a different activation code and ID.

The following procedure describes how to deregister a hybrid-activated node by using the Systems Manager console. For information about how to do this by using the AWS Command Line Interface, see deregister-managed-instance.

For related information, see the following topics:

- Deregister and reregister a managed node (Linux) (Linux)
- Deregister and reregister a managed node (Windows Server) (Windows Server)

To deregister a hybrid-activated node (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the checkbox next to the managed node that you want to deregister.
4. Choose **Node actions, Tools, Deregister this managed node**.
5. Review the information in the **Deregister this managed node** dialog box. If you approve, choose **Deregister**.

Working with OS file systems using Fleet Manager

You can use Fleet Manager, a tool in AWS Systems Manager, to work with the file system on your managed nodes. Using Fleet Manager, you can view information about the directory and file data

stored on the volumes attached to your managed nodes. For example, you can view the name, size, extension, owner, and permissions for your directories and files. Up to 10,000 lines of file data can be previewed as text from the Fleet Manager console. You can also use this feature to `tail` files. When using `tail` to view file data, the last 10 lines of the file are displayed initially. As new lines of data are written to the file, the view is updated in real time. As a result, you can review log data from the console, which can improve the efficiency of your troubleshooting and systems administration. Additionally, you can create directories and copy, cut, paste, rename, or delete files and directories.

We recommend creating regular backups, or taking snapshots of the Amazon Elastic Block Store (Amazon EBS) volumes attached to your managed nodes. When copying, or cutting and pasting files, existing files and directories in the destination path with the same name as the new files or directories are replaced. Serious problems can occur if you replace or modify system files and directories. AWS doesn't guarantee that these problems can be solved. Modify system files at your own risk. You're responsible for all file and directory changes, and ensuring you have backups. Deleting or replacing files and directories can't be undone.

> **Note**
>
> Fleet Manager uses Session Manager, a tool in AWS Systems Manager, to view text previews and `tail` files. For Amazon Elastic Compute Cloud (Amazon EC2) instances, the instance profile attached to your managed instances must provide permissions for Session Manager to use this feature. For more information about adding Session Manager permissions to an instance profile, see Add Session Manager permissions to an existing IAM role.

Topics

Viewing the OS file system using Fleet Manager

You can use Fleet Manager to view the OS file system on a Systems Manager managed node.

To view the file OS system using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the file system you want to view.
4. Choose **Tools, File system**.

Previewing OS files using Fleet Manager

You can use Fleet Manager to preview text files on an OS.

To view text previews of files using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files you want to preview.
4. Choose **Tools, File system**.
5. Select the **File name** of the directory that contains the file you want to preview.
6. Choose the button next to the file whose content you want to preview.
7. Choose **Actions, Preview as text**.

Tailing OS files using Fleet Manager

You can use Fleet Manager to tail a file on a managed node.

To tail OS files with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.

3. Select the link of the managed node with the files you want to tail.
4. Choose **Tools, File system**.
5. Select the **File name** of the directory that contains the file you want to tail.
6. Choose the button next to the file whose content you want to tail.
7. Choose **Actions, Tail file**.

Copying, cutting, and pasting OS files or directories using Fleet Manager

You can use Fleet Manager to copy, cut, and paste OS files on a managed node.

To copy or cut and paste files or directories using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files you want to copy, or cut and paste.
4. Choose **Tools, File system**.
5. To copy or cut a file, select the **File name** of the directory that contains the file you want to copy or cut. To copy or cut a directory, choose the button next to the directory that you want to copy or cut and then proceed to step 8.
6. Choose the button next to the file you want to copy or cut.
7. In the **Actions** menu, choose **Copy** or **Cut**.
8. In the **File system** view, choose the button next to the directory you want to paste the file in.
9. In the **Actions** menu, choose **Paste**.

Renaming OS files and directories using Fleet Manager

You can use Fleet Manager to rename files and directories on a managed node in your account.

To rename files or directories with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.

3. Select the link of the managed node with the files or directories you want to rename.
4. Choose **Tools, File system**.
5. To rename a file, select the **File name** of the directory that contains the file you want to rename. To rename a directory, choose the button next to the directory that you want to rename and then proceed to step 8.
6. Choose the button next to the file whose content you want to rename.
7. Choose **Actions, Rename**.
8. For **File name**, enter the new name for the file and select **Rename**.

Deleting OS files and directories using Fleet Manager

You can use Fleet Manager to delete files and directories on a managed node in your account.

To delete files or directories using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files or directories you want to delete.
4. Choose **Tools, File system**.
5. To delete a file, select the **File name** of the directory that contains the file you want to delete. To delete a directory, choose the button next to the directory that you want to delete and then proceed to step 7.
6. Choose the button next to the file with the content you want to delete.
7. Choose **Actions, Delete**.

Creating OS directories using Fleet Manager

You can use Fleet Manager to create directories on a managed node in your account.

To create a directory using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.

3. Select the link of the managed node you want to create a directory in.
4. Choose **Tools, File system**.
5. Select the **File name** of the directory where you want to create a new directory.
6. Select **Create directory**.
7. For **Directory name**, enter the name for the new directory, and then select **Create directory**.

Cutting, copying, and pasting OS directories using Fleet Manager

You can use Fleet Manager to cut, copy, and paste directories on a managed node in your account.

To copy or cut and paste directories with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files you want to copy, or cut and paste.
4. Choose **Tools, File system**.
5. Choose the button next to the directory that you want to copy or cut and then proceed to step 8.
6. In the **Actions** menu, choose **Copy** or **Cut**.
7. In the **File system** view, choose the button next to the directory you want to paste the file in.
8. In the **Actions** menu, choose **Paste**.

Monitoring managed node performance

You can use Fleet Manager, a tool in AWS Systems Manager, to view performance data about your managed nodes in real time. The performance data is retrieved from performance counters.

The following performance counters are available in Fleet Manager:

- CPU utilization
- Disk input/output (I/O) utilization
- Network traffic
- Memory usage

> **Note**
>
> Fleet Manager uses Session Manager, a tool in AWS Systems Manager, to retrieve performance data. For Amazon Elastic Compute Cloud (Amazon EC2) instances, the instance profile attached to your managed instances must provide permissions for Session Manager to use this feature. For more information about adding Session Manager permissions to an instance profile, see Add Session Manager permissions to an existing IAM role.

To view performance data with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node whose performance you want to monitor.
4. Choose **View details**.
5. Choose **Tools, Performance counters**.

Working with processes

You can use Fleet Manager, a tool in AWS Systems Manager, to work with processes on your managed nodes. Using Fleet Manager, you can view information about processes. For example, you can see the CPU utilization and memory usage of processes in addition to their handles and threads. With Fleet Manager, you can start and terminate processes from the console.

> **Note**
>
> Fleet Manager uses Session Manager, a tool in AWS Systems Manager, to retrieve process data. For Amazon Elastic Compute Cloud (Amazon EC2) instances, the instance profile attached to your managed instances must provide permissions for Session Manager to use this feature. For more information about adding Session Manager permissions to an instance profile, see Add Session Manager permissions to an existing IAM role.

Topics

- Viewing details about OS processes using Fleet Manager
- Starting an OS process on a managed node using Fleet Manager
- Terminating an OS process using Fleet Manager

Viewing details about OS processes using Fleet Manager

You can use Fleet Manager view details about processes on your managed nodes.

To view details about processes with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the node whose processes you want to view.
4. Choose **Tools, Processes**.

Starting an OS process on a managed node using Fleet Manager

You can use Fleet Manager to start a process on a managed node.

To start a process with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node you want to start a process on.
4. Choose **Tools, Processes**.
5. Select **Start new process**.
6. For **Process name or full path**, enter the name of the process or the full path to the executable.
7. (Optional) For **Working directory**, enter the directory path where you want the process to run.

Terminating an OS process using Fleet Manager

To terminate an OS process using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node you want to start a process on.
4. Choose **Tools, Processes**.
5. Choose the button next to the process you want to terminate.
6. Choose **Actions, Terminate process** or **Actions, Terminate process tree**.

> **Note**
>
> Terminating a process tree also terminates all processes and applications using that process.

Viewing logs on managed nodes

You can use Fleet Manager, a tool in AWS Systems Manager, to view log data stored on your managed nodes. For Windows managed nodes, you can view Windows event logs and copy their details from the console. To help you search events, filter Windows event logs by **Event level**, **Event ID**, **Event source**, and **Time created**. You can also view other log data using the procedure to view the file system. For more information about viewing the file system with Fleet Manager, see Working with OS file systems using Fleet Manager.

To view Windows event logs with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node whose event logs you want to view.
4. Choose **View details**.
5. Choose **Tools, Windows event logs**.
6. Choose the **Log name** that contains the events you want to view.

7. Choose the button next to the **Log name** you want to view, and then select **View events**.
8. Choose the button next to the event you want to view, and then select **View event details**.
9. (Optional) Select **Copy as JSON** to copy the event details to your clipboard.

Managing OS user accounts and groups on managed nodes using Fleet Manager

You can use Fleet Manager, a tool in AWS Systems Manager, to manage operating system (OS) user accounts and groups on your managed nodes. For example, you can create and delete users and groups. Additionally, you can view details like group membership, user roles, and status.

> **Important**
>
> Fleet Manager uses Run Command and Session Manager, tools in AWS Systems Manager, for various user management operations. As a result, a user could grant permissions to an operating system user account that they would otherwise be unable to. This is because AWS Systems Manager Agent (SSM Agent) runs on Amazon Elastic Compute Cloud (Amazon EC2) instances using root permissions (Linux) or SYSTEM permissions (Windows Server). For more information about restricting access to root-level commands through SSM Agent, see Restricting access to root-level commands through SSM Agent. To restrict access to this feature, we recommend creating AWS Identity and Access Management (IAM) policies for your users that only allow access to the actions you define. For more information about creating IAM policies for Fleet Manager, see Controlling access to Fleet Manager.

- Creating an OS user or group using Fleet Manager
- Updating user or group membership using Fleet Manager
- Deleting an OS user or group using Fleet Manager

Creating an OS user or group using Fleet Manager

> **Note**
>
> Fleet Manager uses Session Manager to set passwords for new users. For Amazon EC2 instances, the instance profile attached to your managed instances must provide permissions for Session Manager to use this feature. For more information about adding

Session Manager permissions to an instance profile, see Add Session Manager permissions to an existing IAM role.

Instead of logging on directly to a server to create a user account or group, you can use the Fleet Manager console to perform the same tasks.

To create an OS user account using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to create a new user on.
4. Choose **View details**.
5. Choose **Tools, Users and groups**.
6. Choose the **Users** tab, and then choose **Create user**.
7. Enter a value for the **Name** of the new user.
8. (Recommended) Select the check box next to **Set password**. You will be prompted to provide a password for the new user at the end of the procedure.
9. Select **Create user**. If you selected the check box to create a password for the new user, you will be prompted to enter a value for the password and select **Done**. If the password you specify doesn't meet the requirements specified by your managed node's local or domain policies, an error is returned.

To create an OS group using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to create a group in.
4. Choose **View details**.
5. Choose **Tools, Users and groups**.
6. Choose the **Groups** tab, and then choose **Create group**.
7. Enter a value for the **Name** of the new group.

8. (Optional) Enter a value for the **Description** of the new group.
9. (Optional) Select users to add to the **Group members** for the new group.
10. Select **Create group**.

Updating user or group membership using Fleet Manager

Instead of logging on directly to a server to update a user account or group, you can use the Fleet Manager console to perform the same tasks.

To add an OS user account to a new group using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node where the user account exists that you want to update.
4. Choose **View details**.
5. Choose **Tools, Users and groups**.
6. Choose the **Users** tab.
7. Choose the button next to the user you want to update.
8. Choose **Actions, Add user to group**.
9. Choose the group you want to add the user to under **Add to group**.
10. Select **Add user to group**.

To edit an OS group's membership using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node where the group exists that you want to update.
4. Choose **View details**.
5. Choose **Tools, Users and groups**.
6. Choose the **Groups** tab.

7. Choose the button next to the group you want to update.
8. Choose **Actions, Modify group**.
9. Choose the users you want to add or remove under **Group members**.
10. Select **Modify group**.

Deleting an OS user or group using Fleet Manager

Instead of logging on directly to a server to delete a user account or group, you can use the Fleet Manager console to perform the same tasks.

To delete an OS user account using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node where the user account exists that you want to delete.
4. Choose **View details**.
5. Choose **Users and groups**.
6. Choose the **Users** tab.
7. Choose the button next to the user you want to delete.
8. Choose **Actions, Delete local user**.

To delete an OS group using Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node where the group exists that you want to delete.
4. Choose **View details**.
5. Choose **Tools, Users and groups**.
6. Choose the **Group** tab.
7. Choose the button next to the group you want to update.
8. Choose **Actions, Delete local group**.

Managing the Windows registry on managed nodes

You can use Fleet Manager, a tool in AWS Systems Manager, to manage the registry on your Windows Server managed nodes. From the Fleet Manager console you can create, copy, update, and delete registry entries and values.

> **Important**
>
> We recommend creating a backup of the registry, or taking a snapshot of the root Amazon Elastic Block Store (Amazon EBS) volume attached to your managed node, before you modify the registry. Serious problems can occur if you modify the registry incorrectly. These problems might require you to reinstall the operating system, or restore the root volume of your node from a snapshot. AWS doesn't guarantee that these problems can be solved. Modify the registry at your own risk. You're responsible for all registry changes, and ensuring you have backups.

Create a Windows registry key or entry

To create a Windows registry key with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to create a registry key on.
4. Choose **View details**.
5. Choose **Tools, Windows registry**.
6. Choose the hive you want to create a new registry key in by selecting the **Registry name**.
7. Choose **Create, Create registry key**.
8. Choose the button next to the registry entry you want to create a new key in.
9. Choose **Create registry key**.
10. Enter a value for the **Name** of the new registry key, and select **Submit**.

To create a Windows registry entry with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the instance you want to create a registry entry on.
4. Choose **View details**.
5. Choose **Tools, Windows registry**.
6. Choose the hive, and subsequent registry key you want to create a new registry entry in by selecting the **Registry name**.
7. Choose **Create, Create registry entry**.
8. Enter a value for the **Name** of the new registry entry.
9. Choose the **Type** of value you want to create for the registry entry. For more information about registry value types, see Registry value types.
10. Enter a value for the **Value** of the new registry entry.

Update a Windows registry entry

To update a Windows registry entry with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to update a registry entry on.
4. Choose **View details**.
5. Choose **Tools, Windows registry**.
6. Choose the hive, and subsequent registry key you want to update by selecting the **Registry name**.
7. Choose the button next to the registry entry you want to update.
8. Choose **Actions, Update registry entry**.
9. Enter the new value for the **Value** of the registry entry.
10. Choose **Update**.

Delete a Windows registry entry or key

To delete a Windows registry key with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to delete a registry key on.
4. Choose **Tools, Windows registry**.
5. Choose the hive, and subsequent registry key you want to delete by selecting the **Registry name**.
6. Choose the button next to the registry key you want to delete.
7. Choose **Actions, Delete registry key**.

To delete a Windows registry entry with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to delete a registry entry on.
4. Choose **View details**.
5. Choose **Tools, Windows registry**.
6. Choose the hive, and subsequent registry key containing the entry you want to delete by selecting the **Registry name**.
7. Choose the button next to the registry entry you want to delete.
8. Choose **Actions, Delete registry entry**.

Managing EC2 instances automatically with Default Host Management Configuration

The Default Host Management Configuration setting allows AWS Systems Manager to manage your Amazon EC2 instances automatically as *managed instances*. A managed instance is an EC2 instance that is configured for use with Systems Manager.

The benefits of managing your instances with Systems Manager include the following:

- Connect to your EC2 instances securely using Session Manager.
- Perform automated patch scans using Patch Manager.
- View detailed information about your instances using Systems Manager Inventory.
- Track and manage instances using Fleet Manager.
- Keep SSM Agent up to date automatically.

Fleet Manager, Inventory, Patch Manager, and Session Manager are tools in Systems Manager.

Using Default Host Management Configuration, you can manage EC2 instances without having to manually create an AWS Identity and Access Management (IAM) instance profile. Instead, Default Host Management Configuration creates and applies a default IAM role to ensure that Systems Manager has permissions to manage all instances in the AWS account and AWS Region where it's activated.

If the permissions provided aren't sufficient for your use case, you can also add policies to the default IAM role created by the Default Host Management Configuration. Alternatively, if you don't need permissions for all of the capabilities provided by the default IAM role, you can create your own custom role and policies. Any changes made to the IAM role you choose for Default Host Management Configuration applies to all managed Amazon EC2 instances in the Region and account.

For more information about the policy used by Default Host Management Configuration, see AWS managed policy: AmazonSSMManagedEC2InstanceDefaultPolicy.

Implement least privilege access

The procedures in this topic are intended to be performed only by administrators. Therefore, we recommend implementing *least privilege access* in order to prevent non-administrative users from configuring or modifying the Default Host Management Configuration. To view example policies that restrict access to the Default Host Management Configuration, see Least privilege policy examples for Default Host Management Configuration later in this topic.

Important

Registration information for instances registered using Default Host Management Configuration is stored locally in the `var/lib/amazon/ssm` or `C:\ProgramData\Amazon` directories. Removing these directories or their files will prevent the instance from acquiring the necessary credentials to connect to Systems Manager using Default

Host Management Configuration. In these cases, you must use an IAM instance profile to provide the required permissions to your instance, or recreate the instance.

Topics

Prerequisites

In order to use Default Host Management Configuration in the AWS Region and AWS account where you activate the setting, the following requirements must be met.

- An instance to be managed must use Instance Metadata Service Version 2 (IMDSv2).

  Default Host Management Configuration doesn't support Instance Metadata Service Version 1. For information about transitioning to IMDSv2, see Transition to using Instance Metadata Service Version 2 in the *Amazon EC2 User Guide*
- SSM Agent version 3.2.582.0 or later must be installed on the instance to be managed.

  For information about checking the version of SSM Agent installed on your instance, see Checking the SSM Agent version number.

  For information about updating SSM Agent, see Automatically updating SSM Agent.
- You, as the administrator performing the tasks in this topic, must have permissions for the GetServiceSetting, ResetServiceSetting, and UpdateServiceSetting API operations. Additionally, you must have permissions for the `iam:PassRole` permission for the `AWSSystemsManagerDefaultEC2InstanceManagementRole` IAM role. The following is an example policy providing these permissions. Replace each *`example resource placeholder`* with your own information.

  JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetServiceSetting",
                "ssm:ResetServiceSetting",
                "ssm:UpdateServiceSetting"
            ],
            "Resource": "arn:aws:ssm:us-east-1:111122223333:servicesetting/ssm/
managed-instance/default-ec2-instance-management-role"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:PassRole"
            ],
            "Resource": "arn:aws:iam::111122223333:role/service-role/
AWSSystemsManagerDefaultEC2InstanceManagementRole",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "ssm.amazonaws.com"
                    ]
                }
            }
        }
    ]
}
```

- If an IAM instance profile is already attached to an EC2 instance that is to be managed using Systems Manager, you must remove any permissions from it that allow the `ssm:UpdateInstanceInformation` operation. SSM Agent attempts to use instance profile permissions before using the Default Host Management Configuration permissions. If you allow the `ssm:UpdateInstanceInformation` operation in your own IAM instance profile, the instance will not use the Default Host Management Configuration permissions.

Activating the Default Host Management Configuration setting

You can activate Default Host Management Configuration from the Fleet Manager console, or by using the AWS Command Line Interface or AWS Tools for Windows PowerShell.

You must turn on the Default Host Management Configuration one by one in each Region you where you want your Amazon EC2 instances managed by this setting.

After turning on Default Host Management Configuration, it might take up to 30 minutes for your instances to use the credentials of the role you choose in step 5 in the following procedure.

To activate Default Host Management Configuration (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management, Configure Default Host Management Configuration**.
4. Turn on **Enable Default Host Management Configuration**.
5. Choose the AWS Identity and Access Management (IAM) role used to enable Systems Manager tools for your instances. We recommend using the default role provided by Default Host Management Configuration. It contains the minimum set of permissions necessary to manage your Amazon EC2 instances using Systems Manager. If you prefer to use a custom role, the role's trust policy must allow Systems Manager as a trusted entity.
6. Choose **Configure** to complete setup.

To activate Default Host Management Configuration (command line)

1. Create a JSON file on your local machine containing the following trust relationship policy.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"",
            "Effect":"Allow",
            "Principal":{
                "Service":"ssm.amazonaws.com"
            },
            "Action":"sts:AssumeRole"
        }
    ]
}
```

2. Open the AWS CLI or Tools for Windows PowerShell and run one of the following commands, depending on the operating system type of your local machine, to create a service role in your account. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws iam create-role \
   --role-name AWSSystemsManagerDefaultEC2InstanceManagementRole \
   --path /service-role/ \
   --assume-role-policy-document file://trust-policy.json
   ```

   Windows

   ```
   aws iam create-role ^
   --role-name AWSSystemsManagerDefaultEC2InstanceManagementRole ^
   --path /service-role/ ^
   --assume-role-policy-document file://trust-policy.json
   ```

   PowerShell

   ```
   New-IAMRole `
   -RoleName "AWSSystemsManagerDefaultEC2InstanceManagementRole" `
   -Path "/service-role/" `
   -AssumeRolePolicyDocument "file://trust-policy.json"
   ```

3. Run the following command to attach the `AmazonSSMManagedEC2InstanceDefaultPolicy` managed policy to your newly created role. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws iam attach-role-policy \
   --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedEC2InstanceDefaultPolicy \
   --role-name AWSSystemsManagerDefaultEC2InstanceManagementRole
   ```

   Windows

   ```
   aws iam attach-role-policy ^
   --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedEC2InstanceDefaultPolicy ^
   --role-name AWSSystemsManagerDefaultEC2InstanceManagementRole
   ```

PowerShell

```
Register-IAMRolePolicy `
-PolicyArn "arn:aws:iam::aws:policy/AmazonSSMManagedEC2InstanceDefaultPolicy" `
-RoleName "AWSSystemsManagerDefaultEC2InstanceManagementRole"
```

4. Open the AWS CLI or Tools for Windows PowerShell and run the following command. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm update-service-setting \
   --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
   default-ec2-instance-management-role \
   --setting-value service-role/AWSSystemsManagerDefaultEC2InstanceManagementRole
   ```

   Windows

   ```
   aws ssm update-service-setting ^
   --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
   default-ec2-instance-management-role ^
   --setting-value service-role/AWSSystemsManagerDefaultEC2InstanceManagementRole
   ```

   PowerShell

   ```
   Update-SSMServiceSetting `
   -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
   default-ec2-instance-management-role" `
   -SettingValue "service-role/AWSSystemsManagerDefaultEC2InstanceManagementRole"
   ```

   There is no output if the command succeeds.

5. Run the following command to view the current service settings for Default Host Management Configuration in the current AWS account and AWS Region.

   Linux & macOS

   ```
   aws ssm get-service-setting \
   ```

```
--setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
default-ec2-instance-management-role
```

Windows

```
aws ssm get-service-setting ^
--setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
default-ec2-instance-management-role
```

PowerShell

```
Get-SSMServiceSetting `
-SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
default-ec2-instance-management-role"
```

The command returns information like the following.

```
{
    "ServiceSetting": {
        "SettingId": "/ssm/managed-instance/default-ec2-instance-management-role",
        "SettingValue": "service-role/
AWSSystemsManagerDefaultEC2InstanceManagementRole",
        "LastModifiedDate": "2022-11-28T08:21:03.576000-08:00",
        "LastModifiedUser": "System",
        "ARN": "arn:aws:ssm:us-east-2:-123456789012:servicesetting/ssm/managed-
instance/default-ec2-instance-management-role",
        "Status": "Custom"
    }
}
```

Deactivating the Default Host Management Configuration setting

You can deactivate Default Host Management Configuration from the Fleet Manager console, or by using the AWS Command Line Interface or AWS Tools for Windows PowerShell.

You must turn off the Default Host Management Configuration setting one by one in each Region where you no longer want your your Amazon EC2 instances managed by this configuration. Deactivating it in one Region doesn't deactivate it in all Regions.

If you deactivate Default Host Management Configuration, and you have not attached an instance profile to your Amazon EC2 instances that allows access to Systems Manager, they will no longer be managed by Systems Manager.

To deactivate Default Host Management Configuration (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management, Default Host Management Configuration**.
4. Turn off **Enable Default Host Management Configuration**.
5. Choose **Configure** to disable Default Host Management Configuration.

To deactivate Default Host Management Configuration (command line)

- Open the AWS CLI or Tools for Windows PowerShell and run the following command. Replace each *example resource placeholder* with your own information.

  Linux & macOS

  ```
  aws ssm reset-service-setting \
  --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
  default-ec2-instance-management-role
  ```

  Windows

  ```
  aws ssm reset-service-setting ^
  --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
  default-ec2-instance-management-role
  ```

  PowerShell

  ```
  Reset-SSMServiceSetting `
  -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
  default-ec2-instance-management-role"
  ```

Least privilege policy examples for Default Host Management Configuration

The following sample policies demonstrate how to prevent members of your organization from making changes to the Default Host Management Configuration setting in your account.

Service control policy for AWS Organizations

The following policy demonstrates how to prevent non-administrative members in your AWS Organizations from updating your Default Host Management Configuration setting. Replace each *example resource placeholder* with your own information.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Effect": "Deny",
            "Action": [
                "ssm:UpdateServiceSetting",
                "ssm:ResetServiceSetting"
            ],
            "Resource": "arn:aws:ssm:*:*:servicesetting/ssm/managed-instance/
default-ec2-instance-management-role",
            "Condition": {
                "StringNotEqualsIgnoreCase": {
                    "aws:PrincipalTag/job-function": [
                        "administrator"
                    ]
                }
            }
        },
        {
            "Effect": "Deny",
            "Action": [
                "iam:PassRole"
            ],
            "Resource": "arn:aws:iam::*:role/service-role/
AWSSystemsManagerDefaultEC2InstanceManagementRole",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": "ssm.amazonaws.com"
                },
                "StringNotEqualsIgnoreCase": {
```

```
                    "aws:PrincipalTag/job-function": [
                        "administrator"
                    ]
                }
            }
        },
        {
            "Effect": "Deny",
            "Resource": "arn:aws:iam::*:role/service-role/
AWSSystemsManagerDefaultEC2InstanceManagementRole",
            "Action": [

            }
        }
    ]
}
```

Policy for IAM principals

The following policy demonstrates how to prevent IAM groups, roles, or users in your AWS Organizations from updating your Default Host Management Configuration setting. Replace each *example resource placeholder* with your own information.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "ssm:UpdateServiceSetting",
                "ssm:ResetServiceSetting"
```

```
            ],
            "Resource": "arn:aws:ssm:us-east-1:111122223333:servicesetting/ssm/
managed-instance/default-ec2-instance-management-role"
        },
        {
            "Effect": "Deny",
            "Action": [
                "iam:AttachRolePolicy",
                "iam:DeleteRole",
                "iam:PassRole"
            ],
            "Resource": "arn:aws:iam::111122223333:role/service-role/
AWSSystemsManagerDefaultEC2InstanceManagementRole"
        }
    ]
}
```

Connecting to a Windows Server managed instance using Remote Desktop

You can use Fleet Manager, a tool in AWS Systems Manager, to connect to your Windows Server Amazon Elastic Compute Cloud (Amazon EC2) instances using the Remote Desktop Protocol (RDP). Fleet Manager Remote Desktop, which is powered by Amazon DCV, provides you with secure connectivity to your Windows Server instances directly from the Systems Manager console. You can have up to four simultaneous connections in a single browser window.

The Fleet Manager Remote Desktop API is named AWS Systems Manager GUI Connect. For information about using the Systems Manager GUI Connect API, see the *AWS Systems Manager GUI Connect API Reference*.

Currently, you can only use Remote Desktop with instances that are running Windows Server 2012 RTM or higher. Remote Desktop supports only English language inputs.

Fleet Manager Remote Desktop is a console-only service and doesn't support command-line connections to your managed instances. To connect to a Windows Server managed instance through a shell, you can use Session Manager, another tool in AWS Systems Manager. For more information, see AWS Systems Manager Session Manager.

> **Note**
>
> The duration of an RDP connection is not determined by the duration of your AWS Identity and Access Management (IAM) credentials. Instead, the connection persists until the

maximum connection duration or idle time limit is met, whichever comes first. For more information, see Remote connection duration and concurrency.

For information about configuring AWS Identity and Access Management (IAM) permissions to allow your instances to interact with Systems Manager, see Configure instance permissions for Systems Manager.

Topics

Setting up your environment

Before using Remote Desktop, verify that your environment meets the following requirements:

- **Managed node configuration**

  Make sure that your Amazon EC2 instances are configured as managed nodes in Systems Manager.

- **SSM Agent minimum version**

  Verify that nodes are running SSM Agent version 3.0.222.0 or higher. For information about how to check which agent version is running on a node, see Checking the SSM Agent version number. For information about installing or updating SSM Agent, see Working with SSM Agent.

- **RDP port configuration**

  To accept remote connections, the Remote Desktop Services service on your Windows Server nodes must use default RDP port 3389. This is the default configuration on Amazon Machine Images (AMIs) provided by AWS. You are not explicitly required to open any inbound ports to use Remote Desktop.

- **PSReadLine module version for keyboard functionality**

  To ensure that your keyboard functions properly in PowerShell, verify that nodes running Windows Server 2022 have PSReadLine module version 2.2.2 or higher installed. If they are running an older version, you can install the required version using the following commands.

  ```
  Install-PackageProvider -Name NuGet -MinimumVersion 2.8.5.201 -Force
  ```

  After the NuGet package provider is installed, run the following command.

  ```
  Install-Module `
   -Name PSReadLine `
   -Repository PSGallery `
   -MinimumVersion 2.2.2 -Force
  ```

- **Session Manager configuration**

  Before you can use Remote Desktop, you must complete the prerequisites for Session Manager setup. When you connect to an instance using Remote Desktop, any session preferences defined for your AWS account and AWS Region are applied. For more information, see Setting up Session Manager.

  > **Note**
  >
  > If you log Session Manager activity using Amazon Simple Storage Service (Amazon S3), then your Remote Desktop connections will generate the following error in `bucket_name/Port/stderr`. This error is expected behavior and can be safely ignored.
  >
  > ```
  > Setting up data channel with id SESSION_ID failed: failed to create websocket
  >  for datachannel with error: CreateDataChannel failed with no output or
  >  error: createDataChannel request failed: unexpected response from the service
  >  <BadRequest>
  > <ClientErrorMessage>Session is already terminated</ClientErrorMessage>
  > </BadRequest>
  > ```

Configuring IAM permissions for Remote Desktop

In addition to the required IAM permissions for Systems Manager and Session Manager, the user or role you use must be allowed permissions for initiating connections.

Permissions for initiating connections

To make RDP connections to EC2 instances in the console, the following permissions are required:

- `ssm-guiconnect:CancelConnection`
- `ssm-guiconnect:GetConnection`
- `ssm-guiconnect:StartConnection`

Permissions for listing connections

In order to view lists of connections in the console, the following permission is required:

`ssm-guiconnect:ListConnections`

The following are example IAM policies that you can attach to a user or role to allow different types of interaction with Remote Desktop. Replace each *`example resource placeholder`* with your own information.

Standard policy for connecting to EC2 instances

JSON

```
{
    "Version": "2012-10-17",

            ],
            "Resource": "*"
        }
    ]
}
```

Policy for connecting to EC2 instances with specific tags

> **Note**
>
> In the following IAM policy, the `SSMStartSession` section requires an Amazon Resource Name (ARN) for the `ssm:StartSession` action. As shown, the ARN you specify does *not* require an AWS account ID. If you specify an account ID, Fleet Manager returns an `AccessDeniedException`.
> The `AccessTaggedInstances` section, which is located lower in the example policy, also requires ARNs for `ssm:StartSession`. For those ARNs, you do specify AWS account IDs.

            ],
            "Resource": "*"
        }
    ]
}
```

Authenticating Remote Desktop connections

When establishing a remote connection, you can authenticate using Windows credentials or the Amazon EC2 key pair (`.pem` file) that is associated with the instance. For information about using key pairs, see Amazon EC2 key pairs and Windows instances in the *Amazon EC2 User Guide*.

Alternatively, if you're authenticated to the AWS Management Console using AWS IAM Identity Center, you can connect to your instances without providing additional credentials. For an example of a policy to allow remote connection authentication using IAM Identity Center, see Configuring IAM permissions for Remote Desktop.

Before you begin

Note the following conditions for using IAM Identity Center authentication before you begin connecting using Remote Desktop.

- Remote Desktop supports IAM Identity Center authentication for nodes in the same AWS Region where you enabled IAM Identity Center.
- Remote Desktop supports IAM Identity Center user names of up to 16 characters.
- Remote Desktop supports IAM Identity Center user names consisting of alphanumeric characters and the following special characters: `. - _`

> **Important**
>
> Connections won't succeed for IAM Identity Center user names that contain the following characters: + = ,
> IAM Identity Center supports these characters in user names, but Fleet Manager RDP connections do not.
> In addition, if an IAM Identity Center user name contains one or more @ symbols, Fleet Manager disregards the first @ symbol and all characters that follow it, whether or not the @ introduces the domain portion of an email address. For instance, for the IAM Identity Center user name `diego_ramirez@example.com`, the `@example.com` portion is ignored and the user name for Fleet Manager becomes `diego_ramirez`. For `diego_r@mirez@example.com`, Fleet Manager disregards `@mirez@example.com`, and the username for Fleet Manager becomes `diego_r`.

- When a connection is authenticated using IAM Identity Center, Remote Desktop creates a local Windows user in the instance's Local Administrators group. This user persists after the remote connection has ended.
- Remote Desktop does not allow IAM Identity Center authentication for nodes that are Microsoft Active Directory domain controllers.
- Although Remote Desktop allows you to use IAM Identity Center authentication for nodes *joined* to an Active Directory domain, we do not recommend doing so. This authentication method grants administrative permissions to users which might override more restrictive permissions granted by the domain.

Supported Regions for IAM Identity Center authentication

Remote Desktop connections using IAM Identity Center authentication are supported in the following AWS Regions:

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (N. California) (us-west-1)
- US West (Oregon) (us-west-2)
- Africa (Cape Town) (af-south-1)
- Asia Pacific (Hong Kong) (ap-east-1)

- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Osaka) (ap-northeast-3)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Asia Pacific (Jakarta) (ap-southeast-3)
- Canada (Central) (ca-central-1)
- Europe (Frankfurt) (eu-central-1)
- Europe (Stockholm) (eu-north-1)
- Europe (Ireland) (eu-west-1)
- Europe (London) (eu-west-2)
- Europe (Paris) (eu-west-3)
- Israel (Tel Aviv) (il-central-1)
- South America (São Paulo) (sa-east-1)
- Europe (Milan) (eu-south-1)
- Middle East (Bahrain) (me-south-1)
- AWS GovCloud (US-East) (us-gov-east-1)
- AWS GovCloud (US-West) (us-gov-west-1)

Remote connection duration and concurrency

The following conditions apply to active Remote Desktop connections:

- **Connection duration**

  By default, a Remote Desktop connection is disconnected after 60 minutes. To prevent a connection from being disconnected, you can choose **Renew session** before being disconnected to reset the duration timer.
- **Connection timeout**

  A Remote Desktop connection disconnects after it has been idle for more than 10 minutes.
- **Connection persistence**

After you connect to a Windows Server using Remote Desktop, the connection persists until the maximum connection duration (60 minutes) or idle timeout limit (10 minutes) is met. Connection duration is not determined by the duration of your AWS Identity and Access Management (IAM) credentials. The connection persists after IAM credentials expire if the connection duration limits are not met. When using Remote Desktop, you should terminate your connection after your IAM credentials expire by leaving the browser page.

- **Concurrent connections**

  By default, you can have a maximum of 5 active Remote Desktop connections at one time for the same AWS account and AWS Region. To request a service quota increase of up to 50 concurrent connections, see Requesting a quota increase in the *Service Quotas User Guide*.

> **Note**
>
> The standard license for Windows Server allows for two concurrent RDP connections. To support more connections, you must purchase additional Client Access Licenses (CALs) from Microsoft or Microsoft Remote Desktop Services licenses from AWS. For more information on supplemental licensing, see the following topics:
>
> - Client Access Licenses and Management Licenses on the Microsoft website
> - Use License Manager user-based subscriptions for supported software products in the *License Manager User Guide*

Systems Manager GUI Connect handling of AWS IAM Identity Center attributes

Systems Manager GUI Connect is the API that supports Fleet Manager connections to EC2 instances using RDP. The following IAM Identity Center user data is retained after a connection is closed:

- `username`

Systems Manager GUI Connect encrypts this identity attribute at rest using an AWS managed key by default. Customer managed keys are not supported for encrypting this attribute in Systems Manager GUI Connect. If you delete a user in your IAM Identity Center instance, Systems Manager GUI Connect continues to retain the `username` attribute associated with that user for 7 years, after which it is deleted. This data is retained to support auditing events, such as listing Systems Manager GUI Connect connection history. The data can't be deleted manually.

Connect to a managed node using Remote Desktop

Browser copy/paste support for text

Using the Google Chrome and Microsoft Edge browsers, you can copy and paste text from a managed node to your local machine, and from your local machine to a managed node that you are connected to.

Using the Mozilla Firefox browser, you can copy and paste text from a managed node to your local machine only. Copying from your local machine to the managed node is not supported.

To connect to a managed node using Fleet Manager Remote Desktop

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the node that you want to connect to. You can select either the check box or the node name.
4. On the **Node actions** menu, choose **Connect with Remote Desktop**.
5. Choose your preferred **Authentication type**. If you choose **User credentials**, enter the user name and password for a Windows user account on the node that you're connecting to. If you choose **Key pair**, you can provide authentication using one of the following methods:

   a. Choose **Browse local machine** if you want to select the PEM key associated with your instance from your local file system.

   - or -

   b. Choose **Paste key pair content** if you want to copy the contents of the PEM file and paste them in to the provided field.
6. Select **Connect**.
7. To choose your preferred display resolution, in the **Actions** menu, choose **Resolutions**, and then select from the following:

   - **Adapt Automatically**
   - **1920 x 1080**
   - **1400 x 900**
   - **1366 x 768**

- **800 x 600**

The **Adapt Automatically** option sets the resolution based on your detected screen size.

Viewing information about current and completed connections

You can use the Fleet Manager section of the Systems Manager console to view information about RDP connections that have been made in your account. Using a set of filters, you can limit the list of connections displayed to a time range, a specific instance, the user who made the connections, and connections of a specific status. The console also provides tabs that show information about all currently active connections, and all past connections.

To view information about current and completed connections

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management, Connect with Remote Desktop**.
4. Choose one of the following tabs:
   - **Active connections**
   - **Connection history**
5. To further narrow the list of connection results displayed, specify one or more filters in the search
   ()
   box. You can also enter a free-text search term.

Managing Amazon EBS volumes on managed instances

Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with Amazon Elastic Compute Cloud (EC2) instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.

You can use Fleet Manager, a tool in AWS Systems Manager, to manage Amazon EBS volumes on your managed instances. For example, you can initialize an EBS volume, format a partition, and mount the volume to make it available for use.

> **Note**
>
> Fleet Manager currently supports Amazon EBS volume management for Windows Server instances only.

View EBS volume details

To view details for an EBS volume with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed instance for which you want to view EBS volume details.
4. Choose **View details**.
5. Choose **Tools, EBS volumes**.
6. To view details for an EBS volume, choose its ID in the **Volume ID** column.

Initialize and format an EBS volume

To initialize and format an EBS volume with Fleet Manager

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed instance for which you want to initialize, format, and mount an EBS volume. You can only initialize an EBS volume if its disk is empty.
4. Choose **View details**.
5. In the **Tools** menu, choose **EBS volumes**.
6. Choose the button next to the EBS volume you want to initialize and format.
7. Choose **Initialize and format**.
8. In **Partition style**, choose the partition style you want to use for the EBS volume.
9. (Optional) Choose a **Drive letter** for the partition.

10. (Optional) Enter a **Partition name** to identify the partition.
11. Choose the **File system** to use to organize files and data stored in the partition.
12. Choose **Confirm** to make the EBS volume available for use. You can't change the partition configuration from the AWS Management Console after confirming, however, you can use SSH or RDP to log into the instance to change the partition configuration.

Accessing the Red Hat Knowledge base portal

You can use Fleet Manager, a tool in AWS Systems Manager, to access the Knowledge base portal if you are a Red Hat customer. You are considered a Red Hat customer if you run Red Hat Enterprise Linux (RHEL) instances or use RHEL services on AWS. The Knowledge base portal includes binaries, and knowledge-share and discussion forums for community support that are available only to Red Hat licensed customers.

In addition to the required AWS Identity and Access Management (IAM) permissions for Systems Manager and Fleet Manager, the user or role you use to access the console must allow the `rhelkb:GetRhelURL` action to access the Knowledge base portal.

To access the Red Hat Knowledgebase Portal

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the RHEL instance you want to use to connect to the Red Hat Knowledgebase Portal.
4. Choose **Account management**, **Access Red Hat Knowledgebase** to open the Red Hat Knowledge base page.

If you use RHEL on AWS to run fully supported RHEL workloads, you can also access the Red Hat Knowledge base through Red Hat's website by using your AWS credentials.

Troubleshooting managed node availability

For several AWS Systems Manager tools like Run Command, Distributor, and Session Manager, you can choose to manually select the managed nodes on which you want to run an operation. In cases like these, after you specify that you want to choose nodes manually, the system displays a list of managed nodes where you can run the operation.

This topic provides information to help you diagnose why a managed node *that you have confirmed is running* isn't included in your lists of managed nodes in Systems Manager.

In order for a node to be managed by Systems Manager and available in lists of managed nodes, it must meet three requirements:

- SSM Agent must be installed and running on the node with a supported operating system.

> **Note**
>
> Some AWS managed Amazon Machine Images (AMIs) are configured to launch instances with SSM Agent preinstalled. (You can also configure a custom AMI to preinstall SSM Agent.) For more information, see Find AMIs with the SSM Agent preinstalled.

- For Amazon Elastic Compute Cloud (Amazon EC2) instances, you must attach an AWS Identity and Access Management (IAM) instance profile to the instance. The instance profile enables the instance to communicate with the Systems Manager service. If you don't assign an instance profile to the instance, you register it using a hybrid activation, which is not a common scenario.
- SSM Agent must be able to connect to a Systems Manager endpoint in order to register itself with the service. Thereafter, the managed node must be available to the service, which is confirmed by the service sending a signal every five minutes to check the instance's health.
- After the status of a managed node has been `Connection Lost` for at least 30 days, the node might no longer be listed in the Fleet Manager console. To restore it to the list, the issue that caused the lost connection must be resolved.

After you verify that a managed node is running, you can use the following command to check whether SSM Agent successfully registered with the Systems Manager service. This command doesn't return results until a successful registration has taken place.

Linux & macOS

```
aws ssm describe-instance-associations-status \
    --instance-id instance-id
```

Windows

```
aws ssm describe-instance-associations-status ^
    --instance-id instance-id
```

PowerShell

```
Get-SSMInstanceAssociationsStatus `
    -InstanceId instance-id
```

If registration was successful and the managed node is now available for Systems Manager operations, the command returns results similar to the following.

```
{
    "InstanceAssociationStatusInfos": [
        {
            "AssociationId": "fa262de1-6150-4a90-8f53-d7eb5EXAMPLE",
            "Name": "AWS-GatherSoftwareInventory",
            "DocumentVersion": "1",
            "AssociationVersion": "1",
            "InstanceId": "i-02573cafcfEXAMPLE",
            "Status": "Pending",
            "DetailedStatus": "Associated"
        },
        {
            "AssociationId": "f9ec7a0f-6104-4273-8975-82e34EXAMPLE",
            "Name": "AWS-RunPatchBaseline",
            "DocumentVersion": "1",
            "AssociationVersion": "1",
            "InstanceId": "i-02573cafcfEXAMPLE",
            "Status": "Queued",
            "AssociationName": "SystemAssociationForScanningPatches"
        }
    ]
}
```

If registration hasn't completed yet or was unsuccessful, the command returns results similar to the following:

```
{
    "InstanceAssociationStatusInfos": []
}
```

If the command doesn't return results after 5 minutes or so, use the following information to help you troubleshoot problems with your managed nodes.

Topics

Solution 1: Verify that SSM Agent is installed and running on the managed node

Make sure the latest version of SSM Agent is installed and running on the managed node.

To determine whether SSM Agent is installed and running on a managed node, see Checking SSM Agent status and starting the agent.

To install or reinstall SSM Agent on a managed node, see the following topics:

- Manually installing and uninstalling SSM Agent on EC2 instances for Linux
- How to install the SSM Agent on hybrid Linux nodes
- Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server
- How to install the SSM Agent on hybrid Windows nodes

Solution 2: Verify that an IAM instance profile has been specified for the instance (EC2 instances only)

For Amazon Elastic Compute Cloud (Amazon EC2) instances, verify that the instance is configured with an AWS Identity and Access Management (IAM) instance profile that allows the instance to communicate with the Systems Manager API. Also verify that your user has an IAM trust policy that allows your user to communicate with the Systems Manager API.

> **Note**
>
> On-premises servers, edge devices, and virtual machines (VMs) use an IAM service role instead of an instance profile. For more information, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.

To determine whether an instance profile with the necessary permissions is attached to an EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Choose the instance to check for an instance profile.
4. On the **Description** tab in the bottom pane, locate **IAM role** and choose the name of the role.
5. On the role **Summary** page for the instance profile, on the **Permissions** tab, ensure that `AmazonSSMManagedInstanceCore` is listed under **Permissions policies**.

   If a custom policy is used instead, ensure that it provides the same permissions as `AmazonSSMManagedInstanceCore`.

   Open `AmazonSSMManagedInstanceCore` in the console

   For information about other policies that can be attached to an instance profile for Systems Manager, see Configure instance permissions required for Systems Manager.

Solution 3: Verify service endpoint connectivity

Verify that the instance has connectivity to the Systems Manager service endpoints. This connectivity is provided by creating and configuring VPC endpoints for Systems Manager, or by allowing HTTPS (port 443) outbound traffic to the service endpoints.

For Amazon EC2 instances, the Systems Manager service endpoint for the AWS Region is used to register the instance if your virtual private cloud (VPC) configuration allows outbound traffic. However, if the VPC configuration the instance was launched in does not allow outbound traffic and you can't change this configuration to allow connectivity to the public service endpoints, you must configure interface endpoints for your VPC instead.

For more information, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

Solution 4: Verify target operating system support

Verify that the operation you have chosen can be run on the type of managed node you expect to see listed. Some Systems Manager operations can target only Windows instances or only Linux instances. For example, the Systems Manager (SSM) documents `AWS-InstallPowerShellModule` and `AWS-ConfigureCloudWatch` can be run only on Windows instances. In the **Run a command** page, if you choose either of these documents and select **Choose instances manually**, only your Windows instances are listed and available for selection.

Solution 5: Verify you're working in the same AWS Region as the Amazon EC2 instance

Amazon EC2 instances are created and available in specific AWS Regions, such as the US East (Ohio) Region (us-east-2) or Europe (Ireland) Region (eu-west-1). Ensure that you're working in the same AWS Region as the Amazon EC2 instance that you want to work with. For more information, see Choosing a Region in *Getting Started with the AWS Management Console*.

Solution 6: Verify the proxy configuration you applied to SSM Agent on your managed node

Verify that the proxy configuration you applied to SSM Agent on your managed node is correct. If the proxy configuration is incorrect, the node can't connect to the required service endpoints, or Systems Manager might identify the operating system of the managed node incorrectly. For more information, see Configuring SSM Agent to use a proxy on Linux nodes and Configure SSM Agent to use a proxy for Windows Server instances.

Solution 7: Install a TLS certificate on managed instances

A Transport Layer Security (TLS) certificate must be installed on each managed instance you use with AWS Systems Manager. AWS services use these certificates to encrypt calls to other AWS services.

A TLS certificate is already installed by default on each Amazon EC2 instance created from any Amazon Machine Image (AMI). Most modern operating systems include the required TLS certificate from Amazon Trust Services CAs in their trust store.

To verify whether the required certificate is installed on your instance run the following command based on the operating system of your instance. Be sure to replace the *`region`* portion of the URL with the AWS Region where your managed instance is located.

Linux & macOS

```
curl -L https://ssm.region.amazonaws.com
```

Windows

```
Invoke-WebRequest -Uri https://ssm.region.amazonaws.com
```

The command should return an `UnknownOperationException` error. If you receive an SSL/TLS error message instead then the required certificate might not be installed.

If you find the required Amazon Trust Services CA certificates aren't installed on your base operating systems, on instances created from AMIs that aren't supplied by Amazon, or on your own on-premises servers and VMs, you must install and allow a certificate from Amazon Trust Services, or use AWS Certificate Manager (ACM) to create and manage certificates for a supported integrated service.

Each of your managed instances must have one of the following Transport Layer Security (TLS) certificates installed.

- Amazon Root CA 1
- Starfield Services Root Certificate Authority - G2
- Starfield Class 2 Certificate Authority

For information about using ACM, see the *AWS Certificate Manager User Guide*.

If certificates in your computing environment are managed by a Group Policy Object (GPO), then you might need to configure Group Policy to include one of these certificates.

For more information about the Amazon Root and Starfield certificates, see the blog post How to Prepare for AWS's Move to Its Own Certificate Authority.

Troubleshooting managed node availability using `ssm-cli`

The `ssm-cli` is a standalone command line tool included in the SSM Agent installation. When you install SSM Agent 3.1.501.0 or later on a machine, you can run `ssm-cli` commands on that machine. The output of those commands helps you determine whether the machine meets the minimum requirements for an Amazon EC2 instance or non-EC2 machine to be managed by AWS

Systems Manager, and therefore added to lists of managed nodes in Systems Manager. (SSM Agent version 3.1.501.0 was released in November, 2021.)

Minimum requirements

For an Amazon EC2 instance or non-EC2 machine to be managed by AWS Systems Manager, and available in lists of managed nodes, it must meet three primary requirements:

- SSM Agent must be installed and running on a machine with a supported operating system.

  Some AWS managed Amazon Machine Images (AMIs) for EC2 are configured to launch instances with SSM Agent preinstalled. (You can also configure a custom AMI to preinstall SSM Agent.) For more information, see Find AMIs with the SSM Agent preinstalled.
- An AWS Identity and Access Management (IAM) instance profile (for EC2 instances) or IAM service role (for non-EC2 machines) that supplies the required permissions to communicate with the Systems Manager service must be attached to the machine.
- SSM Agent must be able to connect to a Systems Manager endpoint to register itself with the service. Thereafter, the managed node must be available to the service, which is confirmed by the service sending a signal every five minutes to check the managed node's health.

Preconfigured commands in `ssm-cli`

Preconfigured commands are included that gather the required information to help you diagnose why a machine that you have confirmed is running isn't included in your lists of managed nodes in Systems Manager. These commands are run when you specify the `get-diagnostics` option.

On the machine, run the following command to use `ssm-cli` to help you troubleshoot managed node availability.

Linux & macOS

```
ssm-cli get-diagnostics --output table
```

Windows

On Windows Server machines, you must navigate to the `C:\Program Files\Amazon\SSM` directory before running the command.

```
ssm-cli.exe get-diagnostics --output table
```

PowerShell

On Windows Server machines, you must navigate to the `C:\Program Files\Amazon\SSM` directory before running the command.

```
.\ssm-cli.exe get-diagnostics --output table
```

The command returns output as a table similar to the following.

> **Note**
>
> Connectivity checks to the `ssmmessages`, `s3`, `kms`, `logs`, and `monitoring` endpoints are for additional optional features such as Session Manager that can log to Amazon Simple Storage Service (Amazon S3) or Amazon CloudWatch Logs, and use AWS Key Management Service (AWS KMS) encryption.

Linux & macOS

```
[root@instance]# ssm-cli get-diagnostics --output table

```
################################################################################################
```

The following table provides additional details for each of the checks performed by `ssm-cli`.

`ssm-cli` diagnostic checks

Check	Details
Amazon EC2 instance metadata service	Indicates whether the managed node is able to reach the metadata service. A failed test indicates a connectivity issue to `http://169.254.169.254` which can be caused by local route, proxy, or operating system (OS) firewall and proxy configurations.
Hybrid instance registration	Indicates whether SSM Agent is registered using a hybrid activation.
Connectivity to `ssm` endpoint	Indicates whether the node is able to reach the service endpoints for Systems Manager on TCP port 443. A failed test indicates connectivity issues to `https://ssm.`*`region`*`.amazonaws.com` depending on the AWS Region where the node is located. Connectivity issues can be caused by the VPC configuration including security groups, network access control lists, route tables, or OS firewalls and proxies.
Connectivity to `ec2messages` endpoint	Indicates whether the node is able to reach the service endpoints for Systems Manager on TCP port 443. A failed test indicates connectivity issues to `https://ec2messages.`*`region`*`.amazonaws.com` depending on the AWS Region where the node is located. Connectivity issues can be caused by the VPC configuration including security groups,

Check	Details
	network access control lists, route tables, or OS firewalls and proxies.
Connectivity to `ssmmessages` endpoint	Indicates whether the node is able to reach the service endpoints for Systems Manager on TCP port 443. A failed test indicates connectivity issues to `https://ssmmessages.` *region* `.amazonaws.com` depending on the AWS Region where the node is located. Connectivity issues can be caused by the VPC configuration including security groups, network access control lists, route tables, or OS firewalls and proxies.
Connectivity to `s3` endpoint	Indicates whether the node is able to reach the service endpoint for Amazon Simple Storage Service on TCP port 443. A failed test indicates connectivity issues to `https://s3.` *region* `.amazonaws.com` depending on the AWS Region where the node is located. Connectivity to this endpoint is not required for a node to appear in your managed nodes list.
Connectivity to `kms` endpoint	Indicates whether the node is able to reach the service endpoint for AWS Key Management Service on TCP port 443. A failed test indicates connectivity issues to `https://kms.` *region* `.amazonaws.com` depending on the AWS Region where the node is located. Connectivity to this endpoint is not required for a node to appear in your managed nodes list.

Check	Details
Connectivity to `logs` endpoint	Indicates whether the node is able to reach the service endpoint for Amazon CloudWatch Logs on TCP port 443. A failed test indicates connectivity issues to `https://logs.` *`region`*`.amazonaws.com` depending on the AWS Region where the node is located. Connectivity to this endpoint is not required for a node to appear in your managed nodes list.
Connectivity to `monitoring` endpoint	Indicates whether the node is able to reach the service endpoint for Amazon CloudWatch on TCP port 443. A failed test indicates connectivity issues to `https://monitoring.` *`region`*`.amazonaws.com` depending on the AWS Region where the node is located. Connectivity to this endpoint is not required for a node to appear in your managed nodes list.
AWS Credentials	Indicates whether SSM Agent has the required credentials based on the IAM instance profile (for EC2 instances) or IAM service role (for non-EC2 machines) attached to the machine. A failed test indicates that no IAM instance profile or IAM service role is attached to the machine, or it does not contain the required permissions for Systems Manager.
Agent service	Indicates whether SSM Agent service is running, and whether the service is running as root for Linux or macOS, or SYSTEM for Windows Server. A failed test indicates SSM Agent service is not running or is not running as root or SYSTEM.

Check	Details
Proxy configuration	Indicates whether SSM Agent is configured to use a proxy.
Sysprep image state (Windows only)	Indicates the state of `Sysprep` on the node. SSM Agent will not start on the node if the `Sysprep` state is a value other than `IMAGE_STATE_COMPLETE` .
SSM Agent version	Indicates whether the latest available version of SSM Agent is installed.

AWS Systems Manager Hybrid Activations

To configure non-EC2 machines for use with AWS Systems Manager in a hybrid and multicloud environment, you create a *hybrid activation*. Non-EC2 machine types supported as managed nodes include the following:

- Servers on your own premises (on-premises servers)
- AWS IoT Greengrass core devices
- AWS IoT and non-AWS edge devices
- Virtual machines (VMs), including VMs in other cloud environments

When you run the create-activation command to start a hybrid activation process, you receive an activation code and ID in the command response. You then include the activation code and ID with the command to install SSM Agent on the machine, as described in step 3 of Install SSM Agent on hybrid Linux nodes and step 4 of Install SSM Agent on hybrid Windows Server nodes.

This activation process applies to all non-EC2 machine types *except* AWS IoT Greengrass core devices. For information about configuring AWS IoT Greengrass core devices for Systems Manager, see Managing edge devices with Systems Manager.

> **Note**
>
> Support isn't currently provided for non-EC2 macOS machines.

About Systems Manager instances tiers

AWS Systems Manager offers a standard-instances tier and an advanced-instances tier. Both support managed nodes in your hybrid and multicloud environment. The standard-instances tier allows you to register a maximum of 1,000 machines per AWS account per AWS Region. If you need to register more than 1,000 machines in a single account and Region, then use the advanced-instances tier. You can create as many managed nodes as you like in the advanced-instances tier. All managed nodes configured for Systems Manager are priced on a pay-per-use basis. For more information about enabling the advanced instances tier, see Turning on the advanced-instances tier. For more information about pricing, see AWS Systems Manager Pricing.

Note the following additional information about the standard-instances tier and advanced-instances tier:

- Advanced instances also allow you to connect to your non-EC2 nodes in a hybrid and multicloud environment by using AWS Systems Manager Session Manager. Session Manager provides interactive shell access to your instances. For more information, see AWS Systems Manager Session Manager.
- The standard-instances quota also applies to EC2 instances that use a Systems Manager on-premises activation (which isn't a common scenario).
- To patch applications released by Microsoft on virtual machines (VMs) on-premises instances, activate the advanced-instances tier. There is a charge to use the advanced-instances tier. There is no additional charge to patch applications released by Microsoft on Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information, see Patching applications released by Microsoft on Windows Server.

AWS Systems Manager Inventory

AWS Systems Manager Inventory provides visibility into your AWS computing environment. You can use Inventory to collect *metadata* from your managed nodes. You can store this metadata in a central Amazon Simple Storage Service (Amazon S3) bucket, and then use built-in tools to query the data and quickly determine which nodes are running the software and configurations required by your software policy, and which nodes need to be updated. You can configure Inventory on all of your managed nodes by using a one-click procedure. You can also configure and view inventory data from multiple AWS Regions and AWS accounts by using Amazon Athena. To get started with Inventory, open the Systems Manager console. In the navigation pane, choose **Inventory**.

If the pre-configured metadata types collected by Systems Manager Inventory don't meet your needs, then you can create custom inventory. Custom inventory is simply a JSON file with information that you provide and add to the managed node in a specific directory. When Systems Manager Inventory collects data, it captures this custom inventory data. For example, if you run a large data center, you can specify the rack location of each of your servers as custom inventory. You can then view the rack space data when you view other inventory data.

> **Important**
>
> Systems Manager Inventory collects *only* metadata from your managed nodes. Inventory doesn't access proprietary information or data.

The following table describes the types of data you can collect with Systems Manager Inventory. The table also describes different offerings for targeting nodes and the collection intervals you can specify.

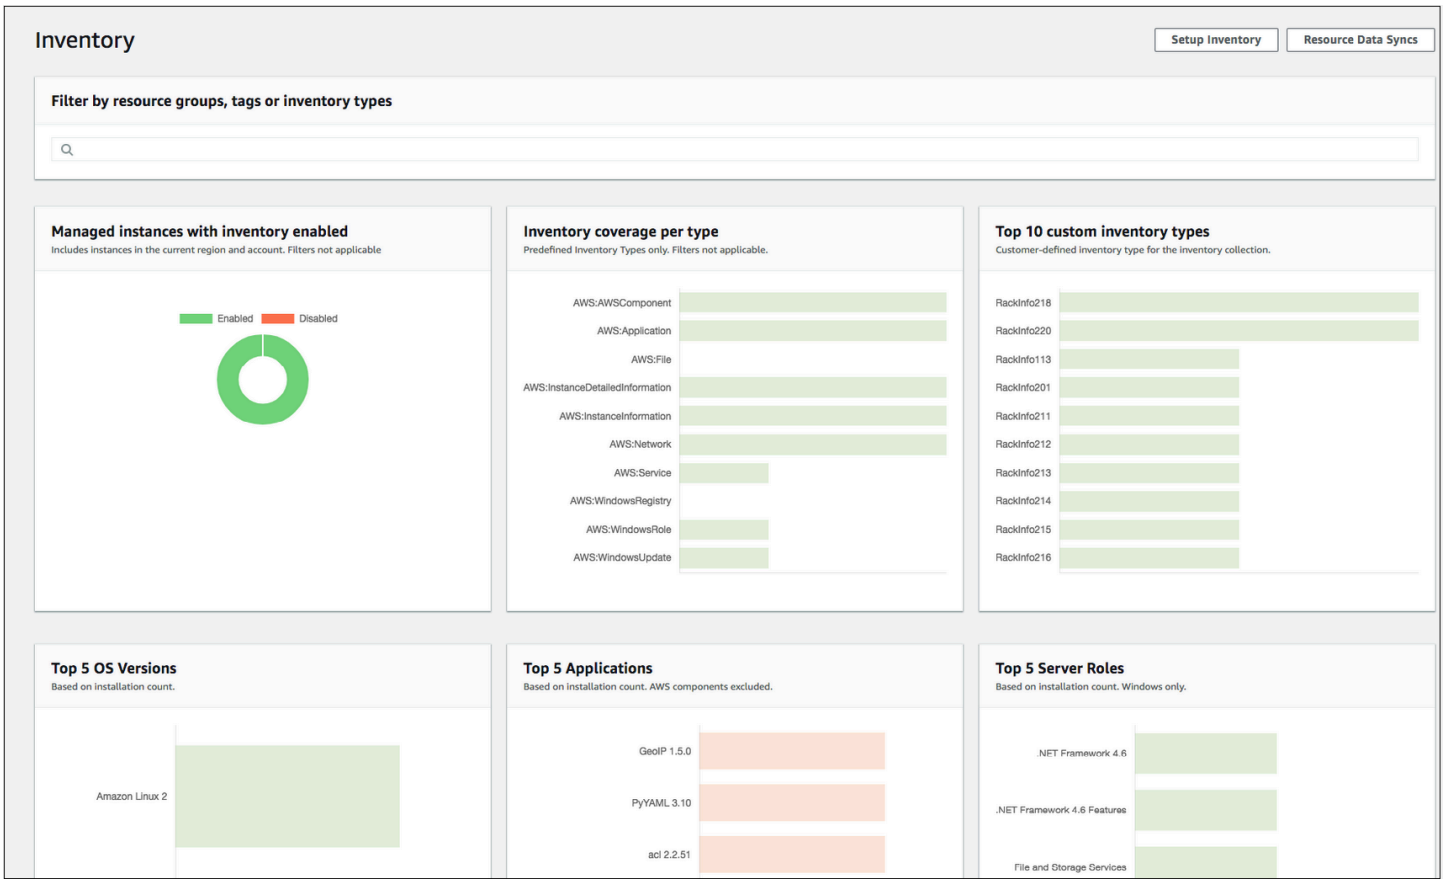
Configuration	Details
Metadata types	You can configure Inventory to collect the following types of data: • **Applications**: Application names, publishers, versions, etc. • **AWS components**: EC2 driver, agents, versions, etc. • **Files**: Name, size, version, installed date, modification and last accessed times, etc. • **Network configuration**: IP address, MAC address, DNS, gateway, subnet mask, etc. • **Windows updates**: Hotfix ID, installed by, installed date, etc. • **Instance details**: CPUModel, CPUCores, CPUs, CPUSpeedMHz, CPUSockets, CPUHyperThreadEnabled, OSService Packetc.

Configuration	Details
	• **Services**: Name, display name, status, dependent services, service type, start type, etc. • **Tags**: Tags assigned to your nodes. • **Windows Registry**: Registry key path, value name, value type, and value. • **Windows roles**: Name, display name, path, feature type, installed state, etc. • **Custom inventory**: Metadata that was assigned to a managed node as described in Working with custom inventory. **Note** To view a list of all metadata collected by Inventory, see Metadata collected by Inventory.
Nodes to target	You can choose to inventory all managed nodes in your AWS account, individually select nodes, or target groups of nodes by using tags. For more information about collectin g inventory data from all of your managed nodes, see Inventory all managed nodes in your AWS account.
When to collect information	You can specify a collection interval in terms of minutes, hours, and days. The shortest collection interval is every 30 minutes.

Note

Depending on the amount of data collected, the system can take several minutes to report the data to the output you specified. After the information is collected, the data is sent over a secure HTTPS channel to a plain-text AWS store that is accessible only from your AWS account.

You can view the data in the Systems Manager console on the **Inventory** page, which includes several predefined cards to help you query the data.



Note

Inventory cards automatically filter out Amazon EC2 managed instances with a state of *Terminated* and *Stopped*. For on-premises and AWS IoT Greengrass core device managed nodes, Inventory cards automatically filter out nodes with a state of *Terminated*.

If you create a resource data sync to synchronize and store all of your data in a single Amazon S3 bucket, then you can drill down into the data on the **Inventory Detailed View** page. For more information, see Querying inventory data from multiple Regions and accounts.

EventBridge support

This Systems Manager tool is supported as an *event* type in Amazon EventBridge rules. For information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

Contents

Learn more about Systems Manager Inventory

When you configure AWS Systems Manager Inventory, you specify the type of metadata to collect, the managed nodes from where the metadata should be collected, and a schedule for metadata collection. These configurations are saved with your AWS account as an AWS Systems Manager State Manager association. An association is simply a configuration.

> **Note**
>
> Inventory only collects metadata. It doesn't collect any personal or proprietary data.

        { "name": "ServerComponentDescriptor",      "dataType": "STRING"},
        { "name": "Parent",                         "dataType": "STRING"}
      ]
    },
    {
      "typeName": "AWS:Tag",
      "version":"1.0",
      "attributes":[
        { "name": "Key",                       "dataType": "STRING"},
```

```
        { "name": "Value",                    "dataType": "STRING"}
      ]
    },
    {
      "typeName": "AWS:ResourceGroup",
      "version":"1.0",
      "attributes":[
        { "name": "Name",                   "dataType": "STRING"},
        { "name": "Arn",                    "dataType": "STRING"}
      ]
    },
    {
      "typeName": "AWS:BillingInfo",
      "version": "1.0",
      "attributes": [
        { "name": "BillingProductId",       "dataType": "STRING"}
      ]
    }
```

Note

- For `"typeName": "AWS:InstanceInformation"`, `InstanceStatus` can be one of the following: Active, ConnectionLost, Stopped, Terminated.
- With the release of version 2.5, RPM Package Manager replaced the Serial attribute with Epoch. The Epoch attribute is a monotonically increasing integer like Serial. When you inventory by using the `AWS:Application` type, a larger value for Epoch means a newer version. If Epoch values are the same or empty, then use the value of the Version or Release attribute to determine the newer version.
- Some metadata is not available from Linux instances. Specifically, for "typeName": "AWS:Network", the following metadata types are not yet supported for Linux instances. They ARE supported for Windows.
  - { "name": "SubnetMask", "dataType": "STRING"},
  - { "name": "DHCPServer", "dataType": "STRING"},
  - { "name": "DNSServer", "dataType": "STRING"},
  - { "name": "Gateway", "dataType": "STRING"},

Working with file and Windows registry inventory

AWS Systems Manager Inventory allows you to search and inventory files on Windows Server, Linux, and macOS operating systems. You can also search and inventory the Windows Registry.

Files: You can collect metadata information about files, including file names, the time files were created, the time files were last modified and accessed, and file sizes, to name a few. To start collecting file inventory, you specify a file path where you want to perform the inventory, one or more patterns that define the types of files you want to inventory, and if the path should be traversed recursively. Systems Manager inventories all file metadata for files in the specified path that match the pattern. File inventory uses the following parameter input.

```
{
"Path": string,
"Pattern": array[string],
"Recursive": true,
"DirScanLimit" : number // Optional
}
```

- **Path**: The directory path where you want to inventory files. For Windows, you can use environment variables like `%PROGRAMFILES%` as long as the variable maps to a single directory path. For example, if you use %PATH% that maps to multiple directory paths, Inventory throws an error.
- **Pattern**: An array of patterns to identify files.
- **Recursive**: A Boolean value indicating whether Inventory should recursively traverse the directories.
- **DirScanLimit**: An optional value specifying how many directories to scan. Use this parameter to minimize performance impact on your managed nodes. Inventory scans a maximum of 5,000 directories.

> **Note**
>
> Inventory collects metadata for a maximum of 500 files across all specified paths.

Here are some examples of how to specify the parameters when performing an inventory of files.

- On Linux and macOS, collect metadata of .sh files in the `/home/ec2-user` directory, excluding all subdirectories.

```
[{"Path":"/home/ec2-user","Pattern":["*.sh", "*.sh"],"Recursive":false}]
```

- On Windows, collect metadata of all ".exe" files in the Program Files folder, including subdirectories recursively.

```
[{"Path":"C:\Program Files","Pattern":["*.exe"],"Recursive":true}]
```

- On Windows, collect metadata of specific log patterns.

```
[{"Path":"C:\ProgramData\Amazon","Pattern":["*amazon*.log"],"Recursive":true}]
```

- Limit the directory count when performing recursive collection.

```
[{"Path":"C:\Users","Pattern":["*.ps1"],"Recursive":true, "DirScanLimit": 1000}]
```

Windows Registry: You can collect Windows Registry keys and values. You can choose a key path and collect all keys and values recursively. You can also collect a specific registry key and its value for a specific path. Inventory collects the key path, name, type, and the value.

```
{
"Path": string,
"Recursive": true,
"ValueNames": array[string] // optional
}
```

- **Path**: The path to the Registry key.
- **Recursive**: A Boolean value indicating whether Inventory should recursively traverse Registry paths.
- **ValueNames**: An array of value names for performing inventory of Registry keys. If you use this parameter, Systems Manager will inventory only the specified value names for the specified path.

> **Note**
>
> Inventory collects a maximum of 250 Registry key values for all specified paths.

Here are some examples of how to specify the parameters when performing an inventory of the Windows Registry.

- Collect all keys and values recursively for a specific path.

```
[{"Path":"HKEY_LOCAL_MACHINE\SOFTWARE\Amazon","Recursive": true}]
```

- Collect all keys and values for a specific path (recursive search turned off).

```
[{"Path":"HKEY_LOCAL_MACHINE\SOFTWARE\Intel\PSIS\PSIS_DECODER", "Recursive": false}]
```

- Collect a specific key by using the `ValueNames` option.

```
{"Path":"HKEY_LOCAL_MACHINE\SOFTWARE\Amazon\MachineImage","ValueNames":["AMIName"]}
```

Setting up Systems Manager Inventory

Before you use AWS Systems Manager Inventory to collect metadata about the applications, services, AWS components and more running on your managed nodes, we recommend that you configure resource data sync to centralize the storage of your inventory data in a single Amazon Simple Storage Service (Amazon S3) bucket. We also recommend that you configure Amazon EventBridge monitoring of inventory events. These processes make it easier to view and manage inventory data and collection.

Topics

Creating a resource data sync for Inventory

This topic describes how to set up and configure resource data sync for AWS Systems Manager Inventory. For information about resource data sync for Systems Manager Explorer, see Setting up Systems Manager Explorer to display data from multiple accounts and Regions.

About resource data sync

You can use Systems Manager resource data sync to send inventory data collected from all of your managed nodes to a single Amazon Simple Storage Service (Amazon S3) bucket. Resource data

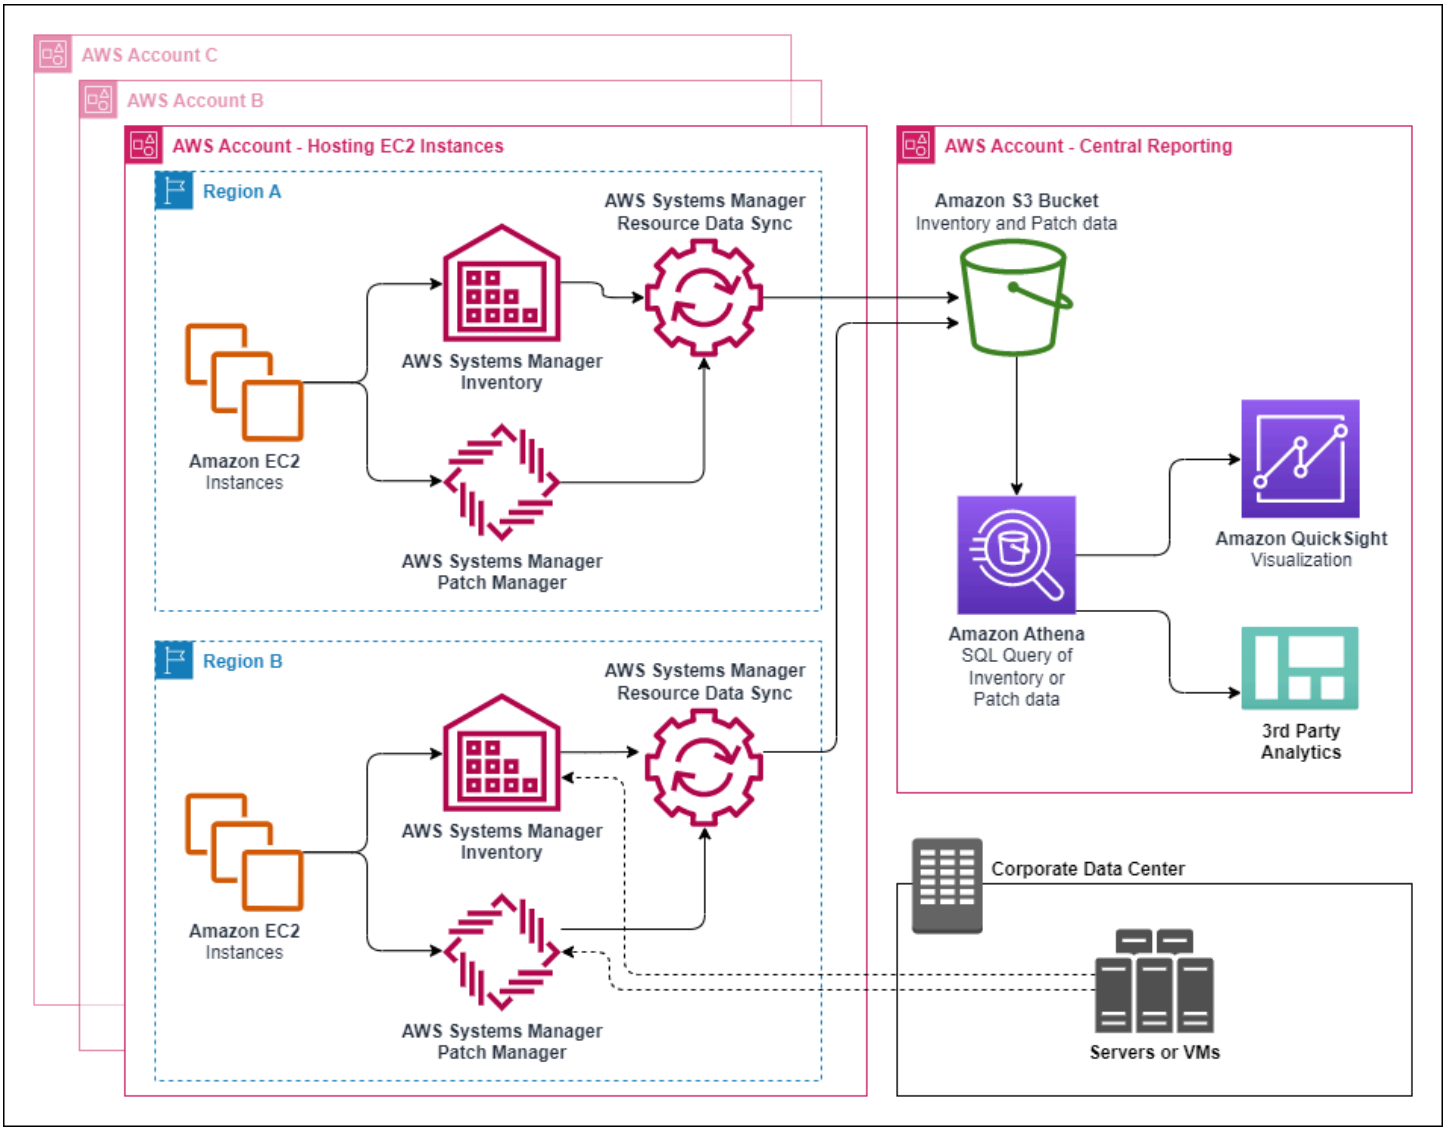
sync then automatically updates the centralized data when new inventory data is collected. With all inventory data stored in a target Amazon S3 bucket, you can use services like Amazon Athena and Amazon QuickSight to query and analyze the aggregated data.

For example, say that you've configured inventory to collect data about the operating system (OS) and applications running on a fleet of 150 managed nodes. Some of these nodes are located in an on-premises data center, and others are running in Amazon Elastic Compute Cloud (Amazon EC2) across multiple AWS Regions. If you have *not* configured resource data sync, you either need to manually gather the collected inventory data for each managed node, or you have to create scripts to gather this information. You would then need to port the data into an application so that you can run queries and analyze it.

With resource data sync, you perform a one-time operation that synchronizes all inventory data from all of your managed nodes. After the sync is successfully created, Systems Manager creates a baseline of all inventory data and saves it in the target Amazon S3 bucket. When new inventory data is collected, Systems Manager automatically updates the data in the Amazon S3 bucket. You can then quickly and cost-effectively port the data to Amazon Athena and Amazon QuickSight.

Diagram 1 shows how resource data sync aggregates inventory data from Amazon EC2 and other machine types in a hybrid and multicloud environment to a target Amazon S3 bucket. This diagram also shows how resource data sync works with multiple AWS accounts and AWS Regions.

Diagram 1: Resource data sync with multiple AWS accounts and AWS Regions



If you delete a managed node, resource data sync preserves the inventory file for the deleted node. For running nodes, however, resource data sync automatically overwrites old inventory files when new files are created and written to the Amazon S3 bucket. If you want to track inventory changes over time, you can use the AWS Config service to track the `SSM:ManagedInstanceInventory` resource type. For more information, see Getting Started with AWS Config.

Use the procedures in this section to create a resource data sync for Inventory by using the Amazon S3 and AWS Systems Manager consoles. You can also use AWS CloudFormation to create or delete a resource data sync. To use AWS CloudFormation, add the `AWS::SSM::ResourceDataSync` resource to your AWS CloudFormation template. For information, see one of the following documentation resources:

- AWS CloudFormation resource for resource data sync in AWS Systems Manager (blog)

- Working with AWS CloudFormation Templates in the *AWS CloudFormation User Guide*

> **Note**
>
> You can use AWS Key Management Service (AWS KMS) to encrypt inventory data in the Amazon S3 bucket. For an example of how to create an encrypted sync by using the AWS Command Line Interface (AWS CLI) and how to work with the centralized data in Amazon Athena and Amazon QuickSight, see Walkthrough: Using resource data sync to aggregate inventory data.

Before you begin

Before you create a resource data sync, use the following procedure to create a central Amazon S3 bucket to store aggregated inventory data. The procedure describes how to assign a bucket policy that allows Systems Manager to write inventory data to the bucket from multiple accounts. If you already have an Amazon S3 bucket that you want to use to aggregate inventory data for resource data sync, then you must configure the bucket to use the policy in the following procedure.

> **Note**
>
> Systems Manager Inventory can't add data to a specified Amazon S3 bucket if that bucket is configured to use Object Lock. Verify that the Amazon S3 bucket you create or choose for resource data sync isn't configured to use Amazon S3 Object Lock. For more information, see How Amazon S3 Object Lock works in the *Amazon Simple Storage Service User Guide*.

To create and configure an Amazon S3 bucket for resource data sync

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Create a bucket to store your aggregated Inventory data. For more information, see Create a Bucket in the *Amazon Simple Storage Service User Guide*. Make a note of the bucket name and the AWS Region where you created it.
3. Choose the **Permissions** tab, and then choose **Bucket Policy**.
4. Copy and paste the following bucket policy into the policy editor. Replace *amzn-s3-demo-bucket* with the name of the S3 bucket you created. Replace *account_ID_number* with a valid AWS account ID number.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SSMBucketPermissionsCheck",
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "s3:GetBucketAcl",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
            "Sid": " SSMBucketDelivery",
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket/*/accountid=111122223333/
*",
                "arn:aws:s3:::amzn-s3-demo-bucket/*/accountid=444455556666/
*",
                "arn:aws:s3:::amzn-s3-demo-bucket/*/accountid=123456789012/
*",
                "arn:aws:s3:::amzn-s3-demo-bucket/*/accountid=777788889999/*"
            ],
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control",
                    "aws:SourceAccount": "111122223333"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:ssm:*:111122223333:resource-
data-sync/*"
                }
            }
        }
    ]
```

```
}
```

5. Save your changes.

Create a resource data sync for Inventory

Use the following procedure to create a resource data sync for Systems Manager Inventory by using the Systems Manager console. For information about how to create a resource data sync by using the AWS CLI, see Using the AWS CLI to configure inventory data collection.

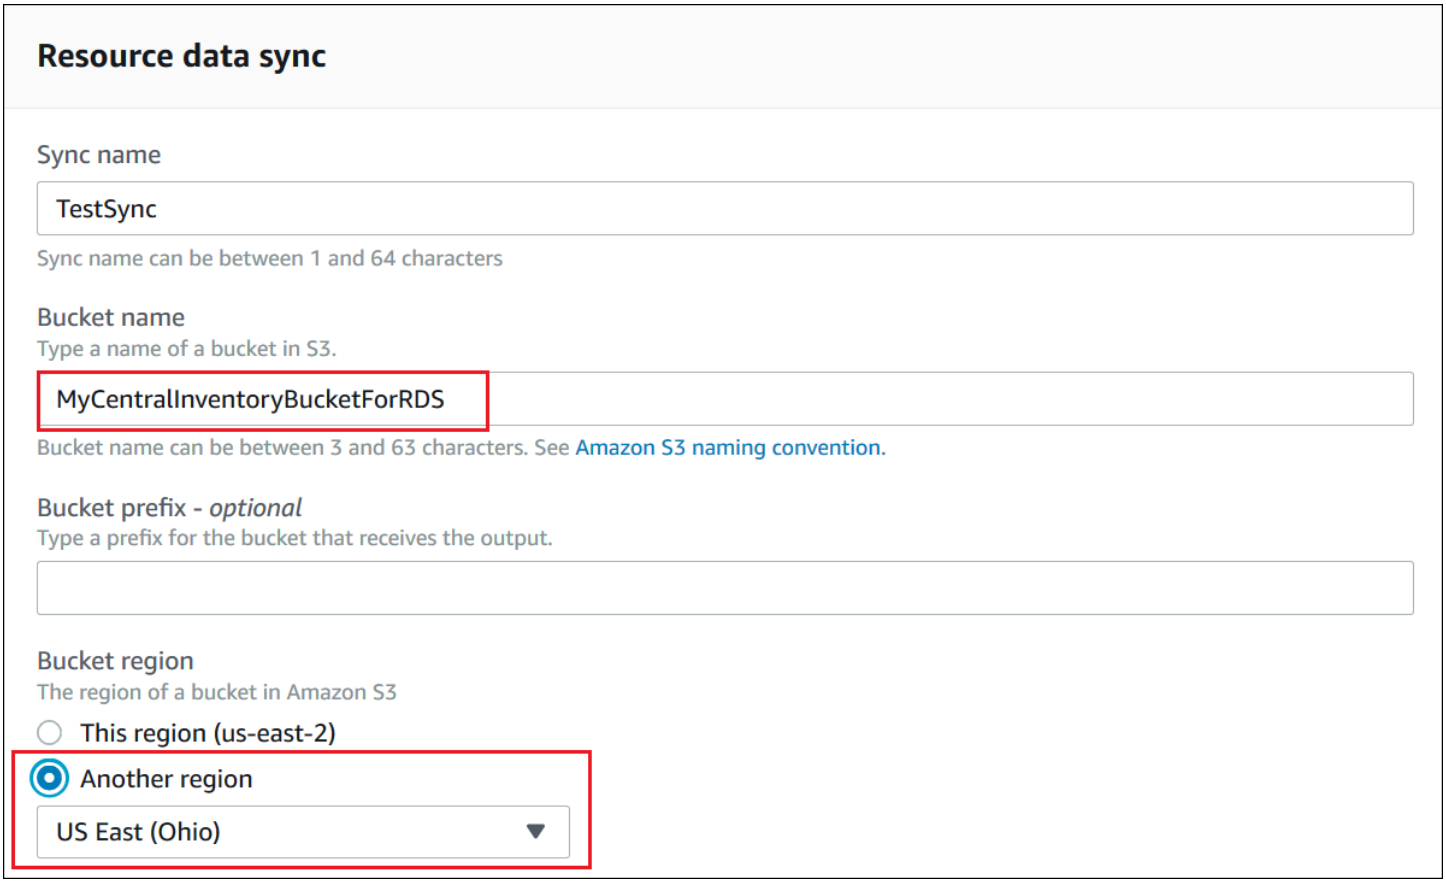
To create a resource data sync

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. In the **Account management** menu, choose **Resource data sync**.
4. Choose **Create resource data sync**.
5. In the **Sync name** field, enter a name for the sync configuration.
6. In the **Bucket name** field, enter the name of the Amazon S3 bucket you created using the **To create and configure an Amazon S3 bucket for resource data sync** procedure.
7. (Optional) In the **Bucket prefix** field, enter the name of an Amazon S3 bucket prefix (subdirectory).
8. In the **Bucket region** field, choose **This region** if the Amazon S3 bucket you created is located in the current AWS Region. If the bucket is located in a different AWS Region, choose **Another region**, and enter the name of the Region.

   > **Note**
   >
   > If the sync and the target Amazon S3 bucket are located in different regions, you might be subject to data transfer pricing. For more information, see Amazon S3 Pricing.

9. (Optional) In the **KMS Key ARN** field, type or paste a KMS Key ARN to encrypt inventory data in Amazon S3.
10. Choose **Create**.

To synchronize inventory data from multiple AWS Regions, you must create a resource data sync in *each* Region. Repeat this procedure in each AWS Region where you want to collect inventory data and send it to the central Amazon S3 bucket. When you create the sync in each Region, specify the central Amazon S3 bucket in the **Bucket name** field. Then use the **Bucket region** option to choose the Region where you created the central Amazon S3 bucket, as shown in the following screen shot. The next time the association runs to collect inventory data, Systems Manager stores the data in the central Amazon S3 bucket.



Creating an inventory resource data sync for accounts defined in AWS Organizations

You can synchronize inventory data from AWS accounts defined in AWS Organizations to a central Amazon S3 bucket. After you complete the following procedures, inventory data is synchronized to *individual* Amazon S3 key prefixes in the central bucket. Each key prefix represents a different AWS account ID.

Before you begin

Before you begin, verify that you set up and configured AWS accounts in AWS Organizations. For more information, see in the *AWS Organizations User Guide.*

Also, be aware that you must create the organization-based resource data sync for each AWS Region and AWS account defined in AWS Organizations.

Creating a central Amazon S3 bucket

Use the following procedure to create a central Amazon S3 bucket to store aggregated inventory data. The procedure describes how to assign a bucket policy that allows Systems Manager to write inventory data to the bucket from your AWS Organizations account ID. If you already have an Amazon S3 bucket that you want to use to aggregate inventory data for resource data sync, then you must configure the bucket to use the policy in the following procedure.

To create and configure an Amazon S3 bucket for resource data sync for multiple accounts defined in AWS Organizations

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Create a bucket to store your aggregated inventory data. For more information, see Create a Bucket in the *Amazon Simple Storage Service User Guide*. Make a note of the bucket name and the AWS Region where you created it.
3. Choose the **Permissions** tab, and then choose **Bucket Policy**.
4. Copy and paste the following bucket policy into the policy editor. Replace *amzn-s3-demo-bucket* and *organization-id* with the name of the Amazon S3 bucket you created and a valid AWS Organizations account ID.

   Optionally, replace *bucket-prefix* with the name of an Amazon S3 prefix (subdirectory). If you didn't create a prefix, remove *bucket-prefix*/ from the ARN in the following policy.

   JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SSMBucketPermissionsCheck",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "s3:GetBucketAcl",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
```

```
    },
    {
      "Sid": " SSMBucketDelivery",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "s3:PutObject",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/bucket-prefix/*/accountid=*/*"
      ],
      "Condition": {
        "StringEquals": {
          "s3:x-amz-acl": "bucket-owner-full-control",
          "aws:SourceOrgID": "organization-id"
                  }
      }
    },
    {
      "Sid": " SSMBucketDeliveryTagging",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "s3:PutObjectTagging",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/bucket-prefix/*/accountid=*/*"
      ]
    }
  ]
}
```

Create an inventory resource data sync for accounts defined in AWS Organizations

The following procedure describes how to use the AWS CLI to create a resource data sync for accounts that are defined in AWS Organizations. You must use the AWS CLI to perform this task. You must also perform this procedure for each AWS Region and AWS account defined in AWS Organizations.

To create a resource data sync for an account defined in AWS Organizations (AWS CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command to verify that you don't have any other *AWS Organizations-based* resource data syncs. You can have multiple standard syncs, including multiple standard syncs and an Organizations-based sync. But, you can only have one Organizations-based resource data sync.

```
aws ssm list-resource-data-sync
```

   If the command returns other Organizations-based resource data sync, you must delete them or choose not to create a new one.

3. Run the following command to create a resource data sync for an account defined in AWS Organizations. For amzn-s3-demo-bucket, specify the name of the Amazon S3 bucket you created earlier in this topic. If you created a prefix (subdirectory) for your bucket, then specify this information for *prefix-name*.

```
aws ssm create-resource-data-sync --sync-name name --s3-
destination "BucketName=amzn-s3-demo-bucket,Prefix=prefix-
name,SyncFormat=JsonSerDe,Region=AWS Region, for example us-
east-2,DestinationDataSharing={DestinationDataSharingType=Organization}"
```

4. Repeat Steps 2 and 3 for every AWS Region and AWS account where you want to synchronize data to the central Amazon S3 bucket.

Managing resource data syncs

Each AWS account can have 5 resource data syncs per AWS Region. You can use the AWS Systems Manager Fleet Manager console to manage your resource data syncs.

To view resource data syncs

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. In the **Account management** dropdown, choose **Resource data syncs**.
4. Select a resource data sync from the table, and then choose **View details** to view information about your resource data sync.

To delete a resource data sync

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. In the **Account management** dropdown, choose **Resource data syncs**.
4. Select a resource data sync from the table, and then choose **Delete**.

Using EventBridge to monitor Inventory events

You can configure a rule in Amazon EventBridge to create an event in response to AWS Systems Manager Inventory resource state changes. EventBridge supports events for the following Inventory state changes. All events are sent on a best effort basis.

Custom inventory type deleted for a specific instance: If a rule is configured to monitor for this event, EventBridge creates an event when a custom inventory type on a specific managed is deleted. EventBridge sends one event per node per custom inventory type. Here is a sample event pattern.

```
{
    "timestampMillis": 1610042981103,
    "source": "SSM",
    "account": "123456789012",
    "type": "INVENTORY_RESOURCE_STATE_CHANGE",
    "startTime": "Jan 7, 2021 6:09:41 PM",
    "resources": [
        {
            "arn": "arn:aws:ssm:us-east-1:123456789012:managed-instance/i-12345678"
        }
    ],
    "body": {
        "action-status": "succeeded",
        "action": "delete",
        "resource-type": "managed-instance",
        "resource-id": "i-12345678",
        "action-reason": "",
        "type-name": "Custom:MyCustomInventoryType"
    }
}
```

Custom inventory type deleted event for all instances: If a rule is configured to monitor for this event, EventBridge creates an event when a custom inventory type for all managed nodes is deleted. Here is a sample event pattern.

```
{
    "timestampMillis": 1610042904712,
    "source": "SSM",
    "account": "123456789012",
    "type": "INVENTORY_RESOURCE_STATE_CHANGE",
    "startTime": "Jan 7, 2021 6:08:24 PM",
    "resources": [

    ],
    "body": {
        "action-status": "succeeded",
        "action": "delete-summary",
        "resource-type": "managed-instance",
        "resource-id": "",
        "action-reason": "The delete for type name Custom:SomeCustomInventoryType
 was completed. The deletion summary is: {\"totalCount\":1,\"remainingCount\":0,
\"summaryItems\":[{\"version\":\"1.1\",\"count\":1,\"remainingCount\":0}]}",
        "type-name": "Custom:MyCustomInventoryType"
    }
}
```

PutInventory call with old schema version event: If a rule is configured to monitor for this event, EventBridge creates an event when a PutInventory call is made that uses a schema version that is lower than the current schema. This event applies to all inventory types. Here is a sample event pattern.

```
{
    "timestampMillis": 1610042629548,
    "source": "SSM",
    "account": "123456789012",
    "type": "INVENTORY_RESOURCE_STATE_CHANGE",
    "startTime": "Jan 7, 2021 6:03:49 PM",
    "resources": [
        {
            "arn": "arn:aws:ssm:us-east-1:123456789012:managed-instance/i-12345678"
        }
    ],
    "body": {
```

```
        "action-status": "failed",
        "action": "put",
        "resource-type": "managed-instance",
        "resource-id": "i-01f017c1b2efbe2bc",
        "action-reason": "The inventory item with type name
 Custom:MyCustomInventoryType was sent with a disabled schema verison 1.0. You must
 send a version greater than 1.0",
        "type-name": "Custom:MyCustomInventoryType"
    }
}
```

For information about how to configure EventBridge to monitor for these events, see Configuring EventBridge for Systems Manager events.

Configuring inventory collection

This section describes how to configure AWS Systems Manager Inventory collection on one or more managed nodes by using the Systems Manager console. For an example of how to configure inventory collection by using the AWS Command Line Interface (AWS CLI), see Using the AWS CLI to configure inventory data collection.

When you configure inventory collection, you start by creating a AWS Systems Manager State Manager association. Systems Manager collects the inventory data when the association is run. If you don't create the association first, and attempt to invoke the `aws:softwareInventory` plugin by using, for example, AWS Systems Manager Run Command, the system returns the following error: `The aws:softwareInventory plugin can only be invoked via ssm-associate.`

> **Note**
>
> Be aware of the following behavior if you create multiple inventory associations for a managed node:
>
> - Each node can be assigned an inventory association that targets *all* nodes (--targets "Key=InstanceIds,Values=*").
> - Each node can also be assigned a specific association that uses either tag key/value pairs or an AWS resource group.
> - If a node is assigned multiple inventory associations, the status shows *Skipped* for the association that hasn't run. The association that ran most recently displays the actual status of the inventory association.

- If a node is assigned multiple inventory associations and each uses a tag key/value pair, then those inventory associations fail to run on the node because of the tag conflict. The association still runs on nodes that don't have the tag key/value conflict.

Before You Begin

Before you configure inventory collection, complete the following tasks.

- Update AWS Systems Manager SSM Agent on the nodes you want to inventory. By running the latest version of SSM Agent, you ensure that you can collect metadata for all supported inventory types. For information about how to update SSM Agent by using State Manager, see Walkthrough: Automatically update SSM Agent with the AWS CLI.
- Verify that you have completed the setup requirements for your Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 machines in a hybrid and multicloud environment. For information, see Setting up managed nodes for AWS Systems Manager.
- For Microsoft Windows Server nodes, verify that your managed node is configured with Windows PowerShell 3.0 (or later). SSM Agent uses the `ConvertTo-Json` cmdlet in PowerShell to convert Windows update inventory data to the required format.
- (Optional) Create a resource data sync to centrally store inventory data in an Amazon S3 bucket. resource data sync then automatically updates the centralized data when new inventory data is collected. For more information, see Walkthrough: Using resource data sync to aggregate inventory data.
- (Optional) Create a JSON file to collect custom inventory. For more information, see Working with custom inventory.

Inventory all managed nodes in your AWS account

You can inventory all managed nodes in your AWS account by creating a global inventory association. A global inventory association performs the following actions:

- Automatically applies the global inventory configuration (association) to all existing managed nodes in your AWS account. Managed nodes that already have an inventory association are skipped when the global inventory association is applied and runs. When a node is skipped, the detailed status message states `Overridden By Explicit Inventory Association`. Those nodes are skipped by the global association, but they will still report inventory when they run their assigned inventory association.

- Automatically adds new nodes created in your AWS account to the global inventory association.

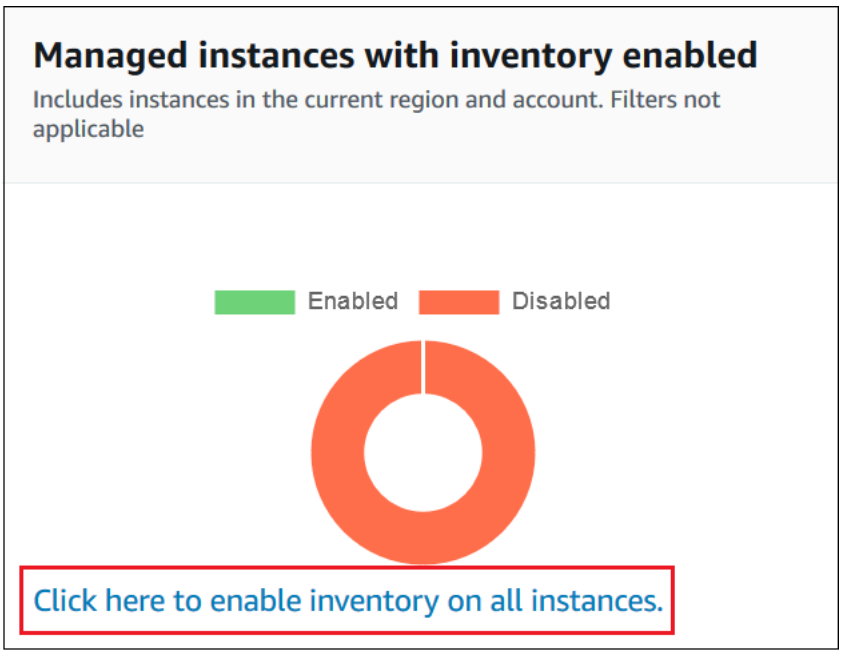
> **Note**
>
> - If a managed node is configured for the global inventory association, and you assign a specific association to that node, then Systems Manager Inventory deprioritizes the global association and applies the specific association.
> - Global inventory associations are available in SSM Agent version 2.0.790.0 or later. For information about how to update SSM Agent on your nodes, see Updating the SSM Agent using Run Command.

Configuring inventory collection with one click (console)

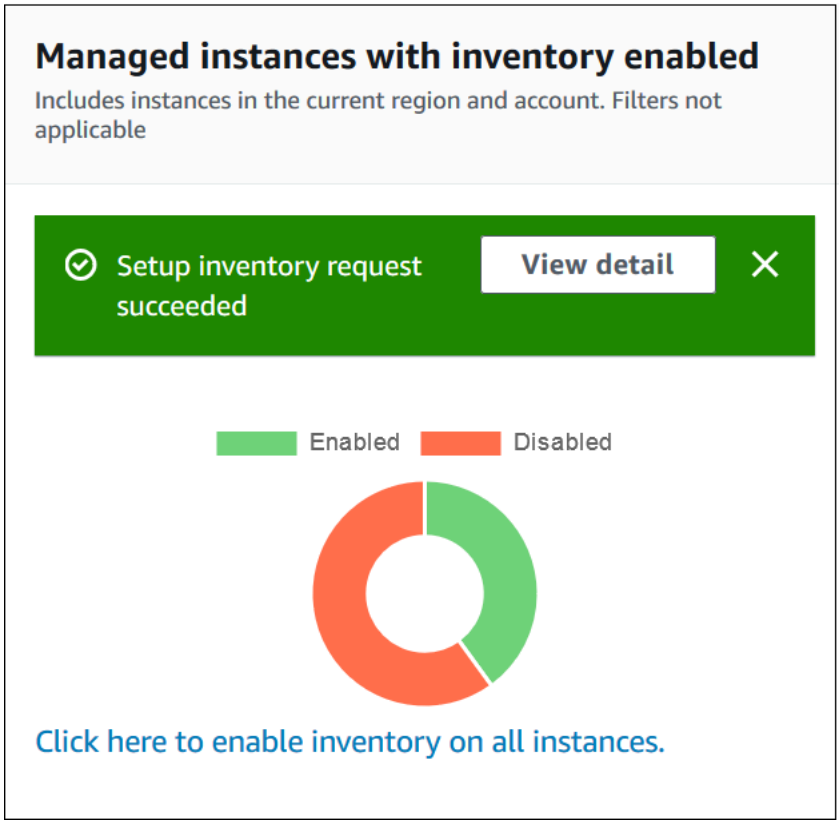
Use the following procedure to configure Systems Manager Inventory for all managed nodes in your AWS account and in a single AWS Region.

To configure all of your managed nodes in the current Region for Systems Manager inventory

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Inventory**.
3. In the **Managed instances with inventory enabled** card, choose **Click here to enable inventory on all instances**.



If successful, the console displays the following message.



Depending on the number of managed nodes in your account, it can take several minutes for the global inventory association to be applied. Wait a few minutes and then refresh the page.

Verify that the graphic changes to reflect that inventory is configured on all of your managed nodes.

Configuring collection by using the console

This section includes information about how to configure Systems Manager Inventory to collect metadata from your managed nodes by using the Systems Manager console. You can quickly collect metadata from all nodes in a specific AWS account (and any future nodes that might be created in that account) or you can selectively collect inventory data by using tags or node IDs.

> **Note**
>
> Before completing this procedure, check to see if a global inventory association already exists. If a global inventory association already exists, anytime you launch a new instance, the association will be applied to it, and the new instance will be inventoried.

To configure inventory collection

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Inventory**.
3. Choose **Setup Inventory**.
4. In the **Targets** section, identify the nodes where you want to run this operation by choosing one of the following.

   - **Selecting all managed instances in this account** - This option selects all managed nodes for which there is no existing inventory association. If you choose this option, nodes that already had inventory associations are skipped during inventory collection, and shown with a status of **Skipped** in inventory results. For more information, see Inventory all managed nodes in your AWS account.
   - **Specifying a tag** - Use this option to specify a single tag to identify nodes in your account from which you want to collect inventory. If you use a tag, any nodes created in the future with the same tag will also report inventory. If there is an existing inventory association with all nodes, using a tag to select specific nodes as a target for a different inventory overrides node membership in the **All managed instances** target group. Managed nodes with the specified tag are skipped on future inventory collection from **All managed instances**.

- **Manually selecting instances** - Use this option to choose specific managed nodes in your account. Explicitly choosing specific nodes by using this option overrides inventory associations on the **All managed instances** target. The node is skipped on future inventory collection from **All managed instances**.

> **Note**
>
> If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

5. In the **Schedule** section, choose how often you want the system to collect inventory metadata from your nodes.
6. In the **Parameters** section, use the lists to turn on or turn off different types of inventory collection. For more information about collecting File and Windows Registry inventory, see Working with file and Windows registry inventory.
7. In the **Advanced** section, choose **Sync inventory execution logs to an Amazon S3 bucket** if you want to store the association execution status in an Amazon S3 bucket.
8. Choose **Setup Inventory**. Systems Manager creates a State Manager association and immediately runs Inventory on the nodes.
9. In the navigation pane, choose **State Manager**. Verify that a new association was created that uses the **`AWS-GatherSoftwareInventory`** document. The association schedule uses a rate expression. Also, verify that the **Status** field shows **Success**. If you chose the option to **Sync inventory execution logs to an Amazon S3 bucket**, then you can view the log data in Amazon S3 after a few minutes. If you want to view inventory data for a specific node, then choose **Managed Instances** in the navigation pane.
10. Choose a node, and then choose **View details**.
11. On the node details page, choose **Inventory**. Use the **Inventory type** lists to filter the inventory.

Querying inventory data from multiple Regions and accounts

AWS Systems Manager Inventory integrates with Amazon Athena to help you query inventory data from multiple AWS Regions and AWS accounts. Athena integration uses resource data sync so that you can view inventory data from all of your managed nodes on the **Detailed View** page in the AWS Systems Manager console.

Important

This feature uses AWS Glue to crawl the data in your Amazon Simple Storage Service (Amazon S3) bucket, and Amazon Athena to query the data. Depending on how much data is crawled and queried, you can be charged for using these services. With AWS Glue, you pay an hourly rate, billed by the second, for crawlers (discovering data) and ETL jobs (processing and loading data). With Athena, you're charged based on the amount of data scanned by each query. We encourage you to view the pricing guidelines for these services before you use Amazon Athena integration with Systems Manager Inventory. For more information, see Amazon Athena pricing and AWS Glue pricing.

You can view inventory data on the **Detailed View** page in all AWS Regions where Amazon Athena is available. For a list of supported Regions, see Amazon Athena Service Endpoints in the *Amazon Web Services General Reference*.

Before you begin

Athena integration uses resource data sync. You must set up and configure resource data sync to use this feature. For more information, see Walkthrough: Using resource data sync to aggregate inventory data.

Also, be aware that the **Detailed View** page displays inventory data for the *owner* of the central Amazon S3 bucket used by resource data sync. If you aren't the owner of the central Amazon S3 bucket, then you won't see inventory data on the **Detailed View** page.

Configuring access

Before you can query and view data from multiple accounts and Regions on the **Detailed View** page in the Systems Manager console, you must configure your IAM entity with permission to view the data.

If the inventory data is stored in an Amazon S3 bucket that uses AWS Key Management Service (AWS KMS) encryption, you must also configure your IAM entity and the `Amazon-GlueServiceRoleForSSM` service role for AWS KMS encryption.

Topics

Configuring your IAM entity to access the Detailed View page

The following describes the minimum permissions required to view inventory data on the **Detailed View** page.

The **`AWSQuicksightAthenaAccess`** managed policy

The following `PassRole` and additional required permissions block

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowGlue",
            "Effect": "Allow",
            "Action": [
                "glue:GetCrawler",
                "glue:GetCrawlers",
                "glue:GetTables",
                "glue:StartCrawler",
                "glue:CreateCrawler"
            ],
            "Resource": "*"
        },
        {
            "Sid": "iamPassRole",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": [
                "arn:aws:iam::111122223333:role/SSMInventoryGlueRole",
                "arn:aws:iam::111122223333:role/SSMInventoryServiceRole"
            ],
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": "glue.amazonaws.com"
                }
            }
        },
        {
            "Sid": "iamRoleCreation",
            "Effect": "Allow",
```

```
            "Action": [
                "iam:CreateRole",
                "iam:AttachRolePolicy"
            ],
            "Resource": "arn:aws:iam::111122223333:role/*"
        },
        {
            "Sid": "iamPolicyCreation",
            "Effect": "Allow",
            "Action": "iam:CreatePolicy",
            "Resource": "arn:aws:iam::111122223333:policy/*"
        }
    ]
}
```

(Optional) If the Amazon S3 bucket used to store inventory data is encrypted by using AWS KMS, you must also add the following block to the policy.

```
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt"
    ],
    "Resource": [
        "arn:aws:kms:Region:account_ID:key/key_ARN"
    ]
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

(Optional) Configure permissions for viewing AWS KMS encrypted data

If the Amazon S3 bucket used to store inventory data is encrypted by using the AWS Key Management Service (AWS KMS), you must configure your IAM entity and the **Amazon-GlueServiceRoleForSSM** role with `kms:Decrypt` permissions for the AWS KMS key.

Before you begin

To provide the `kms:Decrypt` permissions for the AWS KMS key, add the following policy block to your IAM entity:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt"
    ],
    "Resource": [
        "arn:aws:kms:Region:account_ID:key/key_ARN"
    ]
}
```

If you haven't done so already, complete that procedure and add `kms:Decrypt` permissions for the AWS KMS key.

Use the following procedure to configure the **Amazon-GlueServiceRoleForSSM** role with `kms:Decrypt` permissions for the AWS KMS key.

To configure the Amazon-GlueServiceRoleForSSM role with `kms:Decrypt` permissions

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**, and then use the search field to locate the **Amazon-GlueServiceRoleForSSM** role. The **Summary** page opens.
3. Use the search field to find the **Amazon-GlueServiceRoleForSSM** role. Choose the role name. The **Summary** page opens.

4. Choose the role name. The **Summary** page opens.
5. Choose **Add inline policy**. The **Create policy** page opens.
6. Choose the **JSON** tab.
7. Delete the existing JSON text in the editor, and then copy and paste the following policy into the JSON editor.

   JSON

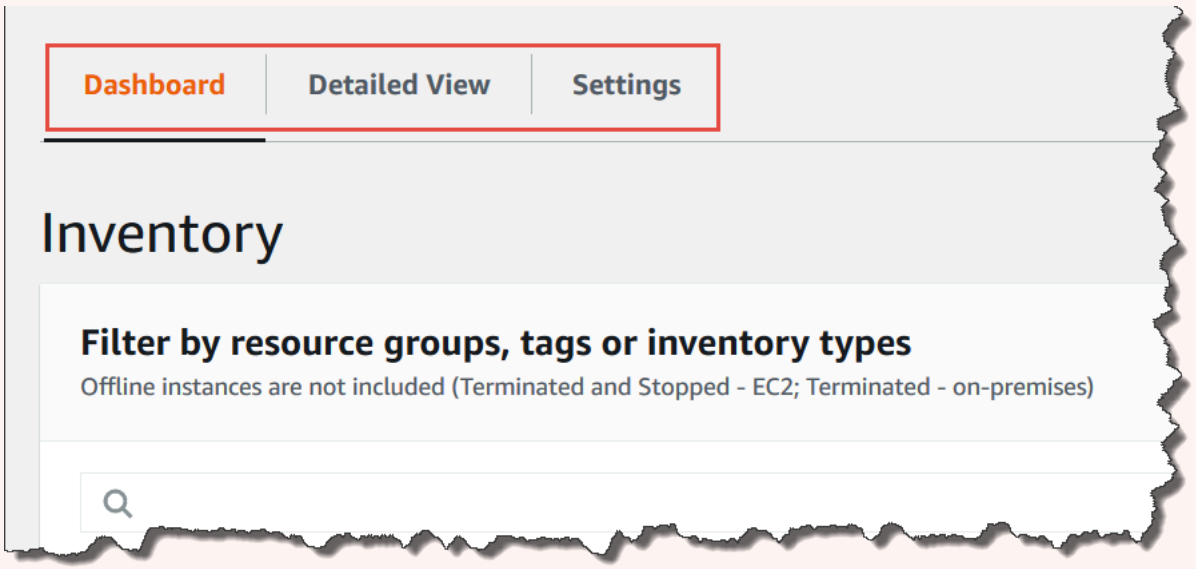
```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Resource": [
                "arn:aws:kms:us-east-1:111122223333:key/key_ARN"
            ]
        }
    ]
}
```

8. Choose **Review policy**
9. On the **Review Policy** page, enter a name in the **Name** field.
10. Choose **Create policy**.

Querying data on the inventory detailed view page

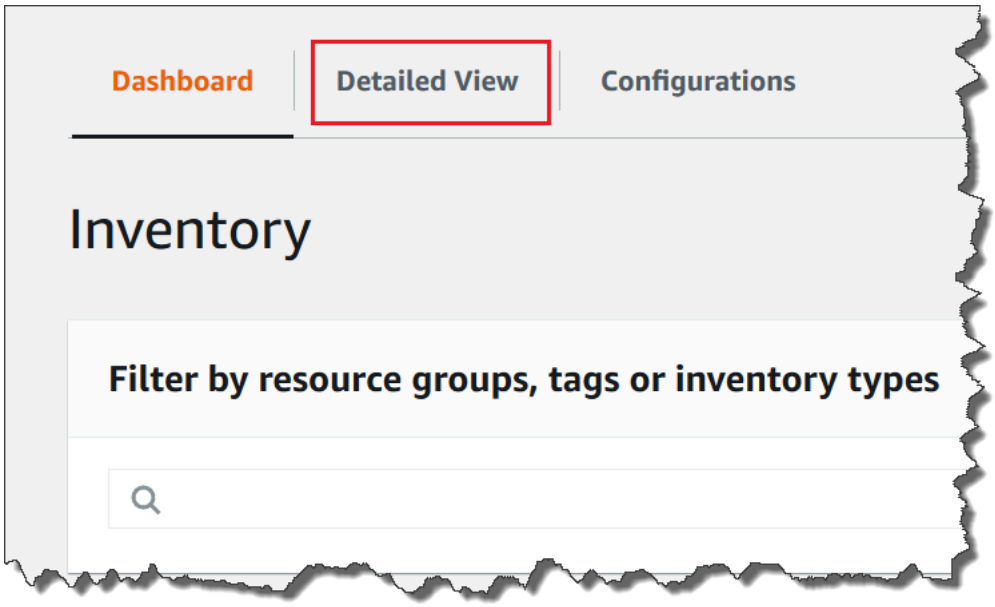
Use the following procedure to view inventory data from multiple AWS Regions and AWS accounts on the Systems Manager Inventory **Detailed View** page.

> **Important**
>
> The Inventory **Detailed View** page is only available in AWS Regions that offer Amazon Athena. If the following tabs aren't displayed on the Systems Manager Inventory page, it means Athena isn't available in the Region and you can't use the **Detailed View** to query data.

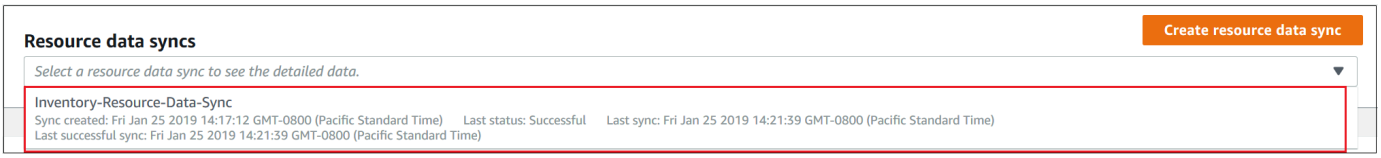


To view inventory data from multiple Regions and accounts in the AWS Systems Manager console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Inventory**.
3. Choose the **Detailed View** tab.

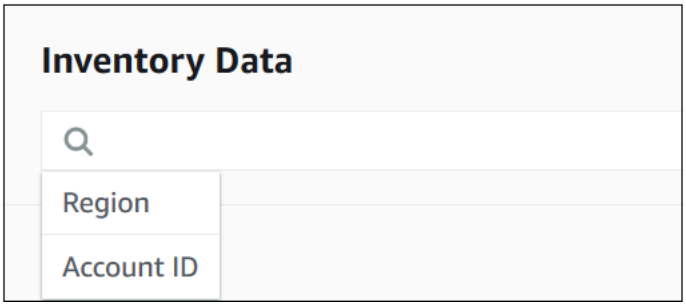


4. Choose the resource data sync for which you want to query data.



5. In the **Inventory Type** list, choose the type of inventory data that you want to query, and then press **Enter**.

6. To filter the data, choose the Filter bar, and then choose a filter option.



You can use the **Export to CSV** button to view the current query set in a spreadsheet application such as Microsoft Excel. You can also use the **Query History** and **Run Advanced Queries** buttons to view history details and interact with your data in Amazon Athena.

Editing the AWS Glue crawler schedule

AWS Glue crawls the inventory data in the central Amazon S3 bucket twice daily, by default. If you frequently change the types of data to collect on your nodes then you might want to crawl the data more frequently, as described in the following procedure.

> **Important**
>
> AWS Glue charges your AWS account based on an hourly rate, billed by the second, for crawlers (discovering data) and ETL jobs (processing and loading data). Before you change the crawler schedule, view the AWS Glue pricing page.

To change the inventory data crawler schedule

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **Crawlers**.
3. In the crawlers list, choose the option next to the Systems Manager Inventory data crawler. The crawler name uses the following format:

   `AWSSystemsManager-s3-bucket-name-Region-account_ID`
4. Choose **Action**, and then choose **Edit crawler**.
5. In the navigation pane, choose **Schedule**.
6. In the **Cron expression** field, specify a new schedule by using a cron format. For more information about the cron format, see Time-Based Schedules for Jobs and Crawlers in the *AWS Glue Developer Guide*.

> **Important**
>
> You can pause the crawler to stop incurring charges from AWS Glue. If you pause the crawler, or if you change the frequency so that the data is crawled less often, then the Inventory **Detailed View** might display data that isn't current.

Querying an inventory collection by using filters

After you collect inventory data, you can use the filter capabilities in AWS Systems Manager to query a list of managed nodes that meet certain filter criteria.

To query nodes based on inventory filters

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Inventory**.
3. In the **Filter by resource groups, tags or inventory types** section, choose the filter box. A list of predefined filters is displayed.
4. Choose an attribute to filter on. For example, choose **`AWS:Application`**. If prompted, choose a secondary attribute to filter. For example, choose **`AWS:Application.Name`**.

5. Choose a delimiter from the list. For example, choose **Begin with**. A text box is displayed in the filter.
6. Enter a value in the text box. For example, enter *Amazon* (SSM Agent is named *Amazon SSM Agent*).
7. Press **Enter**. The system returns a list of managed nodes that include an application name that begins with the word *Amazon*.

> **Note**
>
> You can combine multiple filters to refine your search.

Aggregating inventory data

After you configure your managed nodes for AWS Systems Manager Inventory, you can view aggregated counts of inventory data. For example, say you configured dozens or hundreds of managed nodes to collect the `AWS:Application` inventory type. By using the information in this section, you can see an exact count of how many nodes are configured to collect this data.

You can also see specific inventory details by aggregating on a data type. For example, the `AWS:InstanceInformation` inventory type collects operating system platform information with the `Platform` data type. By aggregating data on the `Platform` data type, you can quickly see how many nodes are running Windows Server, how many are running Linux, and how many are running macOS.

The procedures in this section describe how to view aggregated counts of inventory data by using the AWS Command Line Interface (AWS CLI). You can also view pre-configured aggregated counts in the AWS Systems Manager console on the **Inventory** page. These pre-configured dashboards are called *Inventory Insights* and they offer one-click remediation of your inventory configuration issues.

Note the following important details about aggregation counts of inventory data:

- If you terminate a managed node that is configured to collect inventory data, Systems Manager retains the inventory data for 30 days and then deletes it. For running nodes, the systems deletes inventory data that is older than 30 days. If you need to store inventory data longer than 30 days, you can use AWS Config to record history or periodically query and upload the data to an Amazon Simple Storage Service (Amazon S3) bucket.

- If a node was previously configured to report a specific inventory data type, for example `AWS:Network`, and later you change the configuration to stop collecting that type, aggregation counts still show `AWS:Network` data until the node has been terminated and 30 days have passed.

For information about how to quickly configure and collect inventory data from all nodes in a specific AWS account (and any future nodes that might be created in that account), see Inventory all managed nodes in your AWS account.

Topics

- Aggregating inventory data to see counts of nodes that collect specific types of data
- Aggregating inventory data with groups to see which nodes are and aren't configured to collect an inventory type

Aggregating inventory data to see counts of nodes that collect specific types of data

You can use the AWS Systems Manager GetInventory API operation to view aggregated counts of nodes that collect one or more inventory types and data types. For example, the `AWS:InstanceInformation` inventory type allows you to view an aggregate of operating systems by using the GetInventory API operation with the `AWS:InstanceInformation.PlatformType` data type. Here is an example AWS CLI command and output.

```
aws ssm get-inventory --aggregators "Expression=AWS:InstanceInformation.PlatformType"
```

The system returns information like the following.

```
{
   "Entities":[
      {
         "Data":{
            "AWS:InstanceInformation":{
               "Content":[
                  {
                     "Count":"7",
                     "PlatformType":"windows"
                  },
                  {
                     "Count":"5",
```

```
                    "PlatformType":"linux"
                }
            ]
        }
    }
  ]
}
```

Getting started

Determine the inventory types and data types for which you want to view counts. You can view a list of inventory types and data types that support aggregation by running the following command in the AWS CLI.

```
aws ssm get-inventory-schema --aggregator
```

The command returns a JSON list of inventory types and data types that support aggregation. The **TypeName** field shows supported inventory types. And the **Name** field shows each data type. For example, in the following list, the `AWS:Application` inventory type includes data types for `Name` and `Version`.

```
{
    "Schemas": [
        {
            "TypeName": "AWS:Application",
            "Version": "1.1",
            "DisplayName": "Application",
            "Attributes": [
                {
                    "DataType": "STRING",
                    "Name": "Name"
                },
                {
                    "DataType": "STRING",
                    "Name": "Version"
                }
            ]
        },
        {
            "TypeName": "AWS:InstanceInformation",
            "Version": "1.0",
```

```
            "DisplayName": "Platform",
            "Attributes": [
                {
                    "DataType": "STRING",
                    "Name": "PlatformName"
                },
                {
                    "DataType": "STRING",
                    "Name": "PlatformType"
                },
                {
                    "DataType": "STRING",
                    "Name": "PlatformVersion"
                }
            ]
        },
        {
            "TypeName": "AWS:ResourceGroup",
            "Version": "1.0",
            "DisplayName": "ResourceGroup",
            "Attributes": [
                {
                    "DataType": "STRING",
                    "Name": "Name"
                }
            ]
        },
        {
            "TypeName": "AWS:Service",
            "Version": "1.0",
            "DisplayName": "Service",
            "Attributes": [
                {
                    "DataType": "STRING",
                    "Name": "Name"
                },
                {
                    "DataType": "STRING",
                    "Name": "DisplayName"
                },
                {
                    "DataType": "STRING",
                    "Name": "ServiceType"
                },
```

```
                {
                    "DataType": "STRING",
                    "Name": "Status"
                },
                {
                    "DataType": "STRING",
                    "Name": "StartType"
                }
            ]
        },
        {
            "TypeName": "AWS:WindowsRole",
            "Version": "1.0",
            "DisplayName": "WindowsRole",
            "Attributes": [
                {
                    "DataType": "STRING",
                    "Name": "Name"
                },
                {
                    "DataType": "STRING",
                    "Name": "DisplayName"
                },
                {
                    "DataType": "STRING",
                    "Name": "FeatureType"
                },
                {
                    "DataType": "STRING",
                    "Name": "Installed"
                }
            ]
        }
    ]
}
```

You can aggregate data for any of the listed inventory types by creating a command that uses the following syntax.

```
aws ssm get-inventory --aggregators "Expression=InventoryType.DataType"
```

Here are some examples.

Example 1

This example aggregates a count of the Windows roles used by your nodes.

```
aws ssm get-inventory --aggregators "Expression=AWS:WindowsRole.Name"
```

Example 2

This example aggregates a count of the applications installed on your nodes.

```
aws ssm get-inventory --aggregators "Expression=AWS:Application.Name"
```

Combining multiple aggregators

You can also combine multiple inventory types and data types in one command to help you better understand the data. Here are some examples.

Example 1

This example aggregates a count of the operating system types used by your nodes. It also returns the specific name of the operating systems.

```
aws ssm get-inventory --aggregators '[{"Expression":
 "AWS:InstanceInformation.PlatformType", "Aggregators":[{"Expression":
 "AWS:InstanceInformation.PlatformName"}]}]'
```

Example 2

This example aggregates a count of the applications running on your nodes and the specific version of each application.

```
aws ssm get-inventory --aggregators '[{"Expression": "AWS:Application.Name",
 "Aggregators":[{"Expression": "AWS:Application.Version"}]}]'
```

If you prefer, you can create an aggregation expression with one or more inventory types and data types in a JSON file and call the file from the AWS CLI. The JSON in the file must use the following syntax.

```
[
       {
           "Expression": "string",
```

```
            "Aggregators": [
                {
                   "Expression": "string"
                }
            ]
        }
]
```

You must save the file with the .json file extension.

Here is an example that uses multiple inventory types and data types.

```
[
        {
            "Expression": "AWS:Application.Name",
            "Aggregators": [
                {
                    "Expression": "AWS:Application.Version",
                    "Aggregators": [
                      {
                      "Expression": "AWS:InstanceInformation.PlatformType"
                      }
                    ]
                }
            ]
        }
]
```

Use the following command to call the file from the AWS CLI.

```
aws ssm get-inventory --aggregators file://file_name.json
```

The command returns information like the following.

```
{"Entities":
 [
   {"Data":
     {"AWS:Application":
       {"Content":
         [
           {"Count": "3",
            "PlatformType": "linux",
            "Version": "2.6.5",
```

```
            "Name": "audit-libs"},
           {"Count": "2",
            "PlatformType": "windows",
            "Version": "2.6.5",
            "Name": "audit-libs"},
           {"Count": "4",
            "PlatformType": "windows",
            "Version": "6.2.8",
            "Name": "microsoft office"},
           {"Count": "2",
            "PlatformType": "windows",
            "Version": "2.6.5",
            "Name": "chrome"},
           {"Count": "1",
            "PlatformType": "linux",
            "Version": "2.6.5",
            "Name": "chrome"},
           {"Count": "2",
            "PlatformType": "linux",
            "Version": "6.3",
            "Name": "authconfig"}
         ]
       }
     },
    "ResourceType": "ManagedInstance"}
 ]
}
```

Aggregating inventory data with groups to see which nodes are and aren't configured to collect an inventory type

Groups in Systems Manager Inventory allow you to quickly see a count of which managed nodes are and aren’t configured to collect one or more inventory types. With groups, you specify one or more inventory types and a filter that uses the `exists` operator.

For example, say that you have four managed nodes configured to collect the following inventory types:

- Node 1: `AWS:Application`
- Node 2: `AWS:File`
- Node 3: `AWS:Application`, `AWS:File`
- Node 4: `AWS:Network`

You can run the following command from the AWS CLI to see how many nodes are configured to collect both the `AWS:Application` and `AWS:File inventory` types. The response also returns a count of how many nodes aren't configured to collect both of these inventory types.

```
aws ssm get-inventory --aggregators
 'Groups=[{Name=ApplicationAndFile,Filters=[{Key=TypeName,Values=[AWS:Application],Type=Exists}
{Key=TypeName,Values=[AWS:File],Type=Exists}]}]'
```

The command response shows that only one managed node is configured to collect both the `AWS:Application` and `AWS:File` inventory types.

```
{
   "Entities":[
      {
         "Data":{
            "ApplicationAndFile":{
               "Content":[
                  {
                     "notMatchingCount":"3"
                  },
                  {
                     "matchingCount":"1"
                  }
               ]
            }
         }
      }
   ]
}
```

Note

Groups don't return data type counts. Also, you can't drill-down into the results to see the IDs of nodes that are or aren't configured to collect the inventory type.

If you prefer, you can create an aggregation expression with one or more inventory types in a JSON file and call the file from the AWS CLI. The JSON in the file must use the following syntax:

```
{
   "Aggregators":[
```

```
      {
         "Groups":[
            {
               "Name":"Name",
               "Filters":[
                  {
                     "Key":"TypeName",
                     "Values":[
                        "Inventory_type"
                     ],
                     "Type":"Exists"
                  },
                  {
                     "Key":"TypeName",
                     "Values":[
                        "Inventory_type"
                     ],
                     "Type":"Exists"
                  }
               ]
            }
         ]
      }
   ]
}
```

You must save the file with the .json file extension.

Use the following command to call the file from the AWS CLI.

```
aws ssm get-inventory --cli-input-json file://file_name.json
```

Additional examples

The following examples show you how to aggregate inventory data to see which managed nodes are and aren't configured to collect the specified inventory types. These examples use the AWS CLI. Each example includes a full command with filters that you can run from the command line and a sample input.json file if you prefer to enter the information in a file.

Example 1

This example aggregates a count of nodes that are and aren't configured to collect either the `AWS:Application` or the `AWS:File` inventory types.

Run the following command from the AWS CLI.

```
aws ssm get-inventory --aggregators
 'Groups=[{Name=ApplicationORFile,Filters=[{Key=TypeName,Values=[AWS:Application,
 AWS:File],Type=Exists}]}]'
```

If you prefer to use a file, copy and paste the following sample into a file and save it as input.json.

```
{
   "Aggregators":[
      {
         "Groups":[
            {
               "Name":"ApplicationORFile",
               "Filters":[
                  {
                     "Key":"TypeName",
                     "Values":[
                        "AWS:Application",
                        "AWS:File"
                     ],
                     "Type":"Exists"
                  }
               ]
            }
         ]
      }
   ]
}
```

Run the following command from the AWS CLI.

```
aws ssm get-inventory --cli-input-json file://input.json
```

The command returns information like the following.

```
{
   "Entities":[
      {
         "Data":{
            "ApplicationORFile":{
```

```
               "Content":[
                  {
                     "notMatchingCount":"1"
                  },
                  {
                     "matchingCount":"3"
                  }
               ]
            }
         }
      }
   ]
}
```

Example 2

This example aggregates a count of nodes that are and aren't configured to collect the `AWS:Application`, `AWS:File`, and `AWS:Network` inventory types.

Run the following command from the AWS CLI.

```
aws ssm get-inventory --aggregators
 'Groups=[{Name=Application,Filters=[{Key=TypeName,Values=[AWS:Application],Type=Exists}]},
 {Name=File,Filters=[{Key=TypeName,Values=[AWS:File],Type=Exists}]},
 {Name=Network,Filters=[{Key=TypeName,Values=[AWS:Network],Type=Exists}]}]'
```

If you prefer to use a file, copy and paste the following sample into a file and save it as input.json.

```
{
   "Aggregators":[
      {
         "Groups":[
            {
               "Name":"Application",
               "Filters":[
                  {
                     "Key":"TypeName",
                     "Values":[
                        "AWS:Application"
                     ],
                     "Type":"Exists"
                  }
               ]
```

```
            },
            {
               "Name":"File",
               "Filters":[
                  {
                     "Key":"TypeName",
                     "Values":[
                        "AWS:File"
                     ],
                     "Type":"Exists"
                  }
               ]
            },
            {
               "Name":"Network",
               "Filters":[
                  {
                     "Key":"TypeName",
                     "Values":[
                        "AWS:Network"
                     ],
                     "Type":"Exists"
                  }
               ]
            }
         ]
      }
   ]
}
```

Run the following command from the AWS CLI.

```
aws ssm get-inventory --cli-input-json file://input.json
```

The command returns information like the following.

```
{
   "Entities":[
      {
         "Data":{
            "Application":{
               "Content":[
                  {
```

```
                    "notMatchingCount":"2"
                 },
                 {
                    "matchingCount":"2"
                 }
              ]
           },
           "File":{
              "Content":[
                 {
                    "notMatchingCount":"2"
                 },
                 {
                    "matchingCount":"2"
                 }
              ]
           },
           "Network":{
              "Content":[
                 {
                    "notMatchingCount":"3"
                 },
                 {
                    "matchingCount":"1"
                 }
              ]
           }
        }
     }
  ]
}
```

Working with custom inventory

You can assign any metadata you want to your nodes by creating AWS Systems Manager Inventory *custom inventory*. For example, let's say you manage a large number of servers in racks in your data center, and these servers have been configured as Systems Manager managed nodes. Currently, you store information about server rack location in a spreadsheet. With custom inventory, you can specify the rack location of each node as metadata on the node. When you collect inventory by using Systems Manager, the metadata is collected with other inventory metadata. You can then port all inventory metadata to a central Amazon S3 bucket by using resource data sync and query the data.

> **Note**
>
> Systems Manager supports a maximum of 20 custom inventory types per AWS account.

To assign custom inventory to a node, you can either use the Systems Manager PutInventory API operation, as described in Assigning custom inventory metadata to a managed node. Or, you can create a custom inventory JSON file and upload it to the node. This section describes how to create the JSON file.

The following example JSON file with custom inventory specifies rack information about an on-premises server. This examples specifies one type of custom inventory data (`"TypeName": "Custom:RackInformation"`), with multiple entries under `Content` that describe the data.

```
{
    "SchemaVersion": "1.0",
    "TypeName": "Custom:RackInformation",
    "Content": {
        "Location": "US-EAST-02.CMH.RACK1",
        "InstalledTime": "2016-01-01T01:01:01Z",
        "vendor": "DELL",
        "Zone" : "BJS12",
        "TimeZone": "UTC-8"
      }
 }
```

You can also specify distinct entries in the `Content` section, as shown in the following example.

```
{
"SchemaVersion": "1.0",
"TypeName": "Custom:PuppetModuleInfo",
    "Content": [{
        "Name": "puppetlabs/aws",
        "Version": "1.0"
      },
      {
        "Name": "puppetlabs/dsc",
        "Version": "2.0"
      }
    ]
}
```

The JSON schema for custom inventory requires `SchemaVersion`, `TypeName`, and `Content` sections, but you can define the information in those sections.

```
{
    "SchemaVersion": "user_defined",
    "TypeName": "Custom:user_defined",
    "Content": {
        "user_defined_attribute1": "user_defined_value1",
        "user_defined_attribute2": "user_defined_value2",
        "user_defined_attribute3": "user_defined_value3",
        "user_defined_attribute4": "user_defined_value4"
      }
 }
```

The value of `TypeName` is limited to 100 characters. Also, the `TypeName` value must begin with the capitalized word `Custom`. For example, `Custom:PuppetModuleInfo`. Therefore, the following examples would result in an exception: `CUSTOM:PuppetModuleInfo`, `custom:PuppetModuleInfo`.

The `Content` section includes attributes and *`data`*. These items aren't case-sensitive. However, if you define an attribute (for example: "`Vendor`": "DELL"), then you must consistently reference this attribute in your custom inventory files. If you specify "`Vendor`": "DELL" (using a capital “V” in `vendor`) in one file, and then you specify "`vendor`": "DELL" (using a lowercase “v” in `vendor`) in another file, the system returns an error.

> **Note**
>
> You must save the file with a `.json` extension and the inventory you define must consist only of string values.

After you create the file, you must save it on the node. The following table shows the location where custom inventory JSON files must be stored on the node.

Operating system	Path
Linux	/var/lib/amazon/ssm/*`node-id`*/inventory/custom

Operating system	Path
macOS	`/opt/aws/ssm/data/node-id/inventory/custom`
Windows Server	%SystemDrive%\ProgramData\Amazon\SSM\InstanceData*node-id*\inventory\custom

For an example of how to use custom inventory, see Get Disk Utilization of Your Fleet Using EC2 Systems Manager Custom Inventory Types.

Deleting custom inventory

You can use the DeleteInventory API operation to delete a custom inventory type and the data associated with that type. You call the delete-inventory command by using the AWS Command Line Interface (AWS CLI) to delete all data for an inventory type. You call the delete-inventory command with the `SchemaDeleteOption` to delete a custom inventory type.

> **Note**
>
> An inventory type is also called an inventory schema.

The `SchemaDeleteOption` parameter includes the following options:

- **DeleteSchema**: This option deletes the specified custom type and all data associated with it. You can recreate the schema later, if you want.
- **DisableSchema**: If you choose this option, the system turns off the current version, deletes all data for it, and ignores all new data if the version is less than or equal to the turned off version. You can allow this inventory type again by calling the PutInventory action for a version greater than the turned off version.

To delete or turn off custom inventory by using the AWS CLI

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command to use the `dry-run` option to see which data will be deleted from the system. This command doesn't delete any data.

```
aws ssm delete-inventory --type-name "Custom:custom_type_name" --dry-run
```

The system returns information like the following.

```
{
   "DeletionSummary":{
      "RemainingCount":3,
      "SummaryItems":[
         {
            "Count":2,
            "RemainingCount":2,
            "Version":"1.0"
         },
         {
            "Count":1,
            "RemainingCount":1,
            "Version":"2.0"
         }
      ],
      "TotalCount":3
   },
   "TypeName":"Custom:custom_type_name"
}
```

For information about how to understand the delete inventory summary, see Understanding the delete inventory summary.

3. Run the following command to delete all data for a custom inventory type.

```
aws ssm delete-inventory --type-name "Custom:custom_type_name"
```

> **Note**
>
> The output of this command doesn't show the deletion progress. For this reason, TotalCount and Remaining Count are always the same because the system hasn't deleted anything yet. You can use the describe-inventory-deletions command to show the deletion progress, as described later in this topic.

The system returns information like the following.

```
{
   "DeletionId":"system_generated_deletion_ID",
   "DeletionSummary":{
      "RemainingCount":3,
      "SummaryItems":[
         {
            "Count":2,
            "RemainingCount":2,
            "Version":"1.0"
         },
         {
            "Count":1,
            "RemainingCount":1,
            "Version":"2.0"
         }
      ],
      "TotalCount":3
   },
   "TypeName":"custom_type_name"
}
```

The system deletes all data for the specified custom inventory type from the Systems Manager Inventory service.

4. Run the following command. The command performs the following actions for the current version of the inventory type: turns off the current version, deletes all data for it, and ignores all new data if the version is less than or equal to the turned off version.

```
aws ssm delete-inventory --type-name "Custom:custom_type_name" --schema-delete-
option "DisableSchema"
```

The system returns information like the following.

```
{
   "DeletionId":"system_generated_deletion_ID",
   "DeletionSummary":{
      "RemainingCount":3,
      "SummaryItems":[
```

```
            {
               "Count":2,
               "RemainingCount":2,
               "Version":"1.0"
            },
            {
               "Count":1,
               "RemainingCount":1,
               "Version":"2.0"
            }
         ],
         "TotalCount":3
      },
      "TypeName":"Custom:custom_type_name"
}
```

You can view a turned off inventory type by using the following command.

```
aws ssm get-inventory-schema --type-name Custom:custom_type_name
```

5. Run the following command to delete an inventory type.

```
aws ssm delete-inventory --type-name "Custom:custom_type_name" --schema-delete-
option "DeleteSchema"
```

The system deletes the schema and all inventory data for the specified custom type.

The system returns information like the following.

```
{
   "DeletionId":"system_generated_deletion_ID",
   "DeletionSummary":{
      "RemainingCount":3,
      "SummaryItems":[
         {
            "Count":2,
            "RemainingCount":2,
            "Version":"1.0"
         },
         {
            "Count":1,
            "RemainingCount":1,
```

```
            "Version":"2.0"
         }
      ],
      "TotalCount":3
   },
   "TypeName":"Custom:custom_type_name"
}
```

Viewing the deletion status

You can check the status of a delete operation by using the `describe-inventory-deletions` AWS CLI command. You can specify a deletion ID to view the status of a specific delete operation. Or, you can omit the deletion ID to view a list of all deletions run in the last 30 days.

1. Run the following command to view the status of a deletion operation. The system returned the deletion ID in the delete-inventory summary.

   ```
   aws ssm describe-inventory-deletions --deletion-id system_generated_deletion_ID
   ```

   The system returns the latest status. The delete operation might not be finished yet. The system returns information like the following.

   ```
   {"InventoryDeletions":
     [
       {"DeletionId": "system_generated_deletion_ID",
        "DeletionStartTime": 1521744844,
        "DeletionSummary":
         {"RemainingCount": 1,
          "SummaryItems":
           [
             {"Count": 1,
              "RemainingCount": 1,
              "Version": "1.0"}
           ],
          "TotalCount": 1},
        "LastStatus": "InProgress",
        "LastStatusMessage": "The Delete is in progress",
        "LastStatusUpdateTime": 1521744844,
        "TypeName": "Custom:custom_type_name"}
     ]
   ```

```
}
```

If the delete operation is successful, the `LastStatusMessage` states: Deletion is successful.

```
{"InventoryDeletions":
  [
    {"DeletionId": "system_generated_deletion_ID",
     "DeletionStartTime": 1521744844,

```

Understanding the delete inventory summary

To help you understand the contents of the delete inventory summary, consider the following example. A user assigned Custom:RackSpace inventory to three nodes. Inventory items 1 and 2 use

custom type version 1.0 ("SchemaVersion":"1.0"). Inventory item 3 uses custom type version 2.0 ("SchemaVersion":"2.0").

RackSpace custom inventory 1

```
{
   "CaptureTime":"2018-02-19T10:48:55Z",
   "TypeName":"CustomType:RackSpace",
   "InstanceId":"i-1234567890",
   "SchemaVersion":"1.0"   "Content":[
      {
         content of custom type omitted
      }
   ]
}
```

RackSpace custom inventory 2

```
{
   "CaptureTime":"2018-02-19T10:48:55Z",
   "TypeName":"CustomType:RackSpace",
   "InstanceId":"i-1234567891",
   "SchemaVersion":"1.0"   "Content":[
      {
         content of custom type omitted
      }
   ]
}
```

RackSpace custom inventory 3

```
{
   "CaptureTime":"2018-02-19T10:48:55Z",
   "TypeName":"CustomType:RackSpace",
   "InstanceId":"i-1234567892",
   "SchemaVersion":"2.0"   "Content":[
      {
         content of custom type omitted
      }
   ]
}
```

The user runs the following command to preview which data will be deleted.

```
aws ssm delete-inventory --type-name "Custom:RackSpace" --dry-run
```

The system returns information like the following.

```
{
   "DeletionId":"1111-2222-333-444-66666",
   "DeletionSummary":{
      "RemainingCount":3,
      "TotalCount":3,
                TotalCount and RemainingCount are the number of items that would be
 deleted if this was not a dry run. These numbers are the same because the system
 didn't delete anything.
      "SummaryItems":[
         {
            "Count":2,             The system found two items that use SchemaVersion
 1.0. Neither item was deleted.
            "RemainingCount":2,
            "Version":"1.0"
         },
         {
            "Count":1,             The system found one item that uses SchemaVersion
 1.0. This item was not deleted.
            "RemainingCount":1,
            "Version":"2.0"
         }
      ],

   },
   "TypeName":"Custom:RackSpace"
}
```

The user runs the following command to delete the Custom:RackSpace inventory.

> **Note**
>
> The output of this command doesn't show the deletion progress. For this reason, `TotalCount` and `RemainingCount` are always the same because the system hasn't deleted anything yet. You can use the `describe-inventory-deletions` command to show the deletion progress.

```
aws ssm delete-inventory --type-name "Custom:RackSpace"
```

The system returns information like the following.

```
{
   "DeletionId":"1111-2222-333-444-7777777",
   "DeletionSummary":{
      "RemainingCount":3,           There are three items to delete
      "SummaryItems":[
         {
            "Count":2,              The system found two items that use SchemaVersion
 1.0.
            "RemainingCount":2,
            "Version":"1.0"
         },
         {
            "Count":1,              The system found one item that uses SchemaVersion
 2.0.
            "RemainingCount":1,
            "Version":"2.0"
         }
      ],
      "TotalCount":3
   },
   "TypeName":"RackSpace"
}
```

Viewing inventory delete actions in EventBridge

You can configure Amazon EventBridge to create an event anytime a user deletes custom inventory. EventBridge offers three types of events for custom inventory delete operations:

- **Delete action for an instance**: If the custom inventory for a specific managed node was successfully deleted or not.
- **Delete action summary**: A summary of the delete action.
- **Warning for turned off custom inventory type**: A warning event if a user called the PutInventory API operation for a custom inventory type version that was previously turned off.

Here are examples of each event.

Delete action for an instance

```
{
   "version":"0",
   "id":"998c9cde-56c0-b38b-707f-0411b3ff9d11",
   "detail-type":"Inventory Resource State Change",
   "source":"aws.ssm",
   "account":"478678815555",
   "time":"2018-05-24T22:24:34Z",
   "region":"us-east-1",
   "resources":[
      "arn:aws:ssm:us-east-1:478678815555:managed-instance/i-0a5feb270fc3f0b97"
   ],
   "detail":{
      "action-status":"succeeded",
      "action":"delete",
      "resource-type":"managed-instance",
      "resource-id":"i-0a5feb270fc3f0b97",
      "action-reason":"",
      "type-name":"Custom:MyInfo"
   }
}
```

Delete action summary

```
{
   "version":"0",
   "id":"83898300-f576-5181-7a67-fb3e45e4fad4",
   "detail-type":"Inventory Resource State Change",
   "source":"aws.ssm",
   "account":"478678815555",
   "time":"2018-05-24T22:28:25Z",
   "region":"us-east-1",
   "resources":[

   ],
   "detail":{
      "action-status":"succeeded",
      "action":"delete-summary",
      "resource-type":"managed-instance",
      "resource-id":"",
```

```
      "action-reason":"The delete for type name Custom:MyInfo was completed. The
 deletion summary is: {\"totalCount\":2,\"remainingCount\":0,\"summaryItems\":
[{\"version\":\"1.0\",\"count\":2,\"remainingCount\":0}]}",
      "type-name":"Custom:MyInfo"
   }
}
```

Warning for turned off custom inventory type

```
{
   "version":"0",
   "id":"49c1855c-9c57-b5d7-8518-b64aeeef5e4a",
   "detail-type":"Inventory Resource State Change",
   "source":"aws.ssm",
   "account":"478678815555",
   "time":"2018-05-24T22:46:58Z",
   "region":"us-east-1",
   "resources":[
      "arn:aws:ssm:us-east-1:478678815555:managed-instance/i-0ee2d86a2cfc371f6"
   ],
   "detail":{
      "action-status":"failed",
      "action":"put",
      "resource-type":"managed-instance",
      "resource-id":"i-0ee2d86a2cfc371f6",
      "action-reason":"The inventory item with type name Custom:MyInfo was sent with a
 disabled schema version 1.0. You must send a version greater than 1.0",
      "type-name":"Custom:MyInfo"
   }
}
```

Use the following procedure to create an EventBridge rule for custom inventory delete operations. This procedure shows you how to create a rule that sends notifications for custom inventory delete operations to an Amazon SNS topic. Before you begin, verify that you have an Amazon SNS topic, or create a new one. For more information, see Getting Started in the *Amazon Simple Notification Service Developer Guide*.

To configure EventBridge for delete inventory operations

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose **Rules**.

3. Choose **Create rule**.
4. Enter a name and description for the rule.

   A rule can't have the same name as another rule in the same Region and on the same event bus.
5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own AWS account, select **default**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
6. For **Rule type**, choose **Rule with an event pattern**.
7. Choose **Next**.
8. For **Event source**, choose **AWS events or EventBridge partner events**.
9. In the **Event pattern** section, choose **Event pattern form**.
10. For **Event source**, choose **AWS services**.
11. For **AWS service**, choose **Systems Manager**.
12. For **Event type**, choose **Inventory**.
13. For **Specific detail type(s)**, choose **Inventory Resource State Change**.
14. Choose **Next**.
15. For **Target types**, choose **AWS service**.
16. For **Select a target**, choose **SNS topic**, and then for **Topic**, choose your topic.
17. In the **Additional settings** section, for **Configure target input**, verify that **Matched event** is selected.
18. Choose **Next**.
19. (Optional) Enter one or more tags for the rule. For more information, see Tagging Your Amazon EventBridge Resources in the *Amazon EventBridge User Guide*.
20. Choose **Next**.
21. Review the details of the rule and choose **Create rule**.

Viewing inventory history and change tracking

You can view AWS Systems Manager Inventory history and change tracking for all of your managed nodes by using AWS Config. AWS Config provides a detailed view of the configuration of AWS

resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time. To view inventory history and change tracking, you must turn on the following resources in AWS Config:

- SSM:ManagedInstanceInventory
- SSM:PatchCompliance
- SSM:AssociationCompliance
- SSM:FileData

> **Note**
>
> Note the following important details about Inventory history and change tracking:
>
> - If you use AWS Config to track changes in your system, you must configure Systems Manager Inventory to collect `AWS:File` metadata so that you can view file changes in AWS Config (`SSM:FileData`). If you don't, then AWS Config doesn't track file changes on your system.
> - By turning on SSM:PatchCompliance and SSM:AssociationCompliance, you can view Systems Manager Patch Manager patching and Systems Manager State Manager association compliance history and change tracking. For more information about compliance management for these resources, see Learn details about Compliance.

The following procedure describes how to turn on inventory history and change-track recording in AWS Config by using the AWS Command Line Interface (AWS CLI). For more information about how to choose and configure these resources in AWS Config, see Selecting Which Resources AWS Config Records in the *AWS Config Developer Guide*. For information about AWS Config pricing, see Pricing.

Before you begin

AWS Config requires AWS Identity and Access Management (IAM) permissions to get configuration details about Systems Manager resources. In the following procedure, you must specify an Amazon Resource Name (ARN) for an IAM role that gives AWS Config permission to Systems Manager resources. You can attach the `AWS_ConfigRole` managed policy to the IAM role that you assign to AWS Config. For more information about this role, see AWS managed policy: AWS_ConfigRole in the *AWS Config Developer Guide*. For information about how to create an IAM role and assign the

`AWS_ConfigRole` managed policy to that role, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

To turn on inventory history and change-track recording in AWS Config

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Copy and paste the following JSON sample into a simple text file and save it as recordingGroup.json.

```
{
   "allSupported":false,
   "includeGlobalResourceTypes":false,
   "resourceTypes":[
      "AWS::SSM::AssociationCompliance",
      "AWS::SSM::PatchCompliance",
      "AWS::SSM::ManagedInstanceInventory",
      "AWS::SSM::FileData"
   ]
}
```

3. Run the following command to load the recordingGroup.json file into AWS Config.

```
aws configservice put-configuration-recorder --configuration-recorder
 name=myRecorder,roleARN=arn:aws:iam::123456789012:role/myConfigRole --recording-
group file://recordingGroup.json
```

4. Run the following command to start recording inventory history and change tracking.

```
aws configservice start-configuration-recorder --configuration-recorder-
name myRecorder
```

After you configure history and change tracking, you can drill down into the history for a specific managed node by choosing the **AWS Config** button in the Systems Manager console. You can access the **AWS Config** button from either the **Managed Instances** page or the **Inventory** page. Depending on your monitor size, you might need to scroll to the right side of the page to see the button.

Stopping data collection and deleting inventory data

If you no longer want to use AWS Systems Manager Inventory to view metadata about your AWS resources, you can stop data collection and delete data that has already been collected. This section includes the following information.

Topics

Stopping data collection

When you initially configure Systems Manager to collect inventory data, the system creates a State Manager association that defines the schedule and the resources from which to collect metadata. You can stop data collection by deleting any State Manager associations that use the `AWS-GatherSoftwareInventory` document.

To delete an Inventory association

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Choose an association that uses the `AWS-GatherSoftwareInventory` document and then choose **Delete**.
4. Repeat step three for any remaining associations that use the `AWS-GatherSoftwareInventory` document.

Deleting an Inventory resource data sync

If you no longer want to use AWS Systems Manager Inventory to view metadata about your AWS resources, then we also recommend deleting resource data syncs used for inventory data collection.

To delete an Inventory resource data sync

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Inventory**.

3. Choose **Resource Data Syncs**.
4. Choose a sync in the list.

> **Important**
>
> Make sure you choose the sync used for Inventory. Systems Manager supports resource data sync for multiple tools. If you choose the wrong sync, you could disrupt data aggregation for Systems Manager Explorer or Systems Manager Compliance.

5. Choose **Delete**
6. Repeat these steps for any remaining resource data syncs you want to delete.
7. Delete the Amazon Simple Storage Service (Amazon S3) bucket where the data was stored. For information about deleting an Amazon S3 bucket, see Deleting a bucket.

Assigning custom inventory metadata to a managed node

The following procedure walks you through the process of using the AWS Systems Manager PutInventory API operation to assign custom inventory metadata to a managed node. This example assigns rack location information to a node. For more information about custom inventory, see Working with custom inventory.

To assign custom inventory metadata to a node

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.
2. Run the following command to assign rack location information to a node.

   Linux

```
aws ssm put-inventory --instance-id "ID" --items '[{"CaptureTime":
 "2016-08-22T10:01:01Z", "TypeName": "Custom:RackInfo", "Content":[{"RackLocation":
 "Bay B/Row C/Rack D/Shelf E"}], "SchemaVersion": "1.0"}]'
```

   Windows

```
aws ssm put-inventory --instance-id "ID" --items
 "TypeName=Custom:RackInfo,SchemaVersion=1.0,CaptureTime=2021-05-22T10:01:01Z,Content=[{Rac
 B/Row C/Rack D/Shelf F'}]"
```

3. Run the following command to view custom inventory entries for this node.

```
aws ssm list-inventory-entries --instance-id ID --type-name "Custom:RackInfo"
```

The system responds with information like the following.

```
{
    "InstanceId": "ID",
    "TypeName": "Custom:RackInfo",
    "Entries": [
        {
            "RackLocation": "Bay B/Row C/Rack D/Shelf E"
        }
    ],
    "SchemaVersion": "1.0",
    "CaptureTime": "2016-08-22T10:01:01Z"
}
```

4. Run the following command to view the custom inventory schema.

```
aws ssm get-inventory-schema --type-name Custom:RackInfo
```

The system responds with information like the following.

```
{
    "Schemas": [
        {
            "TypeName": "Custom:RackInfo",
            "Version": "1.0",
            "Attributes": [
                {
                    "DataType": "STRING",
                    "Name": "RackLocation"
                }
            ]
        }
    ]
```

```
}
```

Using the AWS CLI to configure inventory data collection

The following procedures walk you through the process of configuring AWS Systems Manager Inventory to collect metadata from your managed nodes. When you configure inventory collection, you start by creating a Systems Manager State Manager association. Systems Manager collects the inventory data when the association is run. If you don't create the association first, and attempt to invoke the `aws:softwareInventory` plugin by using, for example, Systems Manager Run Command, the system returns the following error:

`The aws:softwareInventory plugin can only be invoked via ssm-associate.`

> **Note**
>
> A node can have only one inventory association configured at a time. If you configure a node with two or more inventory associations, the association doesn't run and no inventory data is collected.

Quickly configure all of your managed nodes for Inventory (CLI)

You can quickly configure all managed nodes in your AWS account and in the current Region to collect inventory data. This is called creating a global inventory association. To create a global inventory association by using the AWS CLI, use the wildcard option for the `instanceIds` value, as shown in the following procedure.

To configure inventory for all managed nodes in your AWS account and in the current Region (CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.
2. Run the following command.

   Linux & macOS

```
aws ssm create-association \
--name AWS-GatherSoftwareInventory \
```

```
--targets Key=InstanceIds,Values=* \
--schedule-expression "rate(1 day)" \
--parameters
 applications=Enabled,awsComponents=Enabled,customInventory=Enabled,instanceDetailedInfo
```

Windows

```
aws ssm create-association ^
--name AWS-GatherSoftwareInventory ^
--targets Key=InstanceIds,Values=* ^
--schedule-expression "rate(1 day)" ^
--parameters
 applications=Enabled,awsComponents=Enabled,customInventory=Enabled,instanceDetailedInfo
```

Note

This command doesn't allow Inventory to collect metadata for the Windows Registry or files. To inventory these datatypes, use the next procedure.

Manually configuring Inventory on your managed nodes (CLI)

Use the following procedure to manually configure AWS Systems Manager Inventory on your managed nodes by using node IDs or tags.

To manually configure your managed nodes for inventory (CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.
2. Run the following command to create a State Manager association that runs Systems Manager Inventory on the node. Replace each *example resource placeholder* with your own information. This command configures the service to run every six hours and to collect network configuration, Windows Update, and application metadata from a node.

   Linux & macOS

   ```
   aws ssm create-association \
   --name "AWS-GatherSoftwareInventory" \
   --targets "Key=instanceids,Values=an_instance_ID" \
   ```

```
--schedule-expression "rate(240 minutes)" \
--output-location "{ \"S3Location\": { \"OutputS3Region\": \"region_ID,
 for example us-east-2\", \"OutputS3BucketName\": \"amzn-s3-demo-bucket\",
 \"OutputS3KeyPrefix\": \"Test\" } }" \
--parameters "networkConfig=Enabled,windowsUpdates=Enabled,applications=Enabled"
```

Windows

```
aws ssm create-association ^
--name "AWS-GatherSoftwareInventory" ^
--targets "Key=instanceids,Values=an_instance_ID" ^
--schedule-expression "rate(240 minutes)" ^
--output-location "{ \"S3Location\": { \"OutputS3Region\": \"region_ID,
 for example us-east-2\", \"OutputS3BucketName\": \"amzn-s3-demo-bucket\",
 \"OutputS3KeyPrefix\": \"Test\" } }" ^
--parameters "networkConfig=Enabled,windowsUpdates=Enabled,applications=Enabled"
```

The system responds with information like the following.

```
{
    "AssociationDescription": {
        "ScheduleExpression": "rate(240 minutes)",
        "OutputLocation": {
            "S3Location": {
                "OutputS3KeyPrefix": "Test",
                "OutputS3BucketName": "Test bucket",
                "OutputS3Region": "us-east-2"
            }
        },
        "Name": "The name you specified",
        "Parameters": {
            "applications": [
                "Enabled"
            ],
            "networkConfig": [
                "Enabled"
            ],
            "windowsUpdates": [
                "Enabled"
            ]
        },
        "Overview": {
```

```
            "Status": "Pending",
            "DetailedStatus": "Creating"
        },
        "AssociationId": "1a2b3c4d5e6f7g-1a2b3c-1a2b3c-1a2b3c-1a2b3c4d5e6f7g",
        "DocumentVersion": "$DEFAULT",
        "LastUpdateAssociationDate": 1480544990.06,
        "Date": 1480544990.06,
        "Targets": [
            {
                "Values": [
                   "i-02573cafcfEXAMPLE"
                ],
                "Key": "InstanceIds"
            }
        ]
    }
}
```

You can target large groups of nodes by using the `Targets` parameter with EC2 tags. See the following example.

Linux & macOS

```
aws ssm create-association \
--name "AWS-GatherSoftwareInventory" \
--targets "Key=tag:Environment,Values=Production" \
--schedule-expression "rate(240 minutes)" \
--output-location "{ \"S3Location\": { \"OutputS3Region\": \"us-east-2\",
 \"OutputS3BucketName\": \"amzn-s3-demo-bucket\", \"OutputS3KeyPrefix\": \"Test
\" } }" \
--parameters "networkConfig=Enabled,windowsUpdates=Enabled,applications=Enabled"
```

Windows

```
aws ssm create-association ^
--name "AWS-GatherSoftwareInventory" ^
--targets "Key=tag:Environment,Values=Production" ^
--schedule-expression "rate(240 minutes)" ^
--output-location "{ \"S3Location\": { \"OutputS3Region\": \"us-east-2\",
 \"OutputS3BucketName\": \"amzn-s3-demo-bucket\", \"OutputS3KeyPrefix\": \"Test
\" } }" ^
--parameters "networkConfig=Enabled,windowsUpdates=Enabled,applications=Enabled"
```

You can also inventory files and Windows Registry keys on a Windows Server node by using the `files` and `windowsRegistry` inventory types with expressions. For more information about these inventory types, see Working with file and Windows registry inventory.

Linux & macOS

```
aws ssm create-association \
--name "AWS-GatherSoftwareInventory" \
--targets "Key=instanceids,Values=i-0704358e3a3da9eb1" \
--schedule-expression "rate(240 minutes)" \
--parameters '{"files":["[{\"Path\": \"C:\\Program Files\", \"Pattern\":
 [\"*.exe\"], \"Recursive\": true}]"], "windowsRegistry": ["[{\"Path\":
\"HKEY_LOCAL_MACHINE\\Software\\Amazon\", \"Recursive\":true}]"]}' \
--profile dev-pdx
```

Windows

```
aws ssm create-association ^
--name "AWS-GatherSoftwareInventory" ^
--targets "Key=instanceids,Values=i-0704358e3a3da9eb1" ^
--schedule-expression "rate(240 minutes)" ^
--parameters '{"files":["[{\"Path\": \"C:\\Program Files\", \"Pattern\":
 [\"*.exe\"], \"Recursive\": true}]"], "windowsRegistry": ["[{\"Path\":
\"HKEY_LOCAL_MACHINE\\Software\\Amazon\", \"Recursive\":true}]"]}' ^
--profile dev-pdx
```

3. Run the following command to view the association status.

```
aws ssm describe-instance-associations-status --instance-id an_instance_ID
```

The system responds with information like the following.

```
{
"InstanceAssociationStatusInfos": [
         {
            "Status": "Pending",
            "DetailedStatus": "Associated",
            "Name": "reInvent2016PolicyDocumentTest",
            "InstanceId": "i-1a2b3c4d5e6f7g",
            "AssociationId": "1a2b3c4d5e6f7g-1a2b3c-1a2b3c-1a2b3c-1a2b3c4d5e6f7g",
```

```
            "DocumentVersion": "1"
        }
]
}
```

Walkthrough: Using resource data sync to aggregate inventory data

The following walkthrough describes how to create a resource data sync configuration for AWS Systems Manager Inventory by using the AWS Command Line Interface (AWS CLI). A resource data sync automatically ports inventory data from all of your managed nodes to a central Amazon Simple Storage Service (Amazon S3) bucket. The sync automatically updates the data in the central Amazon S3 bucket whenever new inventory data is discovered.

This walkthrough also describes how to use Amazon Athena and Amazon QuickSight to query and analyze the aggregated data. For information about creating a resource data sync by using Systems Manager in the AWS Management Console, see Walkthrough: Using resource data sync to aggregate inventory data. For information about querying inventory from multiple AWS Regions and accounts by using Systems Manager in the AWS Management Console, see Querying inventory data from multiple Regions and accounts.

> **Note**
>
> This walkthrough includes information about how to encrypt the sync by using AWS Key Management Service (AWS KMS). Inventory doesn't collect any user-specific, proprietary, or sensitive data so encryption is optional. For more information about AWS KMS, see AWS Key Management Service Developer Guide.

Before you begin

Review or complete the following tasks before you begin the walkthrough in this section:

- Collect inventory data from your managed nodes. For the purpose of the Amazon Athena and Amazon QuickSight sections in this walkthrough, we recommend that you collect Application data. For more information about how to collect inventory data, see Configuring inventory collection or Using the AWS CLI to configure inventory data collection.
- (Optional) If the inventory data is stored in an Amazon Simple Storage Service (Amazon S3) bucket that uses AWS Key Management Service (AWS KMS) encryption, you must also configure

your IAM account and the `Amazon-GlueServiceRoleForSSM` service role for AWS KMS encryption. If you don't configure your IAM account and this role, Systems Manager displays `Cannot load Glue tables` when you choose the **Detailed View** tab in the console. For more information, see [(Optional) Configure permissions for viewing AWS KMS encrypted data](#).

- (Optional) If you want to encrypt the resource data sync by using AWS KMS, then you must either create a new key that includes the following policy, or you must update an existing key and add this policy to it.

  JSON

```
{
    "Version": "2012-10-17",
    "Id": "ssm-access-policy",
    "Statement": [
        {
            "Sid": "ssm-access-policy-statement",
            "Action": [
                "kms:GenerateDataKey"
            ],
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Resource": "arn:aws:kms:us-east-1:123456789012:key/KMS_key_id",
            "Condition": {
                "StringLike": {
                    "aws:SourceAccount": "123456789012"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:ssm:*:123456789012:resource-data-
sync/*"
                }
            }
        }
    ]
}
```

To create a resource data sync for Inventory

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Create a bucket to store your aggregated inventory data. For more information, see Create a Bucket in the *Amazon Simple Storage Service User Guide*. Make a note of the bucket name and the AWS Region where you created it.
3. After you create the bucket, choose the **Permissions** tab, and then choose **Bucket Policy**.
4. Copy and paste the following bucket policy into the policy editor. Replace amzn-s3-demo-bucket and *account-id* with the name of the Amazon S3 bucket you created and a valid AWS account ID. When adding multiple accounts, add an additional condition string and ARN for each account. Remove the additional placeholders from the example when adding one account. Optionally, replace *bucket-prefix* with the name of an Amazon S3 prefix (subdirectory). If you didn't created a prefix, remove *bucket-prefix/* from the ARN in the policy.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": " SSMBucketDelivery",
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket/bucket-prefix/*/
accountid=111122223333/*"
            ],
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control",
                    "aws:SourceAccount": [
                        "111122223333",
                        "444455556666",
                        "123456789012",
                        "777788889999"
                    ]
                },
                "ArnLike": {
                    "aws:SourceArn": [
```

```
                        "arn:aws:ssm:*:111122223333:resource-data-sync/*",
                        "arn:aws:ssm:*:444455556666:resource-data-sync/*",
                        "arn:aws:ssm:*:123456789012:resource-data-sync/*",
                        "arn:aws:ssm:*:777788889999:resource-data-sync/*"
                    ]
                }
            }
        }
    ]
}
```

5. (Optional) If you want to encrypt the sync, then you must add the following conditions to the policy listed in the previous step. Add these in the `StringEquals` section.

```
"s3:x-amz-server-side-encryption":"aws:kms",
"s3:x-amz-server-side-encryption-aws-kms-key-
id":"arn:aws:kms:region:account_ID:key/KMS_key_ID"
```

   Here is an example:

```
"StringEquals": {
          "s3:x-amz-acl": "bucket-owner-full-control",
          "aws:SourceAccount": "account-id",
          "s3:x-amz-server-side-encryption":"aws:kms",
          "s3:x-amz-server-side-encryption-aws-kms-key-
id":"arn:aws:kms:region:account_ID:key/KMS_key_ID"
        }
```

6. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

7. (Optional) If you want to encrypt the sync, run the following command to verify that the bucket policy is enforcing the AWS KMS key requirement. Replace each *example resource placeholder* with your own information.

   Linux & macOS

```
aws s3 cp ./A_file_in_the_bucket s3://amzn-s3-demo-bucket/prefix/ \
--sse aws:kms \
--sse-kms-key-id "arn:aws:kms:region:account_ID:key/KMS_key_id" \
```

```
--region region, for example, us-east-2
```

Windows

```
aws s3 cp ./A_file_in_the_bucket s3://amzn-s3-demo-bucket/prefix/ ^
    --sse aws:kms ^
    --sse-kms-key-id "arn:aws:kms:region:account_ID:key/KMS_key_id" ^
    --region region, for example, us-east-2
```

8. Run the following command to create a resource data sync configuration with the Amazon S3 bucket you created at the start of this procedure. This command creates a sync from the AWS Region you're logged into.

> **Note**
>
> If the sync and the target Amazon S3 bucket are located in different regions, you might be subject to data transfer pricing. For more information, see Amazon S3 Pricing.

Linux & macOS

```
aws ssm create-resource-data-sync \
--sync-name a_name \
--s3-destination "BucketName=amzn-s3-demo-bucket,Prefix=prefix_name,
 if_specified,SyncFormat=JsonSerDe,Region=bucket_region"
```

Windows

```
aws ssm create-resource-data-sync ^
--sync-name a_name ^
--s3-destination "BucketName=amzn-s3-demo-bucket,Prefix=prefix_name,
 if_specified,SyncFormat=JsonSerDe,Region=bucket_region"
```

You can use the `region` parameter to specify where the sync configuration should be created. In the following example, inventory data from the us-west-1 Region, will be synchronized in the Amazon S3 bucket in the us-west-2 Region.

Linux & macOS

```
aws ssm create-resource-data-sync \
    --sync-name InventoryDataWest \
    --s3-destination "BucketName=amzn-s3-demo-
bucket,Prefix=HybridEnv,SyncFormat=JsonSerDe,Region=us-west-2"
    --region us-west-1
```

Windows

```
aws ssm create-resource-data-sync ^
--sync-name InventoryDataWest ^
--s3-destination "BucketName=amzn-s3-demo-
bucket,Prefix=HybridEnv,SyncFormat=JsonSerDe,Region=us-west-2" ^ --region us-
west-1
```

(Optional) If you want to encrypt the sync by using AWS KMS, run the following command to create the sync. If you encrypt the sync, then the AWS KMS key and the Amazon S3 bucket must be in the same Region.

Linux & macOS

```
aws ssm create-resource-data-sync \
--sync-name sync_name \
--s3-destination "BucketName=amzn-s3-demo-bucket,Prefix=prefix_name,
 if_specified,SyncFormat=JsonSerDe,AWSKMSKeyARN=arn:aws:kms:region:account_ID:key/
KMS_key_ID,Region=bucket_region" \
--region region
```

Windows

```
aws ssm create-resource-data-sync ^
--sync-name sync_name ^
--s3-destination "BucketName=amzn-s3-demo-bucket,Prefix=prefix_name,
 if_specified,SyncFormat=JsonSerDe,AWSKMSKeyARN=arn:aws:kms:region:account_ID:key/
KMS_key_ID,Region=bucket_region" ^
--region region
```

9. Run the following command to view the status of sync configuration.

```
aws ssm list-resource-data-sync
```

If you created the sync configuration in a different Region, then you must specify the `region` parameter, as shown in the following example.

```
aws ssm list-resource-data-sync --region us-west-1
```

10. After the sync configuration is created successfully, examine the target bucket in Amazon S3. Inventory data should be displayed within a few minutes.

Working with the Data in Amazon Athena

The following section describes how to view and query the data in Amazon Athena. Before you begin, we recommend that you learn about Athena. For more information, see What is Amazon Athena? and Working with Data in the *Amazon Athena User Guide*.

To view and query the data in Amazon Athena

1. Open the Athena console at https://console.aws.amazon.com/athena/.
2. Copy and paste the following statement into the query editor and then choose **Run Query**.

```
CREATE DATABASE ssminventory
```

The system creates a database called ssminventory.

3. Copy and paste the following statement into the query editor and then choose **Run Query**. Replace amzn-s3-demo-bucket and *`bucket_prefix`* with the name and prefix of the Amazon S3 target.

```
CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_Application (
Name string,
ResourceId string,
ApplicationType string,
Publisher string,
Version string,
InstalledTime string,
Architecture string,
URL string,
Summary string,
```

```
PackageId string
)
PARTITIONED BY (AccountId string, Region string, ResourceType string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (
  'serialization.format' = '1'
) LOCATION 's3://amzn-s3-demo-bucket/bucket_prefix/AWS:Application/'
```

4. Copy and paste the following statement into the query editor and then choose **Run Query**.

```
MSCK REPAIR TABLE ssminventory.AWS_Application
```

The system partitions the table.

> **Note**
>
> If you create resource data syncs from additional AWS Regions or AWS accounts, then you must run this command again to update the partitions. You might also need to update your Amazon S3 bucket policy.

5. To preview your data, choose the view icon next to the `AWS_Application` table.

6. Copy and paste the following statement into the query editor and then choose **Run Query**.

```
SELECT a.name, a.version, count( a.version) frequency
from aws_application a where
a.name = 'aws-cfn-bootstrap'
group by a.name, a.version
order  by frequency desc
```

The query returns a count of different versions of `aws-cfn-bootstrap`, which is an AWS application present on Amazon Elastic Compute Cloud (Amazon EC2) instances for Linux, macOS, and Windows Server.

7. Individually copy and paste the following statements into the query editor, replace amzn-s3-demo-bucket and *`bucket-prefix`* with information for Amazon S3, and then choose **Run Query**. These statements set up additional inventory tables in Athena.

```
CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_AWSComponent (
 `ResourceId` string,
  `Name` string,
  `ApplicationType` string,
  `Publisher` string,
  `Version` string,
  `InstalledTime` string,
  `Architecture` string,
  `URL` string
)
PARTITIONED BY (AccountId string, Region string, ResourceType string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (
  'serialization.format' = '1'
) LOCATION 's3://amzn-s3-demo-bucket/bucket-prefix/AWS:AWSComponent/'
```

```
MSCK REPAIR TABLE ssminventory.AWS_AWSComponent
```

```
CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_WindowsUpdate (
  `ResourceId` string,
  `HotFixId` string,
  `Description` string,
  `InstalledTime` string,
  `InstalledBy` string
)
PARTITIONED BY (AccountId string, Region string, ResourceType string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (
  'serialization.format' = '1'
) LOCATION 's3://amzn-s3-demo-bucket/bucket-prefix/AWS:WindowsUpdate/'
```

```
MSCK REPAIR TABLE ssminventory.AWS_WindowsUpdate
```

```
CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_InstanceInformation (
  `AgentType` string,
  `AgentVersion` string,
  `ComputerName` string,
  `IamRole` string,
  `InstanceId` string,
  `IpAddress` string,
```

```
  `PlatformName` string,
  `PlatformType` string,
  `PlatformVersion` string
)
PARTITIONED BY (AccountId string, Region string, ResourceType string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (
  'serialization.format' = '1'
) LOCATION 's3://amzn-s3-demo-bucket/bucket-prefix/AWS:InstanceInformation/'
```

```
MSCK REPAIR TABLE ssminventory.AWS_InstanceInformation
```

```
CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_Network (
  `ResourceId` string,
  `Name` string,
  `SubnetMask` string,
  `Gateway` string,
  `DHCPServer` string,
  `DNSServer` string,
  `MacAddress` string,
  `IPV4` string,
  `IPV6` string
)
PARTITIONED BY (AccountId string, Region string, ResourceType string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (
  'serialization.format' = '1'
) LOCATION 's3://amzn-s3-demo-bucket/bucket-prefix/AWS:Network/'
```

```
MSCK REPAIR TABLE ssminventory.AWS_Network
```

```
CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_PatchSummary (
  `ResourceId` string,
  `PatchGroup` string,
  `BaselineId` string,
  `SnapshotId` string,
  `OwnerInformation` string,
  `InstalledCount` int,
  `InstalledOtherCount` int,
  `NotApplicableCount` int,
  `MissingCount` int,
```

```
  `FailedCount` int,
  `OperationType` string,
  `OperationStartTime` string,
  `OperationEndTime` string
)
PARTITIONED BY (AccountId string, Region string, ResourceType string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (
  'serialization.format' = '1'
) LOCATION 's3://amzn-s3-demo-bucket/bucket-prefix/AWS:PatchSummary/'
```

```
MSCK REPAIR TABLE ssminventory.AWS_PatchSummary
```

Working with the Data in Amazon QuickSight

The following section provides an overview with links for building a visualization in Amazon QuickSight.

To build a visualization in Amazon QuickSight

1. Sign up for Amazon QuickSight and then log in to the QuickSight console.
2. Create a data set from the `AWS_Application` table and any other tables you created. For more information, see Creating a Data Set Using Amazon Athena Data.
3. Join tables. For example, you could join the `instanceid` column from `AWS_InstanceInformation` because it matches the `resourceid` column in other inventory tables. For more information about joining tables, see Joining Tables.
4. Build a visualization. For more information, see Working with Amazon QuickSight Visuals.

Troubleshooting problems with Systems Manager Inventory

This topic includes information about how to troubleshoot common errors or problems with AWS Systems Manager Inventory. If you're having trouble viewing your nodes in Systems Manager, see Troubleshooting managed node availability.

Topics

- Multiple apply all associations with document 'AWS-GatherSoftwareInventory' are not supported
- Inventory execution status never exits pending

- The AWS-ListWindowsInventory document fails to run
- Console doesn't display Inventory Dashboard | Detailed View | Settings tabs
- UnsupportedAgent
- Skipped
- Failed
- Inventory compliance failed for an Amazon EC2 instance
- S3 bucket object contains old data

Multiple apply all associations with document 'AWS-GatherSoftwareInventory' are not supported

An error that `Multiple apply all associations with document 'AWS-GatherSoftwareInventory' are not supported` means that one or more AWS Regions where you're trying to configure an Inventory association *for all nodes* are already configured with an inventory association for all nodes. If necessary, you can delete the existing inventory association for all nodes and then create a new one. To view existing inventory associations, choose **State Manager** in the Systems Manager console and then locate associations that use the `AWS-GatherSoftwareInventory` SSM document. If the existing inventory association for all nodes was created across multiple Regions, and you want to create a new one, you must delete the existing association from each Region where it exists.

Inventory execution status never exits pending

There are two reasons why inventory collection never exits the `Pending` status:

- No nodes in the selected AWS Region:

  If you create a global inventory association by using Systems Manager Quick Setup, the status of the inventory association (`AWS-GatherSoftwareInventory` document) shows `Pending` if there are no nodes available in the selected Region.
- Insufficient permissions:

  An inventory association shows `Pending` if one or more nodes don't have permission to run Systems Manager Inventory. Verify that the AWS Identity and Access Management (IAM) instance profile includes the **AmazonSSMManagedInstanceCore** managed policy. For information about how to add this policy to an instance profile, see Alternative configuration for EC2 instance permissions.

At a minimum, the instance profile must have the following IAM permissions.

JSON

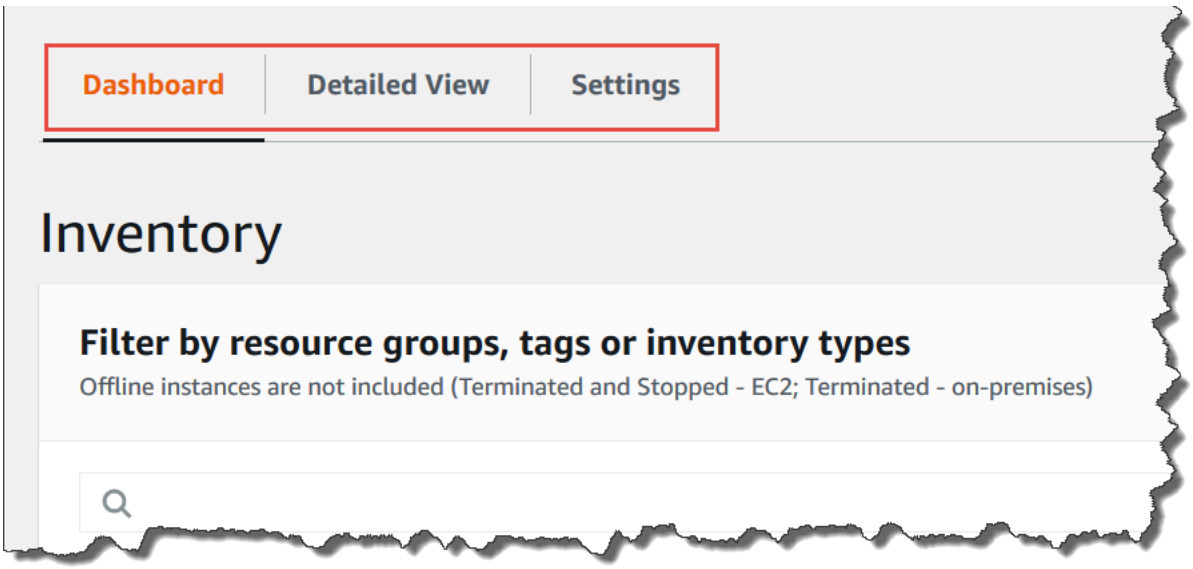
```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:DescribeAssociation",
                "ssm:ListAssociations",
                "ssm:ListInstanceAssociations",
                "ssm:PutInventory",
                "ssm:PutComplianceItems",
                "ssm:UpdateAssociationStatus",
                "ssm:UpdateInstanceAssociationStatus",
                "ssm:UpdateInstanceInformation",
                "ssm:GetDocument",
                "ssm:DescribeDocument"
            ],
            "Resource": "*"
        }
    ]
}
```

The `AWS-ListWindowsInventory` document fails to run

The `AWS-ListWindowsInventory` document is deprecated. Don't use this document to collect inventory. Instead, use one of the processes described in Configuring inventory collection.

Console doesn't display Inventory Dashboard | Detailed View | Settings tabs

The Inventory **Detailed View** page is only available in AWS Regions that offer Amazon Athena. If the following tabs aren't displayed on the Inventory page, it means Athena isn't available in the Region and you can't use the **Detailed View** to query data.



UnsupportedAgent

If the detailed status of an inventory association shows **UnsupportedAgent**, and the **Association status** shows **Failed**, then the version of AWS Systems Manager SSM Agent on the managed node isn't correct. To create a global inventory association (to inventory all nodes in your AWS account) for example, you must use SSM Agent version 2.0.790.0 or later. You can view the agent version running on each of your nodes on the **Managed Instances** page in the **Agent version** column. For information about how to update SSM Agent on your nodes, see Updating the SSM Agent using Run Command.

Skipped

If the status of the inventory association for a node shows **Skipped**, this means that a higher-priority inventory association is already running on that node. Systems Manager follows a specific priority order when multiple inventory associations could apply to the same managed node.

Inventory association priority order

Systems Manager applies inventory associations in the following priority order:

1. **Quick Setup inventory associations** - Associations created using Quick Setup and the unified console. These associations have names that start with `AWS-QuickSetup-SSM-CollectInventory-` and target all managed nodes.
2. **Explicit inventory associations** - Associations that target specific managed nodes using:
   - Instance IDs

- Tag key-value pairs
- AWS resource groups

3. **Global inventory associations** - Associations that target all managed nodes (using `--targets "Key=InstanceIds,Values=*"`) but were **not** created through Quick Setup.

Common scenarios

Scenario 1: Quick Setup association overrides explicit association

- You have a Quick Setup inventory association targeting all instances
- You create a manual association targeting specific managed nodes by tag
- Result: The manual association shows `Skipped` with detailed status `OverriddenByExplicitInventoryAssociation`
- The Quick Setup association continues to collect inventory from all instances

Scenario 2: Explicit association overrides global association

- You have a global inventory association targeting all instances (not created by Quick Setup)
- You create an association targeting specific instances
- Result: The global association shows `Skipped` for the specifically targeted instances
- The explicit association runs on the targeted instances

Resolution steps

If you want to use your own inventory association instead of Quick Setup:

1. **Identify Quick Setup associations**: In the Systems Manager console, go to State Manager and look for associations with names starting with `AWS-QuickSetup-SSM-CollectInventory-`.
2. **Remove Quick Setup configuration**:
   - Go to Quick Setup in the Systems Manager console.
   - Find your inventory collection configuration.
   - Delete the Quick Setup configuration (this removes the associated inventory association).

> **Note**
>
> You don't need to manually delete the association created by Quick Setup.

3. **Verify your association runs**: After removing the Quick Setup configuration, your explicit inventory association should start running successfully.

If you want to modify existing behavior:

- To view all existing inventory associations, choose **State Manager** in the Systems Manager console and locate associations that use the `AWS-GatherSoftwareInventory` SSM document.
- Remember that each managed node can only have one active inventory association at a time.

> **Important**
>
> - Inventory data is still collected from skipped nodes when their assigned (higher-priority) inventory association runs.
> - Quick Setup inventory associations take precedence over all other types, even those with explicit targeting.
> - The detailed status message `OverriddenByExplicitInventoryAssociation` appears when any association is overridden by a higher-priority one, regardless of the association type.

Failed

If the status of the inventory association for a node shows **Failed**, this could mean that the node has multiple inventory associations assigned to it. A node can only have one inventory association assigned at a time. An inventory association uses the `AWS-GatherSoftwareInventory` AWS Systems Manager document (SSM document). You can run the following command by using the AWS Command Line Interface (AWS CLI) to view a list of associations for a node.

```
aws ssm describe-instance-associations-status --instance-id instance-ID
```

Inventory compliance failed for an Amazon EC2 instance

Inventory compliance for an Amazon Elastic Compute Cloud (Amazon EC2) instance can fail if you assign multiple inventory associations to the instance.

To resolve this issue, delete one or more inventory associations assigned to the instance. For more information, see Deleting an association.

> **Note**
>
> Be aware of the following behavior if you create multiple inventory associations for a managed node:
>
> - Each node can be assigned an inventory association that targets *all* nodes (--targets "Key=InstanceIds,Values=*").
> - Each node can also be assigned a specific association that uses either tag key-value pairs or an AWS resource group.
> - If a node is assigned multiple inventory associations, the status shows *Skipped* for the association that hasn't run. The association that ran most recently displays the actual status of the inventory association.
> - If a node is assigned multiple inventory associations and each uses a tag key-value pair, then those inventory associations fail to run on the node because of the tag conflict. The association still runs on nodes that don't have the tag key-value conflict.

S3 bucket object contains old data

Data inside the Amazon S3 bucket object is updated when the inventory association is successful and new data is discovered. The Amazon S3 bucket object is updated for each node when the association runs and fails, but the data inside the object is not updated in this case. Data inside the Amazon S3 bucket object will update only when the association runs successfully. When the inventory association fails, you will see old data in the Amazon S3 bucket object.

AWS Systems Manager Patch Manager

Patch Manager, a tool in AWS Systems Manager, automates the process of patching managed nodes with both security-related updates and other types of updates.

> **Note**
>
> Systems Manager provides support for *patch policies* in Quick Setup, a tool in AWS Systems Manager. Using patch policies is the recommended method for configuring your patching operations. Using a single patch policy configuration, you can define patching for all accounts in all Regions in your organization; for only the accounts and Regions you choose; or for a single account-Region pair. For more information, see Patch policy configurations in Quick Setup.

You can use Patch Manager to apply patches for both operating systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.) You can use Patch Manager to install Service Packs on Windows nodes and perform minor version upgrades on Linux nodes. You can patch fleets of Amazon Elastic Compute Cloud (Amazon EC2) instances, edge devices, on-premises servers, and virtual machines (VMs) by operating system type. This includes supported versions of several operating systems, as listed in Patch Manager prerequisites. You can scan instances to see only a report of missing patches, or you can scan and automatically install all missing patches. To get started with Patch Manager, open the Systems Manager console. In the navigation pane, choose **Patch Manager**.

AWS doesn't test patches before making them available in Patch Manager. Also, Patch Manager doesn't support upgrading major versions of operating systems, such as Windows Server 2016 to Windows Server 2019, or Red Hat Enterprise Linux (RHEL) 7.0 to RHEL 8.0.

For Linux-based operating system types that report a severity level for patches, Patch Manager uses the severity level reported by the software publisher for the update notice or individual patch. Patch Manager doesn't derive severity levels from third-party sources, such as the Common Vulnerability Scoring System (CVSS), or from metrics released by the National Vulnerability Database (NVD).

How can Patch Manager benefit my organization?

Patch Manager automates the process of patching managed nodes with both security-related updates and other types of updates. It provides several key benefits:

- **Centralized patching control** –Using patch policies, you can set up recurring patching operations for all accounts in all Regions in your organization, specific accounts and Regions, or a single account-Region pair.

- **Flexible patching operations** – You can choose to scan instances to see only a report of missing patches, or scan and automatically install all missing patches.
- **Comprehensive compliance reporting** – After scanning operations, you can view detailed information about which managed nodes are out of patch compliance and which patches are missing.
- **Cross-platform support** – Patch Manager supports multiple operating systems including various Linux distributions, macOS, and Windows Server.
- **Custom patch baselines** – You can define what constitutes patch compliance for your organization through custom patch baselines that specify which patches are approved for installation.
- **Integration with other AWS services** – Patch Manager integrates with AWS Organizations, AWS Security Hub, AWS CloudTrail, and AWS Config for enhanced management and security.
- **Deterministic upgrades** – Support for deterministic upgrades through versioned repositories for operating systems like Amazon Linux 2023.

Who should use Patch Manager?

Patch Manager is designed for the following:

- IT administrators who need to maintain patch compliance across their fleet of managed nodes
- Operations managers who need visibility into patch compliance status across their infrastructure
- Cloud architects who want to implement automated patching solutions at scale
- DevOps engineers who need to integrate patching into their operational workflows
- Organizations with multi-account/multi-Region deployments who need centralized patch management
- Anyone responsible for maintaining the security posture and operational health of AWS managed nodes, edge devices, on-premises servers, and virtual machines

What are the main features of Patch Manager?

Patch Manager offers several key features:

- **Patch policies** – Configure patching operations across multiple AWS accounts and Regions using a single policy through integration with AWS Organizations.

- **Custom patch baselines** – Define rules for auto-approving patches within days of their release, along with approved and rejected patch lists.
- **Multiple patching methods** – Choose from patch policies, maintenance windows, or on-demand "Patch now" operations to meet your specific needs.
- **Compliance reporting** – Generate detailed reports on patch compliance status that can be sent to an Amazon S3 bucket in CSV format.
- **Cross-platform support** – Patch both operating systems and applications across Windows Server, various Linux distributions, and macOS.
- **Scheduling flexibility** – Set different schedules for scanning and installing patches using custom CRON or Rate expressions.
- **Lifecycle hooks** – Run custom scripts before and after patching operations using Systems Manager documents.
- **Security focus** – By default, Patch Manager focuses on security-related updates rather than installing all available patches.
- **Rate control** – Configure concurrency and error thresholds for patching operations to minimize operational impact.

What is compliance in Patch Manager?

The benchmark for what constitutes *patch compliance* for the managed nodes in your Systems Manager fleets is not defined by AWS, by operating system (OS) vendors, or by third parties such as security consulting firms.

Instead, you define what patch compliance means for managed nodes in your organization or account in a *patch baseline*. A patch baseline is a configuration that specifies rules for which patches must be installed on a managed node. A managed node is patch compliant when it is up to date with all the patches that meet the approval criteria that you specify in the patch baseline.

Note that being *compliant* with a patch baseline doesn't mean that a managed node is necessarily *secure*. Compliant means that the patches defined by the patch baseline that are both *available* and *approved* have been installed on the node. The overall security of a managed node is determined by many factors outside the scope of Patch Manager. For more information, see *Security*.

Each patch baseline is a configuration for a specific supported operating system (OS) type, such as Red Hat Enterprise Linux (RHEL), macOS, or Windows Server. A patch baseline can define patching

rules for all supported versions of an OS or be limited to only those you specify, such as RHEL 7.8. and RHEL 9.3.

In a patch baseline, you could specify that all patches of certain classifications and severity levels are approved for installation. For example, you might include all patches classified as `Security` but exclude other classifications, such as `Bugfix` or `Enhancement`. And you could include all patches with a severity of `Critical` and exclude others, such as `Important` and `Moderate`.

You can also define patches explicitly in a patch baseline by adding their IDs to lists of specific patches to approve or reject, such as KB2736693 for Windows Server or `dbus.x86_64:1:1.12.28-1.amzn2023.0.1` for Amazon Linux 2023 (AL2023). You can optionally specify a certain number of days to wait for patching after a patch becomes available. For Linux and macOS, you have the option of specifying an external list of patches for compliance (an Install Override list) instead of those defined by the patch baseline rules.

When a patching operation runs, Patch Manager compares the patches currently applied to a managed node to those that should be applied according to the rules set up in the patch baseline or an Install Override list. You can choose for Patch Manager to show you only a report of missing patches (a `Scan` operation), or you can choose for Patch Manager to automatically install all patches it find are missing from a managed node (a `Scan and install` operation).

Patch Manager provides predefined patch baselines that you can use for your patching operations; however, these predefined configurations are provided as examples and not as recommended best practices. We recommend that you create custom patch baselines of your own to exercise greater control over what constitutes patch compliance for your fleet.

For more information about patch baselines, see the following topics:

- Predefined and custom patch baselines
- Package name formats for approved and rejected patch lists
- Viewing AWS predefined patch baselines
- Working with custom patch baselines
- Working with patch compliance reports

Primary components

Before you start working with the Patch Manager tool, you should familiarize yourself with some major components and features of the tool's patching operations.

Patch baselines

Patch Manager uses *patch baselines*, which include rules for auto-approving patches within days of their release, in addition to optional lists of approved and rejected patches. When a patching operation runs, Patch Manager compares the patches currently applied to a managed node to those that should be applied according to the rules set up in the patch baseline. You can choose for Patch Manager to show you only a report of missing patches (a `Scan` operation), or you can choose for Patch Manager to automatically install all patches it find are missing from a managed node (a `Scan and install` operation).

Patching operation methods

Patch Manager currently offers four methods for running `Scan` and `Scan and install` operations:

- **(Recommended) A patch policy configured in Quick Setup** – Based on integration with AWS Organizations, a single patch policy can define patching schedules and patch baselines for an entire organization, including multiple AWS accounts and all AWS Regions those accounts operate in. A patch policy can also target only some organizational units (OUs) in an organization. You can use a single patch policy to scan and install on different schedules. For more information, see Configure patching for instances in an organization using a Quick Setup patch policy and Patch policy configurations in Quick Setup.
- **A Host Management option configured in Quick Setup** – Host Management configurations are also supported by integration with AWS Organizations, making it possible to run a patching operation for up to an entire Organization. However, this option is limited to scanning for missing patches using the current default patch baseline and providing results in compliance reports. This operation method can't install patches. For more information, see Set up Amazon EC2 host management using Quick Setup.
- **A maintenance window to run a patch `Scan` or `Install` task** – A maintenance window, which you set up in the Systems Manager tool called Maintenance Windows, can be configured to run different types of tasks on a schedule you define. A Run Command-type task can be used to run `Scan` or `Scan and install` tasks a set of managed nodes that you choose. Each maintenance window task can target managed nodes in only a single AWS account-AWS Region pair. For more information, see Tutorial: Create a maintenance window for patching using the console.
- **An on-demand Patch now operation in Patch Manager** – The **Patch now** option lets you bypass schedule setups when you need to patch managed nodes as quickly as possible. Using **Patch now**, you specify whether to run `Scan` or `Scan and install` operation and which managed

nodes to run the operation on. You can also choose to running Systems Manager documents (SSM documents) as lifecycle hooks during the patching operation. Each **Patch now** operation can target managed nodes in only a single AWS account-AWS Region pair. For more information, see Patching managed nodes on demand.

Compliance reporting

After a `Scan` operation, you can use the Systems Manager console to view information about which of your managed nodes are out of patch compliance, and which patches are missing from each of those nodes. You can also generate patch compliance reports in .csv format that are sent to an Amazon Simple Storage Service (Amazon S3) bucket of your choice. You can generate one-time reports, or generate reports on a regular schedule. For a single managed node, reports include details of all patches for the node. For a report on all managed nodes, only a summary of how many patches are missing is provided. After a report is generated, you can use a tool like Amazon QuickSight to import and analyze the data. For more information, see Working with patch compliance reports.

> **Note**
>
> A compliance item generated through the use of a patch policy has an execution type of `PatchPolicy`. A compliance item not generated in a patch policy operation has an execution type of `Command`.

Integrations

Patch Manager integrates with the following other AWS services:

- **AWS Identity and Access Management (IAM)** – Use IAM to control which users, groups, and roles have access to Patch Manager operations. For more information, see How AWS Systems Manager works with IAM and Configure instance permissions required for Systems Manager.
- **AWS CloudTrail** – Use CloudTrail to record an auditable history of patching operation events initiated by users, roles, or groups. For more information, see Logging AWS Systems Manager API calls with AWS CloudTrail.
- **AWS Security Hub** – Patch compliance data from Patch Manager can be sent to AWS Security Hub. Security Hub gives you a comprehensive view of your high-priority security alerts and compliance status. It also monitors the patching status of your fleet. For more information, see Integrating Patch Manager with AWS Security Hub.

- **AWS Config** – Set up recording in AWS Config to view Amazon EC2 instance management data in the Patch Manager Dashboard. For more information, see Viewing patch Dashboard summaries.

Topics

Patch policy configurations in Quick Setup

AWS recommends the use of *patch policies* to configure patching for your organization and AWS accounts. Patch policies were introduced in Patch Manager in December, 2022.

A patch policy is a configuration you set up using Quick Setup, a tool in AWS Systems Manager. Patch policies provide more extensive and more centralized control over your patching operations than is available with previous methods of configuring patching. Patch policies can be used with all operating systems supported by Patch Manager, including supported versions of Linux, macOS, and Windows Server. For instructions for creating a patch policy, see Configure patching for instances in an organization using a Quick Setup patch policy.

Major features of patch policies

Instead of using other methods of patching your nodes, use a patch policy to take advantage of these major features:

- **Single setup** – Setting up patching operations using a maintenance window or State Manager association can require multiple tasks in different parts of the Systems Manager console. Using a patch policy, all your patching operations can be set up in a single wizard.

- **Multi-account/Multi-Region support** – Using a maintenance window, a State Manager association, or the **Patch now** feature in Patch Manager, you're limited to targeting managed nodes in a single AWS account-AWS Region pair. If you use multiple accounts and multiple Regions, your setup and maintenance tasks can require a great deal of time, because you must perform setup tasks in each account-Region pair. However, if you use AWS Organizations, you can set up one patch policy that applies to all your managed nodes in all AWS Regions in all your AWS accounts. Or, if you choose, a patch policy can apply to only some organizational units (OUs) in the accounts and Regions you choose. A patch policy can also apply to a single local account, if you choose.
- **Installation support at the organizational level** – The existing Host Management configuration option in Quick Setup provides support for a daily scan of your managed nodes for patch compliance. However, this scan is done at a predetermined time and results in patch compliance information only. No patch installations are performed. Using a patch policy, you can specify different schedules for scanning and installing. You can also choose the frequency and time of these operations by using custom CRON or Rate expressions. For example, you could scan for missing patches every day to provide you with regularly updated compliance information. But, your installation schedule could be just once a week to avoid unwanted downtime.
- **Simplified patch baseline selection** – Patch policies still incorporate patch baselines, and there are no changes to the way patch baselines are configured. However, when you create or update a patch policy, you can select the AWS managed or custom baseline you want to use for each operating system (OS) type in a single list. It's not necessary to specify the default baseline for each OS type in separate tasks.

> **Note**
>
> When patching operations based on a patch policy run, they use the `AWS-RunPatchBaseline` SSM document. For more information, see SSM Command document for patching: `AWS-RunPatchBaseline`.

Related information

Centrally deploy patching operations across your AWS Organization using Systems Manager Quick Setup (AWS Cloud Operations and Migrations Blog)

Other differences with patch policies

Here are some other differences to note when using patch policies instead of previous methods of configuring patching:

- **No patch groups required** – In previous patching operations, you could tag multiple nodes to belong to a patch group, and then specify the patch baseline to use for that patch group. If no patch group was defined, Patch Manager patched instances with the current default patch baseline for the OS type. Using patch policies, it's no longer necessary to set up and maintain patch groups.

  > **Note**
  >
  > Patch group functionality is not supported in the console for account-Region pairs that did not already use patch groups before patch policy support was released on December 22, 2022. Patch group functionality is still available in account-Region pairs that began using patch groups before this date.

- **'Configure patching' page removed** – Before the release of patch policies, you could specify defaults for which nodes to patch, a patching schedule, and a patching operation on a **Configure patching** page. This page has been removed from Patch Manager. These options are now specified in patch policies.
- **No 'Patch now' support** – The ability to patch nodes on demand is still limited to a single AWS account-AWS Region pair at a time. For information, see Patching managed nodes on demand.
- **Patch policies and compliance information** – When your managed nodes are scanned for compliance according to a patching policy configuration, compliance data is made available to you. You can view and work with the data in the same way as with other methods of compliance scanning. Although you can set up a patch policy for an entire organization or multiple organizational units, compliance information is reported individually for each AWS account-AWS Region pair. For more information, see Working with patch compliance reports.
- **Association compliance status and patch policies** – The patching status for a managed node that's under a Quick Setup patch policy matches the status of the State Manager association execution for that node. If the association execution status is `Compliant`, the patching status for the managed node is also marked `Compliant`. If the association execution status is `Non-Compliant`, the patching status for the managed node is also marked `Non-Compliant`.

AWS Regions supported for patch policies

Patch policy configurations in Quick Setup are currently supported in the following Regions:

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (N. California) (us-west-1)
- US West (Oregon) (us-west-2)
- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Canada (Central) (ca-central-1)
- Europe (Frankfurt) (eu-central-1)
- Europe (Ireland) (eu-west-1)
- Europe (London) (eu-west-2)
- Europe (Paris) (eu-west-3)
- Europe (Stockholm) (eu-north-1)
- South America (São Paulo) (sa-east-1)

Patch Manager prerequisites

Make sure that you have met the required prerequisites before using Patch Manager, a tool in AWS Systems Manager.

Topics

SSM Agent version

Version 2.0.834.0 or later of SSM Agent is running on the managed node you want to manage with Patch Manager.

> **Note**
>
> An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Python version

For macOS and most Linux operating systems (OSs), Patch Manager currently supports Python versions 2.6 - 3.10. The AlmaLinux, Debian Server, and Ubuntu Server OSs require a supported version of Python 3 (3.0 - 3.10).

Connectivity to the patch source

If your managed nodes don't have a direct connection to the Internet and you're using an Amazon Virtual Private Cloud (Amazon VPC) with a VPC endpoint, you must ensure that the nodes have access to the source patch repositories (repos). On Linux nodes, patch updates are typically downloaded from the remote repos configured on the node. Therefore, the node must be able to connect to the repos so the patching can be performed. For more information, see How security patches are selected.

Windows Server: Ensure connectivity to Windows Update Catalog or Windows Server Update Services (WSUS)

Windows Server managed nodes must be able to connect to the Windows Update Catalog or Windows Server Update Services (WSUS). Confirm that your nodes have connectivity to the Microsoft Update Catalog through an internet gateway, NAT gateway, or NAT instance. If you are using WSUS, confirm that the node has connectivity to the WSUS server in your environment. For more information, see Issue: managed node doesn't have access to Windows Update Catalog or WSUS.

S3 endpoint access

Whether your managed nodes operate in a private or public network, without access to the required AWS managed Amazon Simple Storage Service (Amazon S3) buckets, patching operations fail. For information about the S3 buckets your managed nodes must be able to access, see SSM Agent communications with AWS managed S3 buckets and Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

Permissions to install patches locally

On Windows Server and Linux operating systems, Patch Manager assumes the Administrator and root user accounts, respectively, to install patches.

On macOS, however, for Brew and Brew Cask, Homebrew doesn't support its commands running under the root user account. As a result, Patch Manager queries for and runs Homebrew commands as either the owner of the Homebrew directory, or as a valid user belonging to the Homebrew directory's owner group. Therefore, in order to install patches, the owner of the `homebrew` directory also needs recursive owner permissions for the `/usr/local` directory.

Tip

The following command provides this permission for the specified user:

```
sudo chown -R $USER:admin /usr/local
```

Supported operating systems for Patch Manager

The Patch Manager tool might not support all the same operating systems versions that are supported by other Systems Manager tools. (For the full list of Systems Manager-supported operating systems, see Supported operating systems for Systems Manager.) Therefore, ensure that the managed nodes you want to use with Patch Manager are running one of the operating systems listed in the following table.

Note

Patch Manager relies on the patch repositories that are configured on a managed node, such as Windows Update Catalog and Windows Server Update Services for Windows, to retrieve available patches to install. Therefore, for end of life (EOL) operating system versions, if no new updates are available, Patch Manager might not be able to report on the

new updates. This can be because no new updates are released by the Linux distribution maintainer, Microsoft, or Apple, or because the managed node does not have the proper license to access the new updates.
Patch Manager reports compliance status against the available patches on the managed node. Therefore, if an instance is running an EOL operating system, and no updates are available, Patch Manager might report the node as Compliant, depending on the patch baselines configured for the patching operation.

Operating system	Details
Linux	• AlmaLinux 8.*x*, 9.*x* • Amazon Linux 2 version 2.0 and all later versions • Amazon Linux 2023 • Debian Server 11.*x*, and 12.*x* • Oracle Linux 7.5–8.*x*, 9.*x* • Red Hat Enterprise Linux (RHEL) 7.x–8.*x*, 9.*x*, 10.*x* • Rocky Linux 8.*x*, 9.*x* • Ubuntu Server 16.04 LTS, 18.04 LTS, 20.04 LTS, 22.04 LTS, and 25.04
macOS	*macOS is supported for Amazon EC2 instances only.* 13.0–13.7 (Ventura) 14.*x* (Sonoma) 15.*x* (Sequoia) **macOS OS updates** Patch Manager doesn't support operating system (OS) updates or upgrades for macOS, such as from 13.1 to 13.2. To

Operating system	Details
	perform OS version updates on macOS, we recommend using Apple's built-in OS upgrade mechanisms. For more information, see Device Management on the Apple Developer Documentation website. **Homebrew support** Patch Manager requires Homebrew, the open-source software package management system, to be installed at either of the following default install locations: • `/usr/local/bin` • `/opt/homebrew/bin` Patching operations using Patch Manager fail to function correctly when Homebrew is not installed. **Region support** macOS is not supported in all AWS Regions. For more information about Amazon EC2 support for macOS, see Amazon EC2 Mac instances in the *Amazon EC2 User Guide*. **macOS edge devices** SSM Agent for AWS IoT Greengrass core devices is not supported on macOS. You can't use Patch Manager to patch macOS edge devices.

Operating system	Details
Windows	Windows Server 2012 through Windows Server 2025, including R2 versions. **Note** SSM Agent for AWS IoT Greengras s core devices is not supported on Windows 10. You can't use Patch Manager to patch Windows 10 edge devices. **Windows Server 2012 and 2012 R2 support** Windows Server 2012 and 2012 R2 reached end of support on October 10, 2023. To use Patch Manager with these versions, we recommend also using Extended Security Updates (ESUs) from Microsoft. For more information, see Windows Server 2012 and 2012 R2 reaching end of support on the Microsoft website.

How Patch Manager operations work

This section provides technical details that explain how Patch Manager, a tool in AWS Systems Manager, determines which patches to install and how it installs them on each supported operating system. For Linux operating systems, it also provides information about specifying a source repository, in a custom patch baseline, for patches other than the default configured on a managed node. This section also provides details about how patch baseline rules work on different distributions of the Linux operating system.

Note

The information in the following topics applies no matter which method or type of configuration you are using for your patching operations:

- A patch policy configured in Quick Setup
- A Host Management option configured in Quick Setup
- A maintenance window to run a patch `Scan` or `Install` task
- An on-demand **Patch now** operation

Topics

How package release dates and update dates are calculated

Important

The information on this page applies to the Amazon Linux 2 and Amazon Linux 2023 operating systems (OSs) for Amazon Elastic Compute Cloud (Amazon EC2) instances. The packages for these OS types are created and maintained by Amazon Web Services. How the manufacturers of other operating systems manage their packages and repositories affect how their release dates and update dates are calculated. For OSs besides Amazon Linux 2 and Amazon Linux 2023, such as Red Hat Enterprise Linux, refer to the manufacturer's documentation for information about how their packages are updated and maintained.

In the settings for custom patch baselines you create, for most OS types, you can specify that patches are auto-approved for installation after a certain number of days. AWS provides several predefined patch baselines that include auto-approval dates of 7 days.

An *auto-approval delay* is the number of days to wait after the patch was released, before the patch is automatically approved for patching. For example, you create a rule using the `CriticalUpdates` classification and configure it for 7 days auto-approval delay. As a result, a new critical patch with a release date or last update date of July 7 is automatically approved on July 14.

To avoid unexpected results with auto-approval delays on Amazon Linux 2 and Amazon Linux 2023, it's important to understand how their release dates and update dates are calculated.

In most cases, the auto-approval wait time before patches are installed is calculated from an `Updated Date` value in `updateinfo.xml`, not a `Release Date` value. The following are important details about these date calculations:

- The `Release Date` is the date a *notice* is released. It does not mean the package is necessarily available in the associated repositories yet.
- The `Update Date` is the last date the notice was updated. An update to a notice can represent something as small as a text or description update. It does not mean the package was released from that date or is necessarily available in the associated repositories yet.

  This means that a package could have an `Update Date` value of July 7 but not be available for installation until (for example) July 13. Suppose for this case that a patch baseline that specifies a 7-day auto-approval delay runs in an `Install` operation on July 14. Because the `Update Date` value is 7 days prior to the run date, the patches and updates in the package are installed on July 14. The installation happens even though only 1 day has passed since the package became available for actual installation.
- A package containing operating system or application patches can be updated more than once after initial release.
- A package can be released into the AWS managed repositories but then rolled back if issues are later discovered with it.

In some patching operations, these factors might not be important. For example, if a patch baseline is configured to install a patch with severity values of `Low` and `Medium`, and a classification of `Recommended`, any auto-approval delay might have little impact on your operations.

However, in cases where the timing of critical or high-severity patches is more important, you might want to exercise more control over when patches are installed. The recommended method

for doing this is to use alternative patch source repositories instead of the default repositories for patching operations on a managed node.

You can specify alternative patch source repositories when you create a custom patch baseline. In each custom patch baseline, you can specify patch source configurations for up to 20 versions of a supported Linux operating system. For more information, see How to specify an alternative patch source repository (Linux).

How security patches are selected

The primary focus of Patch Manager, a tool in AWS Systems Manager, is on installing operating systems security-related updates on managed nodes. By default, Patch Manager doesn't install all available patches, but rather a smaller set of patches focused on security.

By default, Patch Manager doesn't replace a package that has been marked as obsolete in a package repository with any differently named replacement packages unless this replacement is required by the installation of another package update. Instead, for commands that update a package, Patch Manager only reports and installs missing updates for the package that is installed but obsolete. This is because replacing an obsolete package typically requires uninstalling an existing package and installing its replacement. Replacing the obsolete package could introduce breaking changes or additional functionality that you didn't intend.

This behavior is consistent with YUM and DNF's `update-minimal` command, which focuses on security updates rather than feature upgrades. For more information, see the section called “How patches are installed”.

For Linux-based operating system types that report a severity level for patches, Patch Manager uses the severity level reported by the software publisher for the update notice or individual patch. Patch Manager doesn't derive severity levels from third-party sources, such as the Common Vulnerability Scoring System (CVSS), or from metrics released by the National Vulnerability Database (NVD).

> **Note**
>
> On all Linux-based systems supported by Patch Manager, you can choose a different source repository configured for the managed node, typically to install nonsecurity updates. For information, see How to specify an alternative patch source repository (Linux).

The remainder of this section explains how Patch Manager selects security patches for the different supported operating systems.

Amazon Linux 2 and Amazon Linux 2023

Preconfigured repositories are handled differently on Amazon Linux 2 than on Amazon Linux 2023.

On Amazon Linux 2, the Systems Manager patch baseline service uses preconfigured repositories on the managed node. There are usually two preconfigured repositories (repos) on a node:

On Amazon Linux 2

- **Repo ID**: `amzn2-core/2/`*`architecture`*

  Repo name: `Amazon Linux 2 core repository`
- **Repo ID**: `amzn2extra-docker/2/`*`architecture`*

  Repo name: `Amazon Extras repo for docker`

> **Note**
>
> *`architecture`* can be x86_64 or (for Graviton processors) aarch64.

When you create an Amazon Linux 2023 (AL2023) instance, it contains the updates that were available in the version of AL2023 and the specific AMI you selected. Your AL2023 instance doesn't automatically receive additional critical and important security updates at launch time. Instead, with the *deterministic upgrades through versioned repositories* feature supported for AL2023, which is turned on by default, you can apply updates based on a schedule that meets your specific needs. For more information, see Deterministic upgrades through versioned repositories in the *Amazon Linux 2023 User Guide*.

On AL2023, the preconfigured repository is the following:

- **Repo ID**: `amazonlinux`

  Repo name: Amazon Linux 2023 repository

On Amazon Linux 2023 (preview release), the preconfigured repositories are tied to *locked versions* of package updates. When new Amazon Machine Images (AMIs) for AL2023 are released, they are locked to a specific version. For patch updates, Patch Manager retrieves the latest locked version of the patch update repository and then updates packages on the managed node based on the content of that locked version.

Package managers

Amazon Linux 2 managed nodes use Yum as the package manager. Amazon Linux 2023 use DNF as the package manager.

Both package managers use the concept of an *update notice* as a file named `updateinfo.xml`. An update notice is simply a collection of packages that fix specific problems. All packages that are in an update notice are considered Security by Patch Manager. Individual packages aren't assigned classifications or severity levels. For this reason, Patch Manager assigns the attributes of an update notice to the related packages.

> **Note**
>
> If you select the **Include non-security updates** check box in the **Create patch baseline** page, then packages that aren't classified in an `updateinfo.xml` file (or a package that contains a file without properly formatted Classification, Severity, and Date values) can be included in the prefiltered list of patches. However, in order for a patch to be applied, the patch must still meet the user-specified patch baseline rules.
> For more information about the **Include non-security updates** option, see How patches are installed and How patch baseline rules work on Linux-based systems.

Debian Server

On Debian Server, the Systems Manager patch baseline service uses preconfigured repositories (repos) on the instance. These preconfigured repos are used to pull an updated list of available package upgrades. For this, Systems Manager performs the equivalent of a `sudo apt-get update` command.

Packages are then filtered from `debian-security` *`codename`* repos. This means that on each version of Debian Server, Patch Manager only identifies upgrades that are part of the associated repo for that version, as follows:

- Debian Server 11: `debian-security bullseye`
- Debian Server 12: `debian-security bookworm`

Oracle Linux

On Oracle Linux, the Systems Manager patch baseline service uses preconfigured repositories (repos) on the managed node. There are usually two preconfigured repos on a node.

Oracle Linux 7:

- **Repo ID**: `ol7_UEKR5/x86_64`

  Repo name: `Latest Unbreakable Enterprise Kernel Release 5 for Oracle Linux 7Server (x86_64)`
- **Repo ID**: `ol7_latest/x86_64`

  Repo name: `Oracle Linux 7Server Latest (x86_64)`

Oracle Linux 8:

- **Repo ID**: `ol8_baseos_latest`

  Repo name: `Oracle Linux 8 BaseOS Latest (x86_64)`
- **Repo ID**: `ol8_appstream`

  Repo name: `Oracle Linux 8 Application Stream (x86_64)`
- **Repo ID**: `ol8_UEKR6`

  Repo name: `Latest Unbreakable Enterprise Kernel Release 6 for Oracle Linux 8 (x86_64)`

Oracle Linux 9:

- **Repo ID**: `ol9_baseos_latest`

  Repo name: `Oracle Linux 9 BaseOS Latest (x86_64)`
- **Repo ID**: `ol9_appstream`

  Repo name: `Oracle Linux 9 Application Stream Packages(x86_64)`

- **Repo ID**: `ol9_UEKR7`

  Repo name: `Oracle Linux UEK Release 7 (x86_64)`

> **Note**
>
> All updates are downloaded from the remote repos configured on the managed node. Therefore, the node must have outbound access to the internet in order to connect to the repos so the patching can be performed.

Oracle Linux managed nodes use Yum as the package manager, and Yum uses the concept of an update notice as a file named `updateinfo.xml`. An update notice is simply a collection of packages that fix specific problems. Individual packages aren't assigned classifications or severity levels. For this reason, Patch Manager assigns the attributes of an update notice to the related packages and installs packages based on the Classification filters specified in the patch baseline.

> **Note**
>
> If you select the **Include non-security updates** check box in the **Create patch baseline** page, then packages that aren't classified in an `updateinfo.xml` file (or a package that contains a file without properly formatted Classification, Severity, and Date values) can be included in the prefiltered list of patches. However, in order for a patch to be applied, the patch must still meet the user-specified patch baseline rules.

AlmaLinux, RHEL, and Rocky Linux

On AlmaLinux, Red Hat Enterprise Linux, and Rocky Linux the Systems Manager patch baseline service uses preconfigured repositories (repos) on the managed node. There are usually three preconfigured repos on a node.

All updates are downloaded from the remote repos configured on the managed node. Therefore, the node must have outbound access to the internet in order to connect to the repos so the patching can be performed.

> **Note**
>
> If you select the **Include non-security updates** check box in the **Create patch baseline** page, then packages that aren't classified in an `updateinfo.xml` file (or a package that contains a file without properly formatted Classification, Severity, and Date values) can be included in the prefiltered list of patches. However, in order for a patch to be applied, the patch must still meet the user-specified patch baseline rules.

Red Hat Enterprise Linux 7 managed nodes use Yum as the package manager. AlmaLinux, Red Hat Enterprise Linux 8, and Rocky Linux managed nodes use DNF as the package manager. Both package managers use the concept of an update notice as a file named `updateinfo.xml`. An update notice is simply a collection of packages that fix specific problems. Individual packages aren't assigned classifications or severity levels. For this reason, Patch Manager assigns the attributes of an update notice to the related packages and installs packages based on the Classification filters specified in the patch baseline.

RHEL 7

> **Note**
>
> The following repo IDs are associated with RHUI 2. RHUI 3 launched in December 2019 and introduced a different naming scheme for Yum repository IDs. Depending on the RHEL-7 AMI you create your managed nodes from, you might need to update your commands. For more information, see Repository IDs for RHEL 7 in AWS Have Changed on the *Red Hat Customer Portal*.

- **Repo ID**: `rhui-REGION-client-config-server-7/x86_64`

  Repo name: `Red Hat Update Infrastructure 2.0 Client Configuration Server 7`
- **Repo ID**: `rhui-REGION-rhel-server-releases/7Server/x86_64`

  Repo name: `Red Hat Enterprise Linux Server 7 (RPMs)`
- **Repo ID**: `rhui-REGION-rhel-server-rh-common/7Server/x86_64`

  Repo name: `Red Hat Enterprise Linux Server 7 RH Common (RPMs)`

AlmaLinux, 8 RHEL 8, and Rocky Linux 8

- **Repo ID**: `rhel-8-appstream-rhui-rpms`

  Repo name: `Red Hat Enterprise Linux 8 for x86_64 - AppStream from RHUI (RPMs)`
- **Repo ID**: `rhel-8-baseos-rhui-rpms`

  Repo name: `Red Hat Enterprise Linux 8 for x86_64 - BaseOS from RHUI (RPMs)`
- **Repo ID**: `rhui-client-config-server-8`

  Repo name: `Red Hat Update Infrastructure 3 Client Configuration Server 8`

AlmaLinux 9, RHEL 9, and Rocky Linux 9

- **Repo ID**: `rhel-9-appstream-rhui-rpms`

  Repo name: `Red Hat Enterprise Linux 9 for x86_64 - AppStream from RHUI (RPMs)`
- **Repo ID**: `rhel-9-baseos-rhui-rpms`

  Repo name: `Red Hat Enterprise Linux 9 for x86_64 - BaseOS from RHUI (RPMs)`
- **Repo ID**: `rhui-client-config-server-9`

  Repo name: `Red Hat Enterprise Linux 9 Client Configuration`

Ubuntu Server

On Ubuntu Server, the Systems Manager patch baseline service uses preconfigured repositories (repos) on the managed node. These preconfigured repos are used to pull an updated list of available package upgrades. For this, Systems Manager performs the equivalent of a `sudo apt-get update` command.

Packages are then filtered from *`codename`*`-security` repos, where the codename is unique to the release version, such as `trusty` for Ubuntu Server 14. Patch Manager only identifies upgrades that are part of these repos:

-

- Ubuntu Server 16.04 LTS: `xenial-security`
- Ubuntu Server 18.04 LTS: `bionic-security`
- Ubuntu Server 20.04 LTS: `focal-security`
-
- Ubuntu Server 22.04 LTS (`jammy-security`)
-
-
- Ubuntu Server 24.04 LTS (`noble-security`)
-
- Ubuntu Server 25.04 (`plucky-security`)

Windows Server

On Microsoft Windows operating systems, Patch Manager retrieves a list of available updates that Microsoft publishes to Microsoft Update and are automatically available to Windows Server Update Services (WSUS).

> **Note**
>
> Patch Manager only makes available patches for Windows Server operating system versions that are supported for Patch Manager. For example, Patch Manager can't be used to patch Windows RT.

Patch Manager continually monitors for new updates in every AWS Region. The list of available updates is refreshed in each Region at least once per day. When the patch information from Microsoft is processed, Patch Manager removes updates that were replaced by later updates from its patch list . Therefore, only the most recent update is displayed and made available for installation. For example, if `KB4012214` replaces `KB3135456`, only `KB4012214` is made available as an update in Patch Manager.

Similarly, Patch Manager can install only patches that are available on the managed node during the time of the patching operation. By default, Windows Server 2019 and Windows Server 2022 remove updates that are replaced by later updates. As a result, if you use the `ApproveUntilDate` parameter in a Windows Server patch baseline, but the date selected in

the `ApproveUntilDate` parameter is *before* the date of the latest patch, then the following scenario occurs:

- The superseded patch is removed from the node and therefore can't be installed using Patch Manager.
- The latest, replacement patch is present on the node but not yet approved for installation per the `ApproveUntilDate` parameter's specified date.

This means that the managed node is compliant in terms of Systems Manager operations, even though a critical patch from the previous month might not be installed. This same scenario can occur when using the `ApproveAfterDays` parameter. Because of the Microsoft superseded patch behavior, it is possible to set a number (generally greater than 30 days) so that patches for Windows Server are never installed if the latest available patch from Microsoft is released before the number of days in `ApproveAfterDays` has elapsed. Note that this system behavior doesn't apply if you have modified your Windows Group Policy Object (GPO) settings to make the superseded patch available on your managed nodes.

> **Note**
>
> In some cases, Microsoft releases patches for applications that don't specify an updated date and time. In these cases, an updated date and time of `01/01/1970` is supplied by default.

How to specify an alternative patch source repository (Linux)

When you use the default repositories configured on a managed node for patching operations, Patch Manager, a tool in AWS Systems Manager, scans for or installs security-related patches. This is the default behavior for Patch Manager. For complete information about how Patch Manager selects and installs security patches, see How security patches are selected.

On Linux systems, however, you can also use Patch Manager to install patches that aren't related to security, or that are in a different source repository than the default one configured on the managed node. You can specify alternative patch source repositories when you create a custom patch baseline. In each custom patch baseline, you can specify patch source configurations for up to 20 versions of a supported Linux operating system.

For example, suppose that your Ubuntu Server fleet includes both Ubuntu Server 25.04 managed nodes. In this case, you can specify alternate repositories for each version in the same custom patch baseline. For each version, you provide a name, specify the operating system version type (product), and provide a repository configuration. You can also specify a single alternative source repository that applies to all versions of a supported operating system.

> **Note**
>
> Running a custom patch baseline that specifies alternative patch repositories for a managed node doesn't make them the new default repositories on the operating system. After the patching operation is complete, the repositories previously configured as the defaults for the node's operating system remain the defaults.

For a list of example scenarios for using this option, see Sample uses for alternative patch source repositories later in this topic.

For information about default and custom patch baselines, see Predefined and custom patch baselines.

Example: Using the console

To specify alternative patch source repositories when you're working in the Systems Manager console, use the **Patch sources** section on the **Create patch baseline** page. For information about using the **Patch sources** options, see Creating a custom patch baseline for Linux.

Example: Using the AWS CLI

For an example of using the `--sources` option with the AWS Command Line Interface (AWS CLI), see Create a patch baseline with custom repositories for different OS versions.

Topics

- Important considerations for alternative repositories
- Sample uses for alternative patch source repositories

Important considerations for alternative repositories

Keep in mind the following points as you plan your patching strategy using alternative patch repositories.

Only specified repositories are used for patching

Specifying alternative repositories doesn't mean specifying *additional* repositories. You can choose to specify repositories other than those configured as defaults on a managed node. However, you must also specify the default repositories as part of the alternative patch source configuration if you want their updates to be applied.

For example, on Amazon Linux 2 managed nodes, the default repositories are `amzn2-core` and `amzn2extra-docker`. If you want to include the Extra Packages for Enterprise Linux (EPEL) repository in your patching operations, you must specify all three repositories as alternative repositories.

> **Note**
>
> Running a custom patch baseline that specifies alternative patch repositories for a managed node doesn't make them the new default repositories on the operating system. After the patching operation is complete, the repositories previously configured as the defaults for the node's operating system remain the defaults.

Patching behavior for YUM-based distributions depends on the updateinfo.xml manifest

When you specify alternative patch repositories for YUM-based distributions, such as Amazon Linux 2, or Red Hat Enterprise Linux, patching behavior depends on whether the repository includes an update manifest in the form of a complete and correctly formatted `updateinfo.xml` file. This file specifies the release date, classifications, and severities of the various packages. Any of the following will affect the patching behavior:

- If you filter on **Classification** and **Severity**, but they aren't specified in `updateinfo.xml`, the package won't be included by the filter. This also means that packages without an `updateinfo.xml` file won't be included in patching.
- If you filter on **ApprovalAfterDays**, but the package release date isn't in Unix Epoch format (or has no release date specified), the package won't be included by the filter.
- There is an exception if you select the **Include non-security updates** check box in the **Create patch baseline** page. In this case, packages without an `updateinfo.xml` file (or that contains this file without properly formatted **Classification**, **Severity**, and **Date** values) *will* be included in the prefiltered list of patches. (They must still meet the other patch baseline rule requirements in order to be installed.)

Sample uses for alternative patch source repositories

Example 1 – Nonsecurity Updates for Ubuntu Server

You're already using Patch Manager to install security patches on a fleet of Ubuntu Server managed nodes using the AWS-provided predefined patch baseline `AWS-UbuntuDefaultPatchBaseline`. You can create a new patch baseline that is based on this default, but specify in the approval rules that you want nonsecurity related updates that are part of the default distribution to be installed as well. When this patch baseline is run against your nodes, patches for both security and nonsecurity issues are applied. You can also choose to approve nonsecurity patches in the patch exceptions you specify for a baseline.

Example 2 - Personal Package Archives (PPA) for Ubuntu Server

Your Ubuntu Server managed nodes are running software that is distributed through a Personal Package Archives (PPA) for Ubuntu. In this case, you create a patch baseline that specifies a PPA repository that you have configured on the managed node as the source repository for the patching operation. Then use Run Command to run the patch baseline document on the nodes.

Example 3 – Internal Corporate Applications on supported Amazon Linux versions

You need to run some applications needed for industry regulatory compliance on your Amazon Linux managed nodes. You can configure a repository for these applications on the nodes, use YUM to initially install the applications, and then update or create a new patch baseline to include this new corporate repository. After this you can use Run Command to run the `AWS-RunPatchBaseline` document with the `Scan` option to see if the corporate package is listed among the installed packages and is up to date on the managed node. If it isn't up to date, you can run the document again using the `Install` option to update the applications.

How patches are installed

Patch Manager, a tool in AWS Systems Manager, uses the appropriate built-in mechanism for an operating system type to install updates on a managed node. For example, on Windows Server, the Windows Update API is used, and on Amazon Linux 2 the `yum` package manager is used.

Patch Manager doesn't install a new package that replaces an obsolete package that's currently installed. (Exceptions: The new package is a dependency of another package updating being installed, or the new package has the same name as the obsolete package.) Instead, Patch Manager reports on and installs available updates to installed packages. This approach helps prevent unexpected changes to your system functionality that might occur when one package replaces another.

If you need to uninstall a package that has been made obsolete and install its replacement, you might need to use a custom script or use package manager commands outside of Patch Manager's standard operations.

The remainder of this section explains how Patch Manager installs patches on an operating system.

Amazon Linux 2 and Amazon Linux 2023

On Amazon Linux 2 and Amazon Linux 2023 managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the `InstallOverrideList` parameter for the `AWS-RunPatchBaseline` or `AWS-RunPatchBaselineAssociation` documents, the listed patches are installed and steps 2-7 are skipped.
2. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.
3. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

   Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

   If nonsecurity updates are included, patches from other repositories are considered as well.
4. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.
5. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.
6. If multiple versions of a patch are approved, the latest version is applied.
7. The YUM update API (Amazon Linux 2) or the DNF update API (Amazon Linux 2023) is applied to approved patches as follows:
   - For predefined default patch baselines provided by AWS, only patches specified in `updateinfo.xml` are applied (security updates only). This is because the **Include**

nonsecurity updates check box is not selected. The predefined baselines are equivalent to a custom baseline with the following:

- The **Include nonsecurity updates** check box is not selected
- A SEVERITY list of `[Critical, Important]`
- A CLASSIFICATION list of `[Security, Bugfix]`

For Amazon Linux 2, the equivalent yum command for this workflow is:

```
sudo yum update-minimal --sec-severity=Critical,Important --bugfix -y
```

For Amazon Linux 2023, the equivalent dnf command for this workflow is:

```
sudo dnf upgrade-minimal --sec-severity=Critical --sec-severity=Important --
bugfix -y
```

If the **Include nonsecurity updates** check box is selected, patches in `updateinfo.xml` and those not in `updateinfo.xml` are all applied (security and nonsecurity updates).

For Amazon Linux 2, if a baseline with **Include nonsecurity updates** is selected, has a SEVERITY list of `[Critical, Important]` and a CLASSIFICATION list of `[Security, Bugfix]`, the equivalent yum command is:

```
sudo yum update --security --sec-severity=Critical,Important --bugfix -y
```

For Amazon Linux 2023, the equivalent dnf command is:

```
sudo dnf upgrade --security --sec-severity=Critical --sec-severity=Important --
bugfix -y
```

> **Note**
>
> New packages that replace now-obsolete packages with different names are installed if you run these `yum` or `dnf` commands outside of Patch Manager. However, they are *not* installed by the equivalent Patch Manager operations.

Additional patching details for Amazon Linux 2023

Support for severity level 'None'

Amazon Linux 2023 also supports the patch severity level `None`, which is recognized by the DNF package manager.

Support for severity level 'Medium'

For Amazon Linux 2023, a patch severity level of `Medium` is equivalent to a severity of `Moderate` that might be defined in some external repositories. If you include `Medium` severity patches in the patch baseline, `Moderate` severity patches from external patches are also installed on the instances.

When you query for compliance data using the API action DescribeInstancePatches, filtering for the severity level `Medium` reports patches with severity levels of both `Medium` and `Moderate`.

Transitive dependency handling for Amazon Linux 2023

For Amazon Linux 2023, Patch Manager might install different versions of transitive dependencies than the equivalent `dnf` commands install. Transitive dependencies are packages that are automatically installed to satisfy the requirements of other packages (dependencies of dependencies).

For example, `dnf upgrade-minimal --security` installs the *minimal* versions of transitive dependencies needed to resolve known security issues, while Patch Manager installs the latest available versions of the same transitive dependencies.

8. The managed node is rebooted if any updates were installed. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

Debian Server

On Debian Server instances, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the `InstallOverrideList` parameter for the `AWS-`

`RunPatchBaseline` or `AWS-RunPatchBaselineAssociation` documents, the listed patches are installed and steps 2-7 are skipped.

2. If an update is available for `python3-apt` (a Python library interface to `libapt`), it is upgraded to the latest version. (This nonsecurity package is upgraded even if you did not select the **Include nonsecurity updates** option.)
3. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.
4. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

   > **Note**
   >
   > Because it isn't possible to reliably determine the release dates of update packages for Debian Server, the auto-approval options aren't supported for this operating system.

   Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

   If nonsecurity updates are included, patches from other repositories are considered as well.

   > **Note**
   >
   > For Debian Server, patch candidate versions are limited to patches included in `debian-security`.

5. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.
6. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.
7. The APT library is used to upgrade packages.

> **Note**
>
> Patch Manager does not support using the APT `Pin-Priority` option to assign priorities to packages. Patch Manager aggregates available updates from all enabled repositories and selects the most recent update that matches the baseline for each installed package.

8. The managed node is rebooted if any updates were installed. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

macOS

On macOS managed nodes, the patch installation workflow is as follows:

1. The `/Library/Receipts/InstallHistory.plist` property list is a record of software that has been installed and upgraded using the `softwareupdate` and `installer` package managers. Using the `pkgutil` command line tool (for `installer`) and the `softwareupdate` package manager, CLI commands are run to parse this list.

   For `installer`, the response to the CLI commands includes `package name`, `version`, `volume`, `location`, and `install-time` details, but only the `package name` and `version` are used by Patch Manager.

   For `softwareupdate`, the response to the CLI commands includes the package name (`display name`), `version`, and `date`, but only the package name and version are used by Patch Manager.

   For Brew and Brew Cask, Homebrew doesn't support its commands running under the root user. As a result, Patch Manager queries for and runs Homebrew commands as either the owner of the Homebrew directory or as a valid user belonging to the Homebrew directory's owner group. The commands are similar to `softwareupdate` and `installer` and are run through a Python subprocess to gather package data, and the output is parsed to identify package names and versions.
2. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.

3. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.
4. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.
5. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.
6. If multiple versions of a patch are approved, the latest version is applied.
7. Invokes the appropriate package CLI on the managed node to process approved patches as follows:

   Note

   `installer` lacks the functionality to check for and install updates. Therefore, for `installer`, Patch Manager only reports which packages are installed. As a result, `installer` packages are never reported as `Missing`.

   - For predefined default patch baselines provided by AWS, and for custom patch baselines where the **Include non-security updates** check box is *not* selected, only security updates are applied.
   - For custom patch baselines where the **Include non-security updates** check box *is* selected, both security and nonsecurity updates are applied.
8. The managed node is rebooted if any updates were installed. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

Oracle Linux

On Oracle Linux managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the `InstallOverrideList` parameter for the `AWS-RunPatchBaseline` or `AWS-RunPatchBaselineAssociation` documents, the listed patches are installed and steps 2-7 are skipped.

2. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.
3. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

   Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

   If nonsecurity updates are included, patches from other repositories are considered as well.
4. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.
5. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.
6. If multiple versions of a patch are approved, the latest version is applied.
7. On version 7 managed nodes, the YUM update API is applied to approved patches as follows:
   - For predefined default patch baselines provided by AWS, and for custom patch baselines where the **Include non-security updates** check box is *not* selected, only patches specified in `updateinfo.xml` are applied (security updates only).

     The equivalent yum command for this workflow is:

     ```
     sudo yum update-minimal --sec-severity=Important,Moderate --bugfix -y
     ```
   - For custom patch baselines where the **Include non-security updates** check box *is* selected, both patches in `updateinfo.xml` and those not in `updateinfo.xml` are applied (security and nonsecurity updates).

     The equivalent yum command for this workflow is:

     ```
     sudo yum update --security --bugfix -y
     ```

On version 8 and 9 managed nodes, the DNF update API is applied to approved patches as follows:

- For predefined default patch baselines provided by AWS, and for custom patch baselines where the **Include non-security updates** check box is *not* selected, only patches specified in `updateinfo.xml` are applied (security updates only).

  The equivalent yum command for this workflow is:

  ```
  sudo dnf upgrade-minimal --security --sec-severity=Moderate --sec-
  severity=Important
  ```

  Note

  For Oracle Linux, Patch Manager might install different versions of transitive dependencies than the equivalent `dnf` commands install. Transitive dependencies are packages that are automatically installed to satisfy the requirements of other packages (dependencies of dependencies).
  For example, `dnf upgrade-minimal --security` installs the *minimal* versions of transitive dependencies needed to resolve known security issues, while Patch Manager installs the *latest available versions* of the same transitive dependencies.

- For custom patch baselines where the **Include non-security updates** check box *is* selected, both patches in `updateinfo.xml` and those not in `updateinfo.xml` are applied (security and nonsecurity updates).

  The equivalent yum command for this workflow is:

  ```
  sudo dnf upgrade --security --bugfix
  ```

Note

New packages that replace now-obsolete packages with different names are installed if you run these `yum` or `dnf` commands outside of Patch Manager. However, they are *not* installed by the equivalent Patch Manager operations.

8. The managed node is rebooted if any updates were installed. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

AlmaLinux, RHEL, and Rocky Linux

On AlmaLinux, Red Hat Enterprise Linux, and Rocky Linux managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the `InstallOverrideList` parameter for the `AWS-RunPatchBaseline` or `AWS-RunPatchBaselineAssociation` documents, the listed patches are installed and steps 2-7 are skipped.
2. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.
3. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

   Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

   If nonsecurity updates are included, patches from other repositories are considered as well.
4. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.
5. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.
6. If multiple versions of a patch are approved, the latest version is applied.
7. The YUM update API (on RHEL 7) or the DNF update API (on AlmaLinux 8 and 9, RHEL 8, 9, and 10, and Rocky Linux 8 and 9) is applied to approved patches according to the following rules:

Scenario 1: Non-security updates excluded

- **Applies to**: Predefined default patch baselines provided by AWS and custom patch baselines.
- **Include non-security updates** check box: *Not* selected.
- **Patches applied**: Patches specified in `updateinfo.xml` (security updates only) are applied *only* if they both match the patch baseline configuration and are found in the configured repos.

  In some cases, a patch specified in `updateinfo.xml` might no longer be available in a configured repo. Configured repos usually have only the latest version of a patch, which is a cumulative roll-up of all prior updates, but the latest version might not match the patch baseline rules and is omitted from the patching operation.
- **Commands**: For RHEL 7, the equivalent yum command for this workflow is:

  ```
  sudo yum update-minimal --sec-severity=Critical,Important --bugfix -y
  ```

  For AlmaLinux, RHEL 8, and Rocky Linux , the equivalent dnf commands for this workflow are:

  ```
  sudo dnf update-minimal --sec-severity=Critical --bugfix -y ; \
  sudo dnf update-minimal --sec-severity=Important --bugfix -y
  ```

  Note

  For AlmaLinux, RHEL, and Rocky LinuxRocky Linux, Patch Manager might install different versions of transitive dependencies than the equivalent `dnf` commands install. Transitive dependencies are packages that are automatically installed to satisfy the requirements of other packages (dependencies of dependencies). For example, `dnf upgrade-minimal --security` installs the *minimal* versions of transitive dependencies needed to resolve known security issues, while Patch Manager installs the *latest available versions* of the same transitive dependencies.

Scenario 2: Non-security updates included

- **Apples to**: Custom patch baselines.
- **Include non-security updates** check box: Selected.
- **Patches applied**: Patches in `updateinfo.xml` *and* those not in `updateinfo.xml` are applied (security and nonsecurity updates).
- **Commands**: For RHEL 7, the equivalent yum command for this workflow is:

```
sudo yum update --security --bugfix -y
```

For AlmaLinux 8 and 9, RHEL 8 and 9, and Rocky Linux 8 and 9, the equivalent dnf command for this workflow is:

```
sudo dnf update --security --bugfix -y
```

> **Note**
>
> New packages that replace now-obsolete packages with different names are installed if you run these `yum` or `dnf` commands outside of Patch Manager. However, they are *not* installed by the equivalent Patch Manager operations.

8. The managed node is rebooted if any updates were installed. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

Ubuntu Server

On Ubuntu Server managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the `InstallOverrideList` parameter for the `AWS-RunPatchBaseline` or `AWS-RunPatchBaselineAssociation` documents, the listed patches are installed and steps 2-7 are skipped.

2. If an update is available for `python3-apt` (a Python library interface to `libapt`), it is upgraded to the latest version. (This nonsecurity package is upgraded even if you did not select the **Include nonsecurity updates** option.)
3. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.
4. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

> **Note**
>
> Because it's not possible to reliably determine the release dates of update packages for Ubuntu Server, the auto-approval options aren't supported for this operating system.

Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

If nonsecurity updates are included, patches from other repositories are considered as well.

Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

> **Note**
>
> For each version of Ubuntu Server, patch candidate versions are limited to patches that are part of the associated repo for that version, as follows:
>
> - Ubuntu Server 16.04 LTS: `xenial-security`
> - Ubuntu Server 18.04 LTS: `bionic-security`
> - Ubuntu Server 20.04 LTS): `focal-security`
> - Ubuntu Server 22.04 LTS: `jammy-security`
> - Ubuntu Server 24.04 LTS (`noble-security`)

- Ubuntu Server 25.04 (`plucky-security`)

5. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.
6. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.
7. The APT library is used to upgrade packages.

> **Note**
>
> Patch Manager does not support using the APT `Pin-Priority` option to assign priorities to packages. Patch Manager aggregates available updates from all enabled repositories and selects the most recent update that matches the baseline for each installed package.

8. The managed node is rebooted if any updates were installed. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

Windows Server

When a patching operation is performed on a Windows Server managed node, the node requests a snapshot of the appropriate patch baseline from Systems Manager. This snapshot contains the list of all updates available in the patch baseline that were approved for deployment. This list of updates is sent to the Windows Update API, which determines which of the updates are applicable to the managed node and installs them as needed. Windows allows only the latest available version of a KB to be installed. Patch Manager installs the latest version of a KB when it, or any previous version of the KB, matches the applied patch baseline. If any updates are installed, the managed node is rebooted afterwards, as many times as necessary to complete all necessary patching. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)
The summary of the patching operation can be found in the output of the Run Command

request. Additional logs can be found on the managed node in the `%PROGRAMDATA%\Amazon\PatchBaselineOperations\Logs` folder.

Because the Windows Update API is used to download and install KBs, all Group Policy settings for Windows Update are respected. No Group Policy settings are required to use Patch Manager, but any settings that you have defined will be applied, such as to direct managed nodes to a Windows Server Update Services (WSUS) server.

> **Note**
>
> By default, Windows downloads all KBs from Microsoft's Windows Update site because Patch Manager uses the Windows Update API to drive the download and installation of KBs. As a result, the managed node must be able to reach the Microsoft Windows Update site or patching will fail. Alternatively, you can configure a WSUS server to serve as a KB repository and configure your managed nodes to target that WSUS server using Group Policies.
>
> Patch Manager might reference KB IDs when creating custom patch baselines for Windows Server, such as when an **Approved patches** list or **Rejected patches** list is included the the baseline configuration. Only updates that are assigned a KB ID in Microsoft Windows Update or a WSUS server are installed by Patch Manager. Updates that lack a KB ID are not included in patching operations.
>
> For information about creating custom patch baselines, see the following topics:
>
> - Creating a custom patch baseline for Windows Server
> - Create a patch baseline (CLI)
> - Package name formats for Windows operating systems

How patch baseline rules work on Linux-based systems

The rules in a patch baseline for Linux distributions operate differently based on the distribution type. Unlike patch updates on Windows Server managed nodes, rules are evaluated on each node to take the configured repos on the instance into consideration. Patch Manager, a tool in AWS Systems Manager, uses the native package manager to drive the installation of patches approved by the patch baseline.

For Linux-based operating system types that report a severity level for patches, Patch Manager uses the severity level reported by the software publisher for the update notice or individual

patch. Patch Manager doesn't derive severity levels from third-party sources, such as the Common Vulnerability Scoring System (CVSS), or from metrics released by the National Vulnerability Database (NVD).

Topics

How patch baseline rules work on Amazon Linux 2 and Amazon Linux 2023

> **Note**
>
> Amazon Linux 2023 (AL2023) uses versioned repositories that can be locked to a specific version through one or more system settings. For all patching operations on AL2023 EC2 instances, Patch Manager uses the latest repository versions, independent of the system configuration. For more information, see Deterministic upgrades through versioned repositories in the *Amazon Linux 2023 User Guide*.

On Amazon Linux 2 and Amazon Linux 2023, the patch selection process is as follows:

1. On the managed node, the YUM library (Amazon Linux 2) or the DNF library (Amazon Linux 2023) accesses the `updateinfo.xml` file for each configured repo.

   If no `updateinfo.xml` file is found, whether patches are installed depend on settings for **Include non-security updates** and **Auto-approval**. For example, if non-security updates are permitted, they're installed when the auto-approval time arrives.
2. Each update notice in `updateinfo.xml` includes several attributes that denote the properties of the packages in the notice, as described in the following table.

Update notice attributes

Attribute	Description
type	Corresponds to the value of the Classification key attribute in the patch baseline's PatchFilter data type. Denotes the type of package included in the update notice. You can view the list of supported values by using the AWS CLI command **describe-patch-properties** or the API operation **DescribePatchProperties**. You can also view the list in the **Approval rules** area of the **Create patch baseline** page or **Edit patch baseline** page in the Systems Manager console.
severity	Corresponds to the value of the Severity key attribute in the patch baseline's PatchFilter data type. Denotes the severity of the packages included in the update notice. Usually only applicable for *Security* update notices. You can view the list of supported values by using the AWS CLI command **describe-patch-properties** or the API operation **DescribePatchProperties**. You can also view the list in the **Approval rules** area of the **Create patch baseline** page or **Edit patch baseline** page in the Systems Manager console.

Attribute	Description
update_id	Denotes the advisory ID, such as *ALAS-2017-867*. The advisory ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.
references	Contains additional information about the update notice, such as a CVE ID (format: *CVE-2017-1234567*). The CVE ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.
updated	Corresponds to ApproveAfterDays in the patch baseline. Denotes the released date (updated date) of the packages included in the update notice. A comparison between the current timestamp and the value of this attribute plus the `ApproveAfterDays` is used to determine if the patch is approved for deployment.

For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

3. The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline's PatchFilter data type.
4. Packages are selected for the update according to the following guidelines.

Security option	Patch selection
Pre-defined default patch baselines provided by AWS and custom patch baselines where the **Include non-security updates** check box is *not* selected	For each update notice in `updateinfo.xml` , the patch baseline is used as a filter, allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used.

Security option	Patch selection

	For Amazon Linux 2, the equivalent yum command for this workflow is:
	`sudo yum update-minimal --sec-severity=Critical,Important --bugfix -y`
	For Amazon Linux 2023, the equivalent dnf command for this workflow is:
	`sudo dnf upgrade-minimal --sec-severity=Critical --sec-severity=Important --bugfix -y`

Security option	Patch selection

Custom patch baselines where the **Include non-security updates** check box *is* selected with a SEVERITY list of `[Critical, Important]` and a CLASSIFICATION list of `[Security, Bugfix]`	In addition to applying the security updates that were selected from `updateinfo.xml` , Patch Manager applies nonsecurity updates that otherwise meet the patch filtering rules.
	
	For Amazon Linux 2, the equivalent yum command for this workflow is:
	
	`sudo yum update --security --sec-severity=Critical,Important --bugfix -y`
	
	For Amazon Linux 2023, the equivalent dnf command for this workflow is:
	
	`sudo dnf upgrade --security --sec-severity=Critical --sec-severity=Important --bugfix -y`
	
	Note
	New packages that replace now-obsolete packages with different names are installed if you run these `yum` or `dnf` commands outside of Patch Manager. However, they are *not* installed by the equivalent Patch Manager operations.

For information about patch compliance status values, see Patch compliance state values.

How patch baseline rules work on Debian Server

On Debian Server , the patch baseline service offers filtering on the *Priority* and *Section* fields. These fields are typically present for all Debian Server packages. To determine whether a patch is selected by the patch baseline, Patch Manager does the following:

1. On Debian Server systems, the equivalent of `sudo apt-get update` is run to refresh the list of available packages. Repos aren't configured and the data is pulled from repos configured in a `sources` list.
2. If an update is available for `python3-apt` (a Python library interface to `libapt`), it is upgraded to the latest version. (This nonsecurity package is upgraded even if you did not select the **Include nonsecurity updates** option.)
3. Next, the GlobalFilters, ApprovalRules, ApprovedPatches and RejectedPatches lists are applied.

   > **Note**
   >
   > Because it isn't possible to reliably determine the release dates of update packages for Debian Server, the auto-approval options aren't supported for this operating system.

   Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo. In this case, for Debian Server, patch candidate versions are limited to patches included in the following repos:

   These repos are named as follows:

   - Debian Server 11: `debian-security bullseye`
   - Debian Server 12: `debian-security bookworm`

   If nonsecurity updates are included, patches from other repositories are considered as well.

   For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

To view the contents of the *Priority* and *Section* fields, run the following `aptitude` command:

> **Note**
>
> You might need to first install Aptitude on Debian Server systems.

```
aptitude search -F '%p %P %s %t %V#' '~U'
```

In the response to this command, all upgradable packages are reported in this format:

```
name, priority, section, archive, candidate version
```

For information about patch compliance status values, see Patch compliance state values.

How patch baseline rules work on macOS

On macOS, the patch selection process is as follows:

1. On the managed node, Patch Manager accesses the parsed contents of the `InstallHistory.plist` file and identifies package names and versions.

   For details about the parsing process, see the **macOS** section in How patches are installed.
2. The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline's PatchFilter data type.
3. Packages are selected for the update according to the following guidelines.

Security option	Patch selection
Pre-defined default patch baselines provided by AWS and custom patch baselines where the **Include non-security updates** check box is *not* selected	For each available package update, the patch baseline is used as a filter, allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used.
Custom patch baselines where the **Include non-security updates** check box *is* selected	In addition to applying the security updates that were identified by using `InstallHistory.plist`, Patch Manager applies

Security option	Patch selection
	nonsecurity updates that otherwise meet the patch filtering rules.

For information about patch compliance status values, see Patch compliance state values.

How patch baseline rules work on Oracle Linux

On Oracle Linux, the patch selection process is as follows:

1. On the managed node, the YUM library accesses the `updateinfo.xml` file for each configured repo.

   > **Note**
   >
   > The `updateinfo.xml` file might not be available if the repo isn't one managed by Oracle. If there is no `updateinfo.xml` found, whether patches are installed depend on settings for **Include non-security updates** and **Auto-approval**. For example, if non-security updates are permitted, they're installed when the auto-approval time arrives.

2. Each update notice in `updateinfo.xml` includes several attributes that denote the properties of the packages in the notice, as described in the following table.

   Update notice attributes

Attribute	Description
type	Corresponds to the value of the Classification key attribute in the patch baseline's PatchFilter data type. Denotes the type of package included in the update notice. You can view the list of supported values by using the AWS CLI command **describe-patch-properties** or the API operation **DescribePatchProperties**. You can also view the list in the **Approval rules** area of the **Create patch baseline** page or **Edit**

Attribute	Description
	patch baseline page in the Systems Manager console.
severity	Corresponds to the value of the Severity key attribute in the patch baseline's PatchFilter data type. Denotes the severity of the packages included in the update notice. Usually only applicable for *Security* update notices. You can view the list of supported values by using the AWS CLI command **describe-patch-properties** or the API operation **DescribePatchProperties**. You can also view the list in the **Approval rules** area of the **Create patch baseline** page or **Edit patch baseline** page in the Systems Manager console.
update_id	Denotes the advisory ID, such as *CVE-2019-17055*. The advisory ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.
references	Contains additional information about the update notice, such as a CVE ID (format: *CVE-2019-17055*) or a Bugzilla ID (format: *1463241*). The CVE ID and Bugzilla ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.

Attribute	Description
updated	Corresponds to ApproveAfterDays in the patch baseline. Denotes the released date (updated date) of the packages included in the update notice. A comparison between the current timestamp and the value of this attribute plus the `ApproveAfterDays` is used to determine if the patch is approved for deployment.

For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

3. The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline's PatchFilter data type.
4. Packages are selected for the update according to the following guidelines.

Security option	Patch selection
Pre-defined default patch baselines provided by AWS and custom patch baselines where the **Include non-security updates** check box is *not* selected	For each update notice in `updateinfo.xml` , the patch baseline is used as a filter, allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used. For version 7 managed nodes, the equivalent yum command for this workflow is: `sudo yum update-minimal --security --sev erity=Important,Moderate --bugfix -y` For version 8 and 9 managed nodes, the equivalent dnf command for this workflow is:

Security option	Patch selection
	`sudo dnf upgrade-minimal --security --sec-severity=Moderate --sec-severity=Important`

Custom patch baselines where the **Include non-security updates** check box *is* selected with a SEVERITY list of `[Critical, Important]` and a CLASSIFICATION list of `[Security, Bugfix]`	In addition to applying the security updates that were selected from `updateinfo.xml`, Patch Manager applies nonsecurity updates that otherwise meet the patch filtering rules.
	
	For version 7 managed nodes, the equivalent yum command for this workflow is:
	
	`sudo yum update --security --sec-severity=Critical,Important --bugfix -y`
	
	For version 8 and 9 managed nodes, the equivalent dnf command for this workflow is:
	
	`sudo dnf upgrade --security --sec-severity=Critical, --sec-severity=Important --bugfix y`
	
	Note
	New packages that replace now-obsolete packages with different names are installed if you run these `yum` or `dnf` commands outside of Patch Manager. However, they are *not* installed by the equivalent Patch Manager operations.

For information about patch compliance status values, see Patch compliance state values.

How patch baseline rules work on AlmaLinux, RHEL, and Rocky Linux

On AlmaLinux, Red Hat Enterprise Linux (RHEL), and Rocky Linux, the patch selection process is as follows:

1. On the managed node, the YUM library (RHEL 7) or the DNF library (AlmaLinux 8 and 9, RHEL 8, 9, and 10, and Rocky Linux 8 and 9) accesses the `updateinfo.xml` file for each configured repo.

   > **Note**
   >
   > The `updateinfo.xml` file might not be available if the repo isn't one managed by Red Hat. If there is no `updateinfo.xml` found, no patch will be applied.

2. Each update notice in `updateinfo.xml` includes several attributes that denote the properties of the packages in the notice, as described in the following table.

   Update notice attributes

Attribute	Description
type	Corresponds to the value of the Classification key attribute in the patch baseline's PatchFilter data type. Denotes the type of package included in the update notice. You can view the list of supported values by using the AWS CLI command **describe-patch-properties** or the API operation **DescribePatchProperties**. You can also view the list in the **Approval rules** area of the **Create patch baseline** page or **Edit patch baseline** page in the Systems Manager console.
severity	Corresponds to the value of the Severity key attribute in the patch baseline's PatchFilter data type. Denotes the severity of the packages included in the update notice.

Attribute	Description
	Usually only applicable for *Security* update notices. You can view the list of supported values by using the AWS CLI command **describe-patch-properties** or the API operation **DescribePatchProperties**. You can also view the list in the **Approval rules** area of the **Create patch baseline** page or **Edit patch baseline** page in the Systems Manager console.
update_id	Denotes the advisory ID, such as *RHSA-2017:0864*. The advisory ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.
references	Contains additional information about the update notice, such as a CVE ID (format: *CVE-2017-1000371*) or a Bugzilla ID (format: *1463241*). The CVE ID and Bugzilla ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.
updated	Corresponds to ApproveAfterDays in the patch baseline. Denotes the released date (updated date) of the packages included in the update notice. A comparison between the current timestamp and the value of this attribute plus the `ApproveAfterDays` is used to determine if the patch is approved for deployment.

For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

3. The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline's PatchFilter data type.
4. Packages are selected for the update according to the following guidelines.

Security option	Patch selection

Pre-defined default patch baselines provided by AWS and custom patch baselines where the **Include non-security updates** check box is *not* selected in any rule	For each update notice in `updateinfo.xml` , the patch baseline is used as a filter, allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used.
	
	For RHEL 7, the equivalent yum command for this workflow is:
	
	`sudo yum update-minimal --sec-severity=Critical,Important --bugfix -y`
	
	For AlmaLinux 8 and 9, RHEL 8, 9, and 10, and Rocky Linux 8 and 9, the equivalent dnf command for this workflow is:
	
	`sudo dnf upgrade-minimal --sec-severity=Critical --sec-severity=Important --bugfix -y`

Custom patch baselines where the **Include non-security updates** check box *is* selected with a SEVERITY list of `[Critical, Important]` and a CLASSIFICATION list of `[Security, Bugfix]`	In addition to applying the security updates that were selected from `updateinfo.xml` , Patch Manager applies nonsecurity updates that otherwise meet the patch filtering rules. For RHEL 7, the equivalent yum command for this workflow is:

Security option	Patch selection

	`sudo yum update --security --sec-severity=Critical,Important --bugfix -y`
	
	For AlmaLinux 8 and 9, RHEL 8, 9, and 10, and Rocky Linux 8 and 9, the equivalent dnf command for this workflow is:
	
	`sudo dnf upgrade --sec-severity=Critical --sec-severity=Important --bugfix -y`
	
	Note
	New packages that replace now-obsolete packages with different names are installed if you run these `yum` or `dnf` commands outside of Patch Manager. However, they are *not* installed by the equivalent Patch Manager operations.

For information about patch compliance status values, see Patch compliance state values.

How patch baseline rules work on Ubuntu Server

On Ubuntu Server, the patch baseline service offers filtering on the *Priority* and *Section* fields. These fields are typically present for all Ubuntu Server packages. To determine whether a patch is selected by the patch baseline, Patch Manager does the following:

1. On Ubuntu Server systems, the equivalent of `sudo apt-get update` is run to refresh the list of available packages. Repos aren't configured and the data is pulled from repos configured in a `sources` list.

2. If an update is available for `python3-apt` (a Python library interface to `libapt`), it is upgraded to the latest version. (This nonsecurity package is upgraded even if you did not select the **Include nonsecurity updates** option.)
3. Next, the GlobalFilters, ApprovalRules, ApprovedPatches and RejectedPatches lists are applied.

> **Note**
>
> Because it's not possible to reliably determine the release dates of update packages for Ubuntu Server, the auto-approval options aren't supported for this operating system.

Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo. In this case, for Ubuntu Server, patch candidate versions are limited to patches included in the following repos:

- Ubuntu Server 16.04 LTS: `xenial-security`
- Ubuntu Server 18.04 LTS: `bionic-security`
- Ubuntu Server 20.04 LTS: `focal-security`
- Ubuntu Server 22.04 LTS (`jammy-security`)
- Ubuntu Server 24.04 LTS (`noble-security`)
- Ubuntu Server 25.04 (`plucky-security`)

If nonsecurity updates are included, patches from other repositories are considered as well.

For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

To view the contents of the *Priority* and *Section* fields, run the following `aptitude` command:

> **Note**
>
> You might need to first install Aptitude on Ubuntu Server 16 systems.

```
aptitude search -F '%p %P %s %t %V#' '~U'
```

In the response to this command, all upgradable packages are reported in this format:

```
name, priority, section, archive, candidate version
```

For information about patch compliance status values, see Patch compliance state values.

Patching operation differences between Linux and Windows Server

This topic describes important differences between Linux and Windows Server patching in Patch Manager, a tool in AWS Systems Manager.

> **Note**
>
> To patch Linux managed nodes, your nodes must be running SSM Agent version 2.0.834.0 or later.
> An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Difference 1: Patch evaluation

Patch Manager uses different processes on Windows managed nodes and Linux managed nodes in order to evaluate which patches should be present.

Linux

For Linux patching, Systems Manager evaluates patch baseline rules and the list of approved and rejected patches on *each* managed node. Systems Manager must evaluate patching on each node because the service retrieves the list of known patches and updates from the repositories that are configured on the managed node.

Windows

For Windows patching, Systems Manager evaluates patch baseline rules and the list of approved and rejected patches *directly in the service*. It can do this because Windows patches are pulled from a single repository (Windows Update).

Difference 2: `Not Applicable` patches

Due to the large number of available packages for Linux operating systems, Systems Manager doesn't report details about patches in the *Not Applicable* state. A `Not Applicable` patch is, for example, a patch for Apache software when the instance doesn't have Apache installed. Systems Manager does report the number of `Not Applicable` patches in the summary, but if you call the DescribeInstancePatches API for a managed node, the returned data doesn't include patches with a state of `Not Applicable`. This behavior is different from Windows.

Difference 3: SSM document support

The `AWS-ApplyPatchBaseline` Systems Manager document (SSM document) doesn't support Linux managed nodes. For applying patch baselines to Linux, macOS, and Windows Server managed nodes, the recommended SSM document is `AWS-RunPatchBaseline`. For more information, see SSM Command documents for patching managed nodes and SSM Command document for patching: `AWS-RunPatchBaseline`.

Difference 4: Application patches

The primary focus of Patch Manager is applying patches to operating systems. However, you can also use Patch Manager to apply patches to some applications on your managed nodes.

Linux

On Linux operating systems, Patch Manager uses the configured repositories for updates, and doesn't differentiate between operating systems and application patches. You can use Patch Manager to define which repositories to fetch updates from. For more information, see How to specify an alternative patch source repository (Linux).

Windows

On Windows Server managed nodes, you can apply approval rules, as well as *Approved* and *Rejected* patch exceptions, for applications released by Microsoft, such as Microsoft Word 2016 and Microsoft Exchange Server 2016. For more information, see Working with custom patch baselines.

Difference 5: Rejected patch list options in custom patch baselines

When you create a custom patch baseline, you can specify one or more patches for a **Rejected patches** list. For Linux managed nodes, you can also choose to allow them to be installed if they're dependencies for another patch allowed by the baseline.

Windows Server, however, doesn't support the concept of patch dependencies. You can add a patch to the **Rejected patches** list in a custom baseline for Windows Server, but the result depends on (1) whether or not the rejected patch is already installed on a managed node, and (2) which option you choose for **Rejected patches action**.

Refer to the following table for details about rejected patch options on Windows Server.

Installation status	Option: "Allow as dependency"	Option: "Block"
Patch is already installed	Reported status: `INSTALLED_OTHER`	Reported status: `INSTALLED_REJECTED`
Patch is not already installed	Patch skipped	Patch skipped

Each patch for Windows Server that Microsoft releases typically contains all the information needed for the installation to succeed. Occasionally, however, a prerequisite package might be required, which you must install manually. Patch Manager doesn't report information about these prerequisites. For related information, see Windows Update issues troubleshooting on the Microsoft website.

SSM Command documents for patching managed nodes

This topic describes the nine Systems Manager documents (SSM documents) available to help you keep your managed nodes patched with the latest security-related updates.

We recommend using just five of these documents in your patching operations. Together, these five SSM documents provide you with a full range of patching options using AWS Systems Manager. Four of these documents were released later than the four legacy SSM documents they replace and represent expansions or consolidations of functionality.

Recommended SSM documents for patching

We recommend using the following five SSM documents in your patching operations.

- `AWS-ConfigureWindowsUpdate`
- `AWS-InstallWindowsUpdates`
- `AWS-RunPatchBaseline`
- `AWS-RunPatchBaselineAssociation`
- `AWS-RunPatchBaselineWithHooks`

Legacy SSM documents for patching

The following four legacy SSM documents remain available in some AWS Regions but are no longer updated or supported. These documents aren't guaranteed to work in IPv6 environments and support only IPv4. They can't be guaranteed to work in all scenarios and might lose support in the future. We recommend that you don't use these documents for patching operations.

- `AWS-ApplyPatchBaseline`
- `AWS-FindWindowsUpdates`
- `AWS-InstallMissingWindowsUpdates`
- `AWS-InstallSpecificWindowsUpdates`

Refer to the following sections for more information about using these SSM documents in your patching operations.

Topics

SSM documents recommended for patching managed nodes

The following five SSM documents are recommended for use in your managed node patching operations.

Recommended SSM documents

- AWS-ConfigureWindowsUpdate
- AWS-InstallWindowsUpdates
- AWS-RunPatchBaseline
- AWS-RunPatchBaselineAssociation
- AWS-RunPatchBaselineWithHooks

`AWS-ConfigureWindowsUpdate`

Supports configuring basic Windows Update functions and using them to install updates automatically (or to turn off automatic updates). Available in all AWS Regions.

This SSM document prompts Windows Update to download and install the specified updates and reboot managed nodes as needed. Use this document with State Manager, a tool in AWS Systems Manager, to ensure Windows Update maintains its configuration. You can also run it manually using Run Command, a tool in AWS Systems Manager, to change the Windows Update configuration.

The available parameters in this document support specifying a category of updates to install (or whether to turn off automatic updates), as well as specifying the day of the week and time of day to run patching operations. This SSM document is most useful if you don't need strict control over Windows updates and don't need to collect compliance information.

Replaces legacy SSM documents:

- *None*

`AWS-InstallWindowsUpdates`

Installs updates on a Windows Server managed node. Available in all AWS Regions.

This SSM document provides basic patching functionality in cases where you either want to install a specific update (using the `Include Kbs` parameter), or want to install patches with specific classifications or categories but don't need patch compliance information.

Replaces legacy SSM documents:

- `AWS-FindWindowsUpdates`
- `AWS-InstallMissingWindowsUpdates`
- `AWS-InstallSpecificWindowsUpdates`

The three legacy documents perform different functions, but you can achieve the same results by using different parameter settings with the newer SSM document `AWS-InstallWindowsUpdates`. These parameter settings are described in Legacy SSM documents for patching managed nodes.

`AWS-RunPatchBaseline`

Installs patches on your managed nodes or scans nodes to determine whether any qualified patches are missing. Available in all AWS Regions.

`AWS-RunPatchBaseline` allows you to control patch approvals using the patch baseline specified as the "default" for an operating system type. Reports patch compliance information that you can view using the Systems Manager Compliance tools. These tools provide you with insights on the patch compliance state of your managed nodes, such as which nodes are missing patches and what those patches are. When you use `AWS-RunPatchBaseline`, patch compliance information is recorded using the `PutInventory` API command. For Linux operating systems, compliance information is provided for patches from both the default source repository configured on a managed node and from any alternative source repositories you specify in a custom patch baseline. For more information about alternative source repositories, see How to specify an alternative patch source repository (Linux). For more information about the Systems Manager Compliance tools, see AWS Systems Manager Compliance.

Replaces legacy documents:

- `AWS-ApplyPatchBaseline`

The legacy document `AWS-ApplyPatchBaseline` applies only to Windows Server managed nodes, and doesn't provide support for application patching. The newer `AWS-RunPatchBaseline` provides the same support for both Windows and Linux systems. Version 2.0.834.0 or later of SSM Agent is required in order to use the `AWS-RunPatchBaseline` document.

For more information about the AWS-RunPatchBaseline SSM document, see SSM Command document for patching: AWS-RunPatchBaseline.

AWS-RunPatchBaselineAssociation

Installs patches on your instances or scans instances to determine whether any qualified patches are missing. Available in all commercial AWS Regions.

AWS-RunPatchBaselineAssociation differs from AWS-RunPatchBaseline in a few important ways:

- AWS-RunPatchBaselineAssociation is intended for use primarily with State Manager associations created using Quick Setup, a tool in AWS Systems Manager. Specifically, when you use the Quick Setup Host Management configuration type, if you choose the option **Scan instances for missing patches daily**, the system uses AWS-RunPatchBaselineAssociation for the operation.

  In most cases, however, when setting up your own patching operations, you should choose AWS-RunPatchBaseline or AWS-RunPatchBaselineWithHooks instead of AWS-RunPatchBaselineAssociation.

  For more information, see the following topics:

  - AWS Systems Manager Quick Setup
  - SSM Command document for patching: AWS-RunPatchBaselineAssociation
- AWS-RunPatchBaselineAssociation supports the use of tags to identify which patch baseline to use with a set of targets when it runs.
- For patching operations that use AWS-RunPatchBaselineAssociation, patch compliance data is compiled in terms of a specific State Manager association. The patch compliance data collected when AWS-RunPatchBaselineAssociation runs is recorded using the PutComplianceItems API command instead of the PutInventory command. This prevents compliance data that isn't associated with this particular association from being overwritten.

  For Linux operating systems, compliance information is provided for patches from both the default source repository configured on an instance and from any alternative source repositories you specify in a custom patch baseline. For more information about alternative source repositories, see How to specify an alternative patch source repository (Linux). For more information about the Systems Manager Compliance tools, see AWS Systems Manager Compliance.

Replaces legacy documents:

- **None**

For more information about the `AWS-RunPatchBaselineAssociation` SSM document, see SSM Command document for patching: `AWS-RunPatchBaselineAssociation`.

`AWS-RunPatchBaselineWithHooks`

Installs patches on your managed nodes or scans nodes to determine whether any qualified patches are missing, with optional hooks you can use to run SSM documents at three points during the patching cycle. Available in all commercial AWS Regions. Not supported on macOS.

`AWS-RunPatchBaselineWithHooks` differs from `AWS-RunPatchBaseline` in its `Install` operation.

`AWS-RunPatchBaselineWithHooks` supports lifecycle hooks that run at designated points during managed node patching. Because patch installations sometimes require managed nodes to reboot, the patching operation is divided into two events, for a total of three hooks that support custom functionality. The first hook is before the `Install with NoReboot` operation. The second hook is after the `Install with NoReboot` operation. The third hook is available after the reboot of the node.

Replaces legacy documents:

- **None**

For more information about the `AWS-RunPatchBaselineWithHooks` SSM document, see SSM Command document for patching: `AWS-RunPatchBaselineWithHooks`.

Legacy SSM documents for patching managed nodes

The following four SSM documents are still available in some AWS Regions. However, they are no longer updated and might be no longer supported in the future, so we don't recommend their use. Instead, use the documents described in SSM documents recommended for patching managed nodes.

Legacy SSM Documents

- AWS-ApplyPatchBaseline

- AWS-FindWindowsUpdates
- AWS-InstallMissingWindowsUpdates
- AWS-InstallSpecificWindowsUpdates

AWS-ApplyPatchBaseline

Supports only Windows Server managed nodes, but doesn't include support for patching applications that is found in its replacement, `AWS-RunPatchBaseline`. Not available in AWS Regions launched after August 2017.

> **Note**
>
> The replacement for this SSM document, `AWS-RunPatchBaseline`, requires version 2.0.834.0 or a later version of SSM Agent. You can use the `AWS-UpdateSSMAgent` document to update your managed nodes to the latest version of the agent.

AWS-FindWindowsUpdates

Replaced by `AWS-InstallWindowsUpdates`, which can perform all the same actions. Not available in AWS Regions launched after April 2017.

To achieve the same result that you would from this legacy SSM document, use the following parameter configuration with the recommended replacement document, `AWS-InstallWindowsUpdates`:

- `Action` = `Scan`
- `Allow Reboot` = `False`

AWS-InstallMissingWindowsUpdates

Replaced by `AWS-InstallWindowsUpdates`, which can perform all the same actions. Not available in any AWS Regions launched after April 2017.

To achieve the same result that you would from this legacy SSM document, use the following parameter configuration with the recommended replacement document, `AWS-InstallWindowsUpdates`:

- `Action` = `Install`

- `Allow Reboot` = `True`

`AWS-InstallSpecificWindowsUpdates`

Replaced by `AWS-InstallWindowsUpdates`, which can perform all the same actions. Not available in any AWS Regions launched after April 2017.

To achieve the same result that you would from this legacy SSM document, use the following parameter configuration with the recommended replacement document, `AWS-InstallWindowsUpdates`:

- `Action` = `Install`
- `Allow Reboot` = `True`
- `Include Kbs` = *`comma-separated list of KB articles`*

SSM Command document for patching: `AWS-RunPatchBaseline`

AWS Systems Manager supports `AWS-RunPatchBaseline`, a Systems Manager document (SSM document) for Patch Manager, a tool in AWS Systems Manager. This SSM document performs patching operations on managed nodes for both security related and other types of updates. When the document is run, it uses the patch baseline specified as the "default" for an operating system type if no patch group is specified. Otherwise, it uses the patch baseline that is associated with the patch group. For information about patch groups, see Patch groups.

You can use the document `AWS-RunPatchBaseline` to apply patches for both operating systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.)

This document supports Linux, macOS, and Windows Server managed nodes. The document will perform the appropriate actions for each platform.

> **Note**
>
> Patch Manager also supports the legacy SSM document `AWS-ApplyPatchBaseline`. However, this document supports patching on Windows managed nodes only. We encourage you to use `AWS-RunPatchBaseline` instead because it supports patching on Linux, macOS, and Windows Server managed nodes. Version 2.0.834.0 or later of SSM Agent is required in order to use the `AWS-RunPatchBaseline` document.

Windows Server

On Windows Server managed nodes, the `AWS-RunPatchBaseline` document downloads and invokes a PowerShell module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. This patch baseline snapshot contains a list of approved patches that is compiled by querying the patch baseline against a Windows Server Update Services (WSUS) server. This list is passed to the Windows Update API, which controls downloading and installing the approved patches as appropriate.

Linux

On Linux managed nodes, the `AWS-RunPatchBaseline` document invokes a Python module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. This patch baseline snapshot uses the defined rules and lists of approved and blocked patches to drive the appropriate package manager for each node type:

- Amazon Linux 2, Oracle Linux, and RHEL 7 managed nodes use YUM. For YUM operations, Patch Manager requires `Python 2.6` or a later supported version (2.6 - 3.10). Amazon Linux 2023 uses DNF. For DNF operations, Patch Manager requires a supported version of `Python 2` or `Python 3` (2.6 - 3.10).
- RHEL 8 managed nodes use DNF. For DNF operations, Patch Manager requires a supported version of `Python 2` or `Python 3` (2.6 - 3.10). (Neither version is installed by default on RHEL 8. You must install one or the other manually.)
- Debian Server, and Ubuntu Server instances use APT. For APT operations, Patch Manager requires a supported version of `Python 3` (3.0 - 3.10).

macOS

On macOS managed nodes, the `AWS-RunPatchBaseline` document invokes a Python module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. Next, a Python subprocess invokes the AWS Command Line Interface (AWS CLI) on the node to retrieve the installation and update information for the specified package managers and to drive the appropriate package manager for each update package.

Each snapshot is specific to an AWS account, patch group, operating system, and snapshot ID. The snapshot is delivered through a presigned Amazon Simple Storage Service (Amazon S3) URL, which expires 24 hours after the snapshot is created. After the URL expires, however, if you want to apply the same snapshot content to other managed nodes, you can generate a new presigned Amazon

S3 URL up to 3 days after the snapshot was created. To do this, use the get-deployable-patch-snapshot-for-instance command.

After all approved and applicable updates have been installed, with reboots performed as necessary, patch compliance information is generated on a managed node and reported back to Patch Manager.

> **Note**
>
> If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.

For information about viewing patch compliance data, see About patch compliance.

`AWS-RunPatchBaseline` parameters

`AWS-RunPatchBaseline` supports six parameters. The `Operation` parameter is required. The `InstallOverrideList`, `BaselineOverride`, and `RebootOption` parameters are optional. `Snapshot-ID` is technically optional, but we recommend that you supply a custom value for it when you run `AWS-RunPatchBaseline` outside of a maintenance window. Patch Manager can supply the custom value automatically when the document is run as part of a maintenance window operation.

Parameters

- Parameter name: Operation
- Parameter name: AssociationId
- Parameter name: Snapshot ID
- Parameter name: InstallOverrideList
- Parameter name: RebootOption
- Parameter name: BaselineOverride
- Parameter name: StepTimeoutSeconds

Parameter name: `Operation`

Usage: Required.

Options: `Scan` | `Install`.

Scan

When you choose the `Scan` option, `AWS-RunPatchBaseline` determines the patch compliance state of the managed node and reports this information back to Patch Manager. `Scan` doesn't prompt updates to be installed or managed nodes to be rebooted. Instead, the operation identifies where updates are missing that are approved and applicable to the node.

Install

When you choose the `Install` option, `AWS-RunPatchBaseline` attempts to install the approved and applicable updates that are missing from the managed node. Patch compliance information generated as part of an `Install` operation doesn't list any missing updates, but might report updates that are in a failed state if the installation of the update didn't succeed for any reason. Whenever an update is installed on a managed node, the node is rebooted to ensure the update is both installed and active. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

> **Note**
>
> If a patch specified by the baseline rules is installed *before* Patch Manager updates the managed node, the system might not reboot as expected. This can happen when a patch is installed manually by a user or installed automatically by another program, such as the `unattended-upgrades` package on Ubuntu Server.

Parameter name: `AssociationId`

Usage: Optional.

`AssociationId` is the ID of an existing association in State Manager, a tool in AWS Systems Manager. It's used by Patch Manager to add compliance data to a specified association. This association is related to a patching operation that's set up in a patch policy in Quick Setup.

> **Note**
>
> With the `AWS-RunPatchBaseline`, if an `AssociationId` value is provided along with a patch policy baseline override, patching is done as a `PatchPolicy` operation and

the `ExecutionType` value reported in `AWS:ComplianceItem` is also `PatchPolicy`. If no `AssociationId` value is provided, patching is done as a `Command` operation and the `ExecutionType` value report in on the `AWS:ComplianceItem` submitted is also `Command`.

If you don't already have an association you want to use, you can create one by running [create-association] the command.

Parameter name: `Snapshot ID`

Usage: Optional.

`Snapshot ID` is a unique ID (GUID) used by Patch Manager to ensure that a set of managed nodes that are patched in a single operation all have the exact same set of approved patches. Although the parameter is defined as optional, our best practice recommendation depends on whether or not you're running `AWS-RunPatchBaseline` in a maintenance window, as described in the following table.

`AWS-RunPatchBaseline` best practices

Mode	Best practice	Details
Running `AWS-RunPatchBaseline` inside a maintenance window	Don't supply a Snapshot ID. Patch Manager will supply it for you.	If you use a maintenance window to run `AWS-RunPatchBaseline`, you shouldn't provide your own generated Snapshot ID. In this scenario, Systems Manager provides a GUID value based on the maintenance window execution ID. This ensures that a correct ID is used for all the invocations of `AWS-RunPatchBaseline` in that maintenance window. If you do specify a value in this scenario, note that

Mode	Best practice	Details
		the snapshot of the patch baseline might not remain in place for more than 3 days. After that, a new snapshot will be generated even if you specify the same ID after the snapshot expires.

Mode	Best practice	Details
Running AWS-RunPatchBaseline outside of a maintenance window	Generate and specify a custom GUID value for the Snapshot ID.[1]	When you aren't using a maintenance window to run AWS-RunPatchBaseline, we recommend that you generate and specify a unique Snapshot ID for each patch baseline, particularly if you're running the AWS-RunPatchBaseline document on multiple managed nodes in the same operation. If you don't specify an ID in this scenario, Systems Manager generates a different Snapshot ID for each managed node the command is sent to. This might result in varying sets of patches being specified among the managed nodes. For instance, say that you're running the AWS-RunPatchBaseline document directly through Run Command, a tool in AWS Systems Manager, and targeting a group of 50 managed nodes. Specifying a custom Snapshot ID results in the generation of a single baseline snapshot that is used to evaluate and patch all the

Mode	Best practice	Details
		nodes, ensuring that they end up in a consistent state.

[1] You can use any tool capable of generating a GUID to generate a value for the Snapshot ID parameter. For example, in PowerShell, you can use the `New-Guid` cmdlet to generate a GUID in the format of `12345699-9405-4f69-bc5e-9315aEXAMPLE` .

Parameter name: `InstallOverrideList`

Usage: Optional.

Using `InstallOverrideList`, you specify an https URL or an Amazon S3 path-style URL to a list of patches to be installed. This patch installation list, which you maintain in YAML format, overrides the patches specified by the current default patch baseline. This provides you with more granular control over which patches are installed on your managed nodes.

> **Important**
>
> The `InstallOverrideList` file name can't contain the following characters: backtick (`), single quote ('), double quote ("), and dollar sign ($).

The patching operation behavior when using the `InstallOverrideList` parameter differs between Linux & macOS managed nodes and Windows Server managed nodes. On Linux & macOS, Patch Manager attempts to apply patches included in the `InstallOverrideList` patch list that are present in any repository enabled on the node, whether or not the patches match the patch baseline rules. On Windows Server nodes, however, patches in the `InstallOverrideList` patch list are applied *only* if they also match the patch baseline rules.

Be aware that compliance reports reflect patch states according to what's specified in the patch baseline, not what you specify in an `InstallOverrideList` list of patches. In other words, Scan operations ignore the `InstallOverrideList` parameter. This is to ensure that compliance reports consistently reflect patch states according to policy rather than what was approved for a specific patching operation.

For a description of how you might use the `InstallOverrideList` parameter to apply different types of patches to a target group, on different maintenance window schedules, while still using

a single patch baseline, see Sample scenario for using the InstallOverrideList parameter in AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation.

Valid URL formats

> **Note**
>
> If your file is stored in a publicly available bucket, you can specify either an https URL format or an Amazon S3 path-style URL. If your file is stored in a private bucket, you must specify an Amazon S3 path-style URL.

- **https URL format**:

```
https://s3.aws-api-domain/amzn-s3-demo-bucket/my-windows-override-list.yaml
```

- **Amazon S3 path-style URL**:

```
s3://amzn-s3-demo-bucket/my-windows-override-list.yaml
```

Valid YAML content formats

The formats you use to specify patches in your list depends on the operating system of your managed node. The general format, however, is as follows:

```
patches:
    -
        id: '{patch-d}'
        title: '{patch-title}'
        {additional-fields}:{values}
```

Although you can provide additional fields in your YAML file, they're ignored during patch operations.

In addition, we recommend verifying that the format of your YAML file is valid before adding or updating the list in your S3 bucket. For more information about the YAML format, see yaml.org. For validation tool options, perform a web search for "yaml format validators".

Linux

id

The **id** field is required. Use it to specify patches using the package name and architecture. For example: `'dhclient.x86_64'`. You can use wildcards in id to indicate multiple packages. For example: `'dhcp*'` and `'dhcp*1.*'`.

Title

The **title** field is optional, but on Linux systems it does provide additional filtering capabilities. If you use **title**, it should contain the package version information in the one of the following formats:

In this case, apt version 1.2.27 will be blocked from installation and reported as “Failed-NonCompliant.”

Windows Server

id

The **id** field is required. Use it to specify patches using Microsoft Knowledge Base IDs (for example, KB2736693) and Microsoft Security Bulletin IDs (for example, MS17-023).

Any other fields you want to provide in a patch list for Windows are optional and are for your own informational use only. You can use additional fields such as **title**, **classification**, **severity**, or anything else for providing more detailed information about the specified patches.

macOS

id

The **id** field is required. The value for the **id** field can be supplied using either a `{package-name}.{package-version}` format or a {package_name} format.

Sample patch lists

- **Amazon Linux 2**

```
patches:
    -
```

```
        id: 'kernel.x86_64'
    -
        id: 'bind*.x86_64'
        title: '39.11.4-26.P2.amzn2.5.2'

        id: 'glibc*'
    -
        id: 'dhclient*'
        title: '*4.2.5-58.amzn2'
    -
        id: 'dhcp*'
        title: '*4.2.5-77.amzn2'
```

- **Debian Server**

```
patches:
    -
        id: 'apparmor.amd64'
        title: '2.10.95-0ubuntu2.9'
    -
        id: 'cryptsetup.amd64'
        title: '*2:1.6.6-5ubuntu2.1'
    -
        id: 'cryptsetup-bin.*'
        title: '*2:1.6.6-5ubuntu2.1'
    -
        id: 'apt.amd64'
        title: '*1.2.27'
    -
        id: 'apt-utils.amd64'
        title: '*1.2.25'
```

- **macOS**

```
patches:
    -
        id: 'XProtectPlistConfigData'
    -
        id: 'MRTConfigData.1.61'
    -
        id: 'Command Line Tools for Xcode.11.5'
    -
        id: 'Gatekeeper Configuration Data'
```

- **Oracle Linux**

```
patches:
    -
        id: 'audit-libs.x86_64'
        title: '*2.8.5-4.el7'
    -
        id: 'curl.x86_64'
        title: '*.el7'
    -
        id: 'grub2.x86_64'
        title: 'grub2.x86_64:1:2.02-0.81.0.1.el7'
    -
        id: 'grub2.x86_64'
        title: 'grub2.x86_64:1:*-0.81.0.1.el7'
```

- **Red Hat Enterprise Linux (RHEL)**

```
patches:
    -
        id: 'NetworkManager.x86_64'
        title: '*1:1.10.2-14.el7_5'
    -
        id: 'NetworkManager-*.x86_64'
        title: '*1:1.10.2-14.el7_5'
    -
        id: 'audit.x86_64'
        title: '*0:2.8.1-3.el7'
    -
        id: 'dhclient.x86_64'
        title: '*.el7_5.1'
    -
        id: 'dhcp*.x86_64'
        title: '*12:5.2.5-68.el7'
```

- **Ubuntu Server**

```
patches:
    -
        id: 'apparmor.amd64'
        title: '2.10.95-0ubuntu2.9'
    -
        id: 'cryptsetup.amd64'
```

```
        title: '*2:1.6.6-5ubuntu2.1'
    -
        id: 'cryptsetup-bin.*'
        title: '*2:1.6.6-5ubuntu2.1'
    -
        id: 'apt.amd64'
        title: '*1.2.27'
    -
        id: 'apt-utils.amd64'
        title: '*1.2.25'
```

- **Windows**

```
patches:
    -
        id: 'KB4284819'
        title: '2018-06 Cumulative Update for Windows Server 2016 (1709) for x64-
based Systems (KB4284819)'
    -
        id: 'KB4284833'
    -
        id: 'KB4284835'
        title: '2018-06 Cumulative Update for Windows Server 2016 (1803) for x64-
based Systems (KB4284835)'
    -
        id: 'KB4284880'
    -
        id: 'KB4338814'
```

Parameter name: `RebootOption`

Usage: Optional.

Options: `RebootIfNeeded` | `NoReboot`

Default: `RebootIfNeeded`

> **Warning**
>
> The default option is `RebootIfNeeded`. Be sure to select the correct option for your use case. For example, if your managed nodes must reboot immediately to complete a

configuration process, choose `RebootIfNeeded`. Or, if you need to maintain managed node availability until a scheduled reboot time, choose `NoReboot`.

Important

We don't recommend using Patch Manager for patching cluster instances in Amazon EMR (previously called Amazon Elastic MapReduce). In particular, don't select the `RebootIfNeeded` option for the `RebootOption` parameter. (This option is available in the SSM Command documents for patching `AWS-RunPatchBaseline`, `AWS-RunPatchBaselineAssociation`, and `AWS-RunPatchBaselineWithHooks`.) The underlying commands for patching using Patch Manager use `yum` and `dnf` commands. Therefore, the operations result in incompatibilities because of how packages are installed. For information about the preferred methods for updating software on Amazon EMR clusters, see Using the default AMI for Amazon EMR in the *Amazon EMR Management Guide*.

RebootIfNeeded

When you choose the `RebootIfNeeded` option, the managed node is rebooted in either of the following cases:

- Patch Manager installed one or more patches.

  Patch Manager doesn't evaluate whether a reboot is *required* by the patch. The system is rebooted even if the patch doesn't require a reboot.

- Patch Manager detects one or more patches with a status of `INSTALLED_PENDING_REBOOT` during the `Install` operation.

  The `INSTALLED_PENDING_REBOOT` status can mean that the option `NoReboot` was selected the last time the `Install` operation was run, or that a patch was installed outside of Patch Manager since the last time the managed node was rebooted.

Rebooting managed nodes in these two cases ensures that updated packages are flushed from memory and keeps patching and rebooting behavior consistent across all operating systems.

NoReboot

When you choose the `NoReboot` option, Patch Manager doesn't reboot a managed node even if it installed patches during the `Install` operation. This option is useful if you know that your managed nodes don't require rebooting after patches are applied, or you have applications or processes running on a node that shouldn't be disrupted by a patching operation reboot. It's also useful when you want more control over the timing of managed node reboots, such as by using a maintenance window.

If you choose the `NoReboot` option and a patch is installed, the patch is assigned a status of `InstalledPendingReboot`. The managed node itself, however, is marked as `Non-Compliant`. After a reboot occurs and a `Scan` operation is run, the managed node status is updated to `Compliant`.

> **Important**
>
> The `NoReboot` option only prevents operating system-level restarts. Service-level restarts can still occur as part of the patching process. For example, when Docker is updated, dependent services such as Amazon Elastic Container Service might automatically restart even with `NoReboot` enabled. If you have critical services that must not be disrupted, consider additional measures such as temporarily removing instances from service or scheduling patching during maintenance windows.

Patch installation tracking file: To track patch installation, especially patches that were installed since the last system reboot, Systems Manager maintains a file on the managed node.

> **Important**
>
> Don't delete or modify the tracking file. If this file is deleted or corrupted, the patch compliance report for the managed node is inaccurate. If this happens, reboot the node and run a patch Scan operation to restore the file.

This tracking file is stored in the following locations on your managed nodes:

- Linux operating systems:
  - `/var/log/amazon/ssm/patch-configuration/patch-states-configuration.json`

- `/var/log/amazon/ssm/patch-configuration/patch-inventory-from-last-operation.json`
- Windows Server operating system:
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchStatesConfiguration.json`
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchInventoryFromLastOperation.json`

Parameter name: `BaselineOverride`

Usage: Optional.

You can define patching preferences at runtime using the `BaselineOverride` parameter. This baseline override is maintained as a JSON object in an S3 bucket. It ensures patching operations use the provided baselines that match the host operating system instead of applying the rules from the default patch baseline

> **Important**
>
> The `BaselineOverride` file name can't contain the following characters: backtick (`), single quote ('), double quote ("), and dollar sign ($).

For more information about how to use the `BaselineOverride` parameter, see Using the BaselineOverride parameter.

Parameter name: `StepTimeoutSeconds`

Usage: Optional.

The time in seconds—between 1 and 36000 seconds (10 hours)—for a command to be completed before it is considered to have failed.

SSM Command document for patching: `AWS-RunPatchBaselineAssociation`

Like the `AWS-RunPatchBaseline` document, `AWS-RunPatchBaselineAssociation` performs patching operations on instances for both security related and other types of updates. You can also use the document `AWS-RunPatchBaselineAssociation` to apply patches for both operating

systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.)

This document supports Amazon Elastic Compute Cloud (Amazon EC2) instances for Linux, macOS, and Windows Server. It does not support non-EC2 nodes in a hybrid and multicloud environment. The document will perform the appropriate actions for each platform, invoking a Python module on Linux and macOS instances, and a PowerShell module on Windows instances.

`AWS-RunPatchBaselineAssociation`, however, differs from `AWS-RunPatchBaseline` in the following ways:

- `AWS-RunPatchBaselineAssociation` is intended for use primarily with State Manager associations created using Quick Setup, a tool in AWS Systems Manager. Specifically, when you use the Quick Setup Host Management configuration type, if you choose the option **Scan instances for missing patches daily**, the system uses `AWS-RunPatchBaselineAssociation` for the operation.

  In most cases, however, when setting up your own patching operations, you should choose `AWS-RunPatchBaseline` or `AWS-RunPatchBaselineWithHooks` instead of `AWS-RunPatchBaselineAssociation`.
- When you use the `AWS-RunPatchBaselineAssociation` document, you can specify a tag key pair in the document's `BaselineTags` parameter field. If a custom patch baseline in your AWS account shares these tags, Patch Manager, a tool in AWS Systems Manager, uses that tagged baseline when it runs on the target instances instead of the currently specified "default" patch baseline for the operating system type.

  > **Note**
  >
  > If you choose to use `AWS-RunPatchBaselineAssociation` in patching operations other than those set up using Quick Setup, and you want to use its optional `BaselineTags` parameter, you must provide some additional permissions to the instance profile for Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information, see Parameter name: `BaselineTags`.

  Both of the following formats are valid for your `BaselineTags` parameter:

  `Key=`*`tag-key`*`,Values=`*`tag-value`*

`Key=tag-key,Values=tag-value1,tag-value2,tag-value3`

> **Important**
>
> Tag keys and values can't contain the following characters: backtick (`), single quote ('), double quote ("), and dollar sign ($).

- When `AWS-RunPatchBaselineAssociation` runs, the patch compliance data it collects is recorded using the `PutComplianceItems` API command instead of the `PutInventory` command, which is used by `AWS-RunPatchBaseline`. This difference means that the patch compliance information that is stored and reported per a specific *association*. Patch compliance data generated outside of this association isn't overwritten.
- The patch compliance information reported after running `AWS-RunPatchBaselineAssociation` indicates whether or not an instance is in compliance. It doesn't include patch-level details, as demonstrated by the output of the following AWS Command Line Interface (AWS CLI) command. The command filters on `Association` as the compliance type:

```
aws ssm list-compliance-items \
    --resource-ids "i-02573cafcfEXAMPLE" \
    --resource-types "ManagedInstance" \
    --filters "Key=ComplianceType,Values=Association,Type=EQUAL" \
    --region us-east-2
```

The system returns information like the following.

```
{
    "ComplianceItems": [
        {
            "Status": "NON_COMPLIANT",
            "Severity": "UNSPECIFIED",
            "Title": "MyPatchAssociation",
            "ResourceType": "ManagedInstance",
            "ResourceId": "i-02573cafcfEXAMPLE",
            "ComplianceType": "Association",
            "Details": {
                "DocumentName": "AWS-RunPatchBaselineAssociation",
                "PatchBaselineId": "pb-0c10e65780EXAMPLE",
                "DocumentVersion": "1"
```

```
            },
            "ExecutionSummary": {
                "ExecutionTime": 1590698771.0
            },
            "Id": "3e5d5694-cd07-40f0-bbea-040e6EXAMPLE"
        }
    ]
}
```

If a tag key pair value has been specified as a parameter for the `AWS-RunPatchBaselineAssociation` document, Patch Manager searches for a custom patch baseline that matches the operating system type and has been tagged with that same tag-key pair. This search isn't limited to the current specified default patch baseline or the baseline assigned to a patch group. If no baseline is found with the specified tags, Patch Manager next looks for a patch group, if one was specified in the command that runs `AWS-RunPatchBaselineAssociation`. If no patch group is matched, Patch Manager falls back to the current default patch baseline for the operating system account.

If more than one patch baseline is found with the tags specified in the `AWS-RunPatchBaselineAssociation` document, Patch Manager returns an error message indicating that only one patch baseline can be tagged with that key-value pair in order for the operation to proceed.

Note

On Linux nodes, the appropriate package manager for each node type is used to install packages:

- Amazon Linux 2, Oracle Linux, and RHEL instances use YUM. For YUM operations, Patch Manager requires `Python 2.6` or a later supported version (2.6 - 3.10). Amazon Linux 2023 uses DNF. For DNF operations, Patch Manager requires a supported version of `Python 2` or `Python 3` (2.6 - 3.10)
- Debian Server and Ubuntu Server instances use APT. For APT operations, Patch Manager requires a supported version of `Python 3` (3.0 - 3.10).

After a scan is complete, or after all approved and applicable updates have been installed, with reboots performed as necessary, patch compliance information is generated on an instance and reported back to the Patch Compliance service.

> **Note**
>
> If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaselineAssociation` document, the instance isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.

For information about viewing patch compliance data, see About patch compliance.

`AWS-RunPatchBaselineAssociation` parameters

`AWS-RunPatchBaselineAssociation` supports five parameters. The `Operation` and `AssociationId` parameters are required. The `InstallOverrideList`, `RebootOption`, and `BaselineTags` parameters are optional.

Parameters

- Parameter name: Operation
- Parameter name: BaselineTags
- Parameter name: AssociationId
- Parameter name: InstallOverrideList
- Parameter name: RebootOption

Parameter name: `Operation`

Usage: Required.

Options: `Scan` | `Install`.

Scan

When you choose the `Scan` option, `AWS-RunPatchBaselineAssociation` determines the patch compliance state of the instance and reports this information back to Patch Manager. `Scan` doesn't prompt updates to be installed or instances to be rebooted. Instead, the operation identifies where updates are missing that are approved and applicable to the instance.

Install

When you choose the `Install` option, `AWS-RunPatchBaselineAssociation` attempts to install the approved and applicable updates that are missing from the instance. Patch compliance information generated as part of an `Install` operation doesn't list any missing updates, but might report updates that are in a failed state if the installation of the update didn't succeed for any reason. Whenever an update is installed on an instance, the instance is rebooted to ensure the update is both installed and active. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaselineAssociation` document, the instance isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

> **Note**
>
> If a patch specified by the baseline rules is installed *before* Patch Manager updates the instance, the system might not reboot as expected. This can happen when a patch is installed manually by a user or installed automatically by another program, such as the `unattended-upgrades` package on Ubuntu Server.

Parameter name: `BaselineTags`

Usage: Optional.

`BaselineTags` is a unique tag key-value pair that you choose and assign to an individual custom patch baseline. You can specify one or more values for this parameter. Both of the following formats are valid:

`Key=`*`tag-key`*`,Values=`*`tag-value`*

`Key=`*`tag-key`*`,Values=`*`tag-value1`*`,`*`tag-value2`*`,`*`tag-value3`*

> **Important**
>
> Tag keys and values can't contain the following characters: backtick (`), single quote ('), double quote ("), and dollar sign ($).

The `BaselineTags` value is used by Patch Manager to ensure that a set of instances that are patched in a single operation all have the exact same set of approved patches. When the patching

operation runs, Patch Manager checks to see if a patch baseline for the operating system type is tagged with the same key-value pair you specify for `BaselineTags`. If there is a match, this custom patch baseline is used. If there isn't a match, a patch baseline is identified according to any patch group specified for the patching operating. If there is none, the AWS managed predefined patch baseline for that operating system is used.

Additional permission requirements

If you use `AWS-RunPatchBaselineAssociation` in patching operations other than those set up using Quick Setup, and you want to use the optional `BaselineTags` parameter, you must add the following permissions to the instance profile for Amazon Elastic Compute Cloud (Amazon EC2) instances.

> **Note**
>
> Quick Setup and `AWS-RunPatchBaselineAssociation` don't support on-premises servers and virtual machines (VMs).

```
{
    "Effect": "Allow",
    "Action": [
        "ssm:DescribePatchBaselines",
        "tag:GetResources"
    ],
    "Resource": "*"
},
{
    "Effect": "Allow",
    "Action": [
        "ssm:GetPatchBaseline",
        "ssm:DescribeEffectivePatchesForPatchBaseline"
    ],
    "Resource": "patch-baseline-arn"
}
```

Replace *`patch-baseline-arn`* with the Amazon Resource Name (ARN) of the patch baseline to which you want to provide access, in the format `arn:aws:ssm:us-east-2:123456789012:patchbaseline/pb-0c10e65780EXAMPLE`.

Parameter name: `AssociationId`

Usage: Required.

`AssociationId` is the ID of an existing association in State Manager, a tool in AWS Systems Manager. It's used by Patch Manager to add compliance data to a specified association. This association is related to a patch `Scan` operation enabled in a Host Management configuration created in Quick Setup. By sending patching results as association compliance data instead of inventory compliance data, existing inventory compliance information for your instances isn't overwritten after a patching operation, nor for other association IDs. If you don't already have an association you want to use, you can create one by running create-association the command. For example:

Linux & macOS

```
aws ssm create-association \
    --name "AWS-RunPatchBaselineAssociation" \
    --association-name "MyPatchHostConfigAssociation" \
    --targets
 "Key=instanceids,Values=[i-02573cafcfEXAMPLE,i-07782c72faEXAMPLE,i-07782c72faEXAMPLE]"
 \
    --parameters "Operation=Scan" \
    --schedule-expression "cron(0 */30 * * * ? *)" \
    --sync-compliance "MANUAL" \
    --region us-east-2
```

Windows Server

```
aws ssm create-association ^
    --name "AWS-RunPatchBaselineAssociation" ^
    --association-name "MyPatchHostConfigAssociation" ^
    --targets
 "Key=instanceids,Values=[i-02573cafcfEXAMPLE,i-07782c72faEXAMPLE,i-07782c72faEXAMPLE]"
 ^
    --parameters "Operation=Scan" ^
    --schedule-expression "cron(0 */30 * * * ? *)" ^
    --sync-compliance "MANUAL" ^
    --region us-east-2
```

Parameter name: `InstallOverrideList`

Usage: Optional.

Using `InstallOverrideList`, you specify an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL to a list of patches to be installed. This patch installation list, which you maintain in YAML format, overrides the patches specified by the current default patch baseline. This provides you with more granular control over which patches are installed on your instances.

> **Important**
>
> The `InstallOverrideList` file name can't contain the following characters: backtick (`), single quote ('), double quote ("), and dollar sign ($).

The patching operation behavior when using the `InstallOverrideList` parameter differs between Linux & macOS managed nodes and Windows Server managed nodes. On Linux & macOS, Patch Manager attempts to apply patches included in the `InstallOverrideList` patch list that are present in any repository enabled on the node, whether or not the patches match the patch baseline rules. On Windows Server nodes, however, patches in the `InstallOverrideList` patch list are applied *only* if they also match the patch baseline rules.

Be aware that compliance reports reflect patch states according to what's specified in the patch baseline, not what you specify in an `InstallOverrideList` list of patches. In other words, Scan operations ignore the `InstallOverrideList` parameter. This is to ensure that compliance reports consistently reflect patch states according to policy rather than what was approved for a specific patching operation.

Valid URL formats

> **Note**
>
> If your file is stored in a publicly available bucket, you can specify either an https URL format or an Amazon S3 path-style URL. If your file is stored in a private bucket, you must specify an Amazon S3 path-style URL.

- **https URL format example**:

```
https://s3.amazonaws.com/amzn-s3-demo-bucket/my-windows-override-list.yaml
```

- **Amazon S3 path-style URL example**:

```
s3://amzn-s3-demo-bucket/my-windows-override-list.yaml
```

Valid YAML content formats

The formats you use to specify patches in your list depends on the operating system of your instance. The general format, however, is as follows:

```
patches:
    -
        id: '{patch-d}'
        title: '{patch-title}'
        {additional-fields}:{values}
```

Although you can provide additional fields in your YAML file, they're ignored during patch operations.

In addition, we recommend verifying that the format of your YAML file is valid before adding or updating the list in your S3 bucket. For more information about the YAML format, see yaml.org. For validation tool options, perform a web search for "yaml format validators".

- Microsoft Windows

  id

  The **id** field is required. Use it to specify patches using Microsoft Knowledge Base IDs (for example, KB2736693) and Microsoft Security Bulletin IDs (for example, MS17-023).

  Any other fields you want to provide in a patch list for Windows are optional and are for your own informational use only. You can use additional fields such as **title**, **classification**, **severity**, or anything else for providing more detailed information about the specified patches.

- Linux

  id

The **id** field is required. Use it to specify patches using the package name and architecture. For example: `'dhclient.x86_64'`. You can use wildcards in id to indicate multiple packages. For example: `'dhcp*'` and `'dhcp*1.*'`.

title

The **title** field is optional, but on Linux systems it does provide additional filtering capabilities. If you use **title**, it should contain the package version information in the one of the following formats:

YUM/Red Hat Enterprise Linux (RHEL):

```
{name}.{architecture}:{epoch}:{version}-{release}
```

APT

```
{name}.{architecture}:{version}
```

For Linux patch titles, you can use one or more wildcards in any position to expand the number of package matches. For example: `'*32:9.8.2-0.*.rc1.57.amzn1'`.

For example:

- apt package version 1.2.25 is currently installed on your instance, but version 1.2.27 is now available.
- You add apt.amd64 version 1.2.27 to the patch list. It depends on apt utils.amd64 version 1.2.27, but apt-utils.amd64 version 1.2.25 is specified in the list.

In this case, apt version 1.2.27 will be blocked from installation and reported as “Failed-NonCompliant.”

Other fields

Any other fields you want to provide in a patch list for Linux are optional and are for your own informational use only. You can use additional fields such as **classification**, **severity**, or anything else for providing more detailed information about the specified patches.

Sample patch lists

- **Windows**

```
patches:
    -
        id: 'KB4284819'
        title: '2018-06 Cumulative Update for Windows Server 2016 (1709) for x64-
based Systems (KB4284819)'
    -
        id: 'KB4284833'
    -
        id: 'KB4284835'
        title: '2018-06 Cumulative Update for Windows Server 2016 (1803) for x64-
based Systems (KB4284835)'
    -
        id: 'KB4284880'
    -
        id: 'KB4338814'
```

- **APT**

```
patches:
    -
        id: 'apparmor.amd64'
        title: '2.10.95-0ubuntu2.9'
    -
        id: 'cryptsetup.amd64'
        title: '*2:1.6.6-5ubuntu2.1'
    -
        id: 'cryptsetup-bin.*'
        title: '*2:1.6.6-5ubuntu2.1'
    -
        id: 'apt.amd64'
        title: '*1.2.27'
    -
        id: 'apt-utils.amd64'
        title: '*1.2.25'
```

- **Amazon Linux 2**

```
patches:
    -
        id: 'kernel.x86_64'
    -
```

```
        id: 'bind*.x86_64'
        title: '39.11.4-26.P2.amzn2.5.2'

        id: 'glibc*'
    -
        id: 'dhclient*'
        title: '*4.2.5-58.amzn2'
    -
        id: 'dhcp*'
        title: '*4.2.5-77.amzn2'
```

- **Red Hat Enterprise Linux (RHEL)**

```
patches:
    -
        id: 'NetworkManager.x86_64'
        title: '*1:1.10.2-14.el7_5'
    -
        id: 'NetworkManager-*.x86_64'
        title: '*1:1.10.2-14.el7_5'
    -
        id: 'audit.x86_64'
        title: '*0:2.8.1-3.el7'
    -
        id: 'dhclient.x86_64'
        title: '*.el7_5.1'
    -
        id: 'dhcp*.x86_64'
        title: '*12:5.2.5-68.el7'
```

- **Ubuntu Server**

```
patches:
    -
        id: 'apparmor.amd64'
        title: '2.10.95-0ubuntu2.9'
    -
        id: 'cryptsetup.amd64'
        title: '*2:1.6.6-5ubuntu2.1'
    -
        id: 'cryptsetup-bin.*'
        title: '*2:1.6.6-5ubuntu2.1'
    -
```

```
        id: 'apt.amd64'
        title: '*1.2.27'
    -
        id: 'apt-utils.amd64'
        title: '*1.2.25'
```

- **Windows**

```
patches:
    -
        id: 'KB4284819'
        title: '2018-06 Cumulative Update for Windows Server 2016 (1709) for x64-
based Systems (KB4284819)'
    -
        id: 'KB4284833'
    -
        id: 'KB4284835'
        title: '2018-06 Cumulative Update for Windows Server 2016 (1803) for x64-
based Systems (KB4284835)'
    -
        id: 'KB4284880'
    -
        id: 'KB4338814'
```

Parameter name: `RebootOption`

Usage: Optional.

Options: `RebootIfNeeded` | `NoReboot`

Default: `RebootIfNeeded`

> **Warning**
>
> The default option is `RebootIfNeeded`. Be sure to select the correct option for your use case. For example, if your instances must reboot immediately to complete a configuration process, choose `RebootIfNeeded`. Or, if you need to maintain instances availability until a scheduled reboot time, choose `NoReboot`.

Important

The `NoReboot` option only prevents operating system-level restarts. Service-level restarts can still occur as part of the patching process. For example, when Docker is updated, dependent services such as Amazon Elastic Container Service might automatically restart even with `NoReboot` enabled. If you have critical services that must not be disrupted, consider additional measures such as temporarily removing instances from service or scheduling patching during maintenance windows.

Important

We don't recommend using Patch Manager for patching cluster instances in Amazon EMR (previously called Amazon Elastic MapReduce). In particular, don't select the `RebootIfNeeded` option for the `RebootOption` parameter. (This option is available in the SSM Command documents for patching `AWS-RunPatchBaseline`, `AWS-RunPatchBaselineAssociation`, and `AWS-RunPatchBaselineWithHooks`.)
The underlying commands for patching using Patch Manager use `yum` and `dnf` commands. Therefore, the operations result in incompatibilities because of how packages are installed. For information about the preferred methods for updating software on Amazon EMR clusters, see Using the default AMI for Amazon EMR in the *Amazon EMR Management Guide*.

RebootIfNeeded

When you choose the `RebootIfNeeded` option, the instance is rebooted in either of the following cases:

- Patch Manager installed one or more patches.

  Patch Manager doesn't evaluate whether a reboot is *required* by the patch. The system is rebooted even if the patch doesn't require a reboot.

- Patch Manager detects one or more patches with a status of `INSTALLED_PENDING_REBOOT` during the `Install` operation.

The `INSTALLED_PENDING_REBOOT` status can mean that the option `NoReboot` was selected the last time the `Install` operation was run, or that a patch was installed outside of Patch Manager since the last time the managed node was rebooted.

Rebooting instances in these two cases ensures that updated packages are flushed from memory and keeps patching and rebooting behavior consistent across all operating systems.

NoReboot

When you choose the `NoReboot` option, Patch Manager doesn't reboot an instance even if it installed patches during the `Install` operation. This option is useful if you know that your instances don't require rebooting after patches are applied, or you have applications or processes running on an instance that shouldn't be disrupted by a patching operation reboot. It's also useful when you want more control over the timing of instance reboots, such as by using a maintenance window.

Patch installation tracking file: To track patch installation, especially patches that have been installed since the last system reboot, Systems Manager maintains a file on the managed instance.

> **Important**
>
> Don't delete or modify the tracking file. If this file is deleted or corrupted, the patch compliance report for the instance is inaccurate. If this happens, reboot the instance and run a patch Scan operation to restore the file.

This tracking file is stored in the following locations on your managed instances:

- Linux operating systems:
  - `/var/log/amazon/ssm/patch-configuration/patch-states-configuration.json`
  - `/var/log/amazon/ssm/patch-configuration/patch-inventory-from-last-operation.json`
- Windows Server operating system:
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchStatesConfiguration.json`
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchInventoryFromLastOperation.json`

SSM Command document for patching: AWS-RunPatchBaselineWithHooks

AWS Systems Manager supports AWS-RunPatchBaselineWithHooks, a Systems Manager document (SSM document) for Patch Manager, a tool in AWS Systems Manager. This SSM document performs patching operations on managed nodes for both security related and other types of updates.

AWS-RunPatchBaselineWithHooks differs from AWS-RunPatchBaseline in the following ways:

- **A wrapper document** – AWS-RunPatchBaselineWithHooks is a wrapper for AWS-RunPatchBaseline and relies on AWS-RunPatchBaseline for some of its operations.
- **The Install operation** – AWS-RunPatchBaselineWithHooks supports lifecycle hooks that run at designated points during managed node patching. Because patch installations sometimes require managed nodes to reboot, the patching operation is divided into two events, for a total of three hooks that support custom functionality. The first hook is before the Install with NoReboot operation. The second hook is after the Install with NoReboot operation. The third hook is available after the reboot of the managed node.
- **No custom patch list support** – AWS-RunPatchBaselineWithHooks doesn't support the InstallOverrideList parameter.
- **SSM Agent support** – AWS-RunPatchBaselineWithHooks requires that SSM Agent 3.0.502 or later be installed on the managed node to patch.

When the document is run, it uses the patch baseline currently specified as the "default" for an operating system type if no patch group is specified. Otherwise, it uses the patch baselines that is associated with the patch group. For information about patch groups, see Patch groups.

You can use the document AWS-RunPatchBaselineWithHooks to apply patches for both operating systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.)

This document supports Linux and Windows Server managed nodes. The document will perform the appropriate actions for each platform.

> **Note**
>
> AWS-RunPatchBaselineWithHooks isn't supported on macOS.

Linux

On Linux managed nodes, the `AWS-RunPatchBaselineWithHooks` document invokes a Python module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. This patch baseline snapshot uses the defined rules and lists of approved and blocked patches to drive the appropriate package manager for each node type:

- Amazon Linux 2, Oracle Linux, and RHEL 7 managed nodes use YUM. For YUM operations, Patch Manager requires `Python 2.6` or a later supported version (2.6 - 3.10). Amazon Linux 2023 uses DNF. For DNF operations, Patch Manager requires a supported version of `Python 2` or `Python 3` (2.6 - 3.10).
- RHEL 8 managed nodes use DNF. For DNF operations, Patch Manager requires a supported version of `Python 2` or `Python 3` (2.6 - 3.10). (Neither version is installed by default on RHEL 8. You must install one or the other manually.)
- Debian Server and Ubuntu Server instances use APT. For APT operations, Patch Manager requires a supported version of `Python 3` (3.0 - 3.10).

Windows Server

On Windows Server managed nodes, the `AWS-RunPatchBaselineWithHooks` document downloads and invokes a PowerShell module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. This patch baseline snapshot contains a list of approved patches that is compiled by querying the patch baseline against a Windows Server Update Services (WSUS) server. This list is passed to the Windows Update API, which controls downloading and installing the approved patches as appropriate.

Each snapshot is specific to an AWS account, patch group, operating system, and snapshot ID. The snapshot is delivered through a presigned Amazon Simple Storage Service (Amazon S3) URL, which expires 24 hours after the snapshot is created. After the URL expires, however, if you want to apply the same snapshot content to other managed nodes, you can generate a new presigned Amazon S3 URL up to three days after the snapshot was created. To do this, use the get-deployable-patch-snapshot-for-instance command.

After all approved and applicable updates have been installed, with reboots performed as necessary, patch compliance information is generated on an managed node and reported back to Patch Manager.

If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaselineWithHooks document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.

> **Important**
>
> While the NoReboot option prevents operating system restarts, it does not prevent service-level restarts that might occur when certain packages are updated. For example, updating packages like Docker may trigger automatic restarts of dependent services (such as container orchestration services) even when NoReboot is specified.

For information about viewing patch compliance data, see About patch compliance.

AWS-RunPatchBaselineWithHooks operational steps

When the AWS-RunPatchBaselineWithHooks runs, the following steps are performed:

1. **Scan** - A Scan operation using AWS-RunPatchBaseline is run on the managed node, and a compliance report is generated and uploaded.
2. **Verify local patch states** - A script is run to determine what steps will be performed based on the selected operation and Scan result from Step 1.
   a. If the selected operation is Scan, the operation is marked complete. The operation concludes.
   b. If the selected operation is Install, Patch Manager evaluates the Scan result from Step 1 to determine what to run next:
      i. If no missing patches are detected, and no pending reboots required, the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped.
      ii. If no missing patches are detected, but there are pending reboots required and the selected reboot option is NoReboot, the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped.
      iii. Otherwise, the operation proceeds to the next step.
3. **Pre-patch hook operation** - The SSM document you have provided for the first lifecycle hook, PreInstallHookDocName, is run on the managed node.
4. **Install with NoReboot** - An Install operation with the reboot option of NoReboot using AWS-RunPatchBaseline is run on the managed node, and a compliance report is generated and uploaded.

5. **Post-install hook operation** - The SSM document you have provided for the second lifecycle hook, `PostInstallHookDocName`, is run on the managed node.
6. **Verify reboot** - A script runs to determine whether a reboot is needed for the managed node and what steps to run:
   a. If the selected reboot option is `NoReboot`, the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped.
   b. If the selected reboot option is `RebootIfNeeded`, Patch Manager checks whether there are any pending reboots required from the inventory collected in Step 4. This means that the operation continues to Step 7 and the managed node is rebooted in either of the following cases:
      i. Patch Manager installed one or more patches. (Patch Manager doesn't evaluate whether a reboot is required by the patch. The system is rebooted even if the patch doesn't require a reboot.)
      ii. Patch Manager detects one or more patches with a status of `INSTALLED_PENDING_REBOOT` during the Install operation. The `INSTALLED_PENDING_REBOOT` status can mean that the option `NoReboot` was selected the last time the Install operation was run, or that a patch was installed outside of Patch Manager since the last time the managed node was rebooted.

      If no patches meeting these criteria are found, the managed node patching operation is complete, and the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped.
7. **Reboot and report** - An installation operation with the reboot option of `RebootIfNeeded` runs on the managed node using `AWS-RunPatchBaseline`, and a compliance report is generated and uploaded.
8. **Post-reboot hook operation** - The SSM document you have provided for the third lifecycle hook, `OnExitHookDocName`, is run on the managed node.

For a `Scan` operation, if Step 1 fails, the process of running the document stops and the step is reported as failed, although subsequent steps are reported as successful.

For an `Install` operation, if any of the `aws:runDocument` steps fail during the operation, those steps are reported as failed, and the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped. This step is reported as

failed, the last step reports the status of its operation result, and all steps in between are reported as successful.

`AWS-RunPatchBaselineWithHooks` parameters

`AWS-RunPatchBaselineWithHooks` supports six parameters.

The `Operation` parameter is required.

The `RebootOption`, `PreInstallHookDocName`, `PostInstallHookDocName`, and `OnExitHookDocName` parameters are optional.

`Snapshot-ID` is technically optional, but we recommend that you supply a custom value for it when you run `AWS-RunPatchBaselineWithHooks` outside of a maintenance window. Let Patch Manager supply the value automatically when the document is run as part of a maintenance window operation.

Parameters

- Parameter name: Operation
- Parameter name: Snapshot ID
- Parameter name: RebootOption
- Parameter name: PreInstallHookDocName
- Parameter name: PostInstallHookDocName
- Parameter name: OnExitHookDocName

Parameter name: `Operation`

Usage: Required.

Options: `Scan` | `Install`.

Scan

> When you choose the `Scan` option, the systems uses the `AWS-RunPatchBaseline` document to determine the patch compliance state of the managed node and reports this information back to Patch Manager. `Scan` doesn't prompt updates to be installed or managed nodes to be rebooted. Instead, the operation identifies where updates are missing that are approved and applicable to the node.

Install

When you choose the `Install` option, `AWS-RunPatchBaselineWithHooks` attempts to install the approved and applicable updates that are missing from the managed node. Patch compliance information generated as part of an `Install` operation doesn't list any missing updates, but might report updates that are in a failed state if the installation of the update didn't succeed for any reason. Whenever an update is installed on a managed node, the node is rebooted to ensure the update is both installed and active. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaselineWithHooks` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

> **Note**
>
> If a patch specified by the baseline rules is installed *before* Patch Manager updates the managed node, the system might not reboot as expected. This can happen when a patch is installed manually by a user or installed automatically by another program, such as the `unattended-upgrades` package on Ubuntu Server.

Parameter name: `Snapshot ID`

Usage: Optional.

`Snapshot ID` is a unique ID (GUID) used by Patch Manager to ensure that a set of managed nodes that are patched in a single operation all have the exact same set of approved patches. Although the parameter is defined as optional, our best practice recommendation depends on whether or not you're running `AWS-RunPatchBaselineWithHooks` in a maintenance window, as described in the following table.

`AWS-RunPatchBaselineWithHooks` best practices

Mode	Best practice	Details
Running `AWS-RunPatchBaselineWithHooks` inside a maintenance window	Don't supply a Snapshot ID. Patch Manager will supply it for you.	If you use a maintenance window to run `AWS-RunPatchBaselineWithHooks`, you shouldn't provide your own generated Snapshot

Mode	Best practice	Details
		ID. In this scenario, Systems Manager provides a GUID value based on the maintenance window execution ID. This ensures that a correct ID is used for all the invocations of `AWS-RunPatchBaselineWithHooks` in that maintenance window. If you do specify a value in this scenario, note that the snapshot of the patch baseline might not remain in place for more than 3 days. After that, a new snapshot will be generated even if you specify the same ID after the snapshot expires.

Mode	Best practice	Details
Running `AWS-RunPatchBaselineWithHooks` outside of a maintenance window	Generate and specify a custom GUID value for the Snapshot ID.[1]	When you aren't using a maintenance window to run `AWS-RunPatchBaselineWithHooks`, we recommend that you generate and specify a unique Snapshot ID for each patch baseline, particularly if you're running the `AWS-RunPatchBaselineWithHooks` document on multiple managed nodes in the same operation. If you don't specify an ID in this scenario, Systems Manager generates a different Snapshot ID for each managed node the command is sent to. This might result in varying sets of patches being specified among the nodes. For instance, say that you're running the `AWS-RunPatchBaselineWithHooks` document directly through Run Command, a tool inAWS Systems Manager, and targeting a group of 50 managed nodes. Specifying a custom Snapshot ID results in the generation of a single baseline snapshot that is used to evaluate and patch all the managed nodes,

Mode	Best practice	Details
		ensuring that they end up in a consistent state.

[1] You can use any tool capable of generating a GUID to generate a value for the Snapshot ID parameter. For example, in PowerShell, you can use the `New-Guid` cmdlet to generate a GUID in the format of `12345699-9405-4f69-bc5e-9315aEXAMPLE`.

Parameter name: `RebootOption`

Usage: Optional.

Options: `RebootIfNeeded` | `NoReboot`

Default: `RebootIfNeeded`

> **Warning**
>
> The default option is `RebootIfNeeded`. Be sure to select the correct option for your use case. For example, if your managed nodes must reboot immediately to complete a configuration process, choose `RebootIfNeeded`. Or, if you need to maintain managed node availability until a scheduled reboot time, choose `NoReboot`.

> **Important**
>
> We don't recommend using Patch Manager for patching cluster instances in Amazon EMR (previously called Amazon Elastic MapReduce). In particular, don't select the `RebootIfNeeded` option for the `RebootOption` parameter. (This option is available in the SSM Command documents for patching `AWS-RunPatchBaseline`, `AWS-RunPatchBaselineAssociation`, and `AWS-RunPatchBaselineWithHooks`.)
> The underlying commands for patching using Patch Manager use `yum` and `dnf` commands. Therefore, the operations result in incompatibilities because of how packages are installed. For information about the preferred methods for updating software on Amazon EMR clusters, see Using the default AMI for Amazon EMR in the *Amazon EMR Management Guide*.

RebootIfNeeded

When you choose the `RebootIfNeeded` option, the managed node is rebooted in either of the following cases:

- Patch Manager installed one or more patches.

  Patch Manager doesn't evaluate whether a reboot is *required* by the patch. The system is rebooted even if the patch doesn't require a reboot.

- Patch Manager detects one or more patches with a status of `INSTALLED_PENDING_REBOOT` during the `Install` operation.

  The `INSTALLED_PENDING_REBOOT` status can mean that the option `NoReboot` was selected the last time the `Install` operation was run, or that a patch was installed outside of Patch Manager since the last time the managed node was rebooted.

Rebooting managed nodes in these two cases ensures that updated packages are flushed from memory and keeps patching and rebooting behavior consistent across all operating systems.

NoReboot

When you choose the `NoReboot` option, Patch Manager doesn't reboot a managed node even if it installed patches during the `Install` operation. This option is useful if you know that your managed nodes don't require rebooting after patches are applied, or you have applications or processes running on a node that shouldn't be disrupted by a patching operation reboot. It's also useful when you want more control over the timing of managed node reboots, such as by using a maintenance window.

> **Note**
>
> If you choose the `NoReboot` option and a patch is installed, the patch is assigned a status of `InstalledPendingReboot`. The managed node itself, however, is marked as `Non-Compliant`. After a reboot occurs and a `Scan` operation is run, the node status is updated to `Compliant`.

Patch installation tracking file: To track patch installation, especially patches that were installed since the last system reboot, Systems Manager maintains a file on the managed node.

> **Important**
>
> Don't delete or modify the tracking file. If this file is deleted or corrupted, the patch compliance report for the managed node is inaccurate. If this happens, reboot the node and run a patch Scan operation to restore the file.

This tracking file is stored in the following locations on your managed nodes:

- Linux operating systems:
  - `/var/log/amazon/ssm/patch-configuration/patch-states-configuration.json`
  - `/var/log/amazon/ssm/patch-configuration/patch-inventory-from-last-operation.json`
- Windows Server operating system:
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchStatesConfiguration.json`
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchInventoryFromLastOperation.json`

Parameter name: `PreInstallHookDocName`

Usage: Optional.

Default: `AWS-Noop`.

The value to provide for the `PreInstallHookDocName` parameter is the name or Amazon Resource Name (ARN) of an SSM document of your choice. You can provide the name of an AWS managed document or the name or ARN of a custom SSM document that you have created or that has been shared with you. (For an SSM document that has been shared with you from a different AWS account, you must specify the full resource ARN, such as `arn:aws:ssm:us-east-2:123456789012:document/MySharedDocument`.)

The SSM document you specify is run before the `Install` operation and performs any actions supported by SSM Agent, such as a shell script to check application health check before patching is performed on the managed node. (For a list of actions, see Command document plugin reference). The default SSM document name is `AWS-Noop`, which doesn't perform any operation on the managed node.

For information about creating a custom SSM document, see Creating SSM document content.

Parameter name: `PostInstallHookDocName`

Usage: Optional.

Default: `AWS-Noop`.

The value to provide for the `PostInstallHookDocName` parameter is the name or Amazon Resource Name (ARN) of an SSM document of your choice. You can provide the name of an AWS managed document or the name or ARN of a custom SSM document that you have created or that has been shared with you. (For an SSM document that has been shared with you from a different AWS account, you must specify the full resource ARN, such as `arn:aws:ssm:us-east-2:123456789012:document/MySharedDocument`.)

The SSM document you specify is run after the `Install with NoReboot` operation and performs any actions supported by SSM Agent, such as a shell script for installing third party updates before reboot. (For a list of actions, see Command document plugin reference). The default SSM document name is `AWS-Noop`, which doesn't perform any operation on the managed node.

For information about creating a custom SSM document, see Creating SSM document content.

Parameter name: `OnExitHookDocName`

Usage: Optional.

Default: `AWS-Noop`.

The value to provide for the `OnExitHookDocName` parameter is the name or Amazon Resource Name (ARN) of an SSM document of your choice. You can provide the name of an AWS managed document or the name or ARN of a custom SSM document that you have created or that has been shared with you. (For an SSM document that has been shared with you from a different AWS account, you must specify the full resource ARN, such as `arn:aws:ssm:us-east-2:123456789012:document/MySharedDocument`.)

The SSM document you specify is run after the managed node reboot operation and performs any actions supported by SSM Agent, such as a shell script to verify node health after the patching operation is complete. (For a list of actions, see Command document plugin reference). The default SSM document name is `AWS-Noop`, which doesn't perform any operation on the managed node.

For information about creating a custom SSM document, see Creating SSM document content.

Sample scenario for using the InstallOverrideList parameter in AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation

You can use the `InstallOverrideList` parameter when you want to override the patches specified by the current default patch baseline in Patch Manager, a tool in AWS Systems Manager. This topic provides examples that show how to use this parameter to achieve the following:

- Apply different sets of patches to a target group of managed nodes.
- Apply these patch sets on different frequencies.
- Use the same patch baseline for both operations.

Say that you want to install two different categories of patches on your Amazon Linux 2 managed nodes. You want to install these patches on different schedules using maintenance windows. You want one maintenance window to run every week and install all `Security` patches. You want another maintenance window to run once a month and install all available patches, or categories of patches other than `Security`.

However, only one patch baseline at a time can be defined as the default for an operating system. This requirement helps avoid situations where one patch baseline approves a patch while another blocks it, which can lead to issues between conflicting versions.

With the following strategy, you use the `InstallOverrideList` parameter to apply different types of patches to a target group, on different schedules, while still using the same patch baseline:

1. In the default patch baseline, ensure that only `Security` updates are specified.
2. Create a maintenance window that runs `AWS-RunPatchBaseline` or `AWS-RunPatchBaselineAssociation` each week. Don't specify an override list.
3. Create an override list of the patches of all types that you want to apply on a monthly basis and store it in an Amazon Simple Storage Service (Amazon S3) bucket.
4. Create a second maintenance window that runs once a month. However, for the Run Command task you register for this maintenance window, specify the location of your override list.

The result: Only `Security` patches, as defined in your default patch baseline, are installed each week. All available patches, or whatever subset of patches you define, are installed each month.

For more information and sample lists, see Parameter name: `InstallOverrideList`.

Using the BaselineOverride parameter

You can define patching preferences at runtime using the baseline override feature in Patch Manager, a tool in AWS Systems Manager. Do this by specifying an Amazon Simple Storage Service (Amazon S3) bucket containing a JSON object with a list of patch baselines. The patching operation uses the baselines provided in the JSON object that match the host operating system instead of applying the rules from the default patch baseline.

> **Important**
>
> The `BaselineOverride` file name can't contain the following characters: backtick (`), single quote ('), double quote ("), and dollar sign ($).

Except when a patching operation uses a patch policy, using the `BaselineOverride` parameter doesn't overwrite the patch compliance of the baseline provided in the parameter. The output results are recorded in the Stdout logs from Run Command, a tool in AWS Systems Manager. The results only print out packages that are marked as `NON_COMPLIANT`. This means the package is marked as `Missing`, `Failed`, `InstalledRejected`, or `InstalledPendingReboot`.

When a patch operation uses a patch policy, however, the system passes the override parameter from the associated S3 bucket, and the compliance value is updated for the managed node. For more information about patch policy behaviors, see Patch policy configurations in Quick Setup.

Using the patch baseline override with Snapshot Id or Install Override List parameters

There are two cases where the patch baseline override has noteworthy behavior.

Using baseline override and Snapshot Id at the same time

Snapshot Ids ensure that all managed nodes in a particular patching command all apply the same thing. For example, if you patch 1,000 nodes at one time, the patches will be the same.

When using both a Snapshot Id and a patch baseline override, the Snapshot Id takes precedence over the patch baseline override. The baseline override rules will still be used, but they will only be evaluated once. In the earlier example, the patches across your 1,000 managed nodes will still always be the same. If, midway through the patching operation, you changed the JSON file in the referenced S3 bucket to be something different, the patches applied will still be the same. This is because the Snapshot Id was provided.

Using baseline override and Install Override List at the same time

You can't use these two parameters at the same time. The patching document fails if both parameters are supplied, and it doesn't perform any scans or installs on the managed node.

Code examples

The following code example for Python shows how to generate the patch baseline override.

```
import boto3
import json

ssm = boto3.client('ssm')
s3 = boto3.resource('s3')
s3_bucket_name = 'my-baseline-override-bucket'
s3_file_name = 'MyBaselineOverride.json'
baseline_ids_to_export = ['pb-0000000000000000', 'pb-0000000000000001']

baseline_overrides = []
for baseline_id in baseline_ids_to_export:
    baseline_overrides.append(ssm.get_patch_baseline(
        BaselineId=baseline_id
    ))

json_content = json.dumps(baseline_overrides, indent=4, sort_keys=True, default=str)
s3.Object(bucket_name=s3_bucket_name, key=s3_file_name).put(Body=json_content)
```

This produces a patch baseline override like the following.

```
[
    {
        "ApprovalRules": {
            "PatchRules": [
                {

```

Patch baselines

The topics in this section provide information about how patch baselines work in Patch Manager, a tool in AWS Systems Manager, when you run a `Scan` or `Install` operation on your managed nodes.

Topics

- Predefined and custom patch baselines

- Patching applications released by Microsoft on Windows Server

Predefined and custom patch baselines

Patch Manager, a tool in AWS Systems Manager, provides predefined patch baselines for each of the operating systems supported by Patch Manager. You can use these baselines as they are currently configured (you can't customize them) or you can create your own custom patch baselines. Custom patch baselines allows you greater control over which patches are approved or rejected for your environment. Also, the predefined baselines assign a compliance level of `Unspecified` to all patches installed using those baselines. For compliance values to be assigned, you can create a copy of a predefined baseline and specify the compliance values you want to assign to patches. For more information, see Custom baselines and Working with custom patch baselines.

> **Note**
>
> The information in this topic applies no matter which method or type of configuration you are using for your patching operations:
>
> - A patch policy configured in Quick Setup
> - A Host Management option configured in Quick Setup
> - A maintenance window to run a patch `Scan` or `Install` task
> - An on-demand **Patch now** operation

Topics

- Predefined baselines
- Custom baselines

Predefined baselines

The following table describes the predefined patch baselines provided with Patch Manager.

For information about which versions of each operating system Patch Manager supports, see Patch Manager prerequisites.

Name	Supported operating system	Details
AWS-AlmaLinuxDefaultPatchBaseline	AlmaLinux	Approves all operating system patches that are classified as "Security" and that have a severity level of "Critical" or "Important". Also approves all patches that are classified as "Bugfix". Patches are auto-approved 7 days after they are released or updated.[1]
AWS-AmazonLinux2DefaultPatchBaseline	Amazon Linux 2	Approves all operating system patches that are classified as "Security" and that have a severity level of "Critical" or "Important". Also approves all patches with a classification of "Bugfix". Patches are auto-approved 7 days after release.[1]
AWS-AmazonLinux2023DefaultPatchBaseline	Amazon Linux 2023	Approves all operating system patches that are classified as "Security" and that have a severity level of "Critical" or "Important". Patches are auto-approved seven days after release. Also approves all patches with a classification of "Bugfix" seven days after release.
AWS-DebianDefaultPatchBaseline	Debian Server	Immediately approves all operating system security-related patches that have a priority of "Required",

Name	Supported operating system	Details
		"Important", "Standard," "Optional," or "Extra." There is no wait before approval because reliable release dates aren't available in the repositories.
AWS-MacOSDefaultPatchBaseline	macOS	Approves all operating system patches that are classified as "Security". Also approves all packages with a current update.
AWS-OracleLinuxDefaultPatchBaseline	Oracle Linux	Approves all operating system patches that are classified as "Security" and that have a severity level of "Important" or "Moderate". Also approves all patches that are classified as "Bugfix" 7 days after release. Patches are auto-approved 7 days after they are released or updated.[1]
AWS-RedHatDefaultPatchBaseline	Red Hat Enterprise Linux (RHEL)	Approves all operating system patches that are classified as "Security" and that have a severity level of "Critical" or "Important". Also approves all patches that are classified as "Bugfix". Patches are auto-approved 7 days after they are released or updated.[1]

Name	Supported operating system	Details
AWS-RockyLinuxDefaultPatchBaseline	Rocky Linux	Approves all operating system patches that are classified as "Security" and that have a severity level of "Critical" or "Important". Also approves all patches that are classified as "Bugfix". Patches are auto-approved 7 days after they are released or updated.[1]
AWS-UbuntuDefaultPatchBaseline	Ubuntu Server	Immediately approves all operating system security-related patches that have a priority of "Required", "Important", "Standard," "Optional," or "Extra." There is no wait before approval because reliable release dates aren't available in the repositories.
AWS-DefaultPatchBaseline	Windows Server	Approves all Windows Server operating system patches that are classified as "CriticalUpdates" or "SecurityUpdates" and that have an MSRC severity of "Critical" or "Important". Patches are auto-approved 7 days after they are released or updated.[2]

Name	Supported operating system	Details
AWS-WindowsPredefinedPatchBaseline-OS	Windows Server	Approves all Windows Server operating system patches that are classified as "CriticalUpdates" or "SecurityUpdates" and that have an MSRC severity of "Critical" or "Important". Patches are auto-approved 7 days after they are released or updated.[2]
AWS-WindowsPredefinedPatchBaseline-OS-Applications	Windows Server	For the Windows Server operating system, approves all patches that are classified as "CriticalUpdates" or "SecurityUpdates" and that have an MSRC severity of "Critical" or "Important". For applications released by Microsoft, approves all patches. Patches for both OS and applications are auto-approved 7 days after they are released or updated.[2]

[1] For Amazon Linux 2, the 7-day wait before patches are auto-approved is calculated from an `Updated Date` value in `updateinfo.xml`, not a `Release Date` value. Various factors can affect the `Updated Date` value. Other operating systems handle release and update dates differently. For information to help you avoid unexpected results with auto-approval delays, see How package release dates and update dates are calculated.

[2] For Windows Server, default baselines include a 7-day auto-approval delay. To install a patch within 7 days after release, you must create a custom baseline.

Custom baselines

Use the following information to help you create custom patch baselines to meet your patching goals.

Topics

Using auto-approvals in custom baselines

If you create your own patch baseline, you can choose which patches to auto-approve by using the following categories.

- **Operating system**: Supported versions of Windows Server, Amazon Linux, Ubuntu Server, and so on.
- **Product name** (for operating systems): For example, RHEL 7.5, Amazon Linux 2023 2023.8.20250808, Windows Server 2012, Windows Server 2012 R2, and so on.
- **Product name** (for applications released by Microsoft on Windows Server only): For example, Word 2016, BizTalk Server, and so on.
- **Classification**: For example, Critical updates, Security updates, and so on.
- **Severity**: For example, Critical, Important, and so on.

For each approval rule that you create, you can choose to specify an auto-approval delay or specify a patch approval cutoff date.

> **Note**
>
> Because it's not possible to reliably determine the release dates of update packages for Ubuntu Server, the auto-approval options aren't supported for this operating system.

An auto-approval delay is the number of days to wait after the patch was released or last updated, before the patch is automatically approved for patching. For example, if you create a rule using the `CriticalUpdates` classification and configure it for 7 days auto-approval delay, then a new critical patch released on July 7 is automatically approved on July 14.

If a Linux repository does not provide release date information for packages, Patch Manager uses the build time of the package as the date for auto-approval date specifications for Amazon Linux 2, and Red Hat Enterprise Linux (RHEL). If the build time of the package can't be determined, Patch Manager uses a default date of January 1st, 1970. This results in Patch Manager bypassing any auto-approval date specifications in patch baselines that are configured to approve patches for any date after January 1st, 1970.

When you specify an auto-approval cutoff date, Patch Manager automatically applies all patches released or last updated on or before that date. For example, if you specify July 7, 2023 as the cutoff date, no patches released or last updated on or after July 8, 2023 are installed automatically.

When you create a custom patch baseline, you can specify a compliance severity level for patches approved by that patch baseline, such as `Critical` or `High`. If the patch state of any approved patch is reported as `Missing`, then the patch baseline's overall reported compliance severity is the severity level you specified.

Additional information for creating patch baselines

Keep the following in mind when you create a patch baseline:

- Patch Manager provides one predefined patch baseline for each supported operating system. These predefined patch baselines are used as the default patch baselines for each operating system type unless you create your own patch baseline and designate it as the default for the corresponding operating system type.

  > **Note**
  >
  > For Windows Server, three predefined patch baselines are provided. The patch baselines `AWS-DefaultPatchBaseline` and `AWS-WindowsPredefinedPatchBaseline-OS` support only operating system updates on the Windows operating system itself. `AWS-DefaultPatchBaseline` is used as the default patch baseline for Windows Server managed nodes unless you specify a different patch baseline. The configuration settings in these two patch baselines are the same. The newer of the two, `AWS-WindowsPredefinedPatchBaseline-OS`, was created to distinguish it from the third predefined patch baseline for Windows Server. That patch baseline, `AWS-WindowsPredefinedPatchBaseline-OS-Applications`, can be used to apply patches to both the Windows Server operating system and supported applications released by Microsoft.

- By default, Windows Server 2019 and Windows Server 2022 remove updates that are replaced by later updates. As a result, if you use the `ApproveUntilDate` parameter in a Windows Server patch baseline, but the date selected in the `ApproveUntilDate` parameter is before the date of the latest patch, then the new patch isn't installed when the patching operation runs. For more information about Windows Server patching rules, see the Windows Server tab in How security patches are selected.

  This means that the managed node is compliant in terms of Systems Manager operations, even though a critical patch from the previous month might not be installed. This same scenario can occur when using the `ApproveAfterDays` parameter. Because of the Microsoft superseded patch behavior, it is possible to set a number (generally greater than 30 days) so that patches for Windows Server are never installed if the latest available patch from Microsoft is released before the number of days in `ApproveAfterDays` has elapsed.
- For Windows Server only, an available security update patch that is not approved by the patch baseline can have a compliance value or `Compliant` or `Non-Compliant`, as defined in a custom patch baseline.

  When you create or update a patch baseline, you choose the status you want to assign to security patches that are available but not approved because they don't meet the installation criteria specified in the patch baseline. For example, security patches that you might want installed can be skipped if you have specified a long period to wait after a patch is released before installation. If an update to the patch is released during your specified waiting period, the waiting period for installing the patch starts over. If the waiting period is too long, multiple versions of the patch could be released but never installed.

  Using the console to create or update a patch baseline, you specify this option in the **Available security updates compliance status** field. Using the AWS CLI to run the create-patch-baseline or update-patch-baseline command, you specify this option in the `available-security-updates-compliance-status` parameter.
- For on-premises servers and virtual machines (VMs), Patch Manager attempts to use your custom default patch baseline. If no custom default patch baseline exists, the system uses the predefined patch baseline for the corresponding operating system.
- If a patch is listed as both approved and rejected in the same patch baseline, the patch is rejected.
- A managed node can have only one patch baseline defined for it.

- The formats of package names you can add to lists of approved patches and rejected patches for a patch baseline depend on the type of operating system you're patching.

  For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.
- If you are using a patch policy configuration in Quick Setup, updates you make to custom patch baselines are synchronized with Quick Setup once an hour.

  If a custom patch baseline that was referenced in a patch policy is deleted, a banner displays on the Quick Setup **Configuration details** page for your patch policy. The banner informs you that the patch policy references a patch baseline that no longer exists, and that subsequent patching operations will fail. In this case, return to the Quick Setup **Configurations** page, select the Patch Manager configuration , and choose **Actions**, **Edit configuration**. The deleted patch baseline name is highlighted, and you must select a new patch baseline for the affected operating system.

For information about creating a patch baseline, see Working with custom patch baselines and Tutorial: Patch a server environment using the AWS CLI.

Package name formats for approved and rejected patch lists

The formats of package names you can add to lists of approved patches and rejected patches depend on the type of operating system you're patching.

Package name formats for Linux operating systems

The formats you can specify for approved and rejected patches in your patch baseline vary by Linux type. More specifically, the formats that are supported depend on the package manager used by the type of Linux operating system.

Topics

- Amazon Linux 2, Amazon Linux 2023, Oracle Linux, and Red Hat Enterprise Linux (RHEL)
- Debian Server and Ubuntu Server

Amazon Linux 2, Amazon Linux 2023, Oracle Linux, and Red Hat Enterprise Linux (RHEL)

Package manager: YUM, except for Amazon Linux 2023, and RHEL 8, which use DNF as the package manager.

Approved patches: For approved patches, you can specify any of the following:

- Bugzilla IDs, in the format `1234567` (The system processes numbers-only strings as Bugzilla IDs.)
- CVE IDs, in the format `CVE-2018-1234567`
- Advisory IDs, in formats such as `RHSA-2017:0864` and `ALAS-2018-123`
- Package names that are constructed using one or more of the available components for package naming. To illustrate, for the package named `dbus.x86_64:1:1.12.28-1.amzn2023.0.1`, the components are as follows:
  - `name`: `dbus`
  - `architecture`: `x86_64`
  - `epoch`: `1`
  - `version`: `1.12.28`
  - `release`: `1.amzn2023.0.1`

  Package names with the following constructions are supported:
  - `name`
  - `name.arch`
  - `name-version`
  - `name-version-release`
  - `name-version-release.arch`
  - `version`
  - `version-release`
  - `epoch:version-release`
  - `name-epoch:version-release`
  - `name-epoch:version-release.arch`
  - `epoch:name-version-release.arch`
  - `name.arch:epoch:version-release`

  Some examples:
  - `dbus.x86_64`
  - `dbus-1.12.28`
  - `dbus-1.12.28-1.amzn2023.0.1`
  - `dbus-1:1.12.28-1.amzn2023.0.1.x86_64`

- We also support package name components with a single wild card in the above formats, such as the following:
  - `dbus*`
  - `dbus-1.12.2*`
  - `dbus-*:1.12.28-1.amzn2023.0.1.x86_64`

Rejected patches: For rejected patches, you can specify any of the following:

- Package names that are constructed using one or more of the available components for package naming. To illustrate, for the package named `dbus.x86_64:1:1.12.28-1.amzn2023.0.1`, the components are as follows:
  - `name`: `dbus`
  - `architecture`; `x86_64`
  - `epoch`: `1`
  - `version`: `1.12.28`
  - `release`: `1.amzn2023.0.1`

  Package names with the following constructions are supported:
  - `name`
  - `name.arch`
  - `name-version`
  - `name-version-release`
  - `name-version-release.arch`
  - `version`
  - `version-release`
  - `epoch:version-release`
  - `name-epoch:version-release`
  - `name-epoch:version-release.arch`
  - `epoch:name-version-release.arch`
  - `name.arch:epoch:version-release`

  Some examples:
  - `dbus.x86_64`

- `dbus-1.12.28`
- `dbus-1.12.28-1.amzn2023.0.1`
- `dbus-1:1.12.28-1.amzn2023.0.1.x86_64`

- We also support package name components with a single wild card in the above formats, such as the following:
  - `dbus*`
  - `dbus-1.12.2*`
  - `dbus-*:1.12.28-1.amzn2023.0.1.x86_64`

Debian Server and Ubuntu Server

Package manager: APT

Approved patches and **rejected patches**: For both approved and rejected patches, specify the following:

- Package names, in the format `ExamplePkg33`

> **Note**
>
> For Debian Server lists, and Ubuntu Server lists, don't include elements such as architecture or versions. For example, you specify the package name `ExamplePkg33` to include all the following in a patch list:
>
> - `ExamplePkg33.x86.1`
> - `ExamplePkg33.x86.2`
> - `ExamplePkg33.x64.1`
> - `ExamplePkg33.3.2.5-364.noarch`

Package name formats for macOS

Supported package managers: softwareupdate, installer, Brew, Brew Cask

Approved patches and **rejected patches**: For both approved and rejected patch lists, you specify full package names, in formats such as:

- `XProtectPlistConfigData`

- `MRTConfigData`

Wildcards aren't supported in approved and rejected patch lists for macOS.

Package name formats for Windows operating systems

For Windows operating systems, specify patches using Microsoft Knowledge Base IDs and Microsoft Security Bulletin IDs; for example:

```
KB2032276,KB2124261,MS10-048
```

Patch groups

> **Note**
>
> Patch groups are not used in patching operations that are based on *patch policies*. For information about working with patch policies, see Patch policy configurations in Quick Setup.
>
> Patch group functionality is not supported in the console for account-Region pairs that did not already use patch groups before patch policy support was released on December 22, 2022. Patch group functionality is still available in account-Region pairs that began using patch groups before this date.

You can use a *patch group* to associate managed nodes with a specific patch baseline in Patch Manager, a tool in AWS Systems Manager. Patch groups help ensure that you're deploying the appropriate patches, based on the associated patch baseline rules, to the correct set of nodes. Patch groups can also help you avoid deploying patches before they have been adequately tested. For example, you can create patch groups for different environments (such as Development, Test, and Production) and register each patch group to an appropriate patch baseline.

When you run `AWS-RunPatchBaseline` or other SSM Command documents for patching, you can target managed nodes using their ID or tags. SSM Agent and Patch Manager then evaluate which patch baseline to use based on the patch group value that you added to the managed node.

Using tags to define patch groups

You create a patch group by using tags applied to your Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 nodes in a hybrid and multicloud environment. Note the following details about using tags for patch groups:

- A patch group must be defined using either the tag key `Patch Group` or `PatchGroup` applied to your managed nodes. When registering a patch group for a patch baseline, any identical *values* specified for these two keys are interpreted to be part of the same group. For instance, say that you have tagged five nodes with the first of the following key-value pairs, and five with the second:
  - `key=PatchGroup,value=DEV`
  - `key=Patch Group,value=DEV`

  The Patch Manager command to create a baseline combines these 10 managed nodes into a single group based on the value `DEV`. The AWS CLI equivalent for the command to create a patch baseline for patch groups is as follows:

  ```
  aws ssm register-patch-baseline-for-patch-group \
      --baseline-id pb-0c10e65780EXAMPLE \
      --patch-group DEV
  ```

  Combining values from different keys into a single target is unique to this Patch Manager command for creating a new patch group and not supported by other API actions. For example, if you run send-command actions using `PatchGroup` and `Patch Group` keys with the same values, you are targeting two completely different sets of nodes:

  ```
  aws ssm send-command \
      --document-name AWS-RunPatchBaseline \
      --targets "Key=tag:PatchGroup,Values=DEV"
  ```

  ```
  aws ssm send-command \
      --document-name AWS-RunPatchBaseline \
      --targets "Key=tag:Patch Group,Values=DEV"
  ```

- There are limits on tag-based targeting. Each array of targets for `SendCommand` can contain a maximum of five key-value pairs.

- We recommend that you choose only one of these tag key conventions, either `PatchGroup` (without a space) or `Patch Group` (with a space). However, if you have allowed tags in EC2 instance metadata on an instance, you must use `PatchGroup`.
- The key is case-sensitive. You can specify any *value* to help you identify and target the resources in that group, for example "web servers" or "US-EAST-PROD", but the key must be `Patch Group` or `PatchGroup`.

After you create a patch group and tag managed nodes, you can register the patch group with a patch baseline. Registering the patch group with a patch baseline ensures that the nodes within the patch group use the rules defined in the associated patch baseline.

For more information about how to create a patch group and associate the patch group to a patch baseline, see Creating and managing patch groups and Add a patch group to a patch baseline.

To view an example of creating a patch baseline and patch groups by using the AWS Command Line Interface (AWS CLI), see Tutorial: Patch a server environment using the AWS CLI. For more information about Amazon EC2 tags, see Tag your Amazon EC2 resources in the *Amazon EC2 User Guide*.

How it works

When the system runs the task to apply a patch baseline to a managed node, SSM Agent verifies that a patch group value is defined for the node. If the node is assigned to a patch group, Patch Manager then verifies which patch baseline is registered to that group. If a patch baseline is found for that group, Patch Manager notifies SSM Agent to use the associated patch baseline. If a node isn't configured for a patch group, Patch Manager automatically notifies SSM Agent to use the currently configured default patch baseline.

Important

A managed node can only be in one patch group.

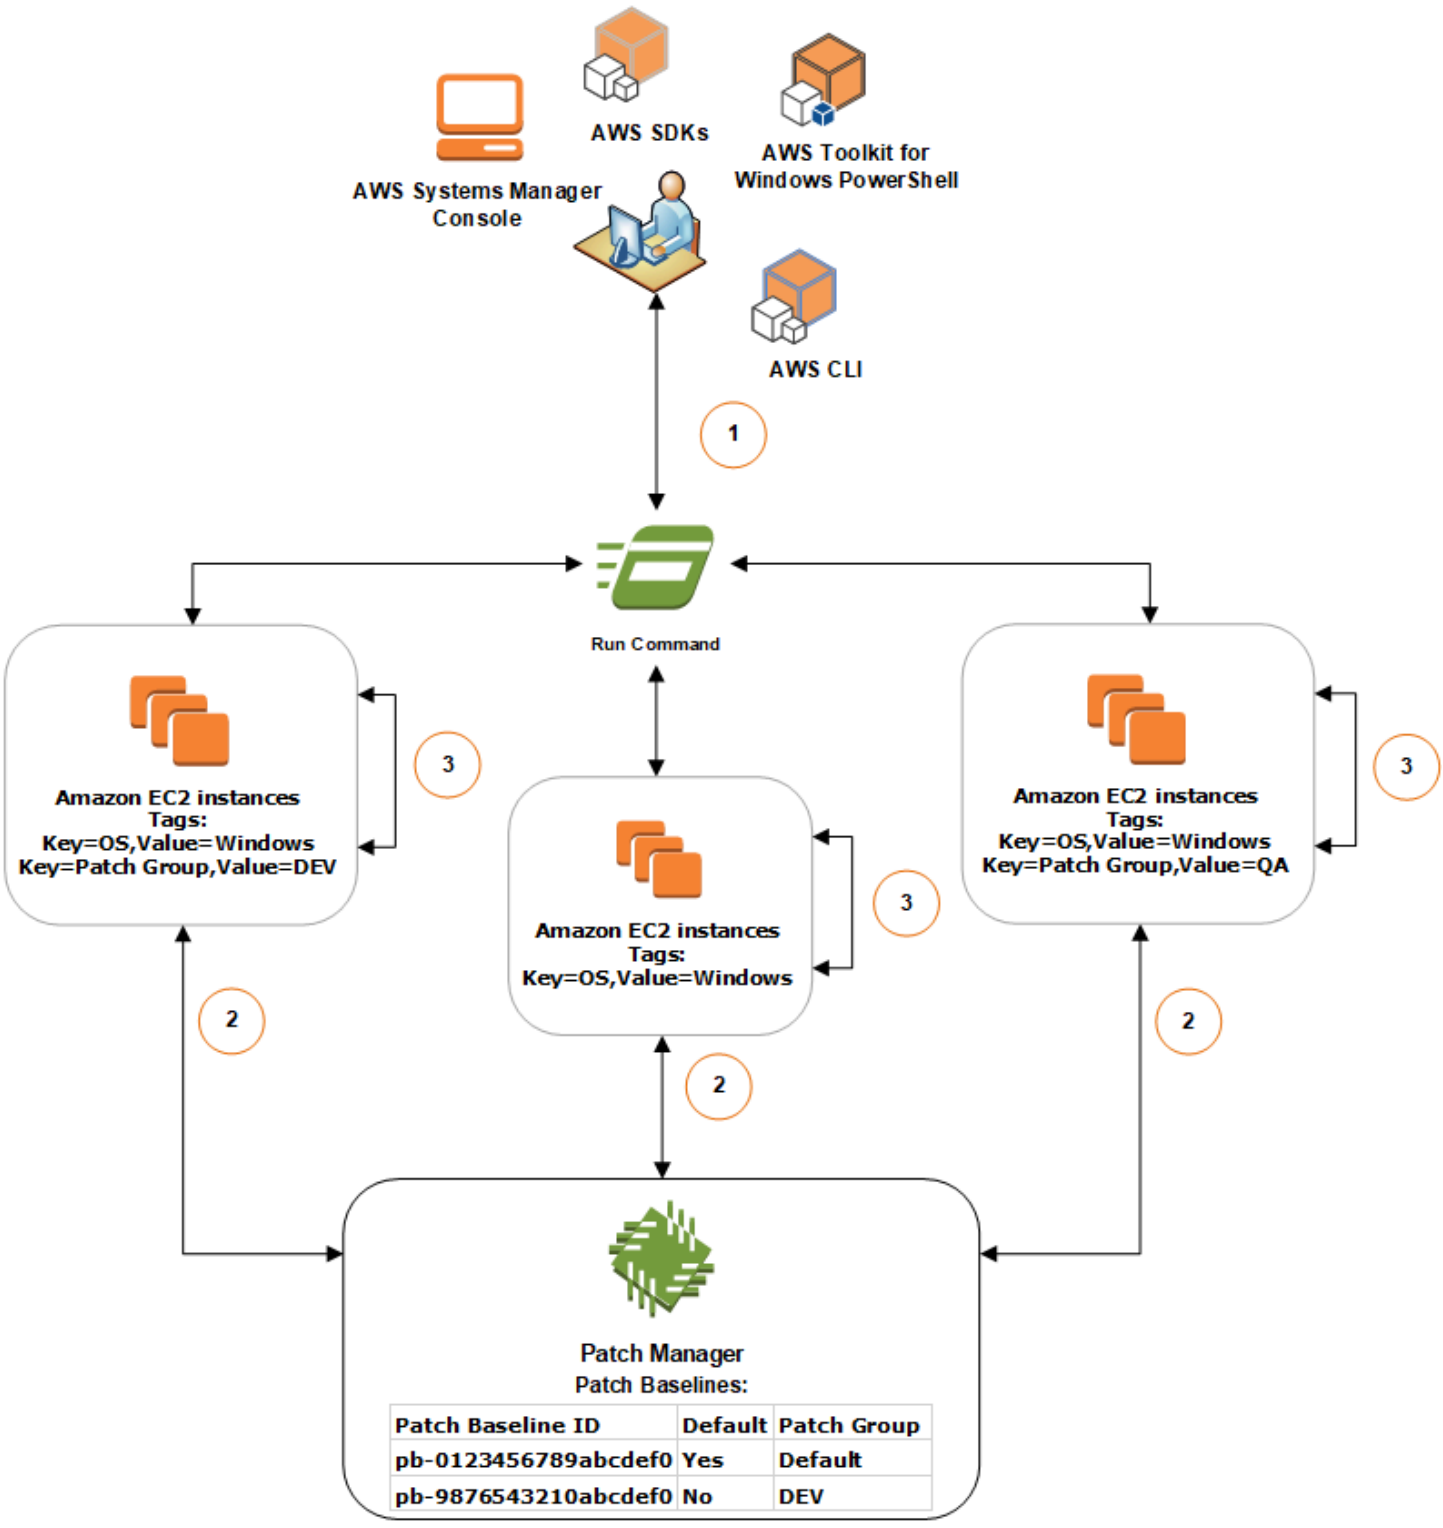
A patch group can be registered with only one patch baseline for each operating system type.

You can't apply the `Patch Group` tag (with a space) to an Amazon EC2 instance if the **Allow tags in instance metadata** option is enabled on the instance. Allowing tags in instance metadata prevents tag key names from containing spaces. If you have allowed tags in EC2 instance metadata, you must use the tag key `PatchGroup` (without a space).

Diagram 1: General example of patching operations process flow

The following illustration shows a general example of the processes that Systems Manager performs when sending a Run Command task to your fleet of servers to patch using Patch Manager. These processes determine which patch baselines to use in patching operations. (A similar process is used when a maintenance window is configured to send a command to patch using Patch Manager.)

The full process is explained below the illustration.



In this example, we have three groups of EC2 instances for Windows Server with the following tags applied:

EC2 instances group	Tags
Group 1	`key=OS,value=Windows` `key=PatchGroup,value=DEV`
Group 2	`key=OS,value=Windows`
Group 3	`key=OS,value=Windows` `key=PatchGroup,value=QA`

For this example, we also have these two Windows Server patch baselines:

Patch baseline ID	Default	Associated patch group
`pb-0123456789abcdef0`	Yes	`Default`
`pb-9876543210abcdef0`	No	`DEV`

The general process to scan or install patches using Run Command, a tool in AWS Systems Manager, and Patch Manager is as follows:

1. **Send a command to patch**: Use the Systems Manager console, SDK, AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell to send a Run Command task using the document `AWS-RunPatchBaseline`. The diagram shows a Run Command task to patch managed instances by targeting the tag `key=OS,value=Windows`.
2. **Patch baseline determination**: SSM Agent verifies the patch group tags applied to the EC2 instance and queries Patch Manager for the corresponding patch baseline.
   - **Matching patch group value associated with patch baseline:**
     1. SSM Agent, which is installed on EC2 instances in group one, receives the command issued in Step 1 to begin a patching operation. SSM Agent validates that the EC2 instances have the patch group tag-value `DEV` applied and queries Patch Manager for an associated patch baseline.

2. Patch Manager verifies that patch baseline `pb-9876543210abcdef0` has the patch group `DEV` associated and notifies SSM Agent.
3. SSM Agent retrieves a patch baseline snapshot from Patch Manager based on the approval rules and exceptions configured in `pb-9876543210abcdef0` and proceeds to the next step.

- **No patch group tag added to instance:**

1. SSM Agent, which is installed on EC2 instances in group two, receives the command issued in Step 1 to begin a patching operation. SSM Agent validates that the EC2 instances don't have a `Patch Group` or `PatchGroup` tag applied and as a result, SSM Agent queries Patch Manager for the default Windows patch baseline.
2. Patch Manager verifies that the default Windows Server patch baseline is `pb-0123456789abcdef0` and notifies SSM Agent.
3. SSM Agent retrieves a patch baseline snapshot from Patch Manager based on the approval rules and exceptions configured in the default patch baseline `pb-0123456789abcdef0` and proceeds to the next step.

- **No matching patch group value associated with a patch baseline:**

1. SSM Agent, which is installed on EC2 instances in group three, receives the command issued in Step 1 to begin a patching operation. SSM Agent validates that the EC2 instances have the patch group tag-value `QA` applied and queries Patch Manager for an associated patch baseline.
2. Patch Manager doesn't find a patch baseline that has the patch group `QA` associated.
3. Patch Manager notifies SSM Agent to use the default Windows patch baseline `pb-0123456789abcdef0`.
4. SSM Agent retrieves a patch baseline snapshot from Patch Manager based on the approval rules and exceptions configured in the default patch baseline `pb-0123456789abcdef0` and proceeds to the next step.

3. **Patch scan or install**: After determining the appropriate patch baseline to use, SSM Agent begins either scanning for or installing patches based on the operation value specified in Step 1. The patches that are scanned for or installed are determined by the approval rules and patch exceptions defined in the patch baseline snapshot provided by Patch Manager.

More info

- Patch compliance state values

Patching applications released by Microsoft on Windows Server

Use the information in this topic to help you prepare to patch applications on Windows Server using Patch Manager, a tool in AWS Systems Manager.

Microsoft application patching

Patching support for applications on Windows Server managed nodes is limited to applications released by Microsoft.

> **Note**
>
> In some cases, Microsoft releases patches for applications that don't specify an updated date and time. In these cases, an updated date and time of `01/01/1970` is supplied by default.

Patch baselines to patch applications released by Microsoft

For Windows Server, three predefined patch baselines are provided. The patch baselines `AWS-DefaultPatchBaseline` and `AWS-WindowsPredefinedPatchBaseline-OS` support only operating system updates on the Windows operating system itself. `AWS-DefaultPatchBaseline` is used as the default patch baseline for Windows Server managed nodes unless you specify a different patch baseline. The configuration settings in these two patch baselines are the same. The newer of the two, `AWS-WindowsPredefinedPatchBaseline-OS`, was created to distinguish it from the third predefined patch baseline for Windows Server. That patch baseline, `AWS-WindowsPredefinedPatchBaseline-OS-Applications`, can be used to apply patches to both the Windows Server operating system and supported applications released by Microsoft.

You can also create a custom patch baseline to update applications released by Microsoft on Windows Server machines.

Support for patching applications released by Microsoft on on-premises servers, edge devices, VMs, and other non-EC2 nodes

To patch applications released by Microsoft on virtual machines (VMs) and other non-EC2 managed nodes, you must turn on the advanced-instances tier. There is a charge to use the advanced-

instances tier. **However, there is no additional charge to patch applications released by Microsoft on Amazon Elastic Compute Cloud (Amazon EC2) instances.** For more information, see Configuring instance tiers.

Windows update option for "other Microsoft products"

In order for Patch Manager to be able to patch applications released by Microsoft on your Windows Server managed nodes, the Windows Update option **Give me updates for other Microsoft products when I update Windows** must be activated on the managed node.

For information about allowing this option on a single managed node, see Update Office with Microsoft Update on the Microsoft Support website.

For a fleet of managed nodes running Windows Server 2016 and later, you can use a Group Policy Object (GPO) to turn on the setting. In the Group Policy Management Editor, go to **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Windows Updates**, and choose **Install updates for other Microsoft products**. We also recommend configuring the GPO with additional parameters that prevent unplanned automatic updates and reboots outside of Patch Manager. For more information, see Configuring Automatic Updates in a Non-Active Directory Environment on the Microsoft technical documentation website.

For a fleet of managed nodes running Windows Server 2012 or 2012 R2 , you can turn on the option by using a script, as described in Enabling and Disabling Microsoft Update in Windows 7 via Script on the Microsoft Docs Blog website. For example, you could do the following:

1. Save the script from the blog post in a file.
2. Upload the file to an Amazon Simple Storage Service (Amazon S3) bucket or other accessible location.
3. Use Run Command, a tool in AWS Systems Manager, to run the script on your managed nodes using the Systems Manager document (SSM document) `AWS-RunPowerShellScript` with a command similar to the following.

```
Invoke-WebRequest `
    -Uri "https://s3.aws-api-domain/amzn-s3-demo-bucket/script.vbs" `
    -Outfile "C:\script.vbs" cscript c:\script.vbs
```

Minimum parameter requirements

To include applications released by Microsoft in your custom patch baseline, you must, at a minimum, specify the product that you want to patch. The following AWS Command Line Interface (AWS CLI) command demonstrates the minimal requirements to patch a product, such as Microsoft Office 2016.

Linux & macOS

```
aws ssm create-patch-baseline \
    --name "My-Windows-App-Baseline" \
    --approval-rules
 "PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=PRODUCT,Values='Office 2016'},
{Key=PATCH_SET,Values='APPLICATION'}]},ApproveAfterDays=5}]"
```

Windows Server

```
aws ssm create-patch-baseline ^
    --name "My-Windows-App-Baseline" ^
    --approval-rules
 "PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=PRODUCT,Values='Office 2016'},
{Key=PATCH_SET,Values='APPLICATION'}]},ApproveAfterDays=5}]"
```

If you specify the Microsoft application product family, each product you specify must be a supported member of the selected product family. For example, to patch the product "Active Directory Rights Management Services Client 2.0," you must specify its product family as "Active Directory" and not, for example, "Office" or "SQL Server." The following AWS CLI command demonstrates a matched pairing of product family and product.

Linux & macOS

```
aws ssm create-patch-baseline \
    --name "My-Windows-App-Baseline" \
    --approval-rules
 "PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=PRODUCT_FAMILY,Values='Active
 Directory'},{Key=PRODUCT,Values='Active Directory Rights Management Services Client
 2.0'},{Key=PATCH_SET,Values='APPLICATION'}]},ApproveAfterDays=5}]"
```

Windows Server

```
aws ssm create-patch-baseline ^
    --name "My-Windows-App-Baseline" ^
```

```
    --approval-rules
"PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=PRODUCT_FAMILY,Values='Active
Directory'},{Key=PRODUCT,Values='Active Directory Rights Management Services Client
2.0'},{Key=PATCH_SET,Values='APPLICATION'}]},ApproveAfterDays=5}]"
```

Note

If you receive an error message about a mismatched product and family pairing, see Issue: mismatched product family/product pairs for help resolving the issue.

Using Kernel Live Patching on Amazon Linux 2 managed nodes

Kernel Live Patching for Amazon Linux 2 allows you to apply security vulnerability and critical bug patches to a running Linux kernel without reboots or disruptions to running applications. This allows you to benefit from improved service and application availability, while keeping your infrastructure secure and up to date. Kernel Live Patching is supported on Amazon EC2 instances, AWS IoT Greengrass core devices, and on-premises virtual machines running Amazon Linux 2.

For general information about Kernel Live Patching, see Kernel Live Patching on AL2 in the *Amazon Linux 2 User Guide*.

After you turn on Kernel Live Patching on an Amazon Linux 2 managed node, you can use Patch Manager, a tool in AWS Systems Manager, to apply kernel live patches to the managed node. Using Patch Manager is an alternative to using existing yum workflows on the node to apply the updates.

Before you begin

To use Patch Manager to apply kernel live patches to your Amazon Linux 2 managed nodes, ensure your nodes are based on the correct architecture and kernel version. For information, see Supported configurations and prerequisites in the *Amazon EC2 User Guide*.

Topics

- How Kernel Live Patching using Patch Manager works
- Turning on Kernel Live Patching using Run Command
- Applying kernel live patches using Run Command

- Turning off Kernel Live Patching using Run Command

Kernel Live Patching using Patch Manager

Updating the kernel version

You don't need to reboot a managed node after applying a kernel live patch update. However, AWS provides kernel live patches for an Amazon Linux 2 kernel version for up to three months after its release. After the three-month period, you must update to a later kernel version to continue to receive kernel live patches. We recommend using a maintenance window to schedule a reboot of your node at least once every three months to prompt the kernel version update.

Uninstalling kernel live patches

Kernel live patches can't be uninstalled using Patch Manager. Instead, you can turn off Kernel Live Patching, which removes the RPM packages for the applied kernel live patches. For more information, see Turning off Kernel Live Patching using Run Command.

Kernel compliance

In some cases, installing all CVE fixes from live patches for the current kernel version can bring that kernel into the same compliance state that a newer kernel version would have. When that happens, the newer version is reported as `Installed`, and the managed node reported as `Compliant`. No installation time is reported for newer kernel version, however.

One kernel live patch, multiple CVEs

If a kernel live patch addresses multiple CVEs, and those CVEs have various classification and severity values, only the highest classification and severity from among the CVEs is reported for the patch.

The remainder of this section describes how to use Patch Manager to apply kernel live patches to managed nodes that meet these requirements.

How Kernel Live Patching using Patch Manager works

AWS releases two types of kernel live patches for Amazon Linux 2: security updates and bug fixes. To apply those types of patches, you use a patch baseline document that targets only the classifications and severities listed in the following table.

Classification	Severity
`Security`	`Critical`, `Important`
`Bugfix`	`All`

You can create a custom patch baseline that targets only these patches, or use the predefined `AWS-AmazonLinux2DefaultPatchBaseline` patch baseline. In other words, you can use `AWS-AmazonLinux2DefaultPatchBaseline` with Amazon Linux 2 managed nodes on which Kernel Live Patching is turned on, and kernel live updates will be applied.

> **Note**
>
> The `AWS-AmazonLinux2DefaultPatchBaseline` configuration specifies a 7-day waiting period after a patch is released or last updated before it's installed automatically. If you don't want to wait 7 days for kernel live patches to be auto-approved, you can create and use a custom patch baseline. In your patch baseline, you can specify no auto-approval waiting period, or specify a shorter or longer one. For more information, see Working with custom patch baselines.

We recommend the following strategy to patch your managed nodes with kernel live updates:

1. Turn on Kernel Live Patching on your Amazon Linux 2 managed nodes.
2. Use Run Command, a tool in AWS Systems Manager, to run a `Scan` operation on your managed nodes using the predefined `AWS-AmazonLinux2DefaultPatchBaseline` or a custom patch baseline that also targets only `Security` updates with severity classified as `Critical` and `Important`, and the `Bugfix` severity of `All`.
3. Use Compliance, a tool in AWS Systems Manager, to review whether non-compliance for patching is reported for any of the managed nodes that were scanned. If so, view the node compliance details to determine whether any kernel live patches are missing from the managed node.
4. To install missing kernel live patches, use Run Command with the same patch baseline you specified before, but this time run an `Install` operation instead of a `Scan` operation.

Because kernel live patches are installed without the need to reboot, you can choose the `NoReboot` reboot option for this operation.

> **Note**
>
> You can still reboot the managed node if required for other types of patches installed on it, or if you want to update to a newer kernel. In these cases, choose the `RebootIfNeeded` reboot option instead.

5. Return to Compliance to verify that the kernel live patches were installed.

Turning on Kernel Live Patching using Run Command

To turn on Kernel Live Patching, you can either run `yum` commands on your managed nodes or use Run Command and a custom Systems Manager document (SSM document) that you create.

For information about turning on Kernel Live Patching by running `yum` commands directly on the managed node, see Enable Kernel Live Patching in the *Amazon EC2 User Guide*.

> **Note**
>
> When you turn on Kernel Live Patching, if the kernel already running on the managed node is *earlier* than `kernel-4.14.165-131.185.amzn2.x86_64` (the minimum supported version), the process installs the latest available kernel version and reboots the managed node. If the node is already running `kernel-4.14.165-131.185.amzn2.x86_64` or later, the process doesn't install a newer version and doesn't reboot the node.

To turn on Kernel Live Patching using Run Command (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose the custom SSM document `AWS-ConfigureKernelLivePatching`.

5. In the **Command parameters** section, specify whether you want managed nodes to reboot as part of this operation.
6. For information about working with the remaining controls on this page, see Running commands from the console.
7. Choose **Run**.

To turn on Kernel Live Patching (AWS CLI)

- Run the following command on your local machine.

  Linux & macOS

  ```
  aws ssm send-command \
      --document-name "AWS-ConfigureKernelLivePatching" \
      --parameters "EnableOrDisable=Enable" \
      --targets "Key=instanceids,Values=instance-id"
  ```

  Windows Server

  ```
  aws ssm send-command ^
      --document-name "AWS-ConfigureKernelLivePatching" ^
      --parameters "EnableOrDisable=Enable" ^
      --targets "Key=instanceids,Values=instance-id"
  ```

  Replace *instance-id* with the ID of the Amazon Linux 2 managed node on which you want to turn on the feature, such as i-02573cafcfEXAMPLE. To turn on the feature on multiple managed nodes, you can use either of the following formats.

  - `--targets "Key=instanceids,Values=instance-id1,instance-id2"`
  - `--targets "Key=tag:tag-key,Values=tag-value"`

  For information about other options you can use in the command, see send-command in the *AWS CLI Command Reference*.

Applying kernel live patches using Run Command

To apply kernel live patches, you can either run `yum` commands on your managed nodes or use Run Command and the SSM document `AWS-RunPatchBaseline`.

For information about applying kernel live patches by running `yum` commands directly on the managed node, see Apply kernel live patches in the *Amazon EC2 User Guide*.

To apply kernel live patches using Run Command (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose the SSM document `AWS-RunPatchBaseline`.
5. In the **Command parameters** section, do one of the following:
   - If you're checking whether new kernel live patches are available, for **Operation**, choose `Scan`. For **Reboot Option**, if don't want your managed nodes to reboot after this operation, choose `NoReboot`. After the operation is complete, you can check for new patches and compliance status in Compliance.
   - If you checked patch compliance already and are ready to apply available kernel live patches, for **Operation**, choose `Install`. For **Reboot Option**, if you don't want your managed nodes to reboot after this operation, choose `NoReboot`.
6. For information about working with the remaining controls on this page, see Running commands from the console.
7. Choose **Run**.

To apply kernel live patches using Run Command (AWS CLI)

1. To perform a `Scan` operation before checking your results in Compliance, run the following command from your local machine.

   Linux & macOS

```
aws ssm send-command \
    --document-name "AWS-RunPatchBaseline" \
```

```
    --targets "Key=InstanceIds,Values=instance-id" \
    --parameters '{"Operation":["Scan"],"RebootOption":["RebootIfNeeded"]}'
```

Windows Server

```
aws ssm send-command ^
    --document-name "AWS-RunPatchBaseline" ^
    --targets "Key=InstanceIds,Values=instance-id" ^
    --parameters {\"Operation\":[\"Scan\"],\"RebootOption\":[\"RebootIfNeeded
\"]}
```

For information about other options you can use in the command, see send-command in the *AWS CLI Command Reference*.

2. To perform an `Install` operation after checking your results in Compliance, run the following command from your local machine.

   Linux & macOS

```
aws ssm send-command \
    --document-name "AWS-RunPatchBaseline" \
    --targets "Key=InstanceIds,Values=instance-id" \
    --parameters '{"Operation":["Install"],"RebootOption":["NoReboot"]}'
```

   Windows Server

```
aws ssm send-command ^
    --document-name "AWS-RunPatchBaseline" ^
    --targets "Key=InstanceIds,Values=instance-id" ^
    --parameters {\"Operation\":[\"Install\"],\"RebootOption\":[\"NoReboot\"]}
```

In both of the preceding commands, replace *instance-id* with the ID of the Amazon Linux 2 managed node on which you want to apply kernel live patches, such as i-02573cafcfEXAMPLE. To turn on the feature on multiple managed nodes, you can use either of the following formats.

- `--targets "Key=instanceids,Values=instance-id1,instance-id2"`
- `--targets "Key=tag:tag-key,Values=tag-value"`

For information about other options you can use in these commands, see send-command in the *AWS CLI Command Reference*.

Turning off Kernel Live Patching using Run Command

To turn off Kernel Live Patching, you can either run `yum` commands on your managed nodes or use Run Command and the custom SSM document `AWS-ConfigureKernelLivePatching`.

> **Note**
>
> If you no longer need to use Kernel Live Patching, you can turn it off at any time. In most cases, turning off the feature isn't necessary.

For information about turning off Kernel Live Patching by running `yum` commands directly on the managed node, see Enable Kernel Live Patching in the *Amazon EC2 User Guide*.

> **Note**
>
> When you turn off Kernel Live Patching, the process uninstalls the Kernel Live Patching plugin and then reboots the managed node.

To turn off Kernel Live Patching using Run Command (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose the SSM document `AWS-ConfigureKernelLivePatching`.
5. In the **Command parameters** section, specify values for required parameters.
6. For information about working with the remaining controls on this page, see Running commands from the console.
7. Choose **Run**.

To turn off Kernel Live Patching (AWS CLI)

- Run a command similar to the following.

  Linux & macOS

  ```
  aws ssm send-command \
      --document-name "AWS-ConfigureKernelLivePatching" \
      --targets "Key=instanceIds,Values=instance-id" \
      --parameters "EnableOrDisable=Disable"
  ```

  Windows Server

  ```
  aws ssm send-command ^
      --document-name "AWS-ConfigureKernelLivePatching" ^
      --targets "Key=instanceIds,Values=instance-id" ^
      --parameters "EnableOrDisable=Disable"
  ```

  Replace *instance-id* with the ID of the Amazon Linux 2 managed node on which you want to turn off the feature, such as i-02573cafcfEXAMPLE. To turn off the feature on multiple managed nodes, you can use either of the following formats.

  - `--targets "Key=instanceids,Values=instance-id1,instance-id2"`
  - `--targets "Key=tag:tag-key,Values=tag-value"`

  For information about other options you can use in the command, see send-command in the *AWS CLI Command Reference*.

Working with Patch Manager resources and compliance using the console

To use Patch Manager, a tool in AWS Systems Manager, complete the following tasks. These tasks are described in more detail in this section.

1. Verify that the AWS predefined patch baseline for each operating system type that you use meets your needs. If it doesn't, create a patch baseline that defines a standard set of patches for that managed node type and set it as the default instead.

2. Organize managed nodes into patch groups by using Amazon Elastic Compute Cloud (Amazon EC2) tags (optional, but recommended).
3. Do one of the following:
   - (Recommended) Configure a patch policy in Quick Setup, a tool in Systems Manager, that lets you install missing patches on a schedule for an entire organization, a subset of organizational units, or a single AWS account. For more information, see Configure patching for instances in an organization using a Quick Setup patch policy.
   - Create a maintenance window that uses the Systems Manager document (SSM document) `AWS-RunPatchBaseline` in a Run Command task type. For more information, see Tutorial: Create a maintenance window for patching using the console.
   - Manually run `AWS-RunPatchBaseline` in a Run Command operation. For more information, see Running commands from the console.
   - Manually patch nodes on demand using the **Patch now** feature. For more information, see Patching managed nodes on demand.
4. Monitor patching to verify compliance and investigate failures.

Topics

- Creating a patch policy
- Viewing patch Dashboard summaries
- Working with patch compliance reports
- Patching managed nodes on demand
- Working with patch baselines
- Viewing available patches
- Creating and managing patch groups
- Integrating Patch Manager with AWS Security Hub

Creating a patch policy

A patch policy is a configuration you set up using Quick Setup, a tool in AWS Systems Manager. Patch policies provide more extensive and more centralized control over your patching operations than is available with other methods of configuring patching. A patch policy defines the schedule and baseline to use when automatically patching your nodes and applications.

For more information, see the following topics:

- Patch policy configurations in Quick Setup
- Configure patching for instances in an organization using a Quick Setup patch policy

Viewing patch Dashboard summaries

The **Dashboard** tab in Patch Manager provides you with a summary view in the console that you can use to monitor your patching operations in a consolidated view. Patch Manager is a tool in AWS Systems Manager. On the **Dashboard** tab, you can view the following:

- A snapshot of how many managed nodes are compliant and noncompliant with patching rules.
- A snapshot of the age of patch compliance results for your managed nodes.
- A linked count of how many noncompliant managed nodes there are for each of the most common reasons for noncompliance.
- A linked list of the most recent patching operations.
- A linked list of the recurring patching tasks that have been set up.

To view patch Dashboard summaries

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Dashboard** tab.
4. Scroll to the section containing summary data that you want to view:

    - **Amazon EC2 instance management**
    - **Compliance summary**
    - **Noncompliance counts**
    - **Compliance reports**
    - **Non-patch policy-based operations**
    - **Non-patch policy-based recurring tasks**

Working with patch compliance reports

Use the information in the following topics to help you generate and work with patch compliance reports in Patch Manager, a tool in AWS Systems Manager.

The information in the following topics apply no matter which method or type of configuration you're using for your patching operations:

- A patch policy configured in Quick Setup
- A Host Management option configured in Quick Setup
- A maintenance window to run a patch `Scan` or `Install` task
- An on-demand **Patch now** operation

> **Important**
>
> If you have multiple types of operations in place to scan your instances for patch compliance, note that each scan overwrites the patch compliance data of previous scans. As a result, you might end up with unexpected results in your patch compliance data. For more information, see Avoiding unintentional patch compliance data overwrites.
> To verify which patch baseline was used to generate the latest compliance information, navigate to the **Compliance reporting** tab in Patch Manager, locate the row for the managed node you want information about, and then choose the baseline ID in the **Baseline ID used** column.

Topics

Viewing patch compliance results

Use these procedures to view patch compliance information about your managed nodes.

This procedure applies to patch operations that use the `AWS-RunPatchBaseline` document. For information about viewing patch compliance information for patch operations that use the `AWS-RunPatchBaselineAssociation` document, see Identifying noncompliant managed nodes.

> **Note**
>
> The patch scanning operations for Quick Setup and Explorer use the `AWS-RunPatchBaselineAssociation` document. Quick Setup and Explorer are both tools in AWS Systems Manager.

Identify the patch solution for a specific CVE issue (Linux)

For many Linux-based operating systems, patch compliance results indicate which Common Vulnerabilities and Exposure (CVE) bulletin issues are resolved by which patches. This information can help you determine how urgently you need to install a missing or failed patch.

CVE details are included for supported versions of the following operating system types:

- AlmaLinux
- Amazon Linux 2
- Amazon Linux 2023
- Oracle Linux
- Red Hat Enterprise Linux (RHEL)
- Rocky Linux

You can also add CVE IDs to your lists of approved or rejected patches in your patch baselines, as the situation and your patching goals warrant.

For information about working with approved and rejected patch lists, see the following topics:

- Working with custom patch baselines
- Package name formats for approved and rejected patch lists
- How patch baseline rules work on Linux-based systems
- How patches are installed

> **Note**
>
> In some cases, Microsoft releases patches for applications that don't specify an updated date and time. In these cases, an updated date and time of `01/01/1970` is supplied by default.

Viewing patching compliance results

Use the following procedures to view patch compliance results in the AWS Systems Manager console.

> **Note**
>
> For information about generating patch compliance reports that are downloaded to an Amazon Simple Storage Service (Amazon S3) bucket, see Generating .csv patch compliance reports.

To view patch compliance results

1. Do one of the following.

   Option 1 (recommended) – Navigate from Patch Manager, a tool in AWS Systems Manager:

   - In the navigation pane, choose **Patch Manager**.
   - Choose the **Compliance reporting** tab.
   - In the **Node patching details** area, choose the node ID of the managed node for which you want to review patch compliance results.
   - In the **Details** area, in the **Properties** list, choose **Patches**.

   Option 2 – Navigate from Compliance, a tool in AWS Systems Manager:

   - In the navigation pane, choose **Compliance**.
   - For **Compliance resources summary**, choose a number in the column for the types of patch resources you want to review, such as **Non-Compliant resources**.
   - Below, in the **Resource** list, choose the ID of the managed node for which you want to review patch compliance results.

- In the **Details** area, in the **Properties** list, choose **Patches**.

Option 3 – Navigate from Fleet Manager, a tool in AWS Systems Manager.

- In the navigation pane, choose **Fleet Manager**.
- In the **Managed instances** area, choose the ID of the managed node for which you want to review patch compliance results.
- In the **Details** area, in the **Properties** list, choose **Patches**.

2. (Optional) In the Search box (), choose from the available filters.

   For example, for Red Hat Enterprise Linux (RHEL), choose from the following:

   - Name
   - Classification
   - State
   - Severity

   For Windows Server, choose from the following:

   - KB
   - Classification
   - State
   - Severity

3. Choose one of the available values for the filter type you chose. For example, if you chose **State**, now choose a compliance state such as **InstalledPendingReboot**, **Failed** or **Missing**.

   > **Note**
   >
   > Currently, CVE ID values are reported only for patches with a status of `Missing` or `Failed`.

4. Depending on the compliance state of the managed node, you can choose what action to take to remedy any noncompliant nodes.

For example, you can choose to patch your noncompliant managed nodes immediately. For information about patching your managed nodes on demand, see Patching managed nodes on demand.

For information about patch compliance states, see Patch compliance state values.

Generating .csv patch compliance reports

You can use the AWS Systems Manager console to generate patch compliance reports that are saved as a .csv file to an Amazon Simple Storage Service (Amazon S3) bucket of your choice. You can generate a single on-demand report or specify a schedule for generating the reports automatically.

Reports can be generated for a single managed node or for all managed nodes in your selected AWS account and AWS Region. For a single node, a report contains comprehensive details, including the IDs of patches related to a node being noncompliant. For a report on all managed nodes, only summary information and counts of noncompliant nodes' patches are provided.

After a report is generated, you can use a tool like Amazon QuickSight to import and analyze the data. QuickSight is a business intelligence (BI) service you can use to explore and interpret information in an interactive visual environment. For more information, see the *Amazon QuickSight User Guide*.

> **Note**
>
> When you create a custom patch baseline, you can specify a compliance severity level for patches approved by that patch baseline, such as `Critical` or `High`. If the patch state of any approved patch is reported as `Missing`, then the patch baseline's overall reported compliance severity is the severity level you specified.

You can also specify an Amazon Simple Notification Service (Amazon SNS) topic to use for sending notifications when a report is generated.

Service roles for generating patch compliance reports

The first time you generate a report, Systems Manager creates an Automation assume role named `AWS-SystemsManager-PatchSummaryExportRole` to use for the export process to S3.

Note

If you are exporting compliance data to an encrypted S3 bucket, you must update its associated AWS KMS key policy to provide the necessary permissions for `AWS-SystemsManager-PatchSummaryExportRole`. For instance, add a permission similar to this to your S3 bucket's AWS KMS policy:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": "role-arn"
}
```

Replace *`role-arn`* with the Amazon Resource Name (ARN) of the created in your account, in the format `arn:aws:iam::111222333444:role/service-role/AWS-SystemsManager-PatchSummaryExportRole`.
For more information, see Key policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

The first time you generate a report on a schedule, Systems Manager creates another service role named `AWS-EventBridge-Start-SSMAutomationRole`, along with the service role `AWS-SystemsManager-PatchSummaryExportRole` (if not created already) to use for the export process. `AWS-EventBridge-Start-SSMAutomationRole` enables Amazon EventBridge to start an automation using the runbook AWS-ExportPatchReportToS3.

We recommend against attempting to modify these policies and roles. Doing so could cause patch compliance report generation to fail. For more information, see Troubleshooting patch compliance report generation.

Topics

- Viewing patch compliance reporting schedules
- Troubleshooting patch compliance report generation

What's in a generated patch compliance report?

This topic provides information about the types of content included in the patch compliance reports that are generated and downloaded to a specified S3 bucket.

Report format for a single managed node

A report generated for a single managed node provides both summary and detailed information.

Download a sample report (single node)

Summary information for a single managed node includes the following:

- Index
- Instance ID
- Instance name
- Instance IP
- Platform name
- Platform version
- SSM Agent version
- Patch baseline
- Patch group
- Compliance status
- Compliance severity
- Noncompliant Critical severity patch count
- Noncompliant High severity patch count
- Noncompliant Medium severity patch count
- Noncompliant Low severity patch count
- Noncompliant Informational severity patch count
- Noncompliant Unspecified severity patch count

Detailed information for a single managed node includes the following:

- Index
- Instance ID
- Instance name
- Patch name
- KB ID/Patch ID
- Patch state
- Last report time
- Compliance level
- Patch severity
- Patch classification
- CVE ID
- Patch baseline
- Logs URL
- Instance IP
- Platform name
- Platform version
- SSM Agent version

> **Note**
>
> When you create a custom patch baseline, you can specify a compliance severity level for patches approved by that patch baseline, such as `Critical` or `High`. If the patch state of any approved patch is reported as `Missing`, then the patch baseline's overall reported compliance severity is the severity level you specified.

Report format for all managed nodes

A report generated for all managed nodes provides only summary information.

Download a sample report (all managed nodes)

Summary information for all managed nodes includes the following:

- Index
- Instance ID
- Instance name
- Instance IP
- Platform name
- Platform version
- SSM Agent version
- Patch baseline
- Patch group
- Compliance status
- Compliance severity
- Noncompliant Critical severity patch count
- Noncompliant High severity patch count
- Noncompliant Medium severity patch count
- Noncompliant Low severity patch count
- Noncompliant Informational severity patch count
- Noncompliant Unspecified severity patch count

Generating patch compliance reports for a single managed node

Use the following procedure to generate a patch summary report for a single managed node in your AWS account. The report for a single managed node provides details about each patch that is out of compliance, including patch names and IDs.

To generate patch compliance reports for a single managed node

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Compliance reporting** tab.
4. Choose the button for the row of the managed node for which you want to generate a report, and then choose **View detail**.
5. In the **Patch summary** section, choose **Export to S3**.

6. For **Report name**, enter a name to help you identify the report later.
7. For **Reporting frequency**, choose one of the following:
   - **On demand** – Create a one-time report. Skip to Step 9.
   - **On a schedule** – Specify a recurring schedule for automatically generating reports. Continue to Step 8.
8. For **Schedule type**, specify either a rate expression, such as every 3 days, or provide a cron expression to set the report frequency.

   For information about cron expressions, see Reference: Cron and rate expressions for Systems Manager.
9. For **Bucket name**, select the name of an S3 bucket where you want to store the .csv report files.

   > **Important**
   >
   > If you're working in an AWS Region that was launched after March 20, 2019, you must select an S3 bucket in that same Region. Regions launched after that date were turned off by default. For more information and a list of these Regions, see Enabling a Region in the *Amazon Web Services General Reference*.
10. (Optional) To send notifications when the report is generated, expend the **SNS topic** section, and then choose an existing Amazon SNS topic from **SNS topic Amazon Resource Name (ARN)**.
11. Choose **Submit**.

For information about viewing a history of generated reports, see Viewing patch compliance reporting history.

For information about viewing details of reporting schedules you have created, see Viewing patch compliance reporting schedules.

Generating patch compliance reports for all managed nodes

Use the following procedure to generate a patch summary report for all managed nodes in your AWS account. The report for all managed nodes indicates which nodes are out of compliance and the numbers of noncompliant patches. It doesn't provide the names or other identifiers of the

patches. For these additional details, you can generate a patch compliance report for a single managed node. For information, see Generating patch compliance reports for a single managed node earlier in this topic.

To generate patch compliance reports for all managed nodes

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Compliance reporting** tab.
4. Choose **Export to S3**. (Don't select a node ID first.)
5. For **Report name**, enter a name to help you identify the report later.
6. For **Reporting frequency**, choose one of the following:
   - **On demand** – Create a one-time report. Skip to Step 8.
   - **On a schedule** – Specify a recurring schedule for automatically generating reports. Continue to Step 7.
7. For **Schedule type**, specify either a rate expression, such as every 3 days, or provide a cron expression to set the report frequency.

   For information about cron expressions, see Reference: Cron and rate expressions for Systems Manager.
8. For **Bucket name**, select the name of an S3 bucket where you want to store the .csv report files.

   > **Important**
   >
   > If you're working in an AWS Region that was launched after March 20, 2019, you must select an S3 bucket in that same Region. Regions launched after that date were turned off by default. For more information and a list of these Regions, see Enabling a Region in the *Amazon Web Services General Reference*.
9. (Optional) To send notifications when the report is generated, expend the **SNS topic** section, and then choose an existing Amazon SNS topic from **SNS topic Amazon Resource Name (ARN)**.
10. Choose **Submit**.

For information about viewing a history of generated reports, see Viewing patch compliance reporting history.

For information about viewing details of reporting schedules you have created, see Viewing patch compliance reporting schedules.

Viewing patch compliance reporting history

Use the information in this topic to help you view details about the patch compliance reports generated in your AWS account.

To view patch compliance reporting history

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Compliance reporting** tab.
4. Choose **View all S3 exports**, and then choose the **Export history** tab.

Viewing patch compliance reporting schedules

Use the information in this topic to help you view details about the patch compliance reporting schedules created in your AWS account.

To view patch compliance reporting history

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Compliance reporting** tab.
4. Choose **View all S3 exports**, and then choose the **Report schedule rules** tab.

Troubleshooting patch compliance report generation

Use the following information to help you troubleshoot problems with generating patch compliance report generation in Patch Manager, a tool in AWS Systems Manager.

Topics

- A message reports that the AWS-SystemsManager-PatchManagerExportRolePolicy policy is corrupted
- After deleting patch compliance policies or roles, scheduled reports aren't generated successfully

A message reports that the `AWS-SystemsManager-PatchManagerExportRolePolicy` policy is corrupted

Problem: You receive an error message similar to the following, indicating the `AWS-SystemsManager-PatchManagerExportRolePolicy` is corrupted:

```
An error occurred while updating the AWS-SystemsManager-PatchManagerExportRolePolicy
policy. If you have edited the policy, you might need to delete the policy, and any
role that uses it, then try again. Systems Manager recreates the roles and policies
you have deleted.
```

- **Solution**: Use the Patch Manager console or AWS CLI to delete the affected roles and policies before generating a new patch compliance report.

  To delete the corrupt policy using the console

  1. Open the IAM console at https://console.aws.amazon.com/iam/.
  2. Do one of the following:

     On-demand reports – If the problem occurred while generating a one-time on-demand report, in the left navigation, choose **Policies**, search for `AWS-SystemsManager-PatchManagerExportRolePolicy`, then delete the policy. Next, choose **Roles**, search for `AWS-SystemsManager-PatchSummaryExportRole`, then delete the role.

     Scheduled reports – If the problem occurred while generating a report on a schedule, in the left navigation, choose **Policies**, search one at a time for `AWS-EventBridge-Start-SSMAutomationRolePolicy` and `AWS-SystemsManager-PatchManagerExportRolePolicy`, and delete each policy. Next, choose **Roles**, search one at a time for `AWS-EventBridge-Start-SSMAutomationRole` and `AWS-SystemsManager-PatchSummaryExportRole`, and delete each role.

  To delete the corrupt policy using the AWS CLI

  Replace the *`placeholder values`* with your account ID.

- If the problem occurred while generating a one-time on-demand report, run the following commands:

```
aws iam delete-policy --policy-arn arn:aws:iam::account-id:policy/AWS-
SystemsManager-PatchManagerExportRolePolicy
```

```
aws iam delete-role --role-name AWS-SystemsManager-PatchSummaryExportRole
```

If the problem occurred while generating a report on a schedule, run the following commands:

```
aws iam delete-policy --policy-arn arn:aws:iam::account-id:policy/AWS-
EventBridge-Start-SSMAutomationRolePolicy
```

```
aws iam delete-policy --policy-arn arn:aws:iam::account-id:policy/AWS-
SystemsManager-PatchManagerExportRolePolicy
```

```
aws iam delete-role --role-name AWS-EventBridge-Start-SSMAutomationRole
```

```
aws iam delete-role --role-name AWS-SystemsManager-PatchSummaryExportRole
```

After completing either procedure, follow the steps to generate or schedule a new patch compliance report.

After deleting patch compliance policies or roles, scheduled reports aren't generated successfully

Problem: The first time you generate a report, Systems Manager creates a service role and a policy to use for the export process (`AWS-SystemsManager-PatchSummaryExportRole` and `AWS-SystemsManager-PatchManagerExportRolePolicy`). The first time you generate a report on a schedule, Systems Manager creates another service role and a policy (`AWS-EventBridge-Start-SSMAutomationRole` and `AWS-EventBridge-Start-SSMAutomationRolePolicy`). These let Amazon EventBridge start an automation using the runbook AWS-ExportPatchReportToS3 .

If you delete any of these policies or roles, the connections between your schedule and your specified S3 bucket and Amazon SNS topic might be lost.

- **Solution**: To work around this problem, we recommend deleting the previous schedule and creating a new schedule to replace the one that was experiencing issues.

Remediating noncompliant managed nodes with Patch Manager

The topics in this section provide overviews of how to identify managed nodes that are out of patch compliance and how to bring nodes into compliance.

Topics

Identifying noncompliant managed nodes

Out-of-compliance managed nodes are identified when either of two AWS Systems Manager documents (SSM documents) are run. These SSM documents reference the appropriate patch baseline for each managed node in Patch Manager, a tool in AWS Systems Manager. They then evaluate the patch state of the managed node and then make compliance results available to you.

There are two SSM documents that are used to identify or update noncompliant managed nodes: `AWS-RunPatchBaseline` and `AWS-RunPatchBaselineAssociation`. Each one is used by different processes, and their compliance results are available through different channels. The following table outlines the differences between these documents.

> **Note**
>
> Patch compliance data from Patch Manager can be sent to AWS Security Hub. Security Hub gives you a comprehensive view of your high-priority security alerts and compliance status. It also monitors the patching status of your fleet. For more information, see Integrating Patch Manager with AWS Security Hub.

	AWS-RunPatchBaseline	AWS-RunPatchBaselineAssociation
Processes that use the document	**Patch on demand** - You can scan or patch managed nodes on demand using the **Patch now** option. For information, see Patching managed nodes on demand. **Systems Manager Quick Setup patch policies** – You can create a patching configuration in Quick Setup, a tool in AWS Systems Manager, that can scan for or install missing patches on separate schedules for an entire organization, a subset of organizational units, or a single AWS account. For information, see Configure patching for instances in an organization using a Quick Setup patch policy. **Run a command** – You can manually run `AWS-RunPatchBaseline` in an operation in Run Command, a tool in AWS Systems Manager. For information, see Running commands from the console. **Maintenance window** – You can create a maintenan	**Systems Manager Quick Setup Host Management** – You can enable a Host Management configuration option in Quick Setup to scan your managed instances for patch compliance each day. For information, see Set up Amazon EC2 host management using Quick Setup. **Systems Manager Explorer** – When you allow Explorer, a tool in AWS Systems Manager, it regularly scans your managed instances for patch compliance and reports results in the Explorer dashboard.

	AWS-RunPatchBaseline	AWS-RunPatchBaselineAssociation
	ce window that uses the SSM document AWS-RunPatchBaseline in a Run Command task type. For information, see Tutorial: Create a maintenance window for patching using the console.	
Format of the patch scan result data	After AWS-RunPatchBaseline runs, Patch Manager sends an AWS:PatchSummary object to Inventory, a tool in AWS Systems Manager.	After AWS-RunPatchBaselineAssociation runs, Patch Manager sends an AWS:ComplianceItem object to Systems Manager Inventory.
Viewing patch compliance reports in the console	You can view patch compliance information for processes that use AWS-RunPatchBaseline in Systems Manager Configuration Compliance and Working with managed nodes. For more information, see Viewing patch compliance results.	If you use Quick Setup to scan your managed instances for patch compliance, you can see the compliance report in Systems Manager Fleet Manager. In the Fleet Manager console, choose the node ID of your managed node. In the **General** menu, choose **Configuration compliance**. If you use Explorer to scan your managed instances for patch compliance, you can see the compliance report in both Explorer and Systems Manager OpsCenter.

	AWS-RunPatchBaseline	AWS-RunPatchBaselineAssociation
AWS CLI commands for viewing patch compliance results	For processes that use AWS-RunPatchBaseline, you can use the following AWS CLI commands to view summary information about patches on a managed node. • describe-instance-patch-states • describe-instance-patch-states-for-patch-group • describe-patch-group-state	For processes that use AWS-RunPatchBaselineAssociation, you can use the following AWS CLI command to view summary information about patches on an instance. • list-compliance-items
Patching operations	For processes that use AWS-RunPatchBaseline, you specify whether you want the operation to run a Scan operation only, or a Scan and install operation. If your goal is to identify noncompliant managed nodes and not remediate them, run only a Scan operation.	Quick Setup and Explorer processes, which use AWS-RunPatchBaselineAssociation, run only a Scan operation.
More info	SSM Command document for patching: AWS-RunPatchBaseline	SSM Command document for patching: AWS-RunPatchBaselineAssociation

For information about the various patch compliance states you might see reported, see Patch compliance state values

For information about remediating managed nodes that are out of patch compliance, see Patching noncompliant managed nodes.

Patch compliance state values

The information about patches for a managed node include a report of the state, or status, of each individual patch.

> **Tip**
>
> If you want to assign a specific patch compliance state to a managed node, you can use the put-compliance-items AWS Command Line Interface (AWS CLI) command or the PutComplianceItems API operation. Assigning compliance state isn't supported in the console.

Use the information in the following tables to help you identify why a managed node might be out of patch compliance.

Patch compliance values for Debian Server and Ubuntu Server

For Debian Server and Ubuntu Server, the rules for package classification into the different compliance states are described in the following table.

> **Note**
>
> Keep the following in mind when you're evaluating the `INSTALLED`, `INSTALLED_OTHER`, and `MISSING` status values: If you don't select the **Include nonsecurity updates** check box when creating or updating a patch baseline, patch candidate versions are limited to patches in the following repositories: .
>
> - Ubuntu Server 16.04 LTS: `xenial-security`
> - Ubuntu Server 18.04 LTS: `bionic-security`
> - Ubuntu Server 20.04 LTS: `focal-security`
> - Ubuntu Server 22.04 LTS (`jammy-security`)
> - Ubuntu Server 24.04 LTS (`noble-security`)
> - Ubuntu Server 25.04 (`plucky-security`)
> - `debian-security` (Debian Server

If you do select the **Include nonsecurity updates** check box, patches from other repositories are considered as well.

Patch state	Description	Compliance status
INSTALLED	The patch is listed in the patch baseline and is installed on the managed node. It could have been installed either manually by an individual or automatically by Patch Manager when the `AWS-RunPatchBaseline` document was run on the managed node.	Compliant
INSTALLED_OTHER	The patch isn't included in the baseline or isn't approved by the baseline but is installed on the managed node. The patch might have been installed manually, the package could be a required dependency of another approved patch, or the patch might have been included in an InstallOverrideList operation. If you don't specify `Block` as the **Rejected patches** action, `INSTALLED_OTHER` patches also includes installed but rejected patches.	Compliant

Patch state	Description	Compliance status
INSTALLED_PENDING_REBOOT	INSTALLED_PENDING_REBOOT can mean either of two things: • The Patch Manager Install operation applied the patch to the managed node, but the node has not been rebooted since the patch was applied. This typically means the NoReboot option was selected for the RebootOption parameter when the AWS-RunPatchBaseline document was last run on the managed node. For more information, see Parameter name: RebootOption . • A patch was installed outside of Patch Manager since the last time the managed node was rebooted. In neither case does it mean that a patch with this status *requires* a reboot, only that the node hasn't been rebooted since the patch was installed.	Non-Compliant

Patch state	Description	Compliance status
INSTALLED_REJECTED	The patch is installed on the managed node but is specified in a **Rejected patches** list. This typically means the patch was installed before it was added to a list of rejected patches.	Non-Compliant
MISSING	Packages that are filtered through the baseline and not already installed.	Non-Compliant
FAILED	Packages that failed to install during the patch operation.	Non-Compliant

Patch compliance values for other operating systems

For all operating systems besides Debian Server and Ubuntu Server, the rules for package classification into the different compliance states are described in the following table.

Patch state	Description	Compliance value
INSTALLED	The patch is listed in the patch baseline and is installed on the managed node. It could have been installed either manually by an individual or automatically by Patch Manager when the `AWS-RunPatchBaseline` document was run on the node.	Compliant
INSTALLED_OTHER [1]	The patch isn't in the baseline, but it is installed on	Compliant

Patch state	Description	Compliance value
	the managed node. There are two possible reasons for this: 1. The patch might have been installed manually. 2. Linux only: The package might have been installed as a required *dependency* of a different, approved patch. If you specify `Allow as dependency` as the **Rejected patches** action, patches that are installed as dependencies are given the reporting status `INSTALLED_OTHER` . Note that Windows Server doesn't support the concept of patch dependencies. For information about how Patch Manager handles patches in the **Rejected patches** list on Windows Server, see Rejected patch list options in custom patch baselines.	

Patch state	Description	Compliance value
INSTALLED_REJECTED	The patch is installed on the managed node but is specified in a rejected patches list. This typically means the patch was installed before it was added to a list of rejected patches.	Non-Compliant

Patch state	Description	Compliance value
INSTALLED_PENDING_REBOOT	INSTALLED_PENDING_REBOOT can mean either of two things: • The Patch Manager Install operation applied the patch to the managed node, but the node has not been rebooted since the patch was applied. This typically means the NoReboot option was selected for the RebootOption parameter when the AWS-RunPatchBaseline document was last run on the managed node. For more information, see Parameter name: RebootOption . • A patch was installed outside of Patch Manager since the last time the managed node was rebooted. In neither case does it mean that a patch with this status *requires* a reboot, only that the node hasn't been rebooted since the patch was installed.	Non-Compliant

Patch state	Description	Compliance value
MISSING	The patch is approved in the baseline, but it isn't installed on the managed node. If you configure the `AWS-RunPatchBaseline` document task to scan (instead of install), the system reports this status for patches that were located during the scan but haven't been installed.	Non-Compliant
FAILED	The patch is approved in the baseline, but it couldn't be installed. To troubleshoot this situation, review the command output for information that might help you understand the problem.	Non-Compliant

Patch state	Description	Compliance value
NOT_APPLICABLE [1]	*This compliance state is reported only for Windows Server operating systems.* The patch is approved in the baseline, but the service or feature that uses the patch isn't installed on the managed node. For example, a patch for a web server service such as Internet Informati on Services (IIS) would show `NOT_APPLICABLE` if it was approved in the baseline, but the web service isn't installed on the managed node. A patch can also be marked `NOT_APPLICABLE` if it has been superseded by a subsequent update. This means that the later update is installed and the `NOT_APPLI CABLE` update is no longer required.	Not applicable

Patch state	Description	Compliance value
AVAILABLE_SECURITY_UPDATES	*This compliance state is reported only for Windows Server operating systems.* An available security update patch that is not approved by the patch baseline can have a compliance value or `Compliant` or `Non-Compliant`, as defined in a custom patch baseline. When you create or update a patch baseline, you choose the status you want to assign to security patches that are available but not approved because they don't meet the installation criteria specified in the patch baseline. For example, security patches that you might want installed can be skipped if you have specified a long period to wait after a patch is released before installation. If an update to the patch is released during your specified waiting period, the waiting period for installing the patch starts over. If the waiting period is too long, multiple versions of the patch could be released but never installed.	Compliant or Non-Compliant, depending on the option selected for available security updates. **Note** Using the console to create or update a patch baseline, you specify this option in the **Available security updates compliance status** field. Using the AWS CLI to run the create-patch-baseline or update-patch-baseline command, you specify this option in the `available-security-updates-compliance-status` parameter.

Patch state	Description	Compliance value
	For patch summary counts, when a patch is reported as `AvailableSecurityUpdate`, it will always be included in `AvailableSecurityUpdateCount`. If the baseline is configured to report these patches as `NonCompliant`, it is also included in `SecurityNonCompliantCount`. If the baseline is configured to report these patches as `Compliant`, they are not included in `SecurityNonCompliantCount`. These patches are always reported with an unspecified severity and are never included in the `CriticalNonCompliantCount`.	

[1] For patches with the state `INSTALLED_OTHER` and `NOT_APPLICABLE`, Patch Manager omits some data from query results based on the describe-instance-patches command, such as the values for `Classification` and `Severity`. This is done to help prevent exceeding the data limit for individual nodes in Inventory, a tool in AWS Systems Manager. To view all patch details, you can use the describe-available-patches command.

Patching noncompliant managed nodes

Many of the same AWS Systems Manager tools and processes you can use to check managed nodes for patch compliance can be used to bring nodes into compliance with the patch rules that currently apply to them. To bring managed nodes into patch compliance, Patch Manager, a tool in AWS Systems Manager, must run a `Scan and install` operation. (If your goal is only to identify

noncompliant managed nodes and not remediate them, run a `Scan` operation instead. For more information, see Identifying noncompliant managed nodes.)

Install patches using Systems Manager

You can choose from several tools to run a `Scan and install` operation:

- (Recommended) Configure a patch policy in Quick Setup, a tool in Systems Manager, that lets you install missing patches on a schedule for an entire organization, a subset of organizational units, or a single AWS account. For more information, see Configure patching for instances in an organization using a Quick Setup patch policy.
- Create a maintenance window that uses the Systems Manager document (SSM document) `AWS-RunPatchBaseline` in a Run Command task type. For information, see Tutorial: Create a maintenance window for patching using the console.
- Manually run `AWS-RunPatchBaseline` in a Run Command operation. For information, see Running commands from the console.

- Install patches on demand using the **Patch now** option. For information, see Patching managed nodes on demand.

Avoiding unintentional patch compliance data overwrites

If you have multiple types of operations in place to scan your instances for patch compliance, each scan overwrites the patch compliance data of previous scans. As a result, you might end up with unexpected results in your patch compliance data.

For example, suppose you create a patch policy that scans for patch compliance each day at 2 AM local time. That patch policy uses a patch baseline that targets patches with severity marked as `Critical`, `Important`, and `Moderate`. This patch baseline also specifies a few specifically rejected patches.

Also suppose that you already had a maintenance window set up to scan the same set of managed nodes each day at 4 AM local time, which you don't delete or deactivate. That maintenance window's task uses a different patch baseline, one that targets only patches with a `Critical` severity and doesn't exclude any specific patches.

When this second scan is performed by the maintenance window, the patch compliance data from the first scan is deleted and replaced with patch compliance from the second scan.

Therefore, we strongly recommend using only one automated method for scanning and installing in your patching operations. If you're setting up patch policies, you should delete or deactivate other methods of scanning for patch compliance. For more information, see the following topics:

- To remove a patching operation task from a maintenance window – Updating or deregistering maintenance window tasks using the console
- To delete a State Manager association – Deleting associations.

To deactivate daily patch compliance scans in a Host Management configuration, do the following in Quick Setup:

1. In the navigation pane, choose **Quick Setup**.
2. Select the Host Management configuration to update.
3. Choose **Actions, Edit configuration**.
4. Clear the **Scan instances for missing patches daily** check box.
5. Choose **Update**.

> **Note**
>
> Using the **Patch now** option to scan a managed node for compliance also results in an overwrite of patch compliance data.

Patching managed nodes on demand

Using the **Patch now** option in Patch Manager, a tool in AWS Systems Manager, you can run on-demand patching operations from the Systems Manager console. This means you don't have to create a schedule in order to update the compliance status of your managed nodes or to install patches on noncompliant nodes. You also don't need to switch the Systems Manager console between Patch Manager and Maintenance Windows, a tool in AWS Systems Manager, in order to set up or modify a scheduled patching window.

Patch now is especially useful when you must apply zero-day updates or install other critical patches on your managed nodes as soon as possible.

> **Note**
>
> Patching on demand is supported for a single AWS account-AWS Region pair at a time. It can't be used with patching operations that are based on *patch policies*. We recommend using patch policies for keeping all your managed nodes in compliance. For more information about working with patch policies, see Patch policy configurations in Quick Setup.

Topics

How 'Patch now' works

To run **Patch now**, you specify just two required settings:

- Whether to scan for missing patches only, or to scan *and* install patches on your managed nodes
- Which managed nodes to run the operation on

When the **Patch now** operation runs, it determines which patch baseline to use in the same way one is selected for other patching operations. If a managed node is associated with a patch group, the patch baseline specified for that group is used. If the managed node isn't associated with a patch group, the operation uses the patch baseline that is currently set as the default for the operating system type of the managed node. This can be a predefined baseline, or the custom baseline you have set as the default. For more information about patch baseline selection, see Patch groups.

Options you can specify for **Patch now** include choosing when, or whether, to reboot managed nodes after patching, specifying an Amazon Simple Storage Service (Amazon S3) bucket to store log data for the patching operation, and running Systems Manager documents (SSM documents) as lifecycle hooks during patching.

Concurrency and error thresholds for 'Patch now'

For **Patch now** operations, concurrency and error threshold options are handled by Patch Manager. You don't need to specify how many managed nodes to patch at once, nor how many errors are

permitted before the operation fails. Patch Manager applies the concurrency and error threshold settings described in the following tables when you patch on demand.

> **Important**
>
> The following thresholds apply to `Scan and install` operations only. For `Scan` operations, Patch Manager attempts to scan up to 1,000 nodes concurrently, and continue scanning until it has encountered up to 1,000 errors.

Concurrency: Install operations

Total number of managed nodes in the Patch now operation	Number of managed nodes scanned or patched at a time
Fewer than 25	1
25-100	5%
101 to 1,000	8%
More than 1,000	10%

Error threshold: Install operations

Total number of managed nodes in the Patch now operation	Number of errors permitted before the operation fails
Fewer than 25	1
25-100	5
101 to 1,000	10
More than 1,000	10

Using 'Patch now' lifecycle hooks

Patch now provides you with the ability to run SSM Command documents as lifecycle hooks during an `Install` patching operation. You can use these hooks for tasks such as shutting down applications before patching or running health checks on your applications after patching or after a reboot.

For more information about using lifecycle hooks, see SSM Command document for patching: `AWS-RunPatchBaselineWithHooks`.

The following table lists the lifecycle hooks available for each of the three **Patch now** reboot options, in addition to sample uses for each hook.

Lifecycle hooks and sample uses

Reboot option	Hook: Before installation	Hook: After installation	Hook: On exit	Hook: After scheduled reboot
Reboot if needed	Run an SSM document before patching begins. Example use: Safely shut down applications before the patching process begins.	Run an SSM document at the end of the patching operation and before managed node reboot. Example use: Run operations such as installing third-party applications before a potential reboot.	Run an SSM document after the patching operation is complete and instances are rebooted. Example use: Ensure that applications are running as expected after patching.	*Not available*
Do not reboot my instances	Same as above.	Run an SSM document at the end of the patching operation.	*Not available*	*Not available*

Reboot option	Hook: Before installation	Hook: After installation	Hook: On exit	Hook: After scheduled reboot
		Example use: Ensure that applications are running as expected after patching.		
Schedule a reboot time	Same as above.	Same as for **Do not reboot my instances**.	*Not available*	Run an SSM document immediately after a scheduled reboot is complete. Example use: Ensure that applications are running as expected after the reboot.

Running 'Patch now'

Use the following procedure to patch your managed nodes on demand.

To run 'Patch now'

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose **Patch now**.
4. For **Patching operation**, choose one of the following:

- **Scan**: Patch Manager finds which patches are missing from your managed nodes but doesn't install them. You can view the results in the **Compliance** dashboard or in other tools you use for viewing patch compliance.
- **Scan and install**: Patch Manager finds which patches are missing from your managed nodes and installs them.

5. Use this step only if you chose **Scan and install** in the previous step. For **Reboot option**, choose one of the following:

   - **Reboot if needed**: After installation, Patch Manager reboots managed nodes only if needed to complete a patch installation.
   - **Don't reboot my instances**: After installation, Patch Manager doesn't reboot managed nodes. You can reboot nodes manually when you choose or manage reboots outside of Patch Manager.
   - **Schedule a reboot time**: Specify the date, time, and UTC time zone for Patch Manager to reboot your managed nodes. After you run the **Patch now** operation, the scheduled reboot is listed as an association in State Manager with the name `AWS-PatchRebootAssociation`.

6. For **Instances to patch**, choose one of the following:

   - **Patch all instances**: Patch Manager runs the specified operation on all managed nodes in your AWS account in the current AWS Region.
   - **Patch only the target instances I specify**: You specify which managed nodes to target in the next step.

7. Use this step only if you chose **Patch only the target instances I specify** in the previous step. In the **Target selection** section, identify the nodes on which you want to run this operation by specifying tags, selecting nodes manually, or specifying a resource group.

   > **Note**
   >
   > If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.
   > If you choose to target a resource group, note that resource groups that are based on an AWS CloudFormation stack must still be tagged with the default `aws:cloudformation:stack-id` tag. If it has been removed, Patch Manager might be unable to determine which managed nodes belong to the resource group.

8. (Optional) For **Patching log storage**, if you want to create and save logs from this patching operation, select the S3 bucket for storing the logs.

   > **Note**
   >
   > The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create the IAM service role required for Systems Manager in hybrid and multicloud environments. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

9. (Optional) If you want to run SSM documents as lifecycle hooks during specific points of the patching operation, do the following:

   - Choose **Use lifecycle hooks**.
   - For each available hook, select the SSM document to run at the specified point of the operation:
     - Before installation
     - After installation
     - On exit
     - After scheduled reboot

   > **Note**
   >
   > The default document, `AWS-Noop`, runs no operations.

10. Choose **Patch now**.

    The **Association execution summary** page opens. (Patch now uses associations in State Manager, a tool in AWS Systems Manager, for its operations.) In the **Operation summary** area, you can monitor the status of scanning or patching on the managed nodes you specified.

Working with patch baselines

A patch baseline in Patch Manager, a tool in AWS Systems Manager, defines which patches are approved for installation on your managed nodes. You can specify approved or rejected patches one by one. You can also create auto-approval rules to specify that certain types of updates (for example, critical updates) should be automatically approved. The rejected list overrides both the rules and the approve list. To use a list of approved patches to install specific packages, you first remove all auto-approval rules. If you explicitly identify a patch as rejected, it won't be approved or installed, even if it matches all of the criteria in an auto-approval rule. Also, a patch is installed on a managed node only if it applies to the software on the node, even if the patch has otherwise been approved for the managed node.

More info

- Patch baselines

Viewing AWS predefined patch baselines

Patch Manager, a tool in AWS Systems Manager, includes a predefined patch baseline for each operating system supported by Patch Manager. You can use these patch baselines (you can't customize them), or you can create your own. The following procedure describes how to view a predefined patch baseline to see if it meets your needs. To learn more about patch baselines, see Predefined and custom patch baselines.

To view AWS predefined patch baselines

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. In the patch baselines list, choose the baseline ID of one of the predefined patch baselines.

   -or-

If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, choose the **Patch baselines** tab, and then choose the baseline ID of one of the predefined patch baselines.

> **Note**
>
> For Windows Server, three predefined patch baselines are provided.
> The patch baselines `AWS-DefaultPatchBaseline` and `AWS-WindowsPredefinedPatchBaseline-OS` support only operating system updates on the Windows operating system itself. `AWS-DefaultPatchBaseline` is used as the default patch baseline for Windows Server managed nodes unless you specify a different patch baseline. The configuration settings in these two patch baselines are the same. The newer of the two, `AWS-WindowsPredefinedPatchBaseline-OS`, was created to distinguish it from the third predefined patch baseline for Windows Server. That patch baseline, `AWS-WindowsPredefinedPatchBaseline-OS-Applications`, can be used to apply patches to both the Windows Server operating system and supported applications released by Microsoft.
> For more information, see Setting an existing patch baseline as the default.

4. In the **Approval rules** section, review the patch baseline configuration.
5. If the configuration is acceptable for your managed nodes, you can skip ahead to the procedure Creating and managing patch groups.

   -or-

   To create your own default patch baseline, continue to the topic Working with custom patch baselines.

Working with custom patch baselines

Patch Manager, a tool in AWS Systems Manager, includes a predefined patch baseline for each operating system supported by Patch Manager. You can use these patch baselines (you can't customize them), or you can create your own.

The following procedures describe how to create, update, and delete your own custom patch baselines. To learn more about patch baselines, see Predefined and custom patch baselines.

Creating a custom patch baseline for Linux

Use the following procedure to create a custom patch baseline for Linux managed nodes in Patch Manager, a tool in AWS Systems Manager.

For information about creating a patch baseline for macOS managed nodes, see Creating a custom patch baseline for macOS. For information about creating a patch baseline for Windows managed nodes, see Creating a custom patch baseline for Windows Server.

To create a custom patch baseline for Linux managed nodes

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Patch baselines** tab, and then choose **Create patch baseline**.

   -or-

   If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, choose the **Patch baselines** tab, and then choose **Create patch baseline**.
4. For **Name**, enter a name for your new patch baseline, for example, `MyRHELPatchBaseline`.
5. (Optional) For **Description**, enter a description for this patch baseline.
6. For **Operating system**, choose an operating system, for example, `Red Hat Enterprise Linux`.
7. If you want to begin using this patch baseline as the default for the selected operating system as soon as you create it, check the box next to **Set this patch baseline as the default patch baseline for *`operating system name`* instances**.

   > **Note**
   >
   > This option is available only if you first accessed Patch Manager before the patch policies release on December 22, 2022.

For information about setting an existing patch baseline as the default, see Setting an existing patch baseline as the default.

8. In the **Approval rules for operating-systems** section, use the fields to create one or more auto-approval rules.

   - **Products**: The version of the operating systems the approval rule applies to, such as `RedhatEnterpriseLinux7.4`. The default selection is `All`.
   - **Classification**: The type of patches the approval rule applies to, such as `Security` or `Enhancement`. The default selection is `All`.

   Tip

   You can configure a patch baseline to control whether minor version upgrades for Linux are installed, such as RHEL 7.8. Minor version upgrades can be installed automatically by Patch Manager provided that the update is available in the appropriate repository.
   For Linux operating systems, minor version upgrades aren't classified consistently. They can be classified as bug fixes or security updates, or not classified, even within the same kernel version. Here are a few options for controlling whether a patch baseline installs them.

   - **Option 1**: The broadest approval rule to ensure minor version upgrades are installed when available is to specify **Classification** as `All` (*) and choose the **Include nonsecurity updates** option.
   - **Option 2**: To ensure patches for an operating system version are installed, you can use a wildcard (*) to specify its kernel format in the **Patch exceptions** section of the baseline. For example, the kernel format for RHEL 7.* is `kernel-3.10.0-*.el7.x86_64`.

     Enter `kernel-3.10.0-*.el7.x86_64` in the **Approved patches** list in your patch baseline to ensure all patches, including minor version upgrades, are applied to your RHEL 7.* managed nodes. (If you know the exact package name of a minor version patch, you can enter that instead.)
   - **Option 3**: You can have the most control over which patches are applied to your managed nodes, including minor version upgrades, by using the InstallOverrideList

parameter in the `AWS-RunPatchBaseline` document. For more information, see SSM Command document for patching: `AWS-RunPatchBaseline`.

- **Severity**: The severity value of patches the rule is to apply to, such as `Critical`. The default selection is `All`.
- **Auto-approval**: The method for selecting patches for automatic approval.

> **Note**
>
> Because it's not possible to reliably determine the release dates of update packages for Ubuntu Server, the auto-approval options aren't supported for this operating system.

  - **Approve patches after a specified number of days**: The number of days for Patch Manager to wait after a patch is released or last updated before a patch is automatically approved. You can enter any integer from zero (0) to 360. For most scenarios, we recommend waiting no more than 100 days.
  - **Approve patches released up to a specific date**: The patch release date for which Patch Manager automatically applies all patches released or updated on or before that date. For example, if you specify July 7, 2023, no patches released or last updated on or after July 8, 2023, are installed automatically.
- (Optional) **Compliance reporting**: The severity level you want to assign to patches approved by the baseline, such as `Critical` or `High`.

> **Note**
>
> If you specify a compliance reporting level and the patch state of any approved patch is reported as `Missing`, then the patch baseline's overall reported compliance severity is the severity level you specified.

- **Include non-security updates**: Select the check box to install nonsecurity Linux operating system patches made available in the source repository, in addition to the security-related patches.

For more information about working with approval rules in a custom patch baseline, see Custom baselines.

9. If you want to explicitly approve any patches in addition to those meeting your approval rules, do the following in the **Patch exceptions** section:

   - For **Approved patches**, enter a comma-separated list of the patches you want to approve.

     For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.
   - (Optional) For **Approved patches compliance level**, assign a compliance level to the patches in the list.
   - If any approved patches you specify aren't related to security, select the **Include non-security updates** check box for these patches to be installed on your Linux operating system as well.

10. If you want to explicitly reject any patches that otherwise meet your approval rules, do the following in the **Patch exceptions** section:

    - For **Rejected patches**, enter a comma-separated list of the patches you want to reject.

      For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.
    - For **Rejected patches action**, select the action for Patch Manager to take on patches included in the **Rejected patches** list.
      - **Allow as dependency**: A package in the **Rejected patches** list is installed only if it's a dependency of another package. It's considered compliant with the patch baseline and its status is reported as *InstalledOther*. This is the default action if no option is specified.
      - **Block**: Packages in the **Rejected patches** list, and packages that include them as dependencies, aren't installed by Patch Manager under any circumstances. If a package was installed before it was added to the **Rejected patches** list, or is installed outside of Patch Manager afterward, it's considered noncompliant with the patch baseline and its status is reported as *InstalledRejected*.

> **Note**
>
> Patch Manager searches for patch dependencies recursively.

11. (Optional) If you want to specify alternative patch repositories for different versions of an operating system, such as *AmazonLinux2016.03* and *AmazonLinux2017.09*, do the following for each product in the **Patch sources** section:

    - In **Name**, enter a name to help you identify the source configuration.
    - In **Product**, select the version of the operating systems the patch source repository is for, such as `RedhatEnterpriseLinux7.4`.
    - In **Configuration**, enter the value of the repository configuration to use in the appropriate format:

      Example for yum repositories

      ```
      [main]
      name=MyCustomRepository
      baseurl=https://my-custom-repository
      enabled=1
      ```

      > **Tip**
      >
      > For information about other options available for your yum repository configuration, see dnf.conf(5).

      Examples for Ubuntu Server and Debian Server

      ```
      deb http://security.ubuntu.com/ubuntu jammy main
      ```

      ```
      deb https://site.example.com/debian distribution component1
      component2 component3
      ```

      Repo information for Ubuntu Server repositories must be specifed in a single line. For more examples and information, see jammy (5) sources.list.5.gz on the *Ubuntu Server Manuals* website and sources.list format on the *Debian Wiki*.

Choose **Add another source** to specify a source repository for each additional operating system version, up to a maximum of 20.

For more information about alternative source patch repositories, see How to specify an alternative patch source repository (Linux).

12. (Optional) For **Manage tags**, apply one or more tag key name/value pairs to the patch baseline.

    Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a patch baseline to identify the severity level of patches it specifies, the operating system family it applies to, and the environment type. In this case, you could specify tags similar to the following key name/value pairs:

    - `Key=PatchSeverity,Value=Critical`
    - `Key=OS,Value=RHEL`
    - `Key=Environment,Value=Production`

13. Choose **Create patch baseline**.

Creating a custom patch baseline for macOS

Use the following procedure to create a custom patch baseline for macOS managed nodes in Patch Manager, a tool in AWS Systems Manager.

For information about creating a patch baseline for Windows Server managed nodes, see Creating a custom patch baseline for Windows Server. For information about creating a patch baseline for Linux managed nodes, see Creating a custom patch baseline for Linux.

> **Note**
>
> macOS is not supported in all AWS Regions. For more information about Amazon EC2 support for macOS, see Amazon EC2 Mac instances in the *Amazon EC2 User Guide*.

To create a custom patch baseline for macOS managed nodes

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Patch baselines** tab, and then choose **Create patch baseline**.

   -or-

   If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, choose the **Patch baselines** tab, and then choose **Create patch baseline**.
4. For **Name**, enter a name for your new patch baseline, for example, `MymacOSPatchBaseline`.
5. (Optional) For **Description**, enter a description for this patch baseline.
6. For **Operating system**, choose macOS.
7. If you want to begin using this patch baseline as the default for macOS as soon as you create it, check the box next to **Set this patch baseline as the default patch baseline for macOS instances**.

   > **Note**
   >
   > This option is available only if you first accessed Patch Manager before the patch policies release on December 22, 2022.
   > For information about setting an existing patch baseline as the default, see Setting an existing patch baseline as the default.
8. In the **Approval rules for operating-systems** section, use the fields to create one or more auto-approval rules.

   - **Products**: The version of the operating systems the approval rule applies to, such as `BigSur11.3.1` or `Ventura13.7`. The default selection is `All`.
   - **Classification**: The package manager or package managers that you want to apply packages during the patching process. You can choose from the following:
     - softwareupdate
     - installer
     - brew
     - brew cask

The default selection is `All`.

- (Optional) **Compliance reporting**: The severity level you want to assign to patches approved by the baseline, such as `Critical` or `High`.

> **Note**
>
> If you specify a compliance reporting level and the patch state of any approved patch is reported as `Missing`, then the patch baseline's overall reported compliance severity is the severity level you specified.

For more information about working with approval rules in a custom patch baseline, see Custom baselines.

9. If you want to explicitly approve any patches in addition to those meeting your approval rules, do the following in the **Patch exceptions** section:

   - For **Approved patches**, enter a comma-separated list of the patches you want to approve.

     For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

   - (Optional) For **Approved patches compliance level**, assign a compliance level to the patches in the list.

10. If you want to explicitly reject any patches that otherwise meet your approval rules, do the following in the **Patch exceptions** section:

    - For **Rejected patches**, enter a comma-separated list of the patches you want to reject.

      For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

    - For **Rejected patches action**, select the action for Patch Manager to take on patches included in the **Rejected patches** list.

      - **Allow as dependency**: A package in the **Rejected patches** list is installed only if it's a dependency of another package. It's considered compliant with the patch baseline and its status is reported as *InstalledOther*. This is the default action if no option is specified.
      - **Block**: Packages in the **Rejected patches** list, and packages that include them as dependencies, aren't installed by Patch Manager under any circumstances. If a package

was installed before it was added to the **Rejected patches** list, or is installed outside of Patch Manager afterward, it's considered noncompliant with the patch baseline and its status is reported as *InstalledRejected*.

11. (Optional) For **Manage tags**, apply one or more tag key name/value pairs to the patch baseline.

    Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a patch baseline to identify the severity level of patches it specifies, the package manager it applies to, and the environment type. In this case, you could specify tags similar to the following key name/value pairs:

    - `Key=PatchSeverity,Value=Critical`
    - `Key=PackageManager,Value=softwareupdate`
    - `Key=Environment,Value=Production`

12. Choose **Create patch baseline**.

Creating a custom patch baseline for Windows Server

Use the following procedure to create a custom patch baseline for Windows managed nodes in Patch Manager, a tool in AWS Systems Manager.

For information about creating a patch baseline for Linux managed nodes, see Creating a custom patch baseline for Linux. Fo information about creating a patch baseline for macOS managed nodes, see Creating a custom patch baseline for macOS.

For an example of creating a patch baseline that is limited to installing Windows Service Packs only, see Tutorial: Create a patch baseline for installing Windows Service Packs using the console.

To create a custom patch baseline (Windows)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Patch baselines** tab, and then choose **Create patch baseline**.

   -or-

If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, choose the **Patch baselines** tab, and then choose **Create patch baseline**.

4. For **Name**, enter a name for your new patch baseline, for example, `MyWindowsPatchBaseline`.
5. (Optional) For **Description**, enter a description for this patch baseline.
6. For **Operating system**, choose `Windows`.
7. For **Available security updates compliance status**, choose the status you want to assign to security patches that are available but not approved because they don't meet the installation criteria specified in the patch baseline, **Non-Compliant** or **Compliant**.

   Example scenario: Security patches that you might want installed can be skipped if you have specified a long period to wait after a patch is released before installation. If an update to the patch is released during your specified waiting period, the waiting period for installing the patch starts over. If the waiting period is too long, multiple versions of the patch could be released but never installed.
8. If you want to begin using this patch baseline as the default for Windows as soon as you create it, select **Set this patch baseline as the default patch baseline for Windows Server instances**.

   > **Note**
   >
   > This option is available only if you first accessed Patch Manager before the patch policies release on December 22, 2022.
   > For information about setting an existing patch baseline as the default, see Setting an existing patch baseline as the default.
9. In the **Approval rules for operating systems** section, use the fields to create one or more auto-approval rules.

   - **Products**: The version of the operating systems the approval rule applies to, such as `WindowsServer2012`. The default selection is `All`.
   - **Classification**: The type of patches the approval rule applies to, such as `CriticalUpdates`, `Drivers`, and `Tools`. The default selection is `All`.

> **Tip**
>
> You can include Windows Service Pack installations in your approval rules by including `ServicePacks` or by choosing `All` in your **Classification** list. For an example, see Tutorial: Create a patch baseline for installing Windows Service Packs using the console.

- **Severity**: The severity value of patches the rule is to apply to, such as `Critical`. The default selection is `All`.
- **Auto-approval**: The method for selecting patches for automatic approval.
  - **Approve patches after a specified number of days**: The number of days for Patch Manager to wait after a patch is released or updated before a patch is automatically approved. You can enter any integer from zero (0) to 360. For most scenarios, we recommend waiting no more than 100 days.
  - **Approve patches released up to a specific date**: The patch release date for which Patch Manager automatically applies all patches released or updated on or before that date. For example, if you specify July 7, 2023, no patches released or last updated on or after July 8, 2023, are installed automatically.
- (Optional) **Compliance reporting**: The severity level you want to assign to patches approved by the baseline, such as `High`.

> **Note**
>
> If you specify a compliance reporting level and the patch state of any approved patch is reported as `Missing`, then the patch baseline's overall reported compliance severity is the severity level you specified.

10. (Optional) In the **Approval rules for applications** section, use the fields to create one or more auto-approval rules.

> **Note**
>
> Instead of specifying approval rules, you can specify lists of approved and rejected patches as patch exceptions. See steps 10 and 11.

- **Product family**: The general Microsoft product family for which you want to specify a rule, such as `Office` or `Exchange Server`.
- **Products**: The version of the application the approval rule applies to, such as `Office 2016` or `Active Directory Rights Management Services Client 2.0 2016`. The default selection is `All`.
- **Classification**: The type of patches the approval rule applies to, such as `CriticalUpdates`. The default selection is `All`.
- **Severity**: The severity value of patches the rule applies to, such as `Critical`. The default selection is `All`.
- **Auto-approval**: The method for selecting patches for automatic approval.
  - **Approve patches after a specified number of days**: The number of days for Patch Manager to wait after a patch is released or updated before a patch is automatically approved. You can enter any integer from zero (0) to 360. For most scenarios, we recommend waiting no more than 100 days.
  - **Approve patches released up to a specific date**: The patch release date for which Patch Manager automatically applies all patches released or updated on or before that date. For example, if you specify July 7, 2023, no patches released or last updated on or after July 8, 2023, are installed automatically.
- (Optional) **Compliance reporting**: The severity level you want to assign to patches approved by the baseline, such as `Critical` or `High`.

> **Note**
>
> If you specify a compliance reporting level and the patch state of any approved patch is reported as `Missing`, then the patch baseline's overall reported compliance severity is the severity level you specified.

11. (Optional) If you want to explicitly approve any patches instead of letting patches be selected according to approval rules, do the following in the **Patch exceptions** section:

    - For **Approved patches**, enter a comma-separated list of the patches you want to approve.

      For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

- (Optional) For **Approved patches compliance level**, assign a compliance level to the patches in the list.

12. If you want to explicitly reject any patches that otherwise meet your approval rules, do the following in the **Patch exceptions** section:

    - For **Rejected patches**, enter a comma-separated list of the patches you want to reject.

      For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

    - For **Rejected patches action**, select the action for Patch Manager to take on patches included in the **Rejected patches** list.
      - **Allow as dependency**: Windows Server doesn't support the concept of package dependencies. If a package in the **Rejected patches** list and already installed on the node, its status is reported as `INSTALLED_OTHER`. Any package not already installed on the node is skipped.
      - **Block**: Packages in the **Rejected patches** list aren't installed by Patch Manager under any circumstances. If a package was installed before it was added to the **Rejected patches** list, or is installed outside of Patch Manager afterward, it's considered noncompliant with the patch baseline and its status is reported as `INSTALLED_REJECTED`.

      For more information about rejected package actions, see Rejected patch list options in custom patch baselines.

13. (Optional) For **Manage tags**, apply one or more tag key name/value pairs to the patch baseline.

    Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a patch baseline to identify the severity level of patches it specifies, the operating system family it applies to, and the environment type. In this case, you could specify tags similar to the following key name/value pairs:

    - `Key=PatchSeverity,Value=Critical`
    - `Key=OS,Value=RHEL`
    - `Key=Environment,Value=Production`

14. Choose **Create patch baseline**.

Updating or deleting a custom patch baseline

You can update or delete a custom patch baseline that you have created in Patch Manager, a tool in AWS Systems Manager. When you update a patch baseline, you can change its name or description, its approval rules, and its exceptions for approved and rejected patches. You can also update the tags that are applied to the patch baseline. You can't change the operating system type that a patch baseline has been created for, and you can't make changes to a predefined patch baseline provided by AWS.

Updating or deleting a patch baseline

Follow these steps to update or delete a patch baseline.

> **Important**
>
> Use caution when deleting a custom patch baseline that might be used by a patch policy configuration in Quick Setup.
> If you are using a patch policy configuration in Quick Setup, updates you make to custom patch baselines are synchronized with Quick Setup once an hour.
> If a custom patch baseline that was referenced in a patch policy is deleted, a banner displays on the Quick Setup **Configuration details** page for your patch policy. The banner informs you that the patch policy references a patch baseline that no longer exists, and that subsequent patching operations will fail. In this case, return to the Quick Setup **Configurations** page, select the Patch Manager configuration , and choose **Actions**, **Edit configuration**. The deleted patch baseline name is highlighted, and you must select a new patch baseline for the affected operating system.

To update or delete a patch baseline

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the patch baseline that you want to update or delete, and then do one of the following:

   - To remove the patch baseline from your AWS account, choose **Delete**. The system prompts you to confirm your actions.

- To make changes to the patch baseline name or description, approval rules, or patch exceptions, choose **Edit**. On the **Edit patch baseline** page, change the values and options that you want, and then choose **Save changes**.
- To add, change, or delete tags applied to the patch baseline, choose the **Tags** tab, and then choose **Edit tags**. On the **Edit patch baseline tags** page, make updates to the patch baseline tags, and then choose **Save changes**.

For information about the configuration choices you can make, see Working with custom patch baselines.

Setting an existing patch baseline as the default

> **Important**
>
> Any default patch baseline selections you make here do not apply to patching operations that are based on a patch policy. Patch policies use their own patch baseline specifications. For more information about patch policies, see Patch policy configurations in Quick Setup.

When you create a custom patch baseline in Patch Manager, a tool in AWS Systems Manager, you can set the baseline as the default for the associated operating system type as soon as you create it. For information, see Working with custom patch baselines.

You can also set an existing patch baseline as the default for an operating system type.

> **Note**
>
> The steps you follow depend on whether you first accessed Patch Manager before or after the patch policies release on December 22, 2022. If you used Patch Manager before that date, you can use the console procedure. Otherwise, use the AWS CLI procedure. The **Actions** menu referenced in the console procedure is not displayed in Regions where Patch Manager wasn't used before the patch policies release.

To set a patch baseline as the default

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Patch baselines** tab.
4. In the patch baselines list, choose the button of a patch baseline that isn't currently set as the default for an operating system type.

   The **Default baseline** column indicates which baselines are currently set as the defaults.
5. In the **Actions** menu, choose **Set default patch baseline**.

   > **Important**
   >
   > The **Actions** menu is not available if you didn't work with Patch Manager in the current AWS account and Region before December 22, 2022. See the **Note** earlier in this topic for more information.
6. In the confirmation dialog box, choose **Set default**.

To set a patch baseline as the default (AWS CLI)

1. Run the describe-patch-baselines command to view a list of available patch baselines and their IDs and Amazon Resource Names (ARNs).

   ```
   aws ssm describe-patch-baselines
   ```
2. Run the register-default-patch-baseline command to set a baseline as the default for the operating system it's associated with. Replace *baseline-id-or-ARN* with the ID of the custom patch baseline or predefined baseline to use.

   Linux & macOS

   ```
   aws ssm register-default-patch-baseline \
       --baseline-id baseline-id-or-ARN
   ```

   The following is an example of a setting a custom baseline as the default.

```
aws ssm register-default-patch-baseline \
    --baseline-id pb-abc123cf9bEXAMPLE
```

The following is an example of a setting a predefined baseline managed by AWS as the default.

```
aws ssm register-default-patch-baseline \
    --baseline-id arn:aws:ssm:us-east-2:733109147000:patchbaseline/
pb-0574b43a65ea646e
```

Windows Server

```
aws ssm register-default-patch-baseline ^
    --baseline-id baseline-id-or-ARN
```

The following is an example of a setting a custom baseline as the default.

```
aws ssm register-default-patch-baseline ^
    --baseline-id pb-abc123cf9bEXAMPLE
```

The following is an example of a setting a predefined baseline managed by AWS as the default.

```
aws ssm register-default-patch-baseline ^
    --baseline-id arn:aws:ssm:us-east-2:733109147000:patchbaseline/
pb-071da192df1226b63
```

Viewing available patches

With Patch Manager, a tool in AWS Systems Manager, you can view all available patches for a specified operating system and, optionally, a specific operating system version.

> **Tip**
>
> To generate a list of available patches and save them to a file, you can use the describe-available-patches command and specify your preferred output.

To view available patches

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Patches** tab.

   -or-

   If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, and then choose the **Patches** tab.

   > **Note**
   >
   > For Windows Server, the **Patches** tab displays updates that are available from Windows Server Update Service (WSUS).

4. For **Operating system**, choose the operating system for which you want to view available patches, such as `Windows` or `Amazon Linux`.
5. (Optional) For **Product**, choose an OS version, such as `WindowsServer2019` or `AmazonLinux2018.03`.
6. (Optional) To add or remove information columns for your results, choose the configure button
   ()
   at the top right of the **Patches** list. (By default, the **Patches** tab displays columns for only some of the available patch metadata.)

   For information about the types of metadata you can add to your view, see Patch in the *AWS Systems Manager API Reference*.

Creating and managing patch groups

If you are *not* using patch policies in your operations, you can organize your patching efforts by adding managed nodes to patch groups by using tags.

> **Note**
>
> Patch groups are not used in patching operations that are based on *patch policies*. For information about working with patch policies, see Patch policy configurations in Quick Setup.
>
> Patch group functionality is not supported in the console for account-Region pairs that did not already use patch groups before patch policy support was released on December 22, 2022. Patch group functionality is still available in account-Region pairs that began using patch groups before this date.

To use tags in patching operations, you must apply the tag key `Patch Group` or `PatchGroup` to your managed nodes. You must also specify the name that you want to give the patch group as the value of the tag. You can specify any tag value, but the tag key must be `Patch Group` or `PatchGroup`.

`PatchGroup` (without a space) is required if you have allowed tags in EC2 instance metadata.

After you group your managed nodes using tags, you add the patch group value to a patch baseline. By registering the patch group with a patch baseline, you ensure that the correct patches are installed during the patching operation. For more information about patch groups, see Patch groups.

Complete the tasks in this topic to prepare your managed nodes for patching using tags with your nodes and patch baseline. Task 1 is required only if you are patching Amazon EC2 instances. Task 2 is required only if you are patching non-EC2 instances in a hybrid and multicloud environment. Task 3 is required for all managed nodes.

> **Tip**
>
> You can also add tags to managed nodes using the AWS CLI command `add-tags-to-resource` or the Systems Manager API operation ssm-agent-minimum-s3-permissions-required`AddTagsToResource`.

Tasks

- Task 1: Add EC2 instances to a patch group using tags
- Task 2: Add managed nodes to a patch group using tags

- Task 3: Add a patch group to a patch baseline

Task 1: Add EC2 instances to a patch group using tags

You can add tags to EC2 instances using the Systems Manager console or the Amazon EC2 console. This task is required only if you are patching Amazon EC2 instances.

> **Important**
>
> You can't apply the `Patch Group` tag (with a space) to an Amazon EC2 instance if the **Allow tags in instance metadata** option is enabled on the instance. Allowing tags in instance metadata prevents tag key names from containing spaces. If you have allowed tags in EC2 instance metadata, you must use the tag key `PatchGroup` (without a space).

Option 1: To add EC2 instances to a patch group (Systems Manager console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. In the **Managed nodes** list, choose the ID of a managed EC2 instance that you want to configure for patching. Node IDs for EC2 instances begin with `i-`.

   > **Note**
   >
   > When using the Amazon EC2 console and AWS CLI, it's possible to apply `Key = Patch Group` or `Key = PatchGroup` tags to instances that aren't yet configured for use with Systems Manager.
   > If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

4. Choose the **Tags** tab, then choose **Edit**.
5. In the left column, enter **`Patch Group`** or **`PatchGroup`**. If you have allowed tags in EC2 instance metadata, you must use `PatchGroup` (without a space).
6. In the right column, enter a tag value to serve as the name for the patch group.
7. Choose **Save**.
8. Repeat this procedure to add other EC2 instances to the same patch group.

Option 2: To add EC2 instances to a patch group (Amazon EC2 console)

1. Open the Amazon EC2 console, and then choose **Instances** in the navigation pane.
2. In the list of instances, choose an instance that you want to configure for patching.
3. In the **Actions** menu, choose **Instance settings**, **Manage tags**.
4. Choose **Add new tag**.
5. For **Key**, enter **`Patch Group`** or **`PatchGroup`**. If you have allowed tags in EC2 instance metadata, you must use `PatchGroup` (without a space).
6. For **Value**, enter a value to serve as the name for the patch group.
7. Choose **Save**.
8. Repeat this procedure to add other instances to the same patch group.

Task 2: Add managed nodes to a patch group using tags

Follow the steps in this topic to add tags to AWS IoT Greengrass core devices and non-EC2 hybrid-activated managed nodes (mi-*). This task is required only if you are patching non-EC2 instances in a hybrid and multicloud environment.

> **Note**
>
> You can't add tags for non-EC2 managed nodes using the Amazon EC2 console.

To add non-EC2 managed nodes to a patch group (Systems Manager console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. In the **Managed nodes** list, choose the name of the managed node that you want to configure for patching.

   > **Note**
   >
   > If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

4. Choose the **Tags** tab, then choose **Edit**.
5. In the left column, enter **`Patch Group`** or **`PatchGroup`**. If you have allowed tags in EC2 instance metadata, you must use `PatchGroup` (without a space).
6. In the right column, enter a tag value to serve as the name for the patch group.
7. Choose **Save**.
8. Repeat this procedure to add other managed nodes to the same patch group.

Task 3: Add a patch group to a patch baseline

To associate a specific patch baseline with your managed nodes, you must add the patch group value to the patch baseline. By registering the patch group with a patch baseline, you can ensure that the correct patches are installed during a patching operation. This task is required whether you are patching EC2 instances, non-EC2 managed nodes, or both.

For more information about patch groups, see Patch groups.

> **Note**
>
> The steps you follow depend on whether you first accessed Patch Manager before or after the patch policies release on December 22, 2022.

To add a patch group to a patch baseline (Systems Manager console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.
3. If you're accessing Patch Manager for the first time in the current AWS Region and the Patch Manager start page opens, choose **Start with an overview**.
4. Choose the **Patch baselines** tab, and then in the **Patch baselines** list, choose the name of the patch baseline that you want to configure for your patch group.

   If you didn't first access Patch Manager until after the patch policies release, you must choose a custom baseline that you have created.
5. If the **Baseline ID** details page includes an **Actions** menu, do the following:

   - Choose **Actions**, then **Modify patch groups**.

- Enter the tag *value* you added to your managed nodes in Task 2: Add managed nodes to a patch group using tags, then choose **Add**.

If the **Baseline ID** details page does *not* include an **Actions** menu, patch groups can't be configured in the console. Instead, you can do either of the following:

- (Recommended) Set up a patch policy in Quick Setup, a tool in AWS Systems Manager, to map a patch baseline to one or more EC2 instances.

  For more information, see Using Quick Setup patch policies and Automate organization-wide patching using a Quick Setup patch policy.
- Use the register-patch-baseline-for-patch-group command in the AWS Command Line Interface (AWS CLI) to configure a patch group.

Integrating Patch Manager with AWS Security Hub

AWS Security Hub provides you with a comprehensive view of your security state in AWS. Security Hub collects security data from across AWS accounts, AWS services, and supported third-party partner products. With Security Hub, you can check your environment against security industry standards and best practices. Security Hub helps you to analyze your security trends and identify the highest priority security issues.

By using the integration between Patch Manager, a tool in AWS Systems Manager, and Security Hub, you can send findings about noncompliant nodes from Patch Manager to Security Hub. A finding is the observable record of a security check or security-related detection. Security Hub can then include those patch-related findings in its analysis of your security posture.

The information in the following topics applies no matter which method or type of configuration you are using for your patching operations:

- A patch policy configured in Quick Setup
- A Host Management option configured in Quick Setup
- A maintenance window to run a patch `Scan` or `Install` task
- An on-demand **Patch now** operation

Contents

- How to stop sending findings

How Patch Manager sends findings to Security Hub

In Security Hub, security issues are tracked as findings. Some findings come from issues that are detected by other AWS services or by third-party partners. Security Hub also has a set of rules that it uses to detect security issues and generate findings.

Patch Manager is one of the Systems Manager tools that sends findings to Security Hub. After you perform a patching operation by running a SSM document (`AWS-RunPatchBaseline`, `AWS-RunPatchBaselineAssociation`, or `AWS-RunPatchBaselineWithHooks`), the patching information is sent to Inventory or Compliance, tools in AWS Systems Manager, or both. After Inventory, Compliance, or both receive the data, Patch Manager receives a notification. Then, Patch Manager evaluates the data for accuracy, formatting, and compliance. If all conditions are met, Patch Manager forwards the data to Security Hub.

Security Hub provides tools to manage findings from across all of these sources. You can view and filter lists of findings and view details for a finding. For more information, see Viewing findings in the *AWS Security Hub User Guide*. You can also track the status of an investigation into a finding. For more information, see Taking action on findings in the *AWS Security Hub User Guide*.

All findings in Security Hub use a standard JSON format called the AWS Security Finding Format (ASFF). The ASFF includes details about the source of the issue, the affected resources, and the current status of the finding. For more information, see AWS Security Finding Format (ASFF) in the *AWS Security Hub User Guide*.

Types of findings that Patch Manager sends

Patch Manager sends the findings to Security Hub using the AWS Security Finding Format (ASFF). In ASFF, the `Types` field provides the finding type. Findings from Patch Manager have the following value for `Types`:

- Software and Configuration Checks/Patch Management

Patch Manager sends one finding per noncompliant managed node. The finding is reported with the resource type `AwsEc2Instance` so that findings can be correlated with other Security Hub integrations that report `AwsEc2Instance` resource types. Patch Manager only forwards a finding to Security Hub if the operation discovered the managed node to be noncompliant. The finding includes the Patch Summary results.

> **Note**
>
> After reporting a noncompliant node to Security Hub. Patch Manager doesn't send an update to Security Hub after the node is made compliant. You can manually resolve findings in Security Hub after the required patches have been applied to the managed node.

For more information about compliance definitions, see Patch compliance state values. For more information about `PatchSummary`, see PatchSummary in the *AWS Security Hub API Reference*.

Latency for sending findings

When Patch Manager creates a new finding, it's usually sent to Security Hub within a few seconds to 2 hours. The speed depends on the traffic in the AWS Region being processed at that time.

Retrying when Security Hub isn't available

If there is a service outage, an AWS Lambda function is run to put the messages back into the main queue after the service is running again. After the messages are in the main queue, the retry is automatic.

If Security Hub isn't available, Patch Manager retries sending the findings until they're received.

Viewing findings in Security Hub

This procedure describes how to view findings in Security Hub about managed nodes in your fleet that are out of patch compliance.

To review Security Hub findings for patch compliance

1. Sign in to the AWS Management Console and open the AWS Security Hub console at https://console.aws.amazon.com/securityhub/.

2. In the navigation pane, choose **Findings**.
3. Choose the **Add filters** () box.
4. In the menu, under **Filters**, choose **Product name**.
5. In the dialog box that opens, choose **is** in the first field and then enter **`Systems Manager Patch Manager`** in the second field.
6. Choose **Apply**.
7. Add any additional filters you want to help narrow down your results.
8. In the list of results, choose the title of a finding you want more information about.

   A pane opens on the right side of the screen with more details about the resource, the issue discovered, and a recommended remediation.

   > **Important**
   >
   > At this time, Security Hub reports the resource type of all managed nodes as `EC2 Instance`. This includes on-premises servers and virtual machines (VMs) that you have registered for use with Systems Manager.

Severity classifications

The list of findings for **`Systems Manager Patch Manager`** includes a report of the severity of the finding. **Severity** levels include the following, from lowest to highest:

- **INFORMATIONAL** – No issue was found.
- **LOW** – The issue does not require remediation.
- **MEDIUM** – The issue must be addressed but is not urgent.
- **HIGH** – The issue must be addressed as a priority.
- **CRITICAL** – The issue must be remediated immediately to avoid escalation.

Severity is determined by the most severe noncompliant package on an instance. Because you can have multiple patch baselines with multiple severity levels, the highest severity is reported out of all the noncompliant packages. For example, suppose you have two noncompliant packages

where the severity of package A is "Critical" and the severity of package B is "Low". "Critical" will be reported as the severity.

Note that the severity field correlates directly with the Patch Manager `Compliance` field. This is a field that you set assign to individual patches that match the rule. Because this `Compliance` field is assigned to individual patches, it is not reflected at the Patch Summary level.

Turning on and configuring the integration

To use the Patch Manager integration with Security Hub, you must turn on Security Hub. For information about how to turn on Security Hub, see Setting up Security Hub in the *AWS Security Hub User Guide*.

The following procedure describes how to integrate Patch Manager and Security Hub when Security Hub is already active but Patch Manager integration is turned off. You only need to complete this procedure if integration was manually turned off.

To add Patch Manager to Security Hub integration

1. In the navigation pane, choose **Patch Manager**.
2. Choose the **Settings** tab.

   -or-

   If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, and then choose the **Settings** tab.
3. Under the **Export to Security Hub** section, to the right of **Patch compliance findings aren't being exported to Security Hub**, choose **Enable**.

How to stop sending findings

To stop sending findings to Security Hub, you can use either the Security Hub console or the API.

For more information, see the following topics in the *AWS Security Hub User Guide*:

- Disabling and enabling the flow of findings from an integration (console)
- Disabling the flow of findings from an integration (Security Hub API, AWS CLI)

Working with Patch Manager resources using the AWS CLI

The section includes examples of AWS Command Line Interface (AWS CLI) commands that you can use to perform configuration tasks for Patch Manager, a tool in AWS Systems Manager.

For an illustration of using the AWS CLI to patch a server environment by using a custom patch baseline, see Tutorial: Patch a server environment using the AWS CLI.

For more information about using the AWS CLI for AWS Systems Manager tasks, see the AWS Systems Manager section of the AWS CLI Command Reference.

Topics

AWS CLI commands for patch baselines

Sample commands for patch baselines

Create a patch baseline

The following command creates a patch baseline that approves all critical and important security updates for Windows Server 2012 R2 5 days after they're released. Patches have also been

specified for the Approved and Rejected patch lists. In addition, the patch baseline has been tagged to indicate that it's for a production environment.

Linux & macOS

```
aws ssm create-patch-baseline \
    --name "Windows-Server-2012R2" \
    --tags "Key=Environment,Value=Production" \
    --description "Windows Server 2012 R2, Important and Critical security updates"
 \
    --approved-patches "KB2032276,MS10-048" \
    --rejected-patches "KB2124261" \
    --rejected-patches-action "ALLOW_AS_DEPENDENCY" \
    --approval-rules
 "PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=MSRC_SEVERITY,Values=[Important,Critical
{Key=CLASSIFICATION,Values=SecurityUpdates},
{Key=PRODUCT,Values=WindowsServer2012R2}]},ApproveAfterDays=5}]"
```

Windows Server

```
aws ssm create-patch-baseline ^
    --name "Windows-Server-2012R2" ^
    --tags "Key=Environment,Value=Production" ^
    --description "Windows Server 2012 R2, Important and Critical security updates"
 ^
    --approved-patches "KB2032276,MS10-048" ^
    --rejected-patches "KB2124261" ^
    --rejected-patches-action "ALLOW_AS_DEPENDENCY" ^
    --approval-rules
 "PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=MSRC_SEVERITY,Values=[Important,Critical
{Key=CLASSIFICATION,Values=SecurityUpdates},
{Key=PRODUCT,Values=WindowsServer2012R2}]},ApproveAfterDays=5}]"
```

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

Create a patch baseline with custom repositories for different OS versions

Applies to Linux managed nodes only. The following command shows how to specify the patch repository to use for a particular version of the Amazon Linux operating system. This sample uses a source repository allowed by default on Amazon Linux 2017.09, but it could be adapted to a different source repository that you have configured for a managed node.

> **Note**
>
> To better demonstrate this more complex command, we're using the `--cli-input-json` option with additional options stored an external JSON file.

1. Create a JSON file with a name like `my-patch-repository.json` and add the following content to it.

```
{
    "Description": "My patch repository for Amazon Linux 2",
    "Name": "Amazon-Linux-2",
    "OperatingSystem": "AMAZON_LINUX_2",
    "ApprovalRules": {
        "PatchRules": [
            {
                "ApproveAfterDays": 7,
                "EnableNonSecurity": true,
                "PatchFilterGroup": {
                    "PatchFilters": [
                        {
                            "Key": "SEVERITY",
                            "Values": [
                                "Important",
                                "Critical"
                            ]
                        },
                        {
                            "Key": "CLASSIFICATION",
                            "Values": [
                                "Security",
                                "Bugfix"
                            ]
                        },
                        {
```

```
                            "Key": "PRODUCT",
                            "Values": [
                                "AmazonLinux2"
                            ]
                        }
                    ]
                }
            }
        ]
    },
    "Sources": [
        {
            "Name": "My-AL2",
            "Products": [
                "AmazonLinux2"
            ],
            "Configuration": "[amzn-main] \nname=amzn-main-Base
\nmirrorlist=http://repo./$awsregion./$awsdomain//$releasever/main/
mirror.list //nmirrorlist_expire=300//nmetadata_expire=300 \npriority=10
 \nfailovermethod=priority \nfastestmirror_enabled=0 \ngpgcheck=1
 \ngpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-amazon-ga \nenabled=1 \nretries=3
 \ntimeout=5\nreport_instanceid=yes"
        }
    ]
}
```

2. In the directory where you saved the file, run the following command.

```
aws ssm create-patch-baseline --cli-input-json file://my-patch-repository.json
```

The system returns information like the following.

```
{
    "BaselineId": "pb-0c10e65780EXAMPLE"
}
```

Update a patch baseline

The following command adds two patches as rejected and one patch as approved to an existing patch baseline.

For information about accepted formats for lists of approved patches and rejected patches, see Package name formats for approved and rejected patch lists.

Linux & macOS

```
aws ssm update-patch-baseline \
    --baseline-id pb-0c10e65780EXAMPLE \
    --rejected-patches "KB2032276" "MS10-048" \
    --approved-patches "KB2124261"
```

Windows Server

```
aws ssm update-patch-baseline ^
    --baseline-id pb-0c10e65780EXAMPLE ^
    --rejected-patches "KB2032276" "MS10-048" ^
    --approved-patches "KB2124261"
```

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE",
   "Name":"Windows-Server-2012R2",
   "RejectedPatches":[
      "KB2032276",
      "MS10-048"
   ],
   "GlobalFilters":{
      "PatchFilters":[

      ]
   },
   "ApprovalRules":{
      "PatchRules":[
         {
            "PatchFilterGroup":{
               "PatchFilters":[
                  {
                     "Values":[
                        "Important",
                        "Critical"
                     ],
                     "Key":"MSRC_SEVERITY"
```

```
                },
                {
                   "Values":[
                      "SecurityUpdates"
                   ],
                   "Key":"CLASSIFICATION"
                },
                {
                   "Values":[
                      "WindowsServer2012R2"
                   ],
                   "Key":"PRODUCT"
                }
             ]
          },
          "ApproveAfterDays":5
       }
    ]
 },
 "ModifiedDate":1481001494.035,
 "CreatedDate":1480997823.81,
 "ApprovedPatches":[
    "KB2124261"
 ],
 "Description":"Windows Server 2012 R2, Important and Critical security updates"
}
```

Rename a patch baseline

Linux & macOS

```
aws ssm update-patch-baseline \
    --baseline-id pb-0c10e65780EXAMPLE \
    --name "Windows-Server-2012-R2-Important-and-Critical-Security-Updates"
```

Windows Server

```
aws ssm update-patch-baseline ^
    --baseline-id pb-0c10e65780EXAMPLE ^
    --name "Windows-Server-2012-R2-Important-and-Critical-Security-Updates"
```

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE",
   "Name":"Windows-Server-2012-R2-Important-and-Critical-Security-Updates",
   "RejectedPatches":[
      "KB2032276",
      "MS10-048"
   ],
   "GlobalFilters":{
      "PatchFilters":[

      ]
   },
   "ApprovalRules":{
      "PatchRules":[
         {
            "PatchFilterGroup":{
               "PatchFilters":[
                  {
                     "Values":[
                        "Important",
                        "Critical"
                     ],
                     "Key":"MSRC_SEVERITY"
                  },
                  {
                     "Values":[
                        "SecurityUpdates"
                     ],
                     "Key":"CLASSIFICATION"
                  },
                  {
                     "Values":[
                        "WindowsServer2012R2"
                     ],
                     "Key":"PRODUCT"
                  }
               ]
            },
            "ApproveAfterDays":5
         }
      ]
   },
   "ModifiedDate":1481001795.287,
```

```
   "CreatedDate":1480997823.81,
   "ApprovedPatches":[
      "KB2124261"
   ],
   "Description":"Windows Server 2012 R2, Important and Critical security updates"
}
```

Delete a patch baseline

```
aws ssm delete-patch-baseline --baseline-id "pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

List all patch baselines

```
aws ssm describe-patch-baselines
```

The system returns information like the following.

```
{
   "BaselineIdentities":[
      {
         "BaselineName":"AWS-DefaultPatchBaseline",
         "DefaultBaseline":true,
         "BaselineDescription":"Default Patch Baseline Provided by AWS.",
         "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/
pb-0c10e65780EXAMPLE"
      },
      {
         "BaselineName":"Windows-Server-2012R2",
         "DefaultBaseline":false,
         "BaselineDescription":"Windows Server 2012 R2, Important and Critical security
 updates",
         "BaselineId":"pb-0c10e65780EXAMPLE"
      }
   ]
}
```

Here is another command that lists all patch baselines in an AWS Region.

Linux & macOS

```
aws ssm describe-patch-baselines \
    --region us-east-2 \
    --filters "Key=OWNER,Values=[All]"
```

Windows Server

```
aws ssm describe-patch-baselines ^
    --region us-east-2 ^
    --filters "Key=OWNER,Values=[All]"
```

The system returns information like the following.

```
{
   "BaselineIdentities":[
      {
         "BaselineName":"AWS-DefaultPatchBaseline",
         "DefaultBaseline":true,
         "BaselineDescription":"Default Patch Baseline Provided by AWS.",
         "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/
pb-0c10e65780EXAMPLE"
      },
      {
         "BaselineName":"Windows-Server-2012R2",
         "DefaultBaseline":false,
         "BaselineDescription":"Windows Server 2012 R2, Important and Critical security
 updates",
         "BaselineId":"pb-0c10e65780EXAMPLE"
      }
   ]
}
```

List all AWS-provided patch baselines

Linux & macOS

```
aws ssm describe-patch-baselines \
    --region us-east-2 \
```

```
    --filters "Key=OWNER,Values=[AWS]"
```

Windows Server

```
aws ssm describe-patch-baselines ^
    --region us-east-2 ^
    --filters "Key=OWNER,Values=[AWS]"
```

The system returns information like the following.

```
{
   "BaselineIdentities":[
      {
         "BaselineName":"AWS-DefaultPatchBaseline",
         "DefaultBaseline":true,
         "BaselineDescription":"Default Patch Baseline Provided by AWS.",
         "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/
pb-0c10e65780EXAMPLE"
      }
   ]
}
```

List my patch baselines

Linux & macOS

```
aws ssm describe-patch-baselines \
    --region us-east-2 \
    --filters "Key=OWNER,Values=[Self]"
```

Windows Server

```
aws ssm describe-patch-baselines ^
    --region us-east-2 ^
    --filters "Key=OWNER,Values=[Self]"
```

The system returns information like the following.

```
{
   "BaselineIdentities":[
```

```
      {
         "BaselineName":"Windows-Server-2012R2",
         "DefaultBaseline":false,
         "BaselineDescription":"Windows Server 2012 R2, Important and Critical security
 updates",
         "BaselineId":"pb-0c10e65780EXAMPLE"
      }
   ]
}
```

Display a patch baseline

```
aws ssm get-patch-baseline --baseline-id pb-0c10e65780EXAMPLE
```

> **Note**
>
> For custom patch baselines, you can specify either the patch baseline ID or the full Amazon Resource Name (ARN). For an AWS-provided patch baseline, you must specify the full ARN. For example, `arn:aws:ssm:us-east-2:075727635805:patchbaseline/pb-0c10e65780EXAMPLE`.

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE",
   "Name":"Windows-Server-2012R2",
   "PatchGroups":[
      "Web Servers"
   ],
   "RejectedPatches":[

   ],
   "GlobalFilters":{
      "PatchFilters":[

      ]
   },
   "ApprovalRules":{
      "PatchRules":[
         {
```

```
            "PatchFilterGroup":{
               "PatchFilters":[
                  {
                     "Values":[
                        "Important",
                        "Critical"
                     ],
                     "Key":"MSRC_SEVERITY"
                  },
                  {
                     "Values":[
                        "SecurityUpdates"
                     ],
                     "Key":"CLASSIFICATION"
                  },
                  {
                     "Values":[
                        "WindowsServer2012R2"
                     ],
                     "Key":"PRODUCT"
                  }
               ]
            },
            "ApproveAfterDays":5
         }
      ]
   },
   "ModifiedDate":1480997823.81,
   "CreatedDate":1480997823.81,
   "ApprovedPatches":[

   ],
   "Description":"Windows Server 2012 R2, Important and Critical security updates"
}
```

Get the default patch baseline

```
aws ssm get-default-patch-baseline --region us-east-2
```

The system returns information like the following.

```
{
   "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
```

```
}
```

Set a custom patch baseline as the default

Linux & macOS

```
aws ssm register-default-patch-baseline \
    --region us-east-2 \
    --baseline-id "pb-0c10e65780EXAMPLE"
```

Windows Server

```
aws ssm register-default-patch-baseline ^
    --region us-east-2 ^
    --baseline-id "pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

Reset an AWS patch baseline as the default

Linux & macOS

```
aws ssm register-default-patch-baseline \
    --region us-east-2 \
    --baseline-id "arn:aws:ssm:us-east-2:123456789012:patchbaseline/
pb-0c10e65780EXAMPLE"
```

Windows Server

```
aws ssm register-default-patch-baseline ^
    --region us-east-2 ^
    --baseline-id "arn:aws:ssm:us-east-2:123456789012:patchbaseline/
pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

Tag a patch baseline

Linux & macOS

```
aws ssm add-tags-to-resource \
    --resource-type "PatchBaseline" \
    --resource-id "pb-0c10e65780EXAMPLE" \
    --tags "Key=Project,Value=Testing"
```

Windows Server

```
aws ssm add-tags-to-resource ^
    --resource-type "PatchBaseline" ^
    --resource-id "pb-0c10e65780EXAMPLE" ^
    --tags "Key=Project,Value=Testing"
```

List the tags for a patch baseline

Linux & macOS

```
aws ssm list-tags-for-resource \
    --resource-type "PatchBaseline" \
    --resource-id "pb-0c10e65780EXAMPLE"
```

Windows Server

```
aws ssm list-tags-for-resource ^
    --resource-type "PatchBaseline" ^
    --resource-id "pb-0c10e65780EXAMPLE"
```

Remove a tag from a patch baseline

Linux & macOS

```
aws ssm remove-tags-from-resource \
```

```
    --resource-type "PatchBaseline" \
    --resource-id "pb-0c10e65780EXAMPLE" \
    --tag-keys "Project"
```

Windows Server

```
aws ssm remove-tags-from-resource ^
    --resource-type "PatchBaseline" ^
    --resource-id "pb-0c10e65780EXAMPLE" ^
    --tag-keys "Project"
```

AWS CLI commands for patch groups

Sample commands for patch groups

- Create a patch group
- Register a patch group "web servers" with a patch baseline
- Register a patch group "Backend" with the AWS-provided patch baseline
- Display patch group registrations
- Deregister a patch group from a patch baseline

Create a patch group

> **Note**
>
> Patch groups are not used in patching operations that are based on *patch policies*. For information about working with patch policies, see Patch policy configurations in Quick Setup.

To help you organize your patching efforts, we recommend that you add managed nodes to patch groups by using tags. Patch groups require use of the tag key `Patch Group` or `PatchGroup`. If you have allowed tags in EC2 instance metadata, you must use `PatchGroup` (without a space). You can specify any tag value, but the tag key must be `Patch Group` or `PatchGroup`. For more information about patch groups, see Patch groups.

After you group your managed nodes using tags, you add the patch group value to a patch baseline. By registering the patch group with a patch baseline, you ensure that the correct patches are installed during the patching operation.

Task 1: Add EC2 instances to a patch group using tags

> **Note**
>
> When using the Amazon Elastic Compute Cloud (Amazon EC2) console and AWS CLI, it's possible to apply `Key = Patch Group` or `Key = PatchGroup` tags to instances that aren't yet configured for use with Systems Manager. If an EC2 instance you expect to see in Patch Manager isn't listed after applying the `Patch Group` or `Key = PatchGroup` tag, see Troubleshooting managed node availability for troubleshooting tips.

Run the following command to add the `PatchGroup` tag to an EC2 instance.

```
aws ec2 create-tags --resources "i-1234567890abcdef0" --tags
 "Key=PatchGroup,Value=GroupValue"
```

Task 2: Add managed nodes to a patch group using tags

Run the following command to add the `PatchGroup` tag to a managed node.

Linux & macOS

```
aws ssm add-tags-to-resource \
    --resource-type "ManagedInstance" \
    --resource-id "mi-0123456789abcdefg" \
    --tags "Key=PatchGroup,Value=GroupValue"
```

Windows Server

```
aws ssm add-tags-to-resource ^
    --resource-type "ManagedInstance" ^
    --resource-id "mi-0123456789abcdefg" ^
    --tags "Key=PatchGroup,Value=GroupValue"
```

Task 3: Add a patch group to a patch baseline

Run the following command to associate a `PatchGroup` tag value to the specified patch baseline.

Linux & macOS

```
aws ssm register-patch-baseline-for-patch-group \
    --baseline-id "pb-0c10e65780EXAMPLE" \
    --patch-group "Development"
```

Windows Server

```
aws ssm register-patch-baseline-for-patch-group ^
    --baseline-id "pb-0c10e65780EXAMPLE" ^
    --patch-group "Development"
```

The system returns information like the following.

```
{
  "PatchGroup": "Development",
  "BaselineId": "pb-0c10e65780EXAMPLE"
}
```

Register a patch group "web servers" with a patch baseline

Linux & macOS

```
aws ssm register-patch-baseline-for-patch-group \
    --baseline-id "pb-0c10e65780EXAMPLE" \
    --patch-group "Web Servers"
```

Windows Server

```
aws ssm register-patch-baseline-for-patch-group ^
    --baseline-id "pb-0c10e65780EXAMPLE" ^
    --patch-group "Web Servers"
```

The system returns information like the following.

```
{
```

```
   "PatchGroup":"Web Servers",
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

Register a patch group "Backend" with the AWS-provided patch baseline

Linux & macOS

```
aws ssm register-patch-baseline-for-patch-group \
    --region us-east-2 \
    --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/
pb-0c10e65780EXAMPLE" \
    --patch-group "Backend"
```

Windows Server

```
aws ssm register-patch-baseline-for-patch-group ^
    --region us-east-2 ^
    --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/
pb-0c10e65780EXAMPLE" ^
    --patch-group "Backend"
```

The system returns information like the following.

```
{
   "PatchGroup":"Backend",
   "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
}
```

Display patch group registrations

```
aws ssm describe-patch-groups --region us-east-2
```

The system returns information like the following.

```
{
   "PatchGroupPatchBaselineMappings":[
      {
         "PatchGroup":"Backend",
         "BaselineIdentity":{
            "BaselineName":"AWS-DefaultPatchBaseline",
```

```
            "DefaultBaseline":false,
            "BaselineDescription":"Default Patch Baseline Provided by AWS.",
            "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/
pb-0c10e65780EXAMPLE"
         }
      },
      {
         "PatchGroup":"Web Servers",
         "BaselineIdentity":{
            "BaselineName":"Windows-Server-2012R2",
            "DefaultBaseline":true,
            "BaselineDescription":"Windows Server 2012 R2, Important and Critical
 updates",
            "BaselineId":"pb-0c10e65780EXAMPLE"
         }
      }
   ]
}
```

Deregister a patch group from a patch baseline

Linux & macOS

```
aws ssm deregister-patch-baseline-for-patch-group \
    --region us-east-2 \
    --patch-group "Production" \
    --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/
pb-0c10e65780EXAMPLE"
```

Windows Server

```
aws ssm deregister-patch-baseline-for-patch-group ^
    --region us-east-2 ^
    --patch-group "Production" ^
    --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/
pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```
{
   "PatchGroup":"Production",
   "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
```

```
}
```

AWS CLI commands for viewing patch summaries and details

Sample commands for viewing patch summaries and details

- Get all patches defined by a patch baseline
- Get all patches for AmazonLinux2018.03 that have a Classification SECURITY and Severity of Critical
- Get all patches for Windows Server 2012 that have a MSRC severity of Critical
- Get all available patches
- Get patch summary states per-managed node
- Get patch compliance details for a managed node
- View patching compliance results (AWS CLI)

Get all patches defined by a patch baseline

> **Note**
>
> This command is supported for Windows Server patch baselines only.

Linux & macOS

```
aws ssm describe-effective-patches-for-patch-baseline \
    --region us-east-2 \
    --baseline-id "pb-0c10e65780EXAMPLE"
```

Windows Server

```
aws ssm describe-effective-patches-for-patch-baseline ^
    --region us-east-2 ^
    --baseline-id "pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```
{
   "NextToken":"--token string truncated--",
```

```
  "EffectivePatches":[
     {
        "PatchStatus":{
           "ApprovalDate":1384711200.0,

Get patch summary states per-managed node

The per-managed node summary gives you the number of patches in the following states per node: "NotApplicable", "Missing", "Failed", "InstalledOther" and "Installed".

Linux & macOS

```
aws ssm describe-instance-patch-states \
    --instance-ids i-08ee91c0b17045407 i-09a618aec652973a9
```

Windows Server

```
aws ssm describe-instance-patch-states ^
    --instance-ids i-08ee91c0b17045407 i-09a618aec652973a9
```

The system returns information like the following.

```
{
   "InstancePatchStates":[
      {
            "InstanceId": "i-08ee91c0b17045407",
            "PatchGroup": "",
            "BaselineId": "pb-0c10e65780EXAMPLE",

        },
    ---output truncated---
```

View patching compliance results (AWS CLI)

To view patch compliance results for a single managed node

Run the following command in the AWS Command Line Interface (AWS CLI) to view patch compliance results for a single managed node.

```
aws ssm describe-instance-patch-states --instance-id instance-id
```

Replace *instance-id* with the ID of the managed node for which you want to view results, in the format `i-02573cafcfEXAMPLE` or `mi-0282f7c436EXAMPLE`.

The systems returns information like the following.

```
{
    "InstancePatchStates": [
        {
            "InstanceId": "i-02573cafcfEXAMPLE",
            "PatchGroup": "mypatchgroup",
            "BaselineId": "pb-0c10e65780EXAMPLE",
            "SnapshotId": "a3f5ff34-9bc4-4d2c-a665-4d1c1EXAMPLE",
            "CriticalNonCompliantCount": 2,
            "SecurityNonCompliantCount": 2,
            "OtherNonCompliantCount": 1,
            "InstalledCount": 123,
            "InstalledOtherCount": 334,
            "InstalledPendingRebootCount": 0,
            "InstalledRejectedCount": 0,
            "MissingCount": 1,
            "FailedCount": 2,
            "UnreportedNotApplicableCount": 11,
            "NotApplicableCount": 2063,
            "OperationStartTime": "2021-05-03T11:00:56-07:00",
            "OperationEndTime": "2021-05-03T11:01:09-07:00",
            "Operation": "Scan",
```

```
            "LastNoRebootInstallOperationTime": "2020-06-14T12:17:41-07:00",
            "RebootOption": "RebootIfNeeded"
        }
    ]
}
```

To view a patch count summary for all EC2 instances in a Region

The `describe-instance-patch-states` supports retrieving results for just one managed instance at a time. However, using a custom script with the `describe-instance-patch-states` command, you can generate a more granular report.

For example, if the jq filter tool is installed on you local machine, you could run the following command to identify which of your EC2 instances in a particular AWS Region have a status of `InstalledPendingReboot`.

```
aws ssm describe-instance-patch-states \
    --instance-ids $(aws ec2 describe-instances --region region | jq
 '.Reservations[].Instances[] | .InstanceId' | tr '\n|"' ' ') \
    --output text --query 'InstancePatchStates[*].{Instance:InstanceId,
 InstalledPendingRebootCount:InstalledPendingRebootCount}'
```

region represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

For example:

```
aws ssm describe-instance-patch-states \
    --instance-ids $(aws ec2 describe-instances --region us-east-2 | jq
 '.Reservations[].Instances[] | .InstanceId' | tr '\n|"' ' ') \
    --output text --query 'InstancePatchStates[*].{Instance:InstanceId,
 InstalledPendingRebootCount:InstalledPendingRebootCount}'
```

The system returns information like the following.

```
1       i-02573cafcfEXAMPLE
0       i-0471e04240EXAMPLE
3       i-07782c72faEXAMPLE
6       i-083b678d37EXAMPLE
0       i-03a530a2d4EXAMPLE
```

```
1       i-01f68df0d0EXAMPLE
0       i-0a39c0f214EXAMPLE
7       i-0903a5101eEXAMPLE
7       i-03823c2fedEXAMPLE
```

In addition to `InstalledPendingRebootCount`, the list of count types you can search for include the following:

- `CriticalNonCompliantCount`
- `SecurityNonCompliantCount`
- `OtherNonCompliantCount`
- `UnreportedNotApplicableCount`
- `InstalledPendingRebootCount`
- `FailedCount`
- `NotApplicableCount`
- `InstalledRejectedCount`
- `InstalledOtherCount`
- `MissingCount`
- `InstalledCount`

AWS CLI commands for scanning and patching managed nodes

After running the following commands to scan for patch compliance or install patches, you can use commands in the AWS CLI commands for viewing patch summaries and details section to view information about patch status and compliance.

Sample commands

- Scan managed nodes for patch compliance (AWS CLI)
- Install patches on managed nodes (AWS CLI)

Scan managed nodes for patch compliance (AWS CLI)

To scan specific managed nodes for patch compliance

Run the following command.

Linux & macOS

```
aws ssm send-command \
    --document-name 'AWS-RunPatchBaseline' \
    --targets Key=InstanceIds,Values='i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE' \
    --parameters 'Operation=Scan' \
    --timeout-seconds 600
```

Windows Server

```
aws ssm send-command ^
    --document-name "AWS-RunPatchBaseline" ^
    --targets Key=InstanceIds,Values="i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE" ^
    --parameters "Operation=Scan" ^
    --timeout-seconds 600
```

The system returns information like the following.

```
{
    "Command": {
        "CommandId": "a04ed06c-8545-40f4-87c2-a0babEXAMPLE",
        "DocumentName": "AWS-RunPatchBaseline",
        "DocumentVersion": "$DEFAULT",
        "Comment": "",
        "ExpiresAfter": 1621974475.267,
        "Parameters": {
            "Operation": [
                "Scan"
            ]
        },
        "InstanceIds": [],
        "Targets": [
            {
                "Key": "InstanceIds",
                "Values": [
                    "i-02573cafcfEXAMPLE,
                     i-0471e04240EXAMPLE"
                ]
            }
        ],
        "RequestedDateTime": 1621952275.267,
        "Status": "Pending",
```

```
        "StatusDetails": "Pending",
        "TimeoutSeconds": 600,

    ---output truncated---

    }
}
```

To scan managed nodes for patch compliance by patch group tag

Run the following command.

Linux & macOS

```
aws ssm send-command \
    --document-name 'AWS-RunPatchBaseline' \
    --targets Key='tag:PatchGroup',Values='Web servers' \
    --parameters 'Operation=Scan' \
    --timeout-seconds 600
```

Windows Server

```
aws ssm send-command ^
    --document-name "AWS-RunPatchBaseline" ^
    --targets Key="tag:PatchGroup",Values="Web servers" ^
    --parameters "Operation=Scan" ^
    --timeout-seconds 600
```

The system returns information like the following.

```
{
    "Command": {
        "CommandId": "87a448ee-8adc-44e0-b4d1-6b429EXAMPLE",
        "DocumentName": "AWS-RunPatchBaseline",
        "DocumentVersion": "$DEFAULT",
        "Comment": "",
        "ExpiresAfter": 1621974983.128,
        "Parameters": {
            "Operation": [
                "Scan"
            ]
        },
```

```
        "InstanceIds": [],
        "Targets": [
            {
                "Key": "tag:PatchGroup",
                "Values": [
                    "Web servers"
                ]
            }
        ],
        "RequestedDateTime": 1621952783.128,
        "Status": "Pending",
        "StatusDetails": "Pending",
        "TimeoutSeconds": 600,

    ---output truncated---

    }
}
```

Install patches on managed nodes (AWS CLI)

To install patches on specific managed nodes

Run the following command.

> **Note**
>
> The target managed nodes reboot as needed to complete patch installation. For more information, see SSM Command document for patching: `AWS-RunPatchBaseline`.

Linux & macOS

```
aws ssm send-command \
    --document-name 'AWS-RunPatchBaseline' \
    --targets Key=InstanceIds,Values='i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE' \
    --parameters 'Operation=Install' \
    --timeout-seconds 600
```

Windows Server

```
aws ssm send-command ^
```

```
    --document-name "AWS-RunPatchBaseline" ^
    --targets Key=InstanceIds,Values="i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE" ^
    --parameters "Operation=Install" ^
    --timeout-seconds 600
```

The system returns information like the following.

```
{
    "Command": {
        "CommandId": "5f403234-38c4-439f-a570-93623EXAMPLE",
        "DocumentName": "AWS-RunPatchBaseline",
        "DocumentVersion": "$DEFAULT",
        "Comment": "",
        "ExpiresAfter": 1621975301.791,
        "Parameters": {
            "Operation": [
                "Install"
            ]
        },
        "InstanceIds": [],
        "Targets": [
            {
                "Key": "InstanceIds",
                "Values": [
                    "i-02573cafcfEXAMPLE,
                     i-0471e04240EXAMPLE"
                ]
            }
        ],
        "RequestedDateTime": 1621953101.791,
        "Status": "Pending",
        "StatusDetails": "Pending",
        "TimeoutSeconds": 600,

    ---output truncated---

    }
}
```

To install patches on managed nodes in a specific patch group

Run the following command.

Linux & macOS

```
aws ssm send-command \
    --document-name 'AWS-RunPatchBaseline' \
    --targets Key='tag:PatchGroup',Values='Web servers' \
    -parameters 'Operation=Install' \
    --timeout-seconds 600
```

Windows Server

```
aws ssm send-command ^
    --document-name "AWS-RunPatchBaseline" ^
    --targets Key="tag:PatchGroup",Values="Web servers" ^
    --parameters "Operation=Install" ^
    --timeout-seconds 600
```

The system returns information like the following.

```
{
    "Command": {
        "CommandId": "fa44b086-7d36-4ad5-ac8d-627ecEXAMPLE",
        "DocumentName": "AWS-RunPatchBaseline",
        "DocumentVersion": "$DEFAULT",
        "Comment": "",
        "ExpiresAfter": 1621975407.865,
        "Parameters": {
            "Operation": [
                "Install"
            ]
        },
        "InstanceIds": [],
        "Targets": [
            {
                "Key": "tag:PatchGroup",
                "Values": [
                    "Web servers"
                ]
            }
        ],

AWS Systems Manager Patch Manager tutorials

The tutorials in this section demonstrate how to use Patch Manager, a tool in AWS Systems Manager, for several patching scenarios.

Topics

- Tutorial: Create a patch baseline for installing Windows Service Packs using the console
- Tutorial: Update application dependencies, patch a managed node, and perform an application-specific health check using the console
- Tutorial: Patch a server environment using the AWS CLI

Tutorial: Create a patch baseline for installing Windows Service Packs using the console

When you create a custom patch baseline, you can specify that all, some, or only one type of supported patch is installed.

In patch baselines for Windows, you can select `ServicePacks` as the only **Classification** option in order to limit patching updates to Service Packs only. Service Packs can be installed automatically by Patch Manager, a tool in AWS Systems Manager, provided that the update is available in Windows Update or Windows Server Update Services (WSUS).

You can configure a patch baseline to control whether Service Packs for all Windows versions are installed, or just those for specific versions, such as Windows 7 or Windows Server 2016.

Use the following procedure to create a custom patch baseline to be used exclusively for installing all Service Packs on your Windows managed nodes.

To create a patch baseline for installing Windows Service Packs (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Patch Manager**.

3. Choose the **Patch baselines** tab, and then choose **Create patch baseline**.
4. For **Name**, enter a name for your new patch baseline, for example, `MyWindowsServicePackPatchBaseline`.
5. (Optional) For **Description**, enter a description for this patch baseline.
6. For **Operating system**, choose `Windows`.
7. If you want to begin using this patch baseline as the default for Windows as soon as you create it, select **Set this patch baseline as the default patch baseline for Windows Server instances**.

> **Note**
>
> This option is available only if you first accessed Patch Manager before the patch policies release on December 22, 2022.
> For information about setting an existing patch baseline as the default, see Setting an existing patch baseline as the default.

8. In the **Approval rules for operating systems** section, use the fields to create one or more auto-approval rules.

- **Products**: The operating system versions that the approval rule applies to, such as `WindowsServer2012`. You can choose one, more than one, or all supported versions of Windows. The default selection is `All`.
- **Classification**: Choose `ServicePacks`.
- **Severity**: The severity value of patches the rule is to apply to. To ensure that all Service Packs are included by the rule, choose `All`.
- **Auto-approval**: The method for selecting patches for automatic approval.
  - **Approve patches after a specified number of days**: The number of days for Patch Manager to wait after a patch is released or updated before a patch is automatically approved. You can enter any integer from zero (0) to 360. For most scenarios, we recommend waiting no more than 100 days.
  - **Approve patches released up to a specific date**: The patch release date for which Patch Manager automatically applies all patches released or updated on or before that date. For example, if you specify July 7, 2023, no patches released or last updated on or after July 8, 2023, are installed automatically.

- (Optional) **Compliance reporting**: The severity level you want to assign to Service Packs approved by the baseline, such as `High`.

> **Note**
>
> If you specify a compliance reporting level and the patch state of any approved Service Pack is reported as `Missing`, then the patch baseline's overall reported compliance severity is the severity level you specified.

9. (Optional) For **Manage tags**, apply one or more tag key name/value pairs to the patch baseline.

   Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For this patch baseline dedicated to updating Service Packs, you could specify key-value pairs such as the following:

   - `Key=OS,Value=Windows`
   - `Key=Classification,Value=ServicePacks`

10. Choose **Create patch baseline**.

Tutorial: Update application dependencies, patch a managed node, and perform an application-specific health check using the console

In many cases, a managed node must be rebooted after it has been patched with the latest software update. However, rebooting a node in production without safeguards in place can cause several problems, such as invoking alarms, recording incorrect metric data, and interrupting data synchronizations.

This tutorial demonstrates how to avoid problems like these by using the AWS Systems Manager document (SSM document) `AWS-RunPatchBaselineWithHooks` to achieve a complex, multi-step patching operation that accomplishes the following:

1. Prevent new connections to the application
2. Install operating system updates
3. Update the package dependencies of the application
4. Restart the system
5. Perform an application-specific health check

For this example, we have set up our infrastructure this way:

- The virtual machines targeted are registered as managed nodes with Systems Manager.
- `Iptables` is used as a local firewall.
- The application hosted on the managed nodes is running on port 443.
- The application hosted on the managed nodes is a `nodeJS` application.
- The application hosted on the managed nodes is managed by the pm2 process manager.
- The application already has a specified health check endpoint.
- The application's health check endpoint requires no end user authentication. The endpoint allows for a health check that meets the organization's requirements in establishing availability. (In your environments, it might be enough to simply ascertain that the `nodeJS` application is running and able to listen for requests. In other cases, you might want to also verify that a connection to the caching layer or database layer has already been established.)

The examples in this tutorial are for demonstration purposes only and not meant to be implemented as-is into production environments. Also, keep in mind that the lifecycle hooks feature of Patch Manager, a tool in Systems Manager, with the `AWS-RunPatchBaselineWithHooks` document can support numerous other scenarios. Here are several examples.

- Stop a metrics reporting agent before patching and restarting it after the managed node reboots.
- Detach the managed node from a CRM or PCS cluster before patching and reattach after the node reboots.
- Update third-party software (for example, Java, Tomcat, Adobe applications, and so on) on Windows Server machines after operating system (OS) updates are applied, but before the managed node reboots.

To update application dependencies, patch a managed node, and perform an application-specific health check

1. Create an SSM document for your preinstallation script with the following contents and name it `NodeJSAppPrePatch`. Replace *`your_application`* with the name of your application.

This script immediately blocks new incoming requests and provides five seconds for already active ones to complete before beginning the patching operation. For the `sleep` option, specify a number of seconds greater than it usually takes for incoming requests to complete.

```
# exit on error
set -e
# set up rule to block incoming traffic
iptables -I INPUT -j DROP -p tcp --syn --destination-port 443 || exit 1
# wait for current connections to end. Set timeout appropriate to your
 application's latency
sleep 5
# Stop your application
pm2 stop your_application
```

For information about creating SSM documents, see Creating SSM document content.

2. Create another SSM document with the following content for your postinstall script to update your application dependencies and name it `NodeJSAppPostPatch`. Replace */your/application/path* with the path to your application.

```
cd /your/application/path
npm update
# you can use npm-check-updates if you want to upgrade major versions
```

3. Create another SSM document with the following content for your `onExit` script to bring your application back up and perform a health check. Name this SSM document `NodeJSApp0nExitPatch`. Replace *your_application* with the name of your application.

```
# exit on error
set -e
# restart nodeJs application
pm2 start your_application
# sleep while your application starts and to allow for a crash
sleep 10
# check with pm2 to see if your application is running
pm2 pid your_application
# re-enable incoming connections
iptables -D INPUT -j DROP -p tcp --syn --destination-port
# perform health check
/usr/bin/curl -m 10 -vk -A "" http://localhost:443/health-check || exit 1
```

4. Create an association in State Manager, a tool in AWS Systems Manager, to issue the operation by performing the following steps:

   1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
   2. In the navigation pane, choose **State Manager**, and then choose **Create association**.
   3. For **Name**, provide a name to help identify the purpose of the association.
   4. In the **Document** list, choose `AWS-RunPatchBaselineWithHooks`.
   5. For **Operation**, choose **Install**.
   6. (Optional) For **Snapshot Id**, provide a GUID that you generate to help speed up the operation and ensure consistency. The GUID value can be as simple as `00000000-0000-0000-0000-111122223333`.
   7. For **Pre Install Hook Doc Name**, enter `NodeJSAppPrePatch`.
   8. For **Post Install Hook Doc Name**, enter `NodeJSAppPostPatch`.
   9. For **On ExitHook Doc Name**,enter `NodeJSAppOnExitPatch`.

5. For **Targets**, identify your managed nodes by specifying tags, choosing nodes manually, choosing a resource group, or choosing all managed nodes.
6. For **Specify schedule**, specify how often to run the association. For managed node patching, once per week is a common cadence.
7. In the **Rate control** section, choose options to control how the association runs on multiple managed nodes. Ensure that only a portion of managed nodes are updated at a time. Otherwise, all or most of your fleet could be taken offline at once. For more information about using rate controls, see Understanding targets and rate controls in State Manager associations.
8. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

   > **Note**
   >
   > The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, verify that

the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

9. Choose **Create Association**.

Tutorial: Patch a server environment using the AWS CLI

The following procedure describes how to patch a server environment by using a custom patch baseline, patch groups, and a maintenance window.

Before you begin

- Install or update the SSM Agent on your managed nodes. To patch Linux managed nodes, your nodes must be running SSM Agent version 2.0.834.0 or later. For more information, see Updating the SSM Agent using Run Command.
- Configure roles and permissions for Maintenance Windows, a tool in AWS Systems Manager. For more information, see Setting up Maintenance Windows.
- Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

  For information, see Installing or updating the latest version of the AWS CLI.

To configure Patch Manager and patch managed nodes (command line)

1. Run the following command to create a patch baseline for Windows named `Production-Baseline`. This patch baseline approves patches for a production environment 7 days after they're released or last updated. That is, we have tagged the patch baseline to indicate that it's for a production environment.

   > **Note**
   >
   > The `OperatingSystem` parameter and `PatchFilters` vary depending on the operating system of the target managed nodes the patch baseline applies to. For more information, see OperatingSystem and PatchFilter.

   Linux & macOS

   ```
   aws ssm create-patch-baseline \
   ```

```
    --name "Production-Baseline" \
    --operating-system "WINDOWS" \
    --tags "Key=Environment,Value=Production" \
    --approval-rules
 "PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=MSRC_SEVERITY,Values=[Critical,Impor
{Key=CLASSIFICATION,Values=[SecurityUpdates,Updates,ServicePacks,UpdateRollups,CriticalU
 \
    --description "Baseline containing all updates approved for production
 systems"
```

Windows Server

```
aws ssm create-patch-baseline ^
    --name "Production-Baseline" ^
    --operating-system "WINDOWS" ^
    --tags "Key=Environment,Value=Production" ^
    --approval-rules
 "PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=MSRC_SEVERITY,Values=[Critical,Impor
{Key=CLASSIFICATION,Values=[SecurityUpdates,Updates,ServicePacks,UpdateRollups,CriticalU
 ^
    --description "Baseline containing all updates approved for production
 systems"
```

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

2. Run the following commands to register the "Production-Baseline" patch baseline for two patch groups. The groups are named "Database Servers" and "Front-End Servers".

   Linux & macOS

   ```
   aws ssm register-patch-baseline-for-patch-group \
       --baseline-id pb-0c10e65780EXAMPLE \
       --patch-group "Database Servers"
   ```

   Windows Server

   ```
   aws ssm register-patch-baseline-for-patch-group ^
   ```

```
    --baseline-id pb-0c10e65780EXAMPLE ^
    --patch-group "Database Servers"
```

The system returns information like the following.

```
{
   "PatchGroup":"Database Servers",
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

Linux & macOS

```
aws ssm register-patch-baseline-for-patch-group \
    --baseline-id pb-0c10e65780EXAMPLE \
    --patch-group "Front-End Servers"
```

Windows Server

```
aws ssm register-patch-baseline-for-patch-group ^
    --baseline-id pb-0c10e65780EXAMPLE ^
    --patch-group "Front-End Servers"
```

The system returns information like the following.

```
{
   "PatchGroup":"Front-End Servers",
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

3. Run the following commands to create two maintenance windows for the production servers. The first window runs every Tuesday at 10 PM. The second window runs every Saturday at 10 PM. In addition, the maintenance window is tagged to indicate that it's for a production environment.

   Linux & macOS

   ```
   aws ssm create-maintenance-window \
       --name "Production-Tuesdays" \
       --tags "Key=Environment,Value=Production" \
   ```

```
    --schedule "cron(0 0 22 ? * TUE *)" \
    --duration 1 \
    --cutoff 0 \
    --no-allow-unassociated-targets
```

Windows Server

```
aws ssm create-maintenance-window ^
    --name "Production-Tuesdays" ^
    --tags "Key=Environment,Value=Production" ^
    --schedule "cron(0 0 22 ? * TUE *)" ^
    --duration 1 ^
    --cutoff 0 ^
    --no-allow-unassociated-targets
```

The system returns information like the following.

```
{
   "WindowId":"mw-0c50858d01EXAMPLE"
}
```

Linux & macOS

```
aws ssm create-maintenance-window \
    --name "Production-Saturdays" \
    --tags "Key=Environment,Value=Production" \
    --schedule "cron(0 0 22 ? * SAT *)" \
    --duration 2 \
    --cutoff 0 \
    --no-allow-unassociated-targets
```

Windows Server

```
aws ssm create-maintenance-window ^
    --name "Production-Saturdays" ^
    --tags "Key=Environment,Value=Production" ^
    --schedule "cron(0 0 22 ? * SAT *)" ^
    --duration 2 ^
    --cutoff 0 ^
    --no-allow-unassociated-targets
```

The system returns information like the following.

```
{
   "WindowId":"mw-9a8b7c6d5eEXAMPLE"
}
```

4. Run the following commands to register the `Database` and `Front-End` servers patch groups with their respective maintenance windows.

   Linux & macOS

   ```
   aws ssm register-target-with-maintenance-window \
       --window-id mw-0c50858d01EXAMPLE \
       --targets "Key=tag:PatchGroup,Values=Database Servers" \
       --owner-information "Database Servers" \
       --resource-type "INSTANCE"
   ```

   Windows Server

   ```
   aws ssm register-target-with-maintenance-window ^
       --window-id mw-0c50858d01EXAMPLE ^
       --targets "Key=tag:PatchGroup,Values=Database Servers" ^
       --owner-information "Database Servers" ^
       --resource-type "INSTANCE"
   ```

   The system returns information like the following.

   ```
   {
      "WindowTargetId":"e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
   }
   ```

   Linux & macOS

   ```
   aws ssm register-target-with-maintenance-window \
   --window-id mw-9a8b7c6d5eEXAMPLE \
   --targets "Key=tag:PatchGroup,Values=Front-End Servers" \
   --owner-information "Front-End Servers" \
   --resource-type "INSTANCE"
   ```

Windows Server

```
aws ssm register-target-with-maintenance-window ^
    --window-id mw-9a8b7c6d5eEXAMPLE ^
    --targets "Key=tag:PatchGroup,Values=Front-End Servers" ^
    --owner-information "Front-End Servers" ^
    --resource-type "INSTANCE"
```

The system returns information like the following.

```
{
   "WindowTargetId":"faa01c41-1d57-496c-ba77-ff9caEXAMPLE"
}
```

5. Run the following commands to register a patch task that installs missing updates on the `Database` and `Front-End` servers during their respective maintenance windows.

Linux & macOS

```
aws ssm register-task-with-maintenance-window \
    --window-id mw-0c50858d01EXAMPLE \
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
 \
    --task-arn "AWS-RunPatchBaseline" \
    --service-role-arn "arn:aws:iam::123456789012:role/MW-Role" \
    --task-type "RUN_COMMAND" \
    --max-concurrency 2 \
    --max-errors 1 \
    --priority 1 \
    --task-invocation-parameters "RunCommand={Parameters={Operation=Install}}"
```

Windows Server

```
aws ssm register-task-with-maintenance-window ^
    --window-id mw-0c50858d01EXAMPLE ^
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
 ^
    --task-arn "AWS-RunPatchBaseline" ^
    --service-role-arn "arn:aws:iam::123456789012:role/MW-Role" ^
    --task-type "RUN_COMMAND" ^
```

```
    --max-concurrency 2 ^
    --max-errors 1 ^
    --priority 1 ^
    --task-invocation-parameters "RunCommand={Parameters={Operation=Install}}"
```

The system returns information like the following.

```
{
   "WindowTaskId":"4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

Linux & macOS

```
aws ssm register-task-with-maintenance-window \
    --window-id mw-9a8b7c6d5eEXAMPLE \
    --targets "Key=WindowTargetIds,Values=faa01c41-1d57-496c-ba77-ff9caEXAMPLE"
 \
    --task-arn "AWS-RunPatchBaseline" \
    --service-role-arn "arn:aws:iam::123456789012:role/MW-Role" \
    --task-type "RUN_COMMAND" \
    --max-concurrency 2 \
    --max-errors 1 \
    --priority 1 \
    --task-invocation-parameters "RunCommand={Parameters={Operation=Install}}"
```

Windows Server

```
aws ssm register-task-with-maintenance-window ^
    --window-id mw-9a8b7c6d5eEXAMPLE ^
    --targets "Key=WindowTargetIds,Values=faa01c41-1d57-496c-ba77-ff9caEXAMPLE"
 ^
    --task-arn "AWS-RunPatchBaseline" ^
    --service-role-arn "arn:aws:iam::123456789012:role/MW-Role" ^
    --task-type "RUN_COMMAND" ^
    --max-concurrency 2 ^
    --max-errors 1 ^
    --priority 1 ^
    --task-invocation-parameters "RunCommand={Parameters={Operation=Install}}"
```

The system returns information like the following.

```
{
   "WindowTaskId":"8a5c4629-31b0-4edd-8aea-33698EXAMPLE"
}
```

6. Run the following command to get the high-level patch compliance summary for a patch group. The high-level patch compliance summary includes the number of managed nodes with patches in the respective patch states.

> **Note**
>
> It's expected to see zeroes for the number of managed nodes in the summary until the patch task runs during the first maintenance window.

Linux & macOS

```
aws ssm describe-patch-group-state \
    --patch-group "Database Servers"
```

Windows Server

```
aws ssm describe-patch-group-state ^
    --patch-group "Database Servers"
```

The system returns information like the following.

```
{
   "Instances": number,
   "InstancesWithFailedPatches": number,
   "InstancesWithInstalledOtherPatches": number,
   "InstancesWithInstalledPatches": number,
   "InstancesWithInstalledPendingRebootPatches": number,
   "InstancesWithInstalledRejectedPatches": number,
   "InstancesWithMissingPatches": number,
   "InstancesWithNotApplicablePatches": number,
   "InstancesWithUnreportedNotApplicablePatches": number
}
```

7. Run the following command to get patch summary states per-managed node for a patch group. The per-managed node summary includes a number of patches in the respective patch states per managed node for a patch group.

   Linux & macOS

   ```
   aws ssm describe-instance-patch-states-for-patch-group \
       --patch-group "Database Servers"
   ```

   Windows Server

   ```
   aws ssm describe-instance-patch-states-for-patch-group ^
       --patch-group "Database Servers"
   ```

   The system returns information like the following.

   ```
   {
      "InstancePatchStates": [
         {
            "BaselineId": "string",
            "FailedCount": number,
            "InstalledCount": number,
            "InstalledOtherCount": number,
            "InstalledPendingRebootCount": number,
            "InstalledRejectedCount": number,
            "InstallOverrideList": "string",
            "InstanceId": "string",
            "LastNoRebootInstallOperationTime": number,
            "MissingCount": number,
            "NotApplicableCount": number,
            "Operation": "string",
            "OperationEndTime": number,
            "OperationStartTime": number,
            "OwnerInformation": "string",
            "PatchGroup": "string",
            "RebootOption": "string",
            "SnapshotId": "string",
            "UnreportedNotApplicableCount": number
         }
      ]
   ```

```
}
```

For examples of other AWS CLI commands you can use for your Patch Manager configuration tasks, see Working with Patch Manager resources using the AWS CLI.

Troubleshooting Patch Manager

Use the following information to help you troubleshoot problems with Patch Manager, a tool in AWS Systems Manager.

Topics

Issue: "Invoke-PatchBaselineOperation : Access Denied" error or "Unable to download file from S3" error for `baseline_overrides.json`

Problem: When the patching operations specified by your patch policy run, you receive an error similar to the following example.

Example error on Windows Server

```
----------ERROR-------
Invoke-PatchBaselineOperation : Access Denied
At C:\ProgramData\Amazon\SSM\InstanceData\i-02573cafcfEXAMPLE\document\orchestr
ation\792dd5bd-2ad3-4f1e-931d-abEXAMPLE\PatchWindows\_script.ps1:219 char:13
+ $response = Invoke-PatchBaselineOperation -Operation Install -Snapsho ...
+ ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
+ CategoryInfo : OperationStopped: (Amazon.Patch.Ba...UpdateOpera
tion:InstallWindowsUpdateOperation) [Invoke-PatchBaselineOperation], Amazo
nS3Exception
```

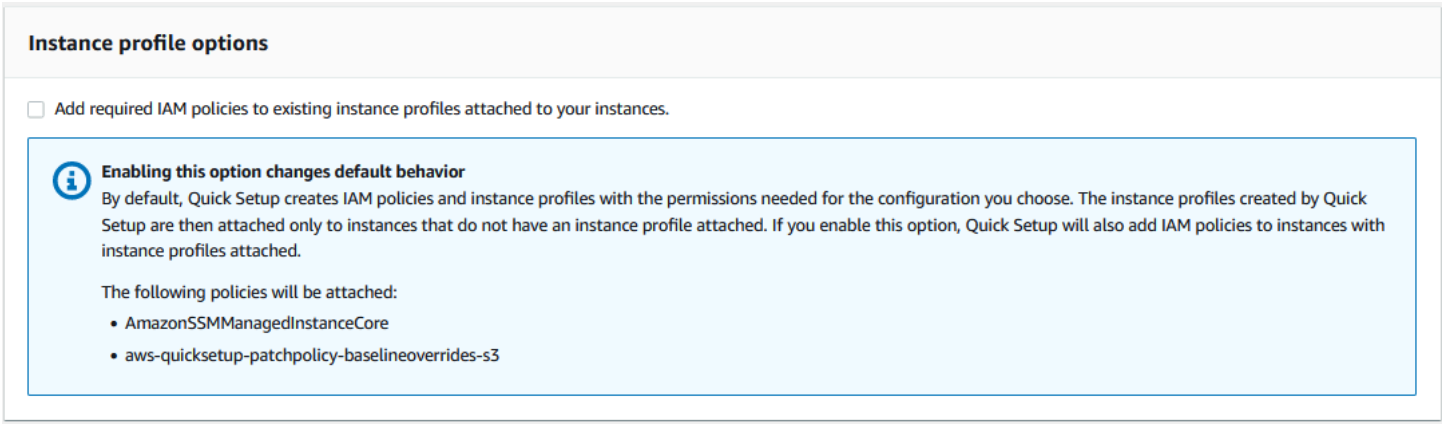
```
+ FullyQualifiedErrorId : PatchBaselineOperations,Amazon.Patch.Baseline.Op
erations.PowerShellCmdlets.InvokePatchBaselineOperation
failed to run commands: exit status 0xffffffff
```

Example error on Linux

```
[INFO]: Downloading Baseline Override from s3://aws-quicksetup-
patchpolicy-123456789012-abcde/baseline_overrides.json
[ERROR]: Unable to download file from S3: s3://aws-quicksetup-
patchpolicy-123456789012-abcde/baseline_overrides.json.
[ERROR]: Error loading entrance module.
```

Cause: You created a patch policy in Quick Setup, and some of your managed nodes already had an instance profile attached (for EC2 instances) or a service role attached (for non-EC2 machines).

However, as shown in the following image, you didn't select the **Add required IAM policies to existing instance profiles attached to your instances** check box.



When you create a patch policy, an Amazon S3 bucket is also created to store the policy's configuration `baseline_overrides.json` file. If you don't select the **Add required IAM policies to existing instance profiles attached to your instances** check box when creating the policy, the IAM policies and resource tags that are needed to access `baseline_overrides.json` in the S3 bucket are not automatically added to your existing IAM instance profiles and service roles.

Solution 1: Delete the existing patch policy configuration, then create a replacement, making sure to select the **Add required IAM policies to existing instance profiles attached to your instances** check box. This selection applies the IAM policies created by this Quick Setup configuration to nodes that already have an instance profile or service role attached. (By default, Quick Setup adds the required policies to instances and nodes that do *not* already have instance profiles or service

roles.) For more information, see Automate organization-wide patching using a Quick Setup patch policy.

Solution 2: Manually add the required permissions and tags to each IAM instance profile and IAM service role that you use with Quick Setup. For instructions, see Permissions for the patch policy S3 bucket.

Issue: Patching fails without an apparent cause or error message

Problem: A patching operation fails without returning an error message.

Possible cause: If more than one invocation of `AWS-RunPatchBaseline` occurs at a time, they can conflict with one another, causing patching tasks to fail. This might not be indicated in patching logs.

To check whether concurrent patching operations might have interrupted each other, review the command history in Run Command, a tool in AWS Systems Manager. For a managed node with a patching failure, check to see if multiple operations attempted to patch the machine within 2 minutes of one another. This scenario can sometimes cause a failure.

You can also use the AWS Command Line Interface (AWS CLI) to check for concurrent patching attempts by using the following command. Replace the value for *`node-id`* with the ID for your managed node.

```
aws ssm list-commands \
    --filter "key=DocumentName,value=AWS-RunPatchBaseline" \
    --query 'Commands[*].
{CommandId:CommandId,RequestedDateTime:RequestedDateTime,Status:Status}' \
    --instance-id node-id \
    --output table
```

Solution: If you determine that patching failed because of competing patching operations on the same managed node, adjust your patching configurations to avoid this occurring again. For example, if two maintenance windows specify overlapping patching times, remove or revise one of them. If a maintenance windows specifies one patching operation, but a patch policy specifies a different one for the same time, consider removing the task from the maintenance window.

If you determine that conflicting patching operations weren't the cause of the failure in this scenario, we recommend contacting AWS Support.

Issue: Unexpected patch compliance results

Problem: When reviewing the patching compliance details generated after a `Scan` operation, the results include information that don't reflect the rules set up in your patch baseline. For example, an exception you added to the **Rejected patches** list in a patch baseline is listed as `Missing`. Or patches classified as `Important` are listed as missing even though your patch baseline specifies `Critical` patches only.

Cause: Patch Manager currently supports multiple methods of running `Scan` operations:

- A patch policy configured in Quick Setup
- A Host Management option configured in Quick Setup
- A maintenance window to run a patch `Scan` or `Install` task
- An on-demand **Patch now** operation

When a `Scan` operation runs, it overwrites the compliance details from the most recent scan. If you have more than one method set up to run a `Scan` operation, and they use different patch baselines with different rules, they will result in differing patch compliance results.

Solution: To avoid unexpected patch compliance results, we recommend using only one method at a time for running the Patch Manager `Scan` operation. For more information, see Avoiding unintentional patch compliance data overwrites.

Errors when running `AWS-RunPatchBaseline` on Linux

Topics

- Issue: Patching fails with 'Error code returned from curl is 23'
- Issue: Patching fails with ‘Error unpacking rpm package…’ message
- Issue: Patching fails with 'Encounter service side error when uploading the inventory'
- Issue: Patching fails with ‘Errors were encountered while downloading packages’ message
- Issue: Patching fails with a message that 'The following signatures couldn't be verified because the public key is not available'
- Issue: Patching fails with a 'NoMoreMirrorsRepoError' message
- Issue: Patching fails with an 'Unable to download payload' message
- Issue: Patching fails with a message 'install errors: dpkg: error: dpkg frontend is locked by another process'
- Issue: Patching on Ubuntu Server fails with a 'dpkg was interrupted' error
- Issue: The package manager utility can't resolve a package dependency

Issue: 'No such file or directory' error

Problem: When you run `AWS-RunPatchBaseline`, patching fails with one of the following errors.

```
IOError: [Errno 2] No such file or directory: 'patch-baseline-operations-X.XX.tar.gz'
```

```
Unable to extract tar file: /var/log/amazon/ssm/patch-baseline-operations/patch-
baseline-operations-1.75.tar.gz.failed to run commands: exit status 155
```

```
Unable to load and extract the content of payload, abort.failed to run commands: exit
 status 152
```

Cause 1: Two commands to run `AWS-RunPatchBaseline` were running at the same time on the same managed node. This creates a race condition that results in the temporary `file patch-baseline-operations*` not being created or accessed properly.

Cause 2: Insufficient storage space remains under the `/var` directory.

Solution 1: Ensure that no maintenance window has two or more Run Command tasks that run `AWS-RunPatchBaseline` with the same Priority level and that run on the same target IDs. If this is the case, reorder the priority. Run Command is a tool in AWS Systems Manager.

Solution 2: Ensure that only one maintenance window at a time is running Run Command tasks that use `AWS-RunPatchBaseline` on the same targets and on the same schedule. If this is the case, change the schedule.

Solution 3: Ensure that only one State Manager association is running `AWS-RunPatchBaseline` on the same schedule and targeting the same managed nodes. State Manager is a tool in AWS Systems Manager.

Solution 4: Free up sufficient storage space under the `/var` directory for the update packages.

Issue: 'another process has acquired yum lock' error

Problem: When you run `AWS-RunPatchBaseline`, patching fails with the following error.

```
12/20/2019 21:41:48 root [INFO]: another process has acquired yum lock, waiting 2 s and
 retry.
```

Cause: The `AWS-RunPatchBaseline` document has started running on a managed node where it's already running in another operation and has acquired the package manager `yum` process.

Solution: Ensure that no State Manager association, maintenance window tasks, or other configurations that run `AWS-RunPatchBaseline` on a schedule are targeting the same managed node around the same time.

Issue: 'Permission denied / failed to run commands' error

Problem: When you run `AWS-RunPatchBaseline`, patching fails with the following error.

```
sh:
/var/lib/amazon/ssm/instanceid/document/orchestration/commandid/PatchLinux/_script.sh:
 Permission denied
failed to run commands: exit status 126
```

Cause: `/var/lib/amazon/` might be mounted with `noexec` permissions. This is an issue because SSM Agent downloads payload scripts to `/var/lib/amazon/ssm` and runs them from that location.

Solution: Ensure that you have configured exclusive partitions to `/var/log/amazon` and `/var/lib/amazon`, and that they're mounted with `exec` permissions.

Issue: 'Unable to download payload' error

Problem: When you run `AWS-RunPatchBaseline`, patching fails with the following error.

```
Unable to download payload: https://s3.amzn-s3-demo-bucket.region.amazonaws.com/
aws-ssm-region/patchbaselineoperations/linux/payloads/patch-baseline-operations-
X.XX.tar.gz.failed to run commands: exit status 156
```

Cause: The managed node doesn't have the required permissions to access the specified Amazon Simple Storage Service (Amazon S3) bucket.

Solution: Update your network configuration so that S3 endpoints are reachable. For more details, see information about required access to S3 buckets for Patch Manager in SSM Agent communications with AWS managed S3 buckets.

Issue: 'unsupported package manager and python version combination' error

Problem: When you run `AWS-RunPatchBaseline`, patching fails with the following error.

```
An unsupported package manager and python version combination was found. Apt requires
 Python3 to be installed.
failed to run commands: exit status 1
```

Cause: A supported version of python3 isn't installed on the Debian Server or Ubuntu Server instance.

Solution: Install a supported version of python3 (3.0 - 3.10) on the server, which is required for Debian Server and Ubuntu Server managed nodes.

Issue: Patch Manager isn't applying rules specified to exclude certain packages

Problem: You have attempted to exclude certain packages by specifying them in the `/etc/yum.conf` file, in the format `exclude=package-name`, but they aren't excluded during the Patch Manager `Install` operation.

Cause: Patch Manager doesn't incorporate exclusions specified in the `/etc/yum.conf` file.

Solution: To exclude specific packages, create a custom patch baseline and create a rule to exclude the packages you don't want installed.

Issue: Patching fails and Patch Manager reports that the Server Name Indication extension to TLS is not available

Problem: The patching operation issues the following message.

```
/var/log/amazon/ssm/patch-baseline-operations/urllib3/util/ssl_.py:369:
SNIMissingWarning: An HTTPS request has been made, but the SNI (Server Name Indication)
 extension
to TLS is not available on this platform. This might cause the server to present an
 incorrect TLS
certificate, which can cause validation failures. You can upgrade to a newer version of
 Python
to solve this.
For more information, see https://urllib3.readthedocs.io/en/latest/advanced-
usage.html#ssl-warnings
```

Cause: This message doesn't indicate an error. Instead, it's a warning that the older version of Python distributed with the operating system doesn't support TLS Server Name Indication. The Systems Manager patch payload script issues this warning when connecting to AWS APIs that support SNI.

Solution: To troubleshoot any patching failures when this message is reported, review the contents of the `stdout` and `stderr` files. If you haven't configured the patch baseline to store these files in an S3 bucket or in Amazon CloudWatch Logs, you can locate the files in the following location on your Linux managed node.

`/var/lib/amazon/ssm/`*`instance-id`*`/document/orchestration/`*`Run-Command-execution-id`*`/awsrunShellScript/PatchLinux`

Issue: Patch Manager reports 'No more mirrors to try'

Problem: The patching operation issues the following message.

```
[Errno 256] No more mirrors to try.
```

Cause: The repositories configured on the managed node are not working correctly. Possible causes for this include:

- The `yum` cache is corrupted.
- A repository URL can't be reached due to network-related issues.

Solution: Patch Manager uses the managed node's default package manager to perform patching operation. Double-check that repositories are configured and operating correctly.

Issue: Patching fails with 'Error code returned from curl is 23'

Problem: A patching operating that uses `AWS-RunPatchBaseline` fails with an error similar to the following:

```
05/01/2025 17:04:30 root [ERROR]: Error code returned from curl is 23
```

Cause: The curl tool in use on your systems lacks the permissions needed to write to the filesystem. This can occur when if the package manager's default curl tool was replaced by a different version, such as one installed with snap.

Solution: If the curl version provided by the package manager was uninstalled when a different version was installed, reinstall it.

If you need to keep multiple curl versions installed, ensure that the version associated with the package manager is in the first directory listed in the `PATH` variable. You can check this by running the command `echo $PATH` to see the current order of directories that are checked for executable files on your system.

Issue: Patching fails with 'Error unpacking rpm package...' message

Problem: A patching operation fails with an error similar to the following:

```
Error : Error unpacking rpm package python-urllib3-1.25.9-1.amzn2.0.2.noarch
python-urllib3-1.25.9-1.amzn2.0.1.noarch was supposed to be removed but is not!
failed to run commands: exit status 1
```

Cause 1: When a particular package is present in multiple package installers, such as both `pip` and `yum` or `dnf`, conflicts can occur when using the default package manager.

A common example occurs with the `urllib3` package, which is found in `pip`, `yum`, and `dnf`.

Cause 2: The `python-urllib3` package is corrupted. This can happen if the package files were installed or updated by `pip` after the `rpm` was package was previously installed by `yum` or `dnf`.

Solution: Remove the `python-urllib3` package from pip by running the command `sudo pip uninstall urllib3`, keeping the package only in the default package manager (`yum` or `dnf`).

Issue: Patching fails with 'Encounter service side error when uploading the inventory'

Problem: When running the `AWS-RunPatchBaseline` document, you receive the following error message:

```
Encounter service side error when uploading the inventory
```

Cause: Two commands to run `AWS-RunPatchBaseline` were running at the same time on the same managed node. This creates a race condition when initializing boto3 client during patching operations.

Solution: Ensure that no State Manager association, maintenance window tasks, or other configurations that run `AWS-RunPatchBaseline` on a schedule are targeting the same managed node around the same time.

Issue: Patching fails with ‘Errors were encountered while downloading packages’ message

Problem: During patching, you receive an error similar to the following:

```
YumDownloadError: [u'Errors were encountered while downloading
packages.', u'libxml2-2.9.1-6.el7_9.6.x86_64: [Errno 5] [Errno 12]
Cannot allocate memory', u'libxslt-1.1.28-6.el7.x86_64: [Errno 5]
[Errno 12] Cannot allocate memory', u'libcroco-0.6.12-6.el7_9.x86_64:
[Errno 5] [Errno 12] Cannot allocate memory', u'openldap-2.4.44-25.el7_9.x86_64:
[Errno 5] [Errno 12] Cannot allocate memory',
```

Cause: This error can occur when insufficient memory is available on a managed node.

Solution: Configure the swap memory, or upgrade the instance to a different type to increase the memory support. Then start a new patching operation.

Issue: Patching fails with a message that 'The following signatures couldn't be verified because the public key is not available'

Problem: Patching fails on Ubuntu Server with an error similar to the following:

```
02/17/2022 21:08:43 root [ERROR]: W:GPG error:
http://repo.mysql.com/apt/ubuntu  bionic InRelease: The following
signatures couldn't be verified because the public key is not available:
NO_PUBKEY 467B942D3A79BD29, E:The repository ' http://repo.mysql.com/apt/ubuntu bionic
```

Cause: The GNU Privacy Guard (GPG) key has expired or is missing.

Solution: Refresh the GPG key, or add the key again.

For example, using the error shown previously, we see that the 467B942D3A79BD29 key is missing and must be added. To do so, run either of the following commands:

```
sudo apt-key adv --keyserver hkps://keyserver.ubuntu.com --recv-keys 467B942D3A79BD29
```

```
sudo apt-key adv --keyserver hkp://keyserver.ubuntu.com:80 --recv-keys 467B942D3A79BD29
```

Or, to refresh all keys, run the following command:

```
sudo apt-key adv --keyserver hkps://keyserver.ubuntu.com --refresh-keys
```

If the error recurs after this, we recommend reporting the issue to the organization that maintains the repository. Until a fix is available, you can edit the `/etc/apt/sources.list` file to omit the repository during the patching process.

To do so, open the `sources.list` file for editing, locate the line for the repository, and insert a # character at the beginning of the line to comment it out. Then save and close the file.

Issue: Patching fails with a 'NoMoreMirrorsRepoError' message

Problem: You receive an error similar to the following:

```
NoMoreMirrorsRepoError: failure: repodata/repomd.xml from pgdg94: [Errno 256] No more
 mirrors to try.
```

Cause: There is an error in the source repository.

Solution: We recommend reporting the issue to the organization that maintains the repository. Until the error is fixed, you can disable the repository at the operating system level. To do so, run the following command, replacing the value for *`repo-name`* with your repository name:

```
yum-config-manager --disable repo-name
```

Following is an example.

```
yum-config-manager --disable pgdg94
```

After you run this command, run another patching operation.

Issue: Patching fails with an 'Unable to download payload' message

Problem: You receive an error similar to the following:

```
Unable to download payload:
https://s3.dualstack.eu-west-1.amazonaws.com/aws-ssm-eu-west-1/patchbaselineoperations/
linux/payloads/patch-baseline-operations-1.83.tar.gz.
failed  to run commands: exit status 156
```

Cause: The managed node configuration contains errors or is incomplete.

Solution: Make sure that the managed node is configured with the following:

- Outbound TCP 443 rule in security group.
- Egress TCP 443 rule in NACL.
- Ingress TCP 1024-65535 rule in NACL.
- NAT/IGW in route table to provide connectivity to an S3 endpoint. If the instance doesn't have internet access, provide it connectivity with the S3 endpoint. To do that, add an S3 gateway endpoint in the VPC and integrate it with the route table of the managed node.

Issue: Patching fails with a message 'install errors: dpkg: error: dpkg frontend is locked by another process'

Problem: Patching fails with an error similar to the following:

```
install errors: dpkg: error: dpkg frontend is locked by another process
failed to run commands: exit status 2
Failed to install package; install status Failed
```

Cause: The package manager is already running another process on a managed node at the operating system level. If that other process takes a long time to complete, the Patch Manager patching operation can time out and fail.

Solution: After the other process that’s using the package manager completes, run a new patching operation.

Issue: Patching on Ubuntu Server fails with a 'dpkg was interrupted' error

Problem: On Ubuntu Server, patching fails with an error similar to the following:

```
E: dpkg was interrupted, you must manually run
'dpkg --configure -a' to correct the problem.
```

Cause: One or more packages is misconfigured.

Solution: Perform the following steps:

1. Check to see which packages are affected, and what the issues are with each package by running the following commands, one at a time:

   ```
   sudo apt-get check
   ```

   ```
   sudo dpkg -C
   ```

   ```
   dpkg-query -W -f='${db:Status-Abbrev} ${binary:Package}\n' | grep -E ^.[^nci]
   ```

2. Correct the packages with issues by running the following command:

   ```
   sudo dpkg --configure -a
   ```

3. If the previous command didn't fully resolve the issue, run the following command:

   ```
   sudo apt --fix-broken install
   ```

Issue: The package manager utility can't resolve a package dependency

Problem: The native package manager on the managed node is unable to resolve a package dependency and patching fails. The following error message example indicates this type of failure on an operating system that uses `yum` as the package manager.

```
09/22/2020 08:56:09 root [ERROR]: yum update failed with result code: 1,
message: [u'rpm-python-4.11.3-25.amzn2.0.3.x86_64 requires rpm = 4.11.3-25.amzn2.0.3',
u'awscli-1.18.107-1.amzn2.0.1.noarch requires python2-botocore = 1.17.31']
```

Cause: On Linux operating systems, Patch Manager uses the native package manager on the machine to run patching operations. such as `yum`, `dnf`, `apt`, and `zypper`. The applications automatically detect, install, update, or remove dependent packages as required. However, some

conditions can result in the package manager being unable to complete a dependency operation, such as:

- Multiple conflicting repositories are configured on the operating system.
- A remote repository URL is inaccessible due to network-related issues.
- A package for the wrong architecture is found in the repository.

Solution: Patching might fail because of a dependency issue for a wide variety of reasons. Therefore, we recommend that you contact AWS Support to assist with troubleshooting.

Errors when running `AWS-RunPatchBaseline` on Windows Server

Topics

Issue: mismatched product family/product pairs

Problem: When you create a patch baseline in the Systems Manager console, you specify a product family and a product. For example, you might choose:

- **Product family**: `Office`

  Product: `Office 2016`

Cause: If you attempt to create a patch baseline with a mismatched product family/product pair, an error message is displayed. The following are reasons this can occur:

- You selected a valid product family and product pair but then removed the product family selection.
- You chose a product from the **Obsolete or mismatched options** sublist instead of the **Available and matching options** sublist.

Items in the product **Obsolete or mismatched options** sublist might have been entered in error through an SDK or AWS Command Line Interface (AWS CLI) `create-patch-baseline` command. This could mean a typo was introduced or a product was assigned to the wrong product family. A product is also included in the **Obsolete or mismatched options** sublist if it was specified for a previous patch baseline but has no patches available from Microsoft.

Solution: To avoid this issue in the console, always choose options from the **Currently available options** sublists.

You can also view the products that have available patches by using the `describe-patch-properties` command in the AWS CLI or the `DescribePatchProperties` API command.

Issue: `AWS-RunPatchBaseline` output returns an `HRESULT` (Windows Server)

Problem: You received an error like the following.

```
----------ERROR-------
Invoke-PatchBaselineOperation : Exception Details: An error occurred when
attempting to search Windows Update.
Exception Level 1:
 Error Message: Exception from HRESULT: 0x80240437
 Stack Trace: at WUApiLib.IUpdateSearcher.Search(String criteria)..
(Windows updates)
11/22/2020 09:17:30 UTC | Info | Searching for Windows Updates.
11/22/2020 09:18:59 UTC | Error | Searching for updates resulted in error: Exception
 from HRESULT: 0x80240437
----------ERROR-------
failed to run commands: exit status 4294967295
```

Cause: This output indicates that the native Windows Update APIs were unable to run the patching operations.

Solution: Check the `HResult` code in the following microsoft.com topics to identify troubleshooting steps for resolving the error:

- Windows Update error codes by component
- Windows Update common errors and mitigation

Issue: managed node doesn't have access to Windows Update Catalog or WSUS

Problem: You received an error like the following.

```
Downloading PatchBaselineOperations PowerShell module from https://s3.aws-api-
domain/path_to_module.zip to C:\Windows\TEMP\Amazon.PatchBaselineOperations-1.29.zip.

Extracting PatchBaselineOperations zip file contents to temporary folder.

Verifying SHA 256 of the PatchBaselineOperations PowerShell module files.

Successfully downloaded and installed the PatchBaselineOperations PowerShell module.

 searc

---Error truncated----
```

Cause: This error could be related to the Windows Update components, or to a lack of connectivity to the Windows Update Catalog or Windows Server Update Services (WSUS).

Solution: Confirm that the managed node has connectivity to the Microsoft Update Catalog through an internet gateway, NAT gateway, or NAT instance. If you're using WSUS, confirm that the managed node has connectivity to the WSUS server in your environment. If connectivity is available to the intended destination, check the Microsoft documentation for other potential causes of `HResult 0x80072EE2`. This might indicate an operating system level issue.

Issue: PatchBaselineOperations PowerShell module is not downloadable

Problem: You received an error like the following.

```
Preparing to download PatchBaselineOperations PowerShell module from S3.

Downloading PatchBaselineOperations PowerShell module from https://s3.aws-api-
domain/path_to_module.zip to C:\Windows\TEMP\Amazon.PatchBaselineOperations-1.29.zip.
----------ERROR-------

C:\ProgramData\Amazon\SSM\InstanceData\i-02573cafcfEXAMPLE\document\orchestration
\aaaaaaaa-bbbb-cccc-dddd-4f6ed6bd5514\

PatchWindows\_script.ps1 : An error occurred when executing PatchBaselineOperations:
 Unable to connect to the remote server

+ CategoryInfo : NotSpecified: (:) [Write-Error], WriteErrorException

+ FullyQualifiedErrorId : Microsoft.PowerShell.Commands.WriteErrorException,_script.ps1

failed to run commands: exit status 4294967295
```

Solution: Check the managed node connectivity and permissions to Amazon Simple Storage Service (Amazon S3). The managed node's AWS Identity and Access Management (IAM) role must use the minimum permissions cited in SSM Agent communications with AWS managed S3 buckets. The node must communicate with the Amazon S3 endpoint through the Amazon S3 gateway endpoint, NAT gateway, or internet gateway. For more information about the VPC Endpoint requirements for AWS Systems Manager SSM Agent (SSM Agent), see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

Issue: missing patches

Problem: `AWS-RunPatchbaseline` completed successfully, but there are some missing patches.

The following are some common causes and their solutions.

Cause 1: The baseline isn't effective.

Solution 1: To check if this is the cause, use the following procedure.

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Select the **Command history** tab and then select the command whose baseline you want to check.
4. Select the managed node that has missing patches.
5. Select **Step 1 - Output** and find the `BaselineId` value.
6. Check the assigned patch baseline configuration, that is, the operating system, product name, classification, and severity for the patch baseline.
7. Go to the Microsoft Update Catalog.
8. Search the Microsoft Knowledge Base (KB) article IDs (for example, KB3216916).
9. Verify that the value under **Product** matches that of your managed node and select the corresponding **Title**. A new **Update Details** window will open.
10. In the **Overview** tab, the **classification** and **MSRC severity** must match the patch baseline configuration you found earlier.

Cause 2: The patch was replaced.

Solution 2: To check if this is true, use the following procedure.

1. Go to the Microsoft Update Catalog.
2. Search the Microsoft Knowledge Base (KB) article IDs (for example, KB3216916).
3. Verify that the value under **Product** matches that of your managed node and select the corresponding **Title**. A new **Update Details** window will open.
4. Go to the **Package Details** tab. Look for an entry under the **This update has been replaced by the following updates:** header.

Cause 3: The same patch might have different KB numbers because the WSUS and Window online updates are handled as independent Release Channels by Microsoft.

Solution 3: Check the patch eligibility. If the package isn't available under WSUS, install OS Build 14393.3115. If the package is available for all operating system builds, install OS Builds 18362.1256 and 18363.1256.

Using AWS Support Automation runbooks

AWS Support provides two Automation runbooks you can use to troubleshoot certain issues related to patching.

- `AWSSupport-TroubleshootWindowsUpdate` – The `AWSSupport-TroubleshootWindowsUpdate` runbook is used to identify issues that could fail the Windows Server updates for Amazon Elastic Compute Cloud (Amazon EC2) Windows Server instances.
- `AWSSupport-TroubleshootPatchManagerLinux` – The `AWSSupport-TroubleshootPatchManagerLinux` runbook troubleshoots common issues that can cause a patch failure on Linux-based managed nodes using Patch Manager. The main goal of this runbook is to identify the patch command failure root cause and suggest a remediation plan.

> **Note**
>
> There is a charge to run Automation runbooks. For information, see AWS Systems Manager Pricing for Automation.

Contacting AWS Support

If you can't find troubleshooting solutions in this section or in the Systems Manager issues in AWS re:Post, and you have a Developer, Business, or Enterprise Support plan, you can create a technical support case at AWS Support.

Before you contact Support, collect the following items:

- SSM agent logs
- Run Command command ID, maintenance window ID, or Automation execution ID
- For Windows Server managed nodes, also collect the following:
  - `%PROGRAMDATA%\Amazon\PatchBaselineOperations\Logs` as described on the **Windows** tab of How patches are installed
  - Windows update logs: For Windows Server 2012 R2 and older, use `%windir%/WindowsUpdate.log`. For Windows Server 2016 and newer, first run the PowerShell command `Get-WindowsUpdateLog` before using `%windir%/WindowsUpdate.log`
- For Linux managed nodes, also collect the following:
  - The contents of the directory `/var/lib/amazon/ssm/`*`instance-id`*`/document/orchestration/`*`Run-Command-execution-id`*`/awsrunShellScript/PatchLinux`

AWS Systems Manager Run Command

Using Run Command, a tool in AWS Systems Manager, you can remotely and securely manage the configuration of your managed nodes. A *managed node* is any Amazon Elastic Compute Cloud (Amazon EC2) instance or non-EC2 machine in your hybrid and multicloud environment that has been configured for Systems Manager. Run Command allows you to automate common administrative tasks and perform one-time configuration changes at scale. You can use Run Command from the AWS Management Console, the AWS Command Line Interface (AWS CLI), AWS Tools for Windows PowerShell, or the AWS SDKs. Run Command is offered at no additional cost. To get started with Run Command, open the Systems Manager console. In the navigation pane, choose **Run Command**.

Administrators use Run Command to install or bootstrap applications, build a deployment pipeline, capture log files when an instance is removed from an Auto Scaling group, join instances to a Windows domain, and more.

The Run Command API follows an eventual consistency model, due to the distributed nature of the system supporting the API. This means that the result of an API command you run that affects your resources might not be immediately visible to all subsequent commands you run. You should keep this in mind when you carry out an API command that immediately follows a previous API command.

Getting Started

The following table includes information to help you get started with Run Command.

Topic	Details
Setting up managed nodes for AWS Systems Manager	Verify that you have completed the setup requirements for your Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 machines in a hybrid and multicloud environment.
Managing nodes in hybrid and multicloud environments with Systems Manager	(Optional) Register on-premises servers and VMs with AWS so you can manage them using Run Command.
the section called “Managing edge devices with Systems Manager”	(Optional) Configure edge devices so you can manage them using Run Command.
Running commands on managed nodes	Learn how to run a command that targets one or more managed nodes by using the AWS Management Console.
Run Command walkthroughs	Learn how to run commands using either Tools for Windows PowerShell or the AWS CLI.

EventBridge support

This Systems Manager tool is supported as both an *event* type and a *target* type in Amazon EventBridge rules. For information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

Topics

Setting up Run Command

Before you can manage nodes by using Run Command, a tool in AWS Systems Manager, configure an AWS Identity and Access Management (IAM) policy for any user who will run commands. If you use any global condition keys for the `SendCommand` action in your IAM policies, you must include the `aws:ViaAWSService` condition key and set the boolean value to `true`. The following is an example.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:SendCommand"
            ],
            "Resource": [
                "arn:aws:ssm:us-east-1:111122223333:document/YourDocument"
            ],
            "Condition": {
                "StringEquals": {
```

```
                    "aws:SourceVpce": [
                        "vpce-1234567890abcdef0"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:SendCommand"
            ],
            "Resource": [
                "arn:aws:ssm:us-east-1:111122223333:document/YourDocument"
            ],
            "Condition": {
                "Bool": {
                    "aws:ViaAWSService": "true"
                }
            }
        }
    ]
}
```

You must also configure your nodes for Systems Manager. For more information, see Setting up managed nodes for AWS Systems Manager.

We recommend completing the following optional setup tasks to help minimize the security posture and day-to-day management of your managed nodes.

Monitor command executions using Amazon EventBridge

You can use EventBridge to log command execution status changes. You can create a rule that runs whenever there is a state transition, or when there is a transition to one or more states that are of interest. You can also specify Run Command as a target action when an EventBridge event occurs. For more information, see Configuring EventBridge for Systems Manager events.

Monitor command executions using Amazon CloudWatch Logs

You can configure Run Command to periodically send all command output and error logs to an Amazon CloudWatch log group. You can monitor these output logs in near real-time, search for specific phrases, values, or patterns, and create alarms based on the search. For more information, see Configuring Amazon CloudWatch Logs for Run Command.

Restrict Run Command access to specific managed nodes

You can restrict a user's ability to run commands on managed nodes by using AWS Identity and Access Management (IAM). Specifically, you can create an IAM policy with a condition that the user can only run commands on managed nodes that are tagged with specific tags. For more information, see Restricting Run Command access based on tags.

Restricting Run Command access based on tags

This section describes how to restrict a user's ability to run commands on managed nodes by specifying a tag condition in an IAM policy. Managed nodes include Amazon EC2 instances and non-EC2 nodes in a hybrid and multicloud environment that are configured for Systems Manager. Though the information is not explicitly presented, you can also restrict access to managed AWS IoT Greengrass core devices. To get started, you must tag your AWS IoT Greengrass devices. For more information, see Tag your AWS IoT Greengrass Version 2 resources in the *AWS IoT Greengrass Version 2 Developer Guide*.

You can restrict command execution to specific managed nodes by creating an IAM policy that includes a condition that the user can only run commands on nodes with specific tags. In the following example, the user is allowed to use Run Command (`Effect: Allow, Action: ssm:SendCommand`) by using any SSM document (`Resource: arn:aws:ssm:*:*:document/*`) on any node (`Resource: arn:aws:ec2:*:*:instance/*`) with the condition that the node is a Finance WebServer (`ssm:resourceTag/Finance: WebServer`). If the user sends a command to a node that isn't tagged or that has any tag other than `Finance: WebServer`, the execution results show `AccessDenied`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "ssm:SendCommand"
         ],
         "Resource":[
            "arn:aws:ssm:*:*:document/*"
         ]
```

```
      },
      {
         "Effect":"Allow",
         "Action":[
            "ssm:SendCommand"
         ],
         "Resource":[
            "arn:aws:ec2:*:*:instance/*"
         ],
         "Condition":{
            "StringLike":{
               "ssm:resourceTag/Finance":[
                  "WebServers"
               ]
            }
         }
      }
   ]
}
```

You can create IAM policies that allow a user to run commands on managed nodes that are tagged with multiple tags. The following policy allows the user to run commands on managed nodes that have two tags. If a user sends a command to a node that isn't tagged with both of these tags, the execution results show `AccessDenied`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "ssm:SendCommand"
         ],
         "Resource":"*",
         "Condition":{
            "StringLike":{
               "ssm:resourceTag/tag_key1":[
                  "tag_value1"
               ],
```

```
                "ssm:resourceTag/tag_key2":[
                   "tag_value2"
                ]
             }
          }
       },
       {
          "Effect":"Allow",
          "Action":[
             "ssm:SendCommand"
          ],
          "Resource":[
             "arn:aws:ssm:us-west-1::document/AWS-*",
             "arn:aws:ssm:us-east-2::document/AWS-*"
          ]
       },
       {
          "Effect":"Allow",
          "Action":[
             "ssm:UpdateInstanceInformation",
             "ssm:ListCommands",
             "ssm:ListCommandInvocations",
             "ssm:GetDocument"
          ],
          "Resource":"*"
       }
    ]
}
```

You can also create IAM policies that allows a user to run commands on multiple groups of tagged managed nodes. The following example policy allows the user to run commands on either group of tagged nodes, or both groups.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
```

```
            "ssm:SendCommand"
         ],
         "Resource":"*",
         "Condition":{
            "StringLike":{
               "ssm:resourceTag/tag_key1":[
                  "tag_value1"
               ]
            }
         }
      },
      {
         "Effect":"Allow",
         "Action":[
            "ssm:SendCommand"
         ],
         "Resource":"*",
         "Condition":{
            "StringLike":{
               "ssm:resourceTag/tag_key2":[
                  "tag_value2"
               ]
            }
         }
      },
      {
         "Effect":"Allow",
         "Action":[
            "ssm:SendCommand"
         ],
         "Resource":[
            "arn:aws:ssm:us-west-1::document/AWS-*",
            "arn:aws:ssm:us-east-2::document/AWS-*"
         ]
      },
      {
         "Effect":"Allow",
         "Action":[
            "ssm:UpdateInstanceInformation",
            "ssm:ListCommands",
            "ssm:ListCommandInvocations",
            "ssm:GetDocument"
         ],
         "Resource":"*"
```

```
        }
    ]
}
```

For more information about creating IAM policies, see Managed policies and inline policies in the *IAM User Guide*. For more information about tagging managed nodes, see Tag Editor in the *AWS Resource Groups User Guide*.

Running commands on managed nodes

This section includes information about how to send commands from the AWS Systems Manager console to managed nodes. This section also includes information about how to cancel a command.

Note that if your node is configured with the `noexec` mount option for the var directory, Run Command is unable to successfuly run commands.

> **Important**
>
> When you send a command using Run Command, don't include sensitive information formatted as plaintext, such as passwords, configuration data, or other secrets. All Systems Manager API activity in your account is logged in an S3 bucket for AWS CloudTrail logs. This means that any user with access to S3 bucket can view the plaintext values of those secrets. For this reason, we recommend creating and using `SecureString` parameters to encrypt sensitive data you use in your Systems Manager operations.
> For more information, see Restricting access to Parameter Store parameters using IAM policies.

Execution history retention

The history of each command is available for up to 30 days. In addition, you can store a copy of all log files in Amazon Simple Storage Service or have an audit trail of all API calls in AWS CloudTrail.

Related information

For information about sending commands using other tools, see the following topics:

- Walkthrough: Use the AWS Tools for Windows PowerShell with Run Command or the examples in the AWS Systems Manager section of the AWS Tools for PowerShell Cmdlet Reference.
- Walkthrough: Use the AWS CLI with Run Command or the examples in the SSM CLI Reference

Contents

Running commands from the console

You can use Run Command, a tool in AWS Systems Manager, from the AWS Management Console to configure managed nodes without having to log into them. This topic includes an example that shows how to update SSM Agent on a managed node by using Run Command.

Before you begin

Before you send a command using Run Command, verify that your managed nodes meet all Systems Manager setup requirements.

To send a command using Run Command

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose a Systems Manager document.
5. In the **Command parameters** section, specify values for required parameters.
6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   > **Tip**
   >
   > If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

7. For **Other parameters**:

   - For **Comment**, enter information about this command.

- For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:

   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

     > **Note**
     >
     > If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) Choose a CloudWatch alarm to apply to your command for monitoring. To attach a CloudWatch alarm to your command, the IAM principal that runs the command must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms. Note that if your alarm activates, any pending command invocations do not run.

10. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

    > **Note**
    >
    > The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service

role associated with the managed node has the necessary permissions to write to that bucket.

11. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

    For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.
12. Choose **Run**.

For information about canceling a command, see the section called "Canceling a command".

Rerunning commands

Systems Manager includes two options to help you rerun a command from the **Run Command** page in the Systems Manager console.

- **Rerun**: This button allows you to run the same command without making changes to it.
- **Copy to new**: This button copies the settings of one command to a new command and gives you the option to edit those settings before you run it.

To rerun a command

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose a command to rerun. You can rerun a command immediately after executing it from the command details page. Or, you can choose a command that you previously ran from the **Command history** tab.
4. Choose either **Rerun** to run the same command without changes, or choose **Copy to new** to edit the command settings before you run it.

Running commands using a specific document version

You can use the document version parameter to specify which version of an AWS Systems Manager document to use when the command runs. You can specify one of the following options for this parameter:

- $DEFAULT
- $LATEST
- Version number

Run the following procedure to run a command using the document version parameter.

Linux

To run commands using the AWS CLI on local Linux machines

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. List all available documents

   This command lists all of the documents available for your account based on AWS Identity and Access Management (IAM) permissions.

   ```
   aws ssm list-documents
   ```

3. Run the following command to view the different versions of a document. Replace *document name* with your own information.

   ```
   aws ssm list-document-versions \
       --name "document name"
   ```

4. Run the following command to run a command that uses an SSM document version. Replace each *example resource placeholder* with your own information.

   ```
   aws ssm send-command \
       --document-name "AWS-RunShellScript" \
       --parameters commands="echo Hello" \
       --instance-ids instance-ID \
       --document-version '$LATEST'
   ```

Windows

To run commands using the AWS CLI on local Windows machines

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. List all available documents

   This command lists all of the documents available for your account based on AWS Identity and Access Management (IAM) permissions.

   ```
   aws ssm list-documents
   ```

3. Run the following command to view the different versions of a document. Replace *document name* with your own information.

   ```
   aws ssm list-document-versions ^
       --name "document name"
   ```

4. Run the following command to run a command that uses an SSM document version. Replace each *example resource placeholder* with your own information.

   ```
   aws ssm send-command ^
       --document-name "AWS-RunShellScript" ^
       --parameters commands="echo Hello" ^
       --instance-ids instance-ID ^
       --document-version "$LATEST"
   ```

PowerShell

To run commands using the Tools for PowerShell

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

   For information, see Installing the AWS Tools for PowerShell.

2. List all available documents

This command lists all of the documents available for your account based on AWS Identity and Access Management (IAM) permissions.

```
Get-SSMDocumentList
```

3. Run the following command to view the different versions of a document. Replace *document name* with your own information.

```
Get-SSMDocumentVersionList `
    -Name "document name"
```

4. Run the following command to run a command that uses an SSM document version. Replace each *example resource placeholder* with your own information.

```
Send-SSMCommand `
    -DocumentName "AWS-RunShellScript" `
    -Parameter @{commands = "echo helloWorld"} `
    -InstanceIds "instance-ID" `
    -DocumentVersion $LATEST
```

Run commands at scale

You can use Run Command, a tool in AWS Systems Manager, to run commands on a fleet of managed nodes by using the `targets`. The `targets` parameter accepts a `Key,Value` combination based on tags that you specified for your managed nodes. When you run the command, the system locates and attempts to run the command on all managed nodes that match the specified tags. For more information about tagging managed instances, see Tagging your AWS resources in the *Tagging AWS Resources User Guide*. For information about tagging your managed IoT devices, see Tag your AWS IoT Greengrass Version 2 resources in the *AWS IoT Greengrass Version 2 Developer Guide*.

You can also use the `targets` parameter to target a list of specific managed node IDs, as described in the next section.

To control how commands run across hundreds or thousands of managed nodes, Run Command also includes parameters for restricting how many nodes can simultaneously process a request and how many errors can be thrown by a command before the command is canceled.

Contents

- Targeting multiple managed nodes
- Using rate controls

Targeting multiple managed nodes

You can run a command and target managed nodes by specifying tags, AWS resource group names, or managed node IDs.

The following examples show the command format when using Run Command from the AWS Command Line Interface (AWS CLI). Replace each *example resource placeholder* with your own information. Sample commands in this section are truncated using `[...]`.

Example 1: Targeting tags

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=tag:tag-name,Values=tag-value \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=tag:tag-name,Values=tag-value ^
    [...]
```

Example 2: Targeting an AWS resource group by name

You can specify a maximum of one resource group name per command. When you create a resource group, we recommend including `AWS::SSM:ManagedInstance` and `AWS::EC2::Instance` as resource types in your grouping criteria.

> **Note**
>
> In order to send commands that target a resource group, you must have been granted AWS Identity and Access Management (IAM) permissions to list or view the resources that belong

to that group. For more information, see Set up permissions in the *AWS Resource Groups User Guide*.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=resource-groups:Name,Values=resource-group-name \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=resource-groups:Name,Values=resource-group-name ^
    [...]
```

Example 3: Targeting an AWS resource group by resource type

You can specify a maximum of five resource group types per command. When you create a resource group, we recommend including `AWS::SSM:ManagedInstance` and `AWS::EC2::Instance` as resource types in your grouping criteria.

Note

In order to send commands that target a resource group, you must have been granted IAM permissions to list, or view, the resources that belong to that group. For more information, see Set up permissions in the *AWS Resource Groups User Guide*.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=resource-groups:ResourceTypeFilters,Values=resource-
type-1,resource-type-2 \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=resource-groups:ResourceTypeFilters,Values=resource-
type-1,resource-type-2 ^
    [...]
```

Example 4: Targeting instance IDs

The following examples show how to target managed nodes by using the `instanceids` key with the `targets` parameter. You can use this key to target managed AWS IoT Greengrass core devices because each device is assigned an mi-*ID_number*. You can view device IDs in Fleet Manager, a tool in AWS Systems Manager.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=instanceids,Values=instance-ID-1,instance-ID-2,instance-ID-3 \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=instanceids,Values=instance-ID-1,instance-ID-2,instance-ID-3 ^
    [...]
```

If you tagged managed nodes for different environments using a `Key` named `Environment` and `Values` of `Development`, `Test`, `Pre-production` and `Production`, then you could send a command to all managed nodes in *one* of these environments by using the `targets` parameter with the following syntax.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=tag:Environment,Values=Development \
```

```
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=tag:Environment,Values=Development ^
    [...]
```

You could target additional managed nodes in other environments by adding to the `Values` list. Separate items using commas.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=tag:Environment,Values=Development,Test,Pre-production \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=tag:Environment,Values=Development,Test,Pre-production ^
    [...]
```

Variation: Refining your targets using multiple `Key` criteria

You can refine the number of targets for your command by including multiple `Key` criteria. If you include more than one `Key` criteria, the system targets managed nodes that meet *all* of the criteria. The following command targets all managed nodes tagged for the Finance Department *and* tagged for the database server role.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=tag:Department,Values=Finance Key=tag:ServerRole,Values=Database \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=tag:Department,Values=Finance Key=tag:ServerRole,Values=Database ^
    [...]
```

Variation: Using multiple `Key` and `Value` criteria

Expanding on the previous example, you can target multiple departments and multiple server roles by including additional items in the `Values` criteria.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=tag:Department,Values=Finance,Marketing
 Key=tag:ServerRole,Values=WebServer,Database \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=tag:Department,Values=Finance,Marketing
 Key=tag:ServerRole,Values=WebServer,Database ^
    [...]
```

Variation: Targeting tagged managed nodes using multiple `Values` criteria

If you tagged managed nodes for different environments using a `Key` named `Department` and `Values` of `Sales` and `Finance`, then you could send a command to all of the nodes in these environments by using the `targets` parameter with the following syntax.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=tag:Department,Values=Sales,Finance \
```

```
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=tag:Department,Values=Sales,Finance ^
    [...]
```

You can specify a maximum of five keys, and five values for each key.

If either a tag key (the tag name) or a tag value includes spaces, enclose the tag key or the value in quotation marks, as shown in the following examples.

Example: Spaces in `Value` tag

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=tag:OS,Values="Windows Server 2016" \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=tag:OS,Values="Windows Server 2016" ^
    [...]
```

Example: Spaces in `tag` key and `Value`

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key="tag:Operating System",Values="Windows Server 2016" \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key="tag:Operating System",Values="Windows Server 2016" ^
    [...]
```

Example: Spaces in one item in a list of `Values`

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --targets Key=tag:Department,Values="Sales","Finance","Systems Mgmt" \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --targets Key=tag:Department,Values="Sales","Finance","Systems Mgmt" ^
    [...]
```

Using rate controls

You can control the rate at which commands are sent to managed nodes in a group by using *concurrency controls* and *error controls*.

Topics

- Using concurrency controls
- Using error controls

Using concurrency controls

You can control the number of managed nodes that run a command simultaneously by using the `max-concurrency` parameter (the **Concurrency** options in the **Run a command** page). You can specify either an absolute number of managed nodes, for example **10**, or a percentage of the target set, for example **10%**. The queueing system delivers the command to a single node and waits

until the system acknowledges the initial invocation before sending the command to two more nodes. The system exponentially sends commands to more nodes until the system meets the value of `max-concurrency`. The default for value `max-concurrency` is 50. The following examples show you how to specify values for the `max-concurrency` parameter.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --max-concurrency 10 \
    --targets Key=tag:Environment,Values=Development \
    [...]
```

```
aws ssm send-command \
    --document-name document-name \
    --max-concurrency 10% \
    --targets Key=tag:Department,Values=Finance,Marketing
 Key=tag:ServerRole,Values=WebServer,Database \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --max-concurrency 10 ^
    --targets Key=tag:Environment,Values=Development ^
    [...]
```

```
aws ssm send-command ^
    --document-name document-name ^
    --max-concurrency 10% ^
    --targets Key=tag:Department,Values=Finance,Marketing
 Key=tag:ServerRole,Values=WebServer,Database ^
    [...]
```

Using error controls

You can also control the execution of a command to hundreds or thousands of managed nodes by setting an error limit using the `max-errors` parameters (the **Error threshold** field in the **Run a command** page). The parameter specifies how many errors are allowed before the system stops

sending the command to additional managed nodes. You can specify either an absolute number of errors, for example **10**, or a percentage of the target set, for example **10%**. If you specify **3**, for example, the system stops sending the command when the fourth error is received. If you specify **0**, then the system stops sending the command to additional managed nodes after the first error result is returned. If you send a command to 50 managed nodes and set `max-errors` to **10%**, then the system stops sending the command to additional nodes when the sixth error is received.

Invocations that are already running a command when `max-errors` is reached are allowed to complete, but some of these invocations might fail as well. If you need to ensure that there won't be more than `max-errors` failed invocations, set `max-concurrency` to **1** so the invocations proceed one at a time. The default for max-errors is 0. The following examples show you how to specify values for the `max-errors` parameter.

Linux & macOS

```
aws ssm send-command \
    --document-name document-name \
    --max-errors 10 \
    --targets Key=tag:Database,Values=Development \
    [...]
```

```
aws ssm send-command \
    --document-name document-name \
    --max-errors 10% \
    --targets Key=tag:Environment,Values=Development \
    [...]
```

```
aws ssm send-command \
    --document-name document-name \
    --max-concurrency 1 \
    --max-errors 1 \
    --targets Key=tag:Environment,Values=Production \
    [...]
```

Windows

```
aws ssm send-command ^
    --document-name document-name ^
    --max-errors 10 ^
    --targets Key=tag:Database,Values=Development ^
```

```
    [...]
```

```
aws ssm send-command ^
    --document-name document-name ^
    --max-errors 10% ^
    --targets Key=tag:Environment,Values=Development ^
    [...]
```

```
aws ssm send-command ^
    --document-name document-name ^
    --max-concurrency 1 ^
    --max-errors 1 ^
    --targets Key=tag:Environment,Values=Production ^
    [...]
```

Canceling a command

You can attempt to cancel a command as long as the service shows that it's in either a Pending or Executing state. However, even if a command is still in one of these states, we can't guarantee that the command will be canceled and the underlying process stopped.

To cancel a command using the console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Select the command invocation that you want to cancel.
4. Choose **Cancel command**.

To cancel a command using the AWS CLI

Run the following command. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm cancel-command \
    --command-id "command-ID" \
```

```
    --instance-ids "instance-ID"
```

Windows

```
aws ssm cancel-command ^
    --command-id "command-ID" ^
    --instance-ids "instance-ID"
```

For information about the status of a canceled command, see Understanding command statuses.

Using exit codes in commands

In some cases, you might need to manage how your commands are handled by using exit codes.

Specify exit codes in commands

Using Run Command, a tool in AWS Systems Manager, you can specify exit codes to determine how commands are handled. By default, the exit code of the last command run in a script is reported as the exit code for the entire script. For example, you have a script that contains three commands. The first one fails but the following ones succeed. Because the final command succeeded, the status of the execution is reported as `succeeded`.

Shell scripts

To fail the entire script at the first command failure, you can include a shell conditional statement to exit the script if any command before the final one fails. Use the following approach.

```
<command 1>
    if [ $? != 0 ]
    then
        exit <N>
    fi
    <command 2>
    <command 3>
```

In the following example, the entire script fails if the first command fails.

```
cd /test
    if [ $? != 0 ]
    then
        echo "Failed"
```

```
        exit 1
    fi
    date
```

PowerShell scripts

PowerShell requires that you call `exit` explicitly in your scripts for Run Command to successfully capture the exit code.

```
<command 1>
    if ($?) {<do something>}
    else {exit <N>}
    <command 2>
    <command 3>
    exit <N>
```

Here is an example:

```
cd C:\
    if ($?) {echo "Success"}
    else {exit 1}
    date
```

Handling reboots when running commands

If you use Run Command, a tool in AWS Systems Manager, to run scripts that reboot managed nodes, we recommend that you specify an exit code in your script. If you attempt to reboot a node from a script by using some other mechanism, the script execution status might not be updated correctly, even if the reboot is the last step in your script. For Windows managed nodes, you specify `exit 3010` in your script. For Linux and macOS managed nodes, you specify `exit 194`. The exit code instructs AWS Systems Manager Agent (SSM Agent) to reboot the managed node, and then restart the script after the reboot completed. Before starting the reboot, SSM Agent informs the Systems Manager service in the cloud that communication will be disrupted during the server reboot.

> **Note**
>
> The reboot script can't be part of an `aws:runDocument` plugin. If a document contains the reboot script and another document tries to run that document through the `aws:runDocument` plugin, SSM Agent returns an error.

Create idempotent scripts

When developing scripts that reboot managed nodes, make the scripts idempotent so the script execution continues where it left off after the reboot. Idempotent scripts manage state and validate if the action was performed or not. This prevents a step from running multiple times when it's only intended to run once.

Here is an outline example of an idempotent script that reboots a managed node multiple times.

```
$name = Get current computer name
If ($name –ne $desiredName)
    {
        Rename computer
        exit 3010
    }

$domain = Get current domain name
If ($domain –ne $desiredDomain)
    {
        Join domain
        exit 3010
    }

If (desired package not installed)
    {
        Install package
        exit 3010
    }
```

Examples

The following script samples use exit codes to restart managed nodes. The Linux example installs package updates on Amazon Linux, and then restarts the node. The Windows Server example installs the Telnet-Client on the node, and then restarts it.

Amazon Linux 2

```
#!/bin/bash
yum -y update
needs-restarting -r
if [ $? -eq 1 ]
then
```

```
        exit 194
else
        exit 0
fi
```

Windows

```
$telnet = Get-WindowsFeature -Name Telnet-Client
if (-not $telnet.Installed)
    {
        # Install Telnet and then send a reboot request to SSM Agent.
        Install-WindowsFeature -Name "Telnet-Client"
        exit 3010
    }
```

Understanding command statuses

Run Command, a tool in AWS Systems Manager, reports detailed status information about the different states a command experiences during processing and for each managed node that processed the command. You can monitor command statuses using the following methods:

- Choose the **Refresh** icon on the **Commands** tab in the Run Command console interface.
- Call list-commands or list-command-invocations using the AWS Command Line Interface (AWS CLI). Or call Get-SSMCommand or Get-SSMCommandInvocation using AWS Tools for Windows PowerShell.
- Configure Amazon EventBridge to respond to state or status changes.
- Configure Amazon Simple Notification Service (Amazon SNS) to send notifications for all status changes or specific statuses such as `Failed` or `TimedOut`.

Run Command status

Run Command reports status details for three areas: plugins, invocations, and an overall command status. A *plugin* is a code-execution block that is defined in your command's SSM document. For more information about plugins, see Command document plugin reference.

When you send a command to multiple managed nodes at the same time, each copy of the command targeting each node is a *command invocation*. For example, if you use the `AWS-RunShellScript` document and send an `ifconfig` command to 20 Linux instances, that

command has 20 invocations. Each command invocation individually reports status. The plugins for a given command invocation individually report status as well.

Lastly, Run Command includes an aggregated command status for all plugins and invocations. The aggregated command status can be different than the status reported by plugins or invocations, as noted in the following tables.

> **Note**
>
> If you run commands to large numbers of managed nodes using the `max-concurrency` or `max-errors` parameters, command status reflects the limits imposed by those parameters, as described in the following tables. For more information about these parameters, see Run commands at scale.

Detailed status for command plugins and invocations

Status	Details
Pending	The command hasn't yet been sent to the managed node or hasn't been received by SSM Agent. If the command isn't received by the agent before the length of time passes that is equal to the sum of the **Timeout (seconds)** parameter and the **Execution timeout** parameter, the status changes to `Delivery Timed Out`.
InProgress	Systems Manager is attempting to send the command to the managed node, or the command was received by SSM Agent and has started running on the instance. Depending on the result of all command plugins, the status changes to `Success`, `Failed`, `Delivery Timed Out`, or `Execution Timed Out`. *Exception*: If the agent isn't running or available on the node, the command status remains at `In Progress` until the agent is

Status	Details
	available again, or until the execution timeout limit is reached. The status then changes to a terminal state.
Delayed	The system attempted to send the command to the managed node but wasn't successful. The system retries again.

Status	Details
Success	This status is returned under a variety of conditions. This status *doesn't* mean the command was processed on the node. For example, the command can be received by SSM Agent on the managed node and return an exit code of zero as a result of your PowerShell `ExecutionPolicy` preventing the command from running. This is a terminal state. Conditions that result in a command returning a `Success` status are: • When targeting a single instance, the command was received by SSM Agent on the managed node and returned an exit code of zero. • When targeting multiple instances, the number of failed invocations has not crossed the error threshold specified in the command. • When targeting multiple instances, at least 1 invocation has succeeded while others have timed out. The specified error threshold still applies. • When targeting a tag, no instances are found associated with the tag. • When targeting a tag, the number of failed invocations has not crossed the error threshold specified in the command. • When targeting a tag, at least 1 invocation has succeeded while others have timed out. The specified error threshold still applies. • You have applications or policies enforced at the OS level that prevent or override the

Status	Details
	execution of a command resulting in an exit code of zero being returned. **Note** The same conditions apply when targeting resource groups. To troubleshoot errors or get more information about the command execution, send a command that handles errors or exceptions by returning appropriate exit codes (non-zero exit codes for command failure).
DeliveryTimedOut	The command wasn't delivered to the managed node before the total timeout expired. Total timeouts don't count against the parent command's `max-errors` limit, but they do contribute to whether the parent command status is `Success`, `Incomplete` , or `Delivery Timed Out`. This is a terminal state.
ExecutionTimedOut	Command automation started on the managed node, but the command wasn't completed before the execution timeout expired. Execution timeouts count as a failure, which will send a non-zero reply and Systems Manager will exit the attempt to run the command automation, and report a failure status.

Status	Details
Failed	The command wasn't successful on the managed node. For a plugin, this indicates that the result code wasn't zero. For a command invocation, this indicates that the result code for one or more plugins wasn't zero. Invocation failures count against the `max-errors` limit of the parent command. This is a terminal state.
Cancelled	The command was canceled before it was completed. This is a terminal state.
Undeliverable	The command can't be delivered to the managed node. The node might not exist or it might not be responding. Undeliverable invocations don't count against the parent command's `max-errors` limit, but they do contribute to whether the parent command status is `Success` or `Incomplete`. For example, if all invocations in a command have the status `Undeliverable`, then the command status returned is `Failed`. However, if a command has five invocations, four of which return the status `Undeliverable` and one of which returns the status `Success`, then the parent command's status is `Success`. This is a terminal state.
Terminated	The parent command exceeded its `max-errors` limit and subsequent command invocations were canceled by the system. This is a terminal state.

Status	Details
InvalidPlatform	The command was sent to a managed node that didn't match the required platforms specified by the chosen document. `Invalid Platform` doesn't count against the parent command's max-errors limit, but it does contribute to whether the parent command status is Success or Failed. For example, if all invocations in a command have the status `Invalid Platform`, then the command status returned is `Failed`. However, if a command has five invocations, four of which return the status `Invalid Platform` and one of which returns the status `Success`, then the parent command's status is `Success`. This is a terminal state.
AccessDenied	The AWS Identity and Access Managemen t (IAM) user or role initiating the command doesn't have access to the targeted managed node. `Access Denied` doesn't count against the parent command's `max-errors` limit, but it does contribute to whether the parent command status is `Success` or `Failed`. For example, if all invocations in a command have the status `Access Denied`, then the command status returned is `Failed`. However, if a command has five invocations, four of which return the status `Access Denied` and one of which returns the status `Success`, then the parent command's status is `Success`. This is a terminal state.

Detailed status for a command

Status	Details
Pending	The command wasn't yet received by an agent on any managed nodes.
InProgress	The command has been sent to at least one managed node but hasn't reached a final state on all nodes.
Delayed	The system attempted to send the command to the node but wasn't successful. The system retries again.
Success	The command was received by SSM Agent on all specified or targeted managed nodes and returned an exit code of zero. All command invocations have reached a terminal state, and the value of `max-errors` wasn't reached. This status *doesn't* mean the command was successfully processed on all specified or targeted managed nodes. This is a terminal state. **Note** To troubleshoot errors or get more information about the command execution, send a command that handles errors or exceptions by returning appropriate exit codes (non-zero exit codes for command failure).
DeliveryTimedOut	The command wasn't delivered to the managed node before the total timeout expired. The value of `max-errors` or more command invocations shows a status of

Status	Details
	`Delivery Timed Out`. This is a terminal state.
Failed	The command wasn't successful on the managed node. The value of `max-errors` or more command invocations shows a status of `Failed`. This is a terminal state.
Incomplete	The command was attempted on all managed nodes and one or more of the invocations doesn't have a value of `Success`. However, not enough invocations failed for the status to be `Failed`. This is a terminal state.
Cancelled	The command was canceled before it was completed. This is a terminal state.
RateExceeded	The number of managed nodes targeted by the command exceeded the account quota for pending invocations. The system has canceled the command before executing it on any node. This is a terminal state.

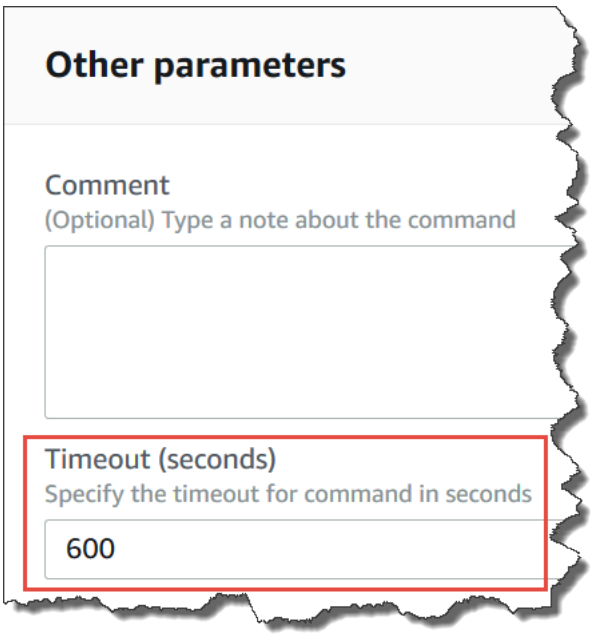
Status	Details
AccessDenied	The user or role initiating the command doesn't have access to the targeted resource group. `AccessDenied` doesn't count against the parent command's `max-errors` limit, but does contribute to whether the parent command status is `Success` or `Failed`. (For example, if all invocations in a command have the status `AccessDenied` , then the command status returned is `Failed`. However, if a command has 5 invocations, 4 of which return the status `AccessDenied` and 1 of which returns the status `Success`, then the parent command's status is `Success`.) This is a terminal state.
No Instances In Tag	The tag key-pair value or resource group targeted by the command doesn't match any managed nodes. This is a terminal state.

Understanding command timeout values

Systems Manager enforces the following timeout values when running commands.

Total Timeout

In the Systems Manager console, you specify the timeout value in the **Timeout (seconds)** field. After a command is sent, Run Command checks whether the command has expired or not. If a command reaches the command expiration limit (total timeout), it changes status to `DeliveryTimedOut` for all invocations that have the status `InProgress`, `Pending` or `Delayed`.



On a more technical level, total timeout (**Timeout (seconds)**) is a combination of two timeout values, as shown here:

```
Total timeout = "Timeout(seconds)" from the console + "timeoutSeconds":
"{{ executionTimeout }}" from your SSM document
```

For example, the default value of **Timeout (seconds)** in the Systems Manager console is 600 seconds. If you run a command by using the `AWS-RunShellScript` SSM document, the default value of **"timeoutSeconds": "{{ executionTimeout }}"** is 3600 seconds, as shown in the following document sample:

```
"executionTimeout": {
    "type": "String",
    "default": "3600",

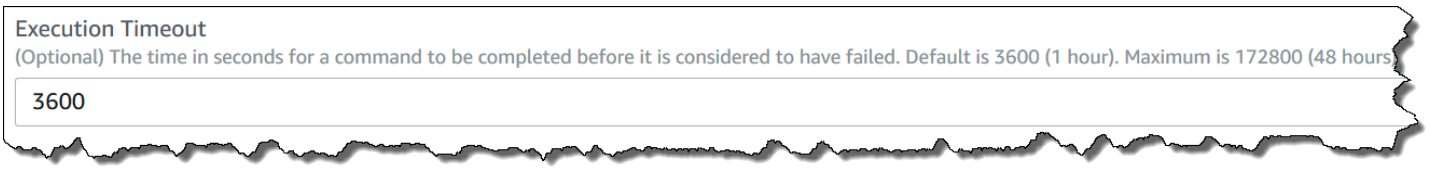
"runtimeConfig": {
  "aws:runShellScript": {
    "properties": [
      {
        "timeoutSeconds": "{{ executionTimeout }}"
```

This means the command runs for 4,200 seconds (70 minutes) before the system sets the command status to `DeliveryTimedOut`.

Execution Timeout

In the Systems Manager console, you specify the execution timeout value in the **Execution Timeout** field, if available. Not all SSM documents require that you specify an execution timeout. The **Execution Timeout** field is only displayed when a corresponding input parameter has been defined in the SSM document. If specified, the command must complete within this time period.

> **Note**
>
> Run Command relies on the SSM Agent document terminal response to determine whether or not the command was delivered to the agent. SSM Agent must send an `ExecutionTimedOut` signal for an invocation or command to be marked as `ExecutionTimedOut`.



Default Execution Timeout

If a SSM document doesn't require that you explicitly specify an execution timeout value, then Systems Manager enforces the hard-coded default execution timeout.

How Systems Manager reports timeouts

If Systems Manager receives an `execution timeout` reply from SSM Agent on a target, then Systems Manager marks the command invocation as `executionTimeout`.

If Run Command doesn't receive a document terminal response from SSM Agent, the command invocation is marked as `deliveryTimeout`.

To determine timeout status on a target, SSM Agent combines all parameters and the content of the SSM document to calculate for `executionTimeout`. When SSM Agent determines that a command has timed out, it sends `executionTimeout` to the service.

The default for **Timeout (seconds)** is 3600 seconds. The default for **Execution Timeout** is also 3600 seconds. Therefore, the total default timeout for a command is 7200 seconds.

> **Note**
>
> SSM Agent processes `executionTimeout` differently depending on the type of SSM document and the document version.

Run Command walkthroughs

The walkthroughs in this section show you how to run commands with Run Command, a tool in AWS Systems Manager, using either the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell.

Contents

You can also view sample commands in the following references.

- Systems Manager AWS CLI Reference
- AWS Tools for Windows PowerShell - AWS Systems Manager

Updating software using Run Command

The following procedures describe how to update software on your managed nodes.

Updating the SSM Agent using Run Command

The following procedure describes how to update the SSM Agent running on your managed nodes. You can update to either the latest version of SSM Agent or downgrade to an older version. When you run the command, the system downloads the version from AWS, installs it, and then uninstalls the version that existed before the command was run. If an error occurs during this process, the system rolls back to the version on the server before the command was run and the command status shows that the command failed.

> **Note**
>
> If an instance is running macOS version 13.0 (Ventura) or later, the instance must have the SSM Agent version 3.1.941.0 or higher to run the AWS-UpdateSSMAgent document. If the instance is running a version of SSM Agent released before 3.1.941.0, you can update your SSM Agent to run the AWS-UpdateSSMAgent document by running `brew update` and `brew upgrade amazon-ssm-agent` commands.

To be notified about SSM Agent updates, subscribe to the SSM Agent Release Notes page on GitHub.

To update SSM Agent using Run Command

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **`AWS-UpdateSSMAgent`**.
5. In the **Command parameters** section, specify values for the following parameters, if you want:
   a. (Optional) For **Version**, enter the version of SSM Agent to install. You can install older versions of the agent. If you don't specify a version, the service installs the latest version.
   b. (Optional) For **Allow Downgrade**, choose **true** to install an earlier version of SSM Agent. If you choose this option, specify the earlier version number. Choose **false** to install only the newest version of the service.
6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   > **Tip**
   >
   > If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

7. For **Other parameters**:
   - For **Comment**, enter information about this command.

- For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:

   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

     > **Note**
     >
     > If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

   > **Note**
   >
   > The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

11. Choose **Run**.

Updating PowerShell using Run Command

The following procedure describes how to update PowerShell to version 5.1 on your Windows Server 2012 and 2012 R2 managed nodes. The script provided in this procedure downloads the Windows Management Framework (WMF) version 5.1 update, and starts the installation of the update. The node reboots during this process because this is required when installing WMF 5.1. The download and installation of the update takes approximately five minutes to complete.

To update PowerShell using Run Command

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **`AWS-RunPowerShellScript`**.
5. In the **Commands** section, paste the following commands for your operating system.

   Windows Server 2012 R2

   ```
   Set-Location -Path "C:\Windows\Temp"

   Invoke-WebRequest "https://go.microsoft.com/fwlink/?linkid=839516" -OutFile
    "Win8.1AndW2K12R2-KB3191564-x64.msu"

   Start-Process -FilePath "$env:systemroot\system32\wusa.exe" -Verb RunAs -
   ArgumentList ('Win8.1AndW2K12R2-KB3191564-x64.msu', '/quiet')
   ```

   Windows Server 2012

   ```
   Set-Location -Path "C:\Windows\Temp"

   Invoke-WebRequest "https://go.microsoft.com/fwlink/?linkid=839513" -OutFile
    "W2K12-KB3191565-x64.msu"
   ```

```
Start-Process -FilePath "$env:systemroot\system32\wusa.exe" -Verb RunAs -
ArgumentList ('W2K12-KB3191565-x64.msu', '/quiet')
```

6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   > **Tip**
   >
   > If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

7. For **Other parameters**:

   - For **Comment**, enter information about this command.
   - For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:

   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

     > **Note**
     >
     > If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

    For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.
11. Choose **Run**.

After the managed node reboots and the installation of the update is complete, connect to your node to confirm that PowerShell successfully upgraded to version 5.1. To check the version of PowerShell on your node, open PowerShell and enter `$PSVersionTable`. The `PSVersion` value in the output table shows 5.1 if the upgrade was successful.

If the `PSVersion` value is different than 5.1, for example 3.0 or 4.0, review the **Setup** logs in Event Viewer under **Windows Logs**. These logs indicate why the update installation failed.

Walkthrough: Use the AWS CLI with Run Command

The following sample walkthrough shows you how to use the AWS Command Line Interface (AWS CLI) to view information about commands and command parameters, how to run commands, and how to view the status of those commands.

> **Important**
>
> Only trusted administrators should be allowed to use AWS Systems Manager pre-configured documents shown in this topic. The commands or scripts specified in Systems Manager documents run with administrative permissions on your managed nodes. If a user has permission to run any of the pre-defined Systems Manager documents (any document

that begins with `AWS-`), then that user also has administrator access to the node. For all other users, you should create restrictive documents and share them with specific users.

Topics

Step 1: Getting started

You must either have administrator permissions on the managed node you want to configure or you must have been granted the appropriate permission in AWS Identity and Access Management (IAM). Also note, this example uses the US East (Ohio) Region (us-east-2). Run Command is available in the AWS Regions listed in Systems Manager service endpoints in the *Amazon Web Services General Reference*. For more information, see Setting up managed nodes for AWS Systems Manager.

To run commands using the AWS CLI

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. List all available documents.

   This command lists all of the documents available for your account based on IAM permissions.

   ```
   aws ssm list-documents
   ```

3. Verify that an managed node is ready to receive commands.

   The output of the following command shows if managed nodes are online.

   Linux & macOS

   ```
   aws ssm describe-instance-information \
   ```

```
    --output text --query "InstanceInformationList[*]"
```

Windows

```
aws ssm describe-instance-information ^
    --output text --query "InstanceInformationList[*]"
```

4. Run the following command to view details about a particular managed node.

> **Note**
>
> To run the commands in this walkthrough, replace the instance and command IDs. For managed AWS IoT Greengrass core devices, use the mi-*ID_number* for instance ID. The command ID is returned as a response to **send-command**. Instance IDs are available from Fleet Manager, a tool in AWS Systems Manager..

Linux & macOS

```
aws ssm describe-instance-information \
    --instance-information-filter-list key=InstanceIds,valueSet=instance-ID
```

Windows

```
aws ssm describe-instance-information ^
    --instance-information-filter-list key=InstanceIds,valueSet=instance-ID
```

Step 2: Run shell scripts to view resource details

Using Run Command and the `AWS-RunShellScript` document, you can run any command or script on a managed node as if you were logged on locally.

View the description and available parameters

Run the following command to view a description of the Systems Manager JSON document.

Linux & macOS

```
aws ssm describe-document \
```

```
    --name "AWS-RunShellScript" \
    --query "[Document.Name,Document.Description]"
```

Windows

```
aws ssm describe-document ^
    --name "AWS-RunShellScript" ^
    --query "[Document.Name,Document.Description]"
```

Run the following command to view the available parameters and details about those parameters.

Linux & macOS

```
aws ssm describe-document \
    --name "AWS-RunShellScript" \
    --query "Document.Parameters[*]"
```

Windows

```
aws ssm describe-document ^
    --name "AWS-RunShellScript" ^
    --query "Document.Parameters[*]"
```

Step 3: Send simple commands using the `AWS-RunShellScript` document

Run the following command to get IP information for a Linux managed node.

If you're targeting a Windows Server managed node, change the `document-name` to `AWS-RunPowerShellScript` and change the `command` from `ifconfig` to `ipconfig`.

Linux & macOS

```
aws ssm send-command \
    --instance-ids "instance-ID" \
    --document-name "AWS-RunShellScript" \
    --comment "IP config" \
    --parameters commands=ifconfig \
    --output text
```

Windows

```
aws ssm send-command ^
    --instance-ids "instance-ID" ^
    --document-name "AWS-RunShellScript" ^
    --comment "IP config" ^
    --parameters commands=ifconfig ^
    --output text
```

Get command information with response data

The following command uses the Command ID that was returned from the previous command to get the details and response data of the command execution. The system returns the response data if the command completed. If the command execution shows `"Pending"` or `"InProgress"` you run this command again to see the response data.

Linux & macOS

```
aws ssm list-command-invocations \
    --command-id $sh-command-id \
    --details
```

Windows

```
aws ssm list-command-invocations ^
    --command-id $sh-command-id ^
    --details
```

Identify user

The following command displays the default user running the commands.

Linux & macOS

```
sh_command_id=$(aws ssm send-command \
    --instance-ids "instance-ID" \
    --document-name "AWS-RunShellScript" \
    --comment "Demo run shell script on Linux managed node" \
    --parameters commands=whoami \
    --output text \
```

```
    --query "Command.CommandId")
```

Get command status

The following command uses the Command ID to get the status of the command execution on the managed node. This example uses the Command ID that was returned in the previous command.

Linux & macOS

```
aws ssm list-commands \
    --command-id "command-ID"
```

Windows

```
aws ssm list-commands ^
    --command-id "command-ID"
```

Get command details

The following command uses the Command ID from the previous command to get the status of the command execution on a per managed node basis.

Linux & macOS

```
aws ssm list-command-invocations \
    --command-id "command-ID" \
    --details
```

Windows

```
aws ssm list-command-invocations ^
    --command-id "command-ID" ^
    --details
```

Get command information with response data for a specific managed node

The following command returns the output of the original `aws ssm send-command` request for a specific managed node.

Linux & macOS

```
aws ssm list-command-invocations \
    --instance-id instance-ID \
    --command-id "command-ID" \
    --details
```

Windows

```
aws ssm list-command-invocations ^
    --instance-id instance-ID ^
    --command-id "command-ID" ^
    --details
```

Display Python version

The following command returns the version of Python running on a node.

Linux & macOS

```
sh_command_id=$(aws ssm send-command \
    --instance-ids "instance-ID" \
    --document-name "AWS-RunShellScript" \
    --comment "Demo run shell script on Linux Instances" \
    --parameters commands='python -V' \
    --output text --query "Command.CommandId") \
    sh -c 'aws ssm list-command-invocations \
    --command-id "$sh_command_id" \
    --details \
    --query "CommandInvocations[].CommandPlugins[].{Status:Status,Output:Output}"'
```

Step 4: Run a simple Python script using Run Command

The following command runs a simple Python "Hello World" script using Run Command.

Linux & macOS

```
sh_command_id=$(aws ssm send-command \
    --instance-ids "instance-ID" \
    --document-name "AWS-RunShellScript" \
```

```
    --comment "Demo run shell script on Linux Instances" \
    --parameters '{"commands":["#!/usr/bin/python","print \"Hello World from python
\""]}' \
    --output text \
    --query "Command.CommandId") \
    sh -c 'aws ssm list-command-invocations \
    --command-id "$sh_command_id" \
    --details \
    --query "CommandInvocations[].CommandPlugins[].{Status:Status,Output:Output}"'
```

Step 5: Run a Bash script using Run Command

The examples in this section demonstrate how to run the following bash script using Run Command.

For examples of using Run Command to run scripts stored in remote locations, see Running scripts from Amazon S3 and Running scripts from GitHub.

```
#!/bin/bash
yum -y update
yum install -y ruby
cd /home/ec2-user
curl -O https://aws-codedeploy-us-east-2.s3.amazonaws.com/latest/install
chmod +x ./install
./install auto
```

This script installs the AWS CodeDeploy agent on Amazon Linux and Red Hat Enterprise Linux (RHEL) instances, as described in Create an Amazon EC2 instance for CodeDeploy in the *AWS CodeDeploy User Guide*.

The script installs the CodeDeploy agent from an AWS managed S3 bucket in thee US East (Ohio) Region (us-east-2), `aws-codedeploy-us-east-2`.

Run a bash script in an AWS CLI command

The following sample demonstrates how to include the bash script in a CLI command using the `--parameters` option.

Linux & macOS

```
aws ssm send-command \
```

```
    --document-name "AWS-RunShellScript" \
    --targets '[{"Key":"InstanceIds","Values":["instance-id"]}]' \
    --parameters '{"commands":["#!/bin/bash","yum -y update","yum
 install -y ruby","cd /home/ec2-user","curl -O https://aws-codedeploy-us-
east-2.s3.amazonaws.com/latest/install","chmod +x ./install","./install auto"]}'
```

Run a bash script in a JSON file

In the following example, the content of the bash script is stored in a JSON file, and the file is included in the command using the `--cli-input-json` option.

Linux & macOS

```
aws ssm send-command \
    --document-name "AWS-RunShellScript" \
    --targets "Key=InstanceIds,Values=instance-id" \
    --cli-input-json file://installCodeDeployAgent.json
```

Windows

```
aws ssm send-command ^
    --document-name "AWS-RunShellScript" ^
    --targets "Key=InstanceIds,Values=instance-id" ^
    --cli-input-json file://installCodeDeployAgent.json
```

The contents of the referenced `installCodeDeployAgent.json` file is shown in the following example.

```
{
    "Parameters": {
        "commands": [
            "#!/bin/bash",
            "yum -y update",
            "yum install -y ruby",
            "cd /home/ec2-user",
            "curl -O https://aws-codedeploy-us-east-2.s3.amazonaws.com/latest/install",
            "chmod +x ./install",
            "./install auto"
        ]
    }
```

```
}
```

Walkthrough: Use the AWS Tools for Windows PowerShell with Run Command

The following examples show how to use the AWS Tools for Windows PowerShell to view information about commands and command parameters, how to run commands, and how to view the status of those commands. This walkthrough includes an example for each of the pre-defined AWS Systems Manager documents.

> **Important**
>
> Only trusted administrators should be allowed to use Systems Manager pre-configured documents shown in this topic. The commands or scripts specified in Systems Manager documents run with administrative permission on your managed nodes. If a user has permission to run any of the predefined Systems Manager documents (any document that begins with AWS), then that user also has administrator access to the node. For all other users, you should create restrictive documents and share them with specific users.

Topics

Configure AWS Tools for Windows PowerShell session settings

Specify your credentials

Open **Tools for Windows PowerShell** on your local computer and run the following command to specify your credentials. You must either have administrator permissions on the managed nodes you want to configure or you must have been granted the appropriate permission in AWS Identity and Access Management (IAM). For more information, see Setting up managed nodes for AWS Systems Manager.

```
Set-AWSCredentials -AccessKey key-name -SecretKey key-name
```

Set a default AWS Region

Run the following command to set the region for your PowerShell session. The example uses the US East (Ohio) Region (us-east-2). Run Command is available in the AWS Regions listed in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

```
Set-DefaultAWSRegion `
    -Region us-east-2
```

List all available documents

This command lists all documents available for your account.

```
Get-SSMDocumentList
```

Run PowerShell commands or scripts

Using Run Command and the `AWS-RunPowerShell` document, you can run any command or script on a managed node as if you were logged on locally. You can issue commands or enter a path to a local script to run the command.

> **Note**
>
> For information about rebooting managed nodes when using Run Command to call scripts, see Handling reboots when running commands.

View the description and available parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-RunPowerShellScript"
```

View more information about parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-RunPowerShellScript" | Select -ExpandProperty Parameters
```

Send a command using the AWS-RunPowerShellScript document

The following command shows the contents of the "C:\Users" directory and the contents of the "C:\" directory on two managed nodes.

```
$runPSCommand = Send-SSMCommand `
    -InstanceIds @("instance-ID-1", "instance-ID-2") `
    -DocumentName "AWS-RunPowerShellScript" `
    -Comment "Demo AWS-RunPowerShellScript with two instances" `
    -Parameter @{'commands'=@('dir C:\Users', 'dir C:\')}
```

Get command request details

The following command uses the CommandId to get the status of the command execution on both managed nodes. This example uses the CommandId that was returned in the previous command.

```
Get-SSMCommand `
    -CommandId $runPSCommand.CommandId
```

The status of the command in this example can be Success, Pending, or InProgress.

Get command information per managed node

The following command uses the CommandId from the previous command to get the status of the command execution on a per managed node basis.

```
Get-SSMCommandInvocation `
    -CommandId $runPSCommand.CommandId
```

Get command information with response data for a specific managed node

The following command returns the output of the original Send-SSMCommand for a specific managed node.

```
Get-SSMCommandInvocation `
    -CommandId $runPSCommand.CommandId `
    -Details $true `
```

```
    -InstanceId instance-ID | Select -ExpandProperty CommandPlugins
```

Cancel a command

The following command cancels the `Send-SSMCommand` for the `AWS-RunPowerShellScript` document.

```
$cancelCommand = Send-SSMCommand `
    -InstanceIds @("instance-ID-1","instance-ID-2") `
    -DocumentName "AWS-RunPowerShellScript" `
    -Comment "Demo AWS-RunPowerShellScript with two instances" `
    -Parameter @{'commands'='Start-Sleep -Seconds 120; dir C:\'}

Stop-SSMCommand -CommandId $cancelCommand.CommandId
```

Check the command status

The following command checks the status of the `Cancel` command.

```
Get-SSMCommand `
    -CommandId $cancelCommand.CommandId
```

Install an application using the `AWS-InstallApplication` document

Using Run Command and the `AWS-InstallApplication` document, you can install, repair, or uninstall applications on managed nodes. The command requires the path or address to an MSI.

> **Note**
>
> For information about rebooting managed nodes when using Run Command to call scripts, see Handling reboots when running commands.

View the description and available parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-InstallApplication"
```

View more information about parameters

```
Get-SSMDocumentDescription `
```

```
    -Name "AWS-InstallApplication" | Select -ExpandProperty Parameters
```

Send a command using the AWS-InstallApplication document

The following command installs a version of Python on your managed node in unattended mode, and logs the output to a local text file on your C: drive.

```
$installAppCommand = Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-InstallApplication" `
    -Parameter @{'source'='https://www.python.org/ftp/python/2.7.9/python-2.7.9.msi';
 'parameters'='/norestart /quiet /log c:\pythoninstall.txt'}
```

Get command information per managed node

The following command uses the CommandId to get the status of the command execution.

```
Get-SSMCommandInvocation `
    -CommandId $installAppCommand.CommandId `
    -Details $true
```

Get command information with response data for a specific managed node

The following command returns the results of the Python installation.

```
Get-SSMCommandInvocation `
    -CommandId $installAppCommand.CommandId `
    -Details $true `
    -InstanceId instance-ID | Select -ExpandProperty CommandPlugins
```

Install a PowerShell module using the AWS-InstallPowerShellModule JSON document

You can use Run Command to install PowerShell modules on managed nodes. For more information about PowerShell modules, see Windows PowerShell Modules.

View the description and available parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-InstallPowerShellModule"
```

View more information about parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-InstallPowerShellModule" | Select -ExpandProperty Parameters
```

Install a PowerShell module

The following command downloads the EZOut.zip file, installs it, and then runs an additional command to install XPS viewer. Lastly, the output of this command is uploaded to an S3 bucket named "amzn-s3-demo-bucket".

```
$installPSCommand = Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-InstallPowerShellModule" `
    -Parameter @{'source'='https://gallery.technet.microsoft.com/EZOut-33ae0fb7/
file/110351/1/EZOut.zip';'commands'=@('Add-WindowsFeature -name XPS-Viewer -restart')}
 `
    -OutputS3BucketName amzn-s3-demo-bucket
```

Get command information per managed node

The following command uses the `CommandId` to get the status of the command execution.

```
Get-SSMCommandInvocation `
    -CommandId $installPSCommand.CommandId `
    -Details $true
```

Get command information with response data for the managed node

The following command returns the output of the original `Send-SSMCommand` for the specific `CommandId`.

```
Get-SSMCommandInvocation `
    -CommandId $installPSCommand.CommandId `
    -Details $true | Select -ExpandProperty CommandPlugins
```

Join a managed node to a Domain using the `AWS-JoinDirectoryServiceDomain` JSON document

Using Run Command, you can quickly join a managed node to an AWS Directory Service domain. Before executing this command, create a directory. We also recommend that you learn more about the AWS Directory Service. For more information, see the AWS Directory Service Administration Guide.

You can only join a managed node to a domain. You can't remove a node from a domain.

> **Note**
>
> For information about managed nodes when using Run Command to call scripts, see Handling reboots when running commands.

View the description and available parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-JoinDirectoryServiceDomain"
```

View more information about parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-JoinDirectoryServiceDomain" | Select -ExpandProperty Parameters
```

Join a managed node to a domain

The following command joins a managed node to the given AWS Directory Service domain and uploads any generated output to the example Amazon Simple Storage Service (Amazon S3) bucket.

```
$domainJoinCommand = Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-JoinDirectoryServiceDomain" `
    -Parameter @{'directoryId'='d-example01'; 'directoryName'='ssm.example.com';
 'dnsIpAddresses'=@('192.168.10.195', '192.168.20.97')} `
    -OutputS3BucketName amzn-s3-demo-bucket
```

Get command information per managed node

The following command uses the CommandId to get the status of the command execution.

```
Get-SSMCommandInvocation `
    -CommandId $domainJoinCommand.CommandId `
    -Details $true
```

Get command information with response data for the managed node

This command returns the output of the original `Send-SSMCommand` for the specific `CommandId`.

```
Get-SSMCommandInvocation `
    -CommandId $domainJoinCommand.CommandId `
    -Details $true | Select -ExpandProperty CommandPlugins
```

Send Windows metrics to Amazon CloudWatch Logs using the `AWS-ConfigureCloudWatch` document

You can send Windows Server messages in the application, system, security, and Event Tracing for Windows (ETW) logs to Amazon CloudWatch Logs. When you allow logging for the first time, Systems Manager sends all logs generated within one (1) minute from the time that you start uploading logs for the application, system, security, and ETW logs. Logs that occurred before this time aren't included. If you turn off logging and then later turn logging back on, Systems Manager sends logs from the time it left off. For any custom log files and Internet Information Services (IIS) logs, Systems Manager reads the log files from the beginning. In addition, Systems Manager can also send performance counter data to CloudWatch Logs.

If you previously turned on CloudWatch integration in EC2Config, the Systems Manager settings override any settings stored locally on the managed node in the `C:\Program Files\Amazon\EC2ConfigService\Settings\AWS.EC2.Windows.CloudWatch.json` file. For more information about using EC2Config to manage performance counters and logs on a single managed node, see Collecting metrics and logs from Amazon EC2 instances and on-premises servers with the CloudWatch agent in the *Amazon CloudWatch User Guide*.

View the description and available parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-ConfigureCloudWatch"
```

View more information about parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-ConfigureCloudWatch" | Select -ExpandProperty Parameters
```

Send application logs to CloudWatch

The following command configures the managed node and moves Windows Applications logs to CloudWatch.

```
$cloudWatchCommand = Send-SSMCommand `
    -InstanceID instance-ID `
    -DocumentName "AWS-ConfigureCloudWatch" `
    -Parameter @{'properties'='{"engineConfiguration": {"PollInterval":"00:00:15",
 "Components":[{"Id":"ApplicationEventLog",
 "FullName":"AWS.EC2.Windows.CloudWatch.EventLog.EventLogInputComponent,AWS.EC2.Windows.CloudWa
 "Parameters":{"LogName":"Application", "Levels":"7"}},{"Id":"CloudWatch",
 "FullName":"AWS.EC2.Windows.CloudWatch.CloudWatchLogsOutput,AWS.EC2.Windows.CloudWatch",
 "Parameters":{"Region":"region", "LogGroup":"my-log-group", "LogStream":"instance-
id"}}], "Flows":{"Flows":["ApplicationEventLog,CloudWatch"]}}}'}
```

Get command information per managed node

The following command uses the `CommandId` to get the status of the command execution.

```
Get-SSMCommandInvocation `
    -CommandId $cloudWatchCommand.CommandId `
    -Details $true
```

Get command information with response data for a specific managed node

The following command returns the results of the Amazon CloudWatch configuration.

```
Get-SSMCommandInvocation `
    -CommandId $cloudWatchCommand.CommandId `
    -Details $true `
    -InstanceId instance-ID | Select -ExpandProperty CommandPlugins
```

Send performance counters to CloudWatch using the `AWS-ConfigureCloudWatch` document

The following demonstration command uploads performance counters to CloudWatch. For more information, see the *Amazon CloudWatch User Guide*.

```
$cloudWatchMetricsCommand = Send-SSMCommand `
    -InstanceID instance-ID `
    -DocumentName "AWS-ConfigureCloudWatch" `
    -Parameter @{'properties'='{"engineConfiguration": {"PollInterval":"00:00:15",
 "Components":[{"Id":"PerformanceCounter",
 "FullName":"AWS.EC2.Windows.CloudWatch.PerformanceCounterComponent.PerformanceCounterInputComp
 "Parameters":{"CategoryName":"Memory", "CounterName":"Available
 MBytes", "InstanceName":"", "MetricName":"AvailableMemory",
 "Unit":"Megabytes","DimensionName":"", "DimensionValue":""}},{"Id":"CloudWatch",
```

```
 "FullName":"AWS.EC2.Windows.CloudWatch.CloudWatch.CloudWatchOutputComponent,AWS.EC2.Windows.Cl
 "Parameters":{"AccessKey":"", "SecretKey":"","Region":"region", "NameSpace":"Windows-
Default"}}], "Flows":{"Flows":["PerformanceCounter,CloudWatch"]}}}'}
```

Update EC2Config using the AWS-UpdateEC2Config document

Using Run Command and the AWS-EC2ConfigUpdate document, you can update the EC2Config service running on your Windows Server managed nodes. This command can update the EC2Config service to the latest version or a version you specify.

View the description and available parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-UpdateEC2Config"
```

View more information about parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-UpdateEC2Config" | Select -ExpandProperty Parameters
```

Update EC2Config to the latest version

```
$ec2ConfigCommand = Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-UpdateEC2Config"
```

Get command information with response data for the managed node

This command returns the output of the specified command from the previous Send-SSMCommand.

```
Get-SSMCommandInvocation `
    -CommandId $ec2ConfigCommand.CommandId `
    -Details $true `
    -InstanceId instance-ID | Select -ExpandProperty CommandPlugins
```

Update EC2Config to a specific version

The following command downgrades EC2Config to an older version.

```
Send-SSMCommand `
```

```
    -InstanceId instance-ID `
    -DocumentName "AWS-UpdateEC2Config" `
    -Parameter @{'version'='4.9.3519'; 'allowDowngrade'='true'}
```

Turn on or turn off Windows automatic update using the AWS-ConfigureWindowsUpdate document

Using Run Command and the AWS-ConfigureWindowsUpdate document, you can turn on or turn off automatic Windows updates on your Windows Server managed nodes. This command configures the Windows Update Agent to download and install Windows updates on the day and hour that you specify. If an update requires a reboot, the managed node reboots automatically 15 minutes after updates have been installed. With this command you can also configure Windows Update to check for updates but not install them. The AWS-ConfigureWindowsUpdate document is officially supported on Windows Server 2012 and later versions.

View the description and available parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-ConfigureWindowsUpdate"
```

View more information about parameters

```
Get-SSMDocumentDescription `
    -Name "AWS-ConfigureWindowsUpdate" | Select -ExpandProperty Parameters
```

Turn on Windows automatic update

The following command configures Windows Update to automatically download and install updates daily at 10:00 PM.

```
$configureWindowsUpdateCommand = Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-ConfigureWindowsUpdate" `
    -Parameters @{'updateLevel'='InstallUpdatesAutomatically';
 'scheduledInstallDay'='Daily'; 'scheduledInstallTime'='22:00'}
```

View command status for allowing Windows automatic update

The following command uses the CommandId to get the status of the command execution for allowing Windows automatic update.

```
Get-SSMCommandInvocation `
    -Details $true `
    -CommandId $configureWindowsUpdateCommand.CommandId | Select -ExpandProperty
 CommandPlugins
```

Turn off Windows automatic update

The following command lowers the Windows Update notification level so the system checks for updates but doesn't automatically update the managed node.

```
$configureWindowsUpdateCommand = Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-ConfigureWindowsUpdate" `
    -Parameters @{'updateLevel'='NeverCheckForUpdates'}
```

View command status for turning off Windows automatic update

The following command uses the `CommandId` to get the status of the command execution for turning off Windows automatic update.

```
Get-SSMCommandInvocation `
    -Details $true `
    -CommandId $configureWindowsUpdateCommand.CommandId | Select -ExpandProperty
 CommandPlugins
```

Manage Windows updates using Run Command

Using Run Command and the `AWS-InstallWindowsUpdates` document, you can manage updates for Windows Server managed nodes. This command scans for or installs missing updates on your managed nodes and optionally reboots following installation. You can also specify the appropriate classifications and severity levels for updates to install in your environment.

> **Note**
>
> For information about rebooting managed nodes when using Run Command to call scripts, see Handling reboots when running commands.

The following examples demonstrate how to perform the specified Windows Update management tasks.

Search for all missing Windows updates

```
Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-InstallWindowsUpdates" `
    -Parameters @{'Action'='Scan'}
```

Install specific Windows updates

```
Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-InstallWindowsUpdates" `
    -Parameters @{'Action'='Install';'IncludeKbs'='kb-ID-1,kb-ID-2,kb-
ID-3';'AllowReboot'='True'}
```

Install important missing Windows updates

```
Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-InstallWindowsUpdates" `
    -Parameters @{'Action'='Install';'SeverityLevels'='Important';'AllowReboot'='True'}
```

Install missing Windows updates with specific exclusions

```
Send-SSMCommand `
    -InstanceId instance-ID `
    -DocumentName "AWS-InstallWindowsUpdates" `
    -Parameters @{'Action'='Install';'ExcludeKbs'='kb-ID-1,kb-
ID-2';'AllowReboot'='True'}
```

Troubleshooting Systems Manager Run Command

Run Command, a tool in AWS Systems Manager, provides status details with each command execution. For more information about the details of command statuses, see Understanding command statuses. You can also use the information in this topic to help troubleshoot problems with Run Command.

Topics

- SSM Agent isn't running properly

Some of my managed nodes are missing

In the **Run a command** page, after you choose an SSM document to run and select **Manually selecting instances** in the **Targets** section, a list is displayed of managed nodes you can choose to run the command on.

If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

After you create, activate, reboot, or restart a managed node, install Run Command on a node, or attach an AWS Identity and Access Management (IAM) instance profile to a node, it can take a few minutes for the managed node to be added to the list.

A step in my script failed, but the overall status is 'succeeded'

Using Run Command, you can define how your scripts handle exit codes. By default, the exit code of the last command run in a script is reported as the exit code for the entire script. You can, however, include a conditional statement to exit the script if any command before the final one fails. For information and examples, see Specify exit codes in commands.

SSM Agent isn't running properly

If you experience problems running commands using Run Command, there might be a problem with the SSM Agent. For information about investigating issues with SSM Agent, see Troubleshooting SSM Agent.

AWS Systems Manager Session Manager

Session Manager is a fully managed AWS Systems Manager tool. With Session Manager, you can manage your Amazon Elastic Compute Cloud (Amazon EC2) instances, edge devices, on-premises servers, and virtual machines (VMs). You can use either an interactive one-click browser-based shell or the AWS Command Line Interface (AWS CLI). Session Manager provides secure node management without the need to open inbound ports, maintain bastion hosts, or manage SSH keys. Session Manager also allows you to comply with corporate policies that require controlled access to managed nodes, strict security practices, and logs with node access details, while providing end users with simple one-click cross-platform access to your managed nodes. To get started with Session Manager, open the Systems Manager console. In the navigation pane, choose **Session Manager**.

How can Session Manager benefit my organization?

Session Manager offers these benefits:

- **Centralized access control to managed nodes using IAM policies**

  Administrators have a single place to grant and revoke access to managed nodes. Using only AWS Identity and Access Management (IAM) policies, you can control which individual users or groups in your organization can use Session Manager and which managed nodes they can access.

- **No open inbound ports and no need to manage bastion hosts or SSH keys**

  Leaving inbound SSH ports and remote PowerShell ports open on your managed nodes greatly increases the risk of entities running unauthorized or malicious commands on the managed nodes. Session Manager helps you improve your security posture by letting you close these inbound ports, freeing you from managing SSH keys and certificates, bastion hosts, and jump boxes.

- **One-click access to managed nodes from the console and CLI**

  Using the AWS Systems Manager console or Amazon EC2 console, you can start a session with a single click. Using the AWS CLI, you can also start a session that runs a single command or a sequence of commands. Because permissions to managed nodes are provided through IAM policies instead of SSH keys or other mechanisms, the connection time is greatly reduced.

- **Connect to both Amazon EC2 instances and non-EC2 managed nodes in hybrid and multicloud environments**

  You can connect to both Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 nodes in your hybrid and multicloud environment.

  To connect to non-EC2 nodes using Session Manager, you must first activate the advanced-instances tier. **There is a charge to use the advanced-instances tier.** However, there is no additional charge to connect to EC2 instances using Session Manager. For information, see Configuring instance tiers.

- **Port forwarding**

  Redirect any port inside your managed node to a local port on a client. After that, connect to the local port and access the server application that is running inside the node.

- **Cross-platform support for Windows, Linux, and macOS**

Session Manager provides support for Windows, Linux, and macOS from a single tool. For example, you don't need to use an SSH client for Linux and macOS managed nodes or an RDP connection for Windows Server managed nodes.

- **Logging session activity**

  To meet operational or security requirements in your organization, you might need to provide a record of the connections made to your managed nodes and the commands that were run on them. You can also receive notifications when a user in your organization starts or ends session activity.

  Logging capabilities are provided through integration with the following AWS services:

  - **AWS CloudTrail** – AWS CloudTrail captures information about Session Manager API calls made in your AWS account and writes it to log files that are stored in an Amazon Simple Storage Service (Amazon S3) bucket you specify. One bucket is used for all CloudTrail logs for your account. For more information, see Logging AWS Systems Manager API calls with AWS CloudTrail.
  - **Amazon Simple Storage Service** – You can choose to store session log data in an Amazon S3 bucket of your choice for debugging and troubleshooting purposes. Log data can be sent to your Amazon S3 bucket with or without encryption using your AWS KMS key. For more information, see Logging session data using Amazon S3 (console).
  - **Amazon CloudWatch Logs** – CloudWatch Logs allows you to monitor, store, and access log files from various AWS services. You can send session log data to a CloudWatch Logs log group for debugging and troubleshooting purposes. Log data can be sent to your log group with or without AWS KMS encryption using your KMS key. For more information, see Logging session data using Amazon CloudWatch Logs (console).
  - **Amazon EventBridge** and **Amazon Simple Notification Service** – EventBridge allows you to set up rules to detect when changes happen to AWS resources that you specify. You can create a rule to detect when a user in your organization starts or stops a session, and then receive a notification through Amazon SNS (for example, a text or email message) about the event. You can also configure a CloudWatch event to initiate other responses. For more information, see Monitoring session activity using Amazon EventBridge (console).

> **Note**
>
> Logging isn't available for Session Manager sessions that connect through port forwarding or SSH. This is because SSH encrypts all session data, and Session Manager only serves as a tunnel for SSH connections.

Who should use Session Manager?

- Any AWS customer who wants to improve their security posture, reduce operational overhead by centralizing access control on managed nodes, and reduce inbound node access.
- Information Security experts who want to monitor and track managed node access and activity, close down inbound ports on managed nodes, or allow connections to managed nodes that don't have a public IP address.
- Administrators who want to grant and revoke access from a single location, and who want to provide one solution to users for Linux, macOS, and Windows Server managed nodes.
- Users who want to connect to a managed node with just one click from the browser or AWS CLI without having to provide SSH keys.

What are the main features of Session Manager?

- **Support for Windows Server, Linux and macOS managed nodes**

  Session Manager enables you to establish secure connections to your Amazon Elastic Compute Cloud (EC2) instances, edge devices, on-premises servers, and virtual machines (VMs). For a list of supported operating system types, see Setting up Session Manager.

  > **Note**
  >
  > Session Manager support for on-premises machines is provided for the advanced-instances tier only. For information, see Turning on the advanced-instances tier.

- **Console, CLI, and SDK access to Session Manager capabilities**

  You can work with Session Manager in the following ways:

The **AWS Systems Manager console** includes access to all the Session Manager capabilities for both administrators and end users. You can perform any task that is related to your sessions by using the Systems Manager console.

The Amazon EC2 console provides the ability for end users to connect to EC2 instances for which they have been granted session permissions.

The **AWS CLI** includes access to Session Manager capabilities for end users. You can start a session, view a list of sessions, and permanently end a session by using the AWS CLI.

> **Note**
>
> To use the AWS CLI to run session commands, you must be using version 1.16.12 of the CLI (or later), and you must have installed the Session Manager plugin on your local machine. For information, see Install the Session Manager plugin for the AWS CLI. To view the plugin on GitHub, see session-manager-plugin.

- **IAM access control**

  Through the use of IAM policies, you can control which members of your organization can initiate sessions to managed nodes and which nodes they can access. You can also provide temporary access to your managed nodes. For example, you might want to give an on-call engineer (or a group of on-call engineers) access to production servers only for the duration of their rotation.

- **Logging support**

  Session Manager provide you with options for logging session histories in your AWS account through integration with a number of other AWS services. For more information, see Logging session activity and Enabling and disabling session logging.

- **Configurable shell profiles**

  Session Manager provides you with options to configure preferences within sessions. These customizable profiles allow you to define preferences such as shell preferences, environment variables, working directories, and running multiple commands when a session is started.

- **Customer key data encryption support**

  You can configure Session Manager to encrypt the session data logs that you send to an Amazon Simple Storage Service (Amazon S3) bucket or stream to a CloudWatch Logs log group. You can also configure Session Manager to further encrypt the data transmitted between client machines

and your managed nodes during your sessions. For information, see Enabling and disabling session logging and Configure session preferences.

- **AWS PrivateLink support for managed nodes without public IP addresses**

  You can also set up VPC Endpoints for Systems Manager using AWS PrivateLink to further secure your sessions. AWS PrivateLink limits all network traffic between your managed nodes, Systems Manager, and Amazon EC2 to the Amazon network. For more information, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

- **Tunneling**

  In a session, use a Session-type AWS Systems Manager (SSM) document to tunnel traffic, such as http or a custom protocol, between a local port on a client machine and a remote port on a managed node.

- **Interactive commands**

  Create a Session-type SSM document that uses a session to interactively run a single command, giving you a way to manage what users can do on a managed node.

What is a session?

A session is a connection made to a managed node using Session Manager. Sessions are based on a secure bi-directional communication channel between the client (you) and the remote managed node that streams inputs and outputs for commands. Traffic between a client and a managed node is encrypted using TLS 1.2, and requests to create the connection are signed using Sigv4. This two-way communication allows interactive bash and PowerShell access to managed nodes. You can also use an AWS Key Management Service (AWS KMS) key to further encrypt data beyond the default TLS encryption.

For example, say that John is an on-call engineer in your IT department. He receives notification of an issue that requires him to remotely connect to a managed node, such as a failure that requires troubleshooting or a directive to change a simple configuration option on a node. Using the AWS Systems Manager console, the Amazon EC2 console, or the AWS CLI, John starts a session connecting him to the managed node, runs commands on the node needed to complete the task, and then ends the session.

When John sends that first command to start the session, the Session Manager service authenticates his ID, verifies the permissions granted to him by an IAM policy, checks configuration settings (such as verifying allowed limits for the sessions), and sends a message to SSM Agent

to open the two-way connection. After the connection is established and John types the next command, the command output from SSM Agent is uploaded to this communication channel and sent back to his local machine.

Topics

Setting up Session Manager

Before you use AWS Systems Manager Session Manager to connect to the managed nodes in your account, complete the steps in the following topics.

Topics

Step 1: Complete Session Manager prerequisites

Before using Session Manager, make sure your environment meets the following requirements.

Session Manager prerequisites

Requirement	Description
Supported operating systems	Session Manager supports connecting to Amazon Elastic Compute Cloud (Amazon EC2) instances, in addition to non-EC2 machines in your hybrid and multicloud environment that use the *advanced-instances* tier. Session Manager supports the following operating system versions: **Note** Session Manager supports EC2 instances, edge devices, and on-premises servers and virtual machines (VMs) in your hybrid and multicloud environment that use the *advanced-instances* tier. For more informati on about advanced instances, see Configuring instance tiers. **Linux and macOS** Session Manager supports all the versions of Linux and macOS that are supported by AWS Systems Manager. For information, see Supported operating systems and machine types. **Windows** Session Manager supports Windows Server 2012 and later versions.

Requirement	Description
	Note Microsoft Windows Server 2016 Nano isn't supported.

Requirement	Description
SSM Agent	At minimum, AWS Systems Manager SSM Agent version 2.3.68.0 or later must be installed on the managed nodes you want to connect to through sessions. To use the option to encrypt session data using a key created in AWS Key Managemen t Service (AWS KMS), version 2.3.539.0 or later of SSM Agent must be installed on the managed node. To use shell profiles in a session, SSM Agent version 3.0.161.0 or later must be installed on the managed node. To start a Session Manager port forwarding or SSH session, SSM Agent version 3.0.222.0 or later must be installed on the managed node. To stream session data using Amazon CloudWatch Logs, SSM Agent version 3.0.284.0 or later must be installed on the managed node. For information about how to determine the version number running on an instance, see Checking the SSM Agent version number. For information about manually installing or automatically updating SSM Agent, see Working with SSM Agent. **About the ssm-user account** Starting with version 2.3.50.0 of SSM Agent, the agent creates a user account on the managed node, with root or administrator permissions, called `ssm-user`. (On versions

Requirement	Description
	before 2.3.612.0, the account is created when SSM Agent starts or restarts. On version 2.3.612.0 and later, `ssm-user` is created the first time a session starts on the managed node.) Sessions are launched using the administrative credentials of this user account. For information about restricting administr ative control for this account, see Turn off or turn on ssm-user account administrative permissions. **ssm-user on Windows Server domain controllers** Beginning with SSM Agent version 2.3.612.0, the `ssm-user` account isn't created automatic ally on managed nodes that are used as Windows Server domain controllers. To use Session Manager on a Windows Server machine being used as a domain controlle r, you must create the `ssm-user` account manually if it isn't already present, and assign Domain Administrator permissions to the user. On Windows Server, SSM Agent sets a new password for the `ssm-user` account each time a session starts, so you don't need to specify a password when you create the account.

Requirement	Description
Connectivity to endpoints	The managed nodes you connect to must also allow HTTPS (port 443) outbound traffic to the following endpoints: • ec2messages.*region*.amazonaws.com • ssm.*region*.amazonaws.com • ssmmessages.*region*.amazonaws.com For more information, see the following topics: • Reference: ec2messages, ssmmessages, and other API operations • How do I create VPC endpoints so that I can use Systems Manager to manage private EC2 instances without internet access? in the AWS re:Post Knowledge Center. Alternatively, you can connect to the required endpoints by using interface endpoints. For more information, see Step 6: (Optional) Use AWS PrivateLink to set up a VPC endpoint for Session Manager.

Requirement	Description
AWS CLI	(Optional) If you use the AWS Command Line Interface (AWS CLI) to start your sessions (instead of using the AWS Systems Manager console or Amazon EC2 console), version 1.16.12 or later of the CLI must be installed on your local machine. You can call `aws --version` to check the version. If you need to install or upgrade the CLI, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide. **Important** An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For informati on, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Requirement	Description
	In addition, to use the CLI to manage your nodes with Session Manager, you must first install the Session Manager plugin on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.
Turn on advanced-instances tier (hybrid and multicloud environments)	To connect to non-EC2 machines using Session Manager, you must turn on the advanced-instances tier in the AWS account and AWS Region where you create hybrid activations to register non-EC2 machines as managed nodes. There is a charge to use the advanced-instances tier. For more information about the advanced-instance tier, see Configuring instance tiers.

Requirement	Description
Verify IAM service role permissions (hybrid and multicloud environments)	Hybrid-activated nodes use the AWS Identity and Access Management (IAM) service role specified in the hybrid activation to communicate with Systems Manager API operations. This service role must contain the permissions required to connect to your hybrid and multicloud machines using Session Manager. If your service role contains the AWS managed policy `AmazonSSMManagedInstanceCore`, the required permissions for Session Manager are already provided. If you find that the service role does not contain the required permissions, you must deregister the managed instance and register it with a new hybrid activation that uses an IAM service role with the required permissions. For more information about deregistering managed instances, see Deregistering managed nodes in a hybrid and multicloud environment. For more information about creating IAM policies with Session Manager permissions, see Step 2: Verify or add instance permissions for Session Manager.

Step 2: Verify or add instance permissions for Session Manager

By default, AWS Systems Manager doesn't have permission to perform actions on your instances. You can provide instance permissions at the account level using an AWS Identity and Access Management (IAM) role, or at the instance level using an instance profile. If your use case allows, we recommend granting access at the account level using the Default Host Management Configuration. If you've already set up the Default Host Management Configuration for your account using the `AmazonSSMManagedEC2InstanceDefaultPolicy` policy, you can proceed to the next step. For more information about the Default Host Management Configuration, see Managing EC2 instances automatically with Default Host Management Configuration.

Alternatively, you can use instance profiles to provide the required permissions to your instances. An instance profile passes an IAM role to an Amazon EC2 instance. You can attach an IAM instance profile to an Amazon EC2 instance as you launch it or to a previously launched instance. For more information, see Using instance profiles.

For on-premises servers or virtual machines (VMs), permissions are provided by the IAM service role associated with the hybrid activation used to register your on-premises servers and VMs with Systems Manager. On-premises servers and VMs do not use instance profiles.

If you already use other Systems Manager tools, such as Run Command or Parameter Store, an instance profile with the required basic permissions for Session Manager might already be attached to your Amazon EC2 instances. If an instance profile that contains the AWS managed policy `AmazonSSMManagedInstanceCore` is already attached to your instances, the required permissions for Session Manager are already provided. This is also true if the IAM service role used in your hybrid activation contains the `AmazonSSMManagedInstanceCore` managed policy.

However, in some cases, you might need to modify the permissions attached to your instance profile. For example, you want to provide a narrower set of instance permissions, you have created a custom policy for your instance profile, or you want to use Amazon Simple Storage Service (Amazon S3) encryption or AWS Key Management Service (AWS KMS) encryption options for securing session data. For these cases, do one of the following to allow Session Manager actions to be performed on your instances:

- **Embed permissions for Session Manager actions in a custom IAM role**

  To add permissions for Session Manager actions to an existing IAM role that doesn't rely on the AWS-provided default policy `AmazonSSMManagedInstanceCore`, follow the steps in Add Session Manager permissions to an existing IAM role.

- **Create a custom IAM role with Session Manager permissions only**

  To create an IAM role that contains permissions only for Session Manager actions, follow the steps in Create a custom IAM role for Session Manager.

- **Create and use a new IAM role with permissions for all Systems Manager actions**

  To create an IAM role for Systems Manager managed instances that uses a default policy supplied by AWS to grant all Systems Manager permissions, follow the steps in Configure instance permissions required for Systems Manager.

Topics

Add Session Manager permissions to an existing IAM role

Use the following procedure to add Session Manager permissions to an existing AWS Identity and Access Management (IAM) role. By adding permissions to an existing role, you can enhance the security of your computing environment without having to use the AWS `AmazonSSMManagedInstanceCore` policy for instance permissions.

> **Note**
>
> Note the following information:
>
> - This procedure assumes that your existing role already includes other Systems Manager `ssm` permissions for actions you want to allow access to. This policy alone isn't enough to use Session Manager.
> - The following policy example includes an `s3:GetEncryptionConfiguration` action. This action is required if you chose the **Enforce S3 log encryption** option in Session Manager logging preferences.

To add Session Manager permissions to an existing role (console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Select the name of the role that you are adding the permissions to.
4. Choose the **Permissions** tab.
5. Choose **Add permissions**, and then select **Create inline policy**.
6. Choose the **JSON** tab.
7. Replace the default policy content with the following content. Replace *`key-name`* with the Amazon Resource Name (ARN) of the AWS Key Management Service key (AWS KMS key) that you want to use.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssmmessages:CreateControlChannel",
                "ssmmessages:CreateDataChannel",
                "ssmmessages:OpenControlChannel",
                "ssmmessages:OpenDataChannel"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetEncryptionConfiguration"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-name"
        }
    ]
}
```

For information about using a KMS key to encrypt session data, see Turn on KMS key encryption of session data (console).

If you won't use AWS KMS encryption for your session data, you can remove the following content from the policy.

```
,
        {
```

```
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Resource": "key-name"
        }
```

8. Choose **Next: Tags**.
9. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the policy.
10. Choose **Next: Review**.
11. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **`SessionManagerPermissions`**.
12. (Optional) For **Description**, enter a description for the policy.

    Choose **Create policy**.

For information about the `ssmmessages` actions, see Reference: ec2messages, ssmmessages, and other API operations.

Create a custom IAM role for Session Manager

You can create an AWS Identity and Access Management (IAM) role that grants Session Manager the permission to perform actions on your Amazon EC2 managed instances. You can also include a policy to grant the permissions needed for session logs to be sent to Amazon Simple Storage Service (Amazon S3) and Amazon CloudWatch Logs.

After you create the IAM role, for information about how to attach the role to an instance, see Attach or Replace an Instance Profile at the AWS re:Post website. For more information about IAM instance profiles and roles, see Using instance profiles in the *IAM User Guide* and IAM roles for Amazon EC2 in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*. For more information about creating an IAM service role for on-premises machines, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.

Topics

- Creating an IAM role with minimal Session Manager permissions (console)
- Creating an IAM role with permissions for Session Manager and Amazon S3 and CloudWatch Logs (console)

Creating an IAM role with minimal Session Manager permissions (console)

Use the following procedure to create a custom IAM role with a policy that provides permissions for only Session Manager actions on your instances.

To create an instance profile with minimal Session Manager permissions (console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**. (If a **Get Started** button is displayed, choose it, and then choose **Create Policy**.)
3. Choose the **JSON** tab.
4. Replace the default content with the following policy. To encrypt session data using AWS Key Management Service (AWS KMS), replace *key-name* with the Amazon Resource Name (ARN) of the AWS KMS key that you want to use.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:UpdateInstanceInformation",
                "ssmmessages:CreateControlChannel",
                "ssmmessages:CreateDataChannel",
                "ssmmessages:OpenControlChannel",
                "ssmmessages:OpenDataChannel"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-name"
        }
    ]
```

```
}
```

For information about using a KMS key to encrypt session data, see Turn on KMS key encryption of session data (console).

If you won't use AWS KMS encryption for your session data, you can remove the following content from the policy.

```
,
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Resource": "key-name"
        }
```

5. Choose **Next: Tags**.
6. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the policy.
7. Choose **Next: Review**.
8. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **`SessionManagerPermissions`**.
9. (Optional) For **Description**, enter a description for the policy.
10. Choose **Create policy**.
11. In the navigation pane, choose **Roles**, and then choose **Create role**.
12. On the **Create role** page, choose **AWS service**, and for **Use case**, choose **EC2**.
13. Choose **Next**.
14. On the **Add permissions** page, select the check box to the left of name of the policy you just created, such as **`SessionManagerPermissions`**.
15. Choose **Next**.
16. On the **Name, review, and create** page, for **Role name**, enter a name for the IAM role, such as **`MySessionManagerRole`**.
17. (Optional) For **Role description**, enter a description for the instance profile.
18. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the role.

Choose **Create role**.

For information about `ssmmessages` actions, see Reference: ec2messages, ssmmessages, and other API operations.

Creating an IAM role with permissions for Session Manager and Amazon S3 and CloudWatch Logs (console)

Use the following procedure to create a custom IAM role with a policy that provides permissions for Session Manager actions on your instances. The policy also provides the permissions needed for session logs to be stored in Amazon Simple Storage Service (Amazon S3) buckets and Amazon CloudWatch Logs log groups.

> **Important**
>
> To output session logs to an Amazon S3 bucket owned by a different AWS account, you must add the `s3:PutObjectAcl` permission to the IAM role policy. Additionally, you must ensure that the bucket policy grants cross-account access to the IAM role used by the owning account to grant Systems Manager permissions for managed instances. If the bucket uses Key Management Service (KMS) encryption, then the bucket's KMS policy must also grant this cross-account access. For more information about configuring cross-account bucket permissions in Amazon S3, see Granting cross-account bucket permissions in the *Amazon Simple Storage Service User Guide*. If the cross-account permissions aren't added, the account that owns the Amazon S3 bucket can't access the session output logs.

For information about specifying preferences for storing session logs, see Enabling and disabling session logging.

To create an IAM role with permissions for Session Manager and Amazon S3 and CloudWatch Logs (console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**. (If a **Get Started** button is displayed, choose it, and then choose **Create Policy**.)
3. Choose the **JSON** tab.

4. Replace the default content with the following policy. Replace each *example resource placeholder* with your own information.

   JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssmmessages:CreateControlChannel",
                "ssmmessages:CreateDataChannel",
                "ssmmessages:OpenControlChannel",
                "ssmmessages:OpenDataChannel",
                "ssm:UpdateInstanceInformation"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:DescribeLogGroups",
                "logs:DescribeLogStreams"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/s3-prefix/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetEncryptionConfiguration"
            ],
            "Resource": "*"
```

```
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-name"
        },
        {
            "Effect": "Allow",
            "Action": "kms:GenerateDataKey",
            "Resource": "*"
        }
    ]
}
```

5. Choose **Next: Tags**.
6. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the policy.
7. Choose **Next: Review**.
8. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **`SessionManagerPermissions`**.
9. (Optional) For **Description**, enter a description for the policy.
10. Choose **Create policy**.
11. In the navigation pane, choose **Roles**, and then choose **Create role**.
12. On the **Create role** page, choose **AWS service**, and for **Use case**, choose **EC2**.
13. Choose **Next**.
14. On the **Add permissions** page, select the check box to the left of name of the policy you just created, such as **`SessionManagerPermissions`**.
15. Choose **Next**.
16. On the **Name, review, and create** page, for **Role name**, enter a name for the IAM role, such as **`MySessionManagerRole`**.
17. (Optional) For **Role description**, enter a description for the role.
18. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the role.
19. Choose **Create role**.

Step 3: Control session access to managed nodes

You grant or revoke Session Manager access to managed nodes by using AWS Identity and Access Management (IAM) policies. You can create a policy and attach it to an IAM user or group that specifies which managed nodes the user or group can connect to. You can also specify the Session Manager API operations the user or groups can perform on those managed nodes.

To help you get started with IAM permission policies for Session Manager, we've created sample policies for an end user and an administrator user. You can use these policies with only minor changes. Or, use them as a guide to create custom IAM policies. For more information, see Sample IAM policies for Session Manager. For information about how to create IAM policies and attach them to users or groups, see Creating IAM Policies and Adding and Removing IAM Policies in the *IAM User Guide*.

About session ID ARN formats

When you create an IAM policy for Session Manager access, you specify a session ID as part of the Amazon Resource Name (ARN). The session ID includes the user name as a variable. To help illustrate this, here's the format of a Session Manager ARN and an example:

```
arn:aws:ssm:region-id:account-id:session/session-id
```

For example:

```
arn:aws:ssm:us-east-2:123456789012:session/JohnDoe-1a2b3c4d5eEXAMPLE
```

For more information about using variables in IAM policies, see IAM Policy Elements: Variables.

Start a default shell session by specifying the default session document in IAM policies

When you configure Session Manager for your AWS account or when you change session preferences in the Systems Manager console, the system creates an SSM session document called

`SSM-SessionManagerRunShell`. This is the default session document. Session Manager uses this document to store your session preferences, which include information like the following:

- A location where you want to save session data, such an Amazon Simple Storage Service (Amazon S3) bucket or a Amazon CloudWatch Logs log group.
- An AWS Key Management Service (AWS KMS) key ID for encrypting session data.
- Whether Run As support is allowed for your sessions.

Here is an example of the information contained in the `SSM-SessionManagerRunShell` session preferences document.

```
{
  "schemaVersion": "1.0",
  "description": "Document to hold regional settings for Session Manager",
  "sessionType": "Standard_Stream",
  "inputs": {
    "s3BucketName": "amzn-s3-demo-bucket",
    "s3KeyPrefix": "MyS3Prefix",
    "s3EncryptionEnabled": true,
    "cloudWatchLogGroupName": "MyCWLogGroup",
    "cloudWatchEncryptionEnabled": false,
    "kmsKeyId": "1a2b3c4d",
    "runAsEnabled": true,
    "runAsDefaultUser": "RunAsUser"
  }
}
```

By default, Session Manager uses the default session document when a user starts a session from the AWS Management Console. This applies to either Fleet Manager or Session Manager in the Systems Manager console, or EC2 Connect in the Amazon EC2 console. Session Manager also uses the default session document when a user starts a session by using an AWS CLI command like the following example:

```
aws ssm start-session \
    --target i-02573cafcfEXAMPLE
```

To start a default shell session, you must specify the default session document in the IAM policy, as shown in the following example.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnableSSMSession",
      "Effect": "Allow",
      "Action": [
        "ssm:StartSession"
      ],
      "Resource": [
        "arn:aws:ec2:us-east-1:111122223333:instance/instance-id",
        "arn:aws:ssm:us-east-1:111122223333:document/SSM-SessionManagerRunShell"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssmmessages:OpenDataChannel"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Start a session with a document by specifying the session documents in IAM policies

If you use the start-session AWS CLI command using the default session document, you can omit the document name. The system automatically calls the `SSM-SessionManagerRunShell` session document.

In all other cases, you must specify a value for the `document-name` parameter. When a user specifies the name of a session document in a command, the systems checks their IAM policy to verify they have permission to access the document. If they don't have permission, the connection request fails. The following examples includes the `document-name` parameter with the `AWS-StartPortForwardingSession` session document.

```
aws ssm start-session \
    --target i-02573cafcfEXAMPLE \
    --document-name AWS-StartPortForwardingSession \
    --parameters '{"portNumber":["80"], "localPortNumber":["56789"]}'
```

For an example of how to specify a Session Manager session document in an IAM policy, see Quickstart end user policies for Session Manager.

> **Note**
>
> To start a session using SSH, you must complete configuration steps on the target managed node *and* the user's local machine. For information, see (Optional) Allow and control permissions for SSH connections through Session Manager.

Sample IAM policies for Session Manager

Use the samples in this section to help you create AWS Identity and Access Management (IAM) policies that provide the most commonly needed permissions for Session Manager access.

> **Note**
>
> You can also use an AWS KMS key policy to control which IAM entities (users or roles) and AWS accounts are given access to your KMS key. For information, see Overview of Managing Access to Your AWS KMS Resources and Using Key Policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

Topics

Quickstart end user policies for Session Manager

Use the following examples to create IAM end user policies for Session Manager.

You can create a policy that allows users to start sessions from only the Session Manager console and AWS Command Line Interface (AWS CLI), from only the Amazon Elastic Compute Cloud (Amazon EC2) console, or from all three.

These policies provide end users the ability to start a session to a particular managed node and the ability to end only their own sessions. Refer to Additional sample IAM policies for Session Manager for examples of customizations you might want to make to the policy.

In the following sample policies, replace each *example resource placeholder* with your own information.

Refer to the following sections to view sample policies for the range of session access you want to provide.

Session Manager and Fleet Manager

Use this sample policy to give users the ability to start and resume sessions from only the Session Manager and Fleet Manager consoles.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession"
            ],
            "Resource": [
                "arn:aws:ec2:us-
east-1:111122223333:instance/i-02573cafcfEXAMPLE",
                "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
            ]
        },
        {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
       },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:DescribeSessions",
                "ssm:GetConnectionStatus",
```

```
                "ssm:DescribeInstanceProperties",
                "ec2:DescribeInstances"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:TerminateSession",
                "ssm:ResumeSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-name"
        }
    ]
}
```

Amazon EC2

Use this sample policy to give users the ability to start and resume sessions from only the Amazon EC2 console. This policy doesn't provide all the permissions needed to start sessions from the Session Manager console and the AWS CLI.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:SendCommand"
```

```
            ],
            "Resource": [
                "arn:aws:ec2:us-
east-1:111122223333:instance/i-02573cafcfEXAMPLE",
                "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
            ]
        },
        {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
       },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetConnectionStatus",
                "ssm:DescribeInstanceInformation"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:TerminateSession",
                "ssm:ResumeSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:username}-*"
            ]
        }
    ]
}
```

AWS CLI

Use this sample policy to give users the ability to start and resume sessions from the AWS CLI.

JSON

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:SendCommand"
            ],
            "Resource": [
                "arn:aws:ec2:us-
east-1:111122223333:instance/i-02573cafcfEXAMPLE",
                "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
            ]
        },
        {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
       },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:TerminateSession",
                "ssm:ResumeSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-name"
        }
    ]
}
```

Note

`SSM-SessionManagerRunShell` is the default name of the SSM document that Session Manager creates to store your session configuration preferences. You can create a custom Session document and specify it in this policy instead. You can also specify the AWS-provided document `AWS-StartSSHSession` for users who are starting sessions using SSH. For information about configuration steps needed to support sessions using SSH, see (Optional) Allow and control permissions for SSH connections through Session Manager.
The `kms:GenerateDataKey` permission enables the creation of a data encryption key that will be used to encrypt session data. If you will use AWS Key Management Service (AWS KMS) encryption for your session data, replace *key-name* with the Amazon Resource Name (ARN) of the KMS key you want to use, in the format `arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-12345EXAMPLE`. If you won't use KMS key encryption for your session data, remove the following content from the policy.

```
{
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey"
            ],
            "Resource": "key-name"
        }
```

For information about using AWS KMS for encrypting session data, see Turn on KMS key encryption of session data (console).
The permission for SendCommand is needed for cases where a user attempts to start a session from the Amazon EC2 console, but the SSM Agent must be updated to the minimum required version for Session Manager first. Run Command is used to send a command to the instance to update the agent.

Quickstart administrator policy for Session Manager

Use the following examples to create IAM administrator policies for Session Manager.

These policies provide administrators the ability to start a session to managed nodes that are tagged with `Key=Finance,Value=WebServers`, permission to create, update, and delete

preferences, and permission to end only their own sessions. Refer to Additional sample IAM policies for Session Manager for examples of customizations you might want to make to the policy.

You can create a policy that allows administrators to perform these tasks from only the Session Manager console and AWS CLI, from only the Amazon EC2 console, or from all three.

In the following sample policies, replace each *example resource placeholder* with your own information.

Refer to the following sections to view sample policies for the three permissions scenarios.

Session Manager and CLI

Use this sample policy to give administrators the ability to perform session-related tasks from only the Session Manager console and the AWS CLI. This policy doesn't provide all the permissions needed to perform session-related tasks from the Amazon EC2 console.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession"
            ],
            "Resource": [
                "arn:aws:ec2:*:111122223333:instance/*"
            ],
            "Condition": {
                "StringLike": {
                    "ssm:resourceTag/Finance": [
                        "WebServers"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssmmessages:OpenDataChannel"
```

```
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:DescribeSessions",
                "ssm:GetConnectionStatus",
                "ssm:DescribeInstanceProperties",
                "ec2:DescribeInstances"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:CreateDocument",
                "ssm:UpdateDocument",
                "ssm:GetDocument",
                "ssm:StartSession"
            ],
            "Resource": "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssmmessages:OpenDataChannel"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:TerminateSession",
                "ssm:ResumeSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
```

```
        }
    ]
}
```

Amazon EC2

Use this sample policy to give administrators the ability to perform session-related tasks from only the Amazon EC2 console. This policy doesn't provide all the permissions needed to perform session-related tasks from the Session Manager console and the AWS CLI.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:SendCommand"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1:111122223333:instance/*"
            ],
            "Condition": {
                "StringLike": {
                    "ssm:resourceTag/tag-key": [
                        "tag-value"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession"
            ],
            "Resource": [
                "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
            ]
```

```
        },
        {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
       },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetConnectionStatus",
                "ssm:DescribeInstanceInformation"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:TerminateSession",
                "ssm:ResumeSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        }
    ]
}
```

Session Manager, CLI, and Amazon EC2

Use this sample policy to give administrators the ability to perform session-related tasks from the Session Manager console, the AWS CLI, and the Amazon EC2 console.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:SendCommand"
```

```
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1:111122223333:instance/*"
            ],

                "ssm:DescribeSessions",
                "ssm:GetConnectionStatus",
                "ssm:DescribeInstanceInformation",
                "ssm:DescribeInstanceProperties",
                "ec2:DescribeInstances"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:CreateDocument",
                "ssm:UpdateDocument",
                "ssm:GetDocument",
                "ssm:StartSession"
            ],
            "Resource": "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:TerminateSession",
                "ssm:ResumeSession"
```

```
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        }
    ]
}
```

> **Note**
>
> The permission for SendCommand is needed for cases where a user attempts to start a session from the Amazon EC2 console, but a command must be sent to update SSM Agent first.

Additional sample IAM policies for Session Manager

Refer to the following example policies to help you create a custom AWS Identity and Access Management (IAM) policy for any Session Manager user access scenarios you want to support.

Topics

- Example 1: Grant access to documents in the console
- Example 2: Restrict access to specific managed nodes
- Example 3: Restrict access based on tags
- Example 4: Allow a user to end only sessions they started
- Example 5: Allow full (administrative) access to all sessions

Example 1: Grant access to documents in the console

You can allow users to specify a custom document when they launch a session using the Session Manager console. The following example IAM policy grants permission to access documents with names that begin with **`SessionDocument-`** in the specified AWS Region and AWS account.

To use this policy, replace each *`example resource placeholder`* with your own information.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetDocument",
                "ssm:ListDocuments"
            ],
            "Resource": [
                "arn:aws:ssm:us-east-1:111122223333:document/SessionDocument-*"
            ]
        }
    ]
}
```

Note

The Session Manager console only supports Session documents that have a `sessionType` of `Standard_Stream` which are used to define session preferences. For more information, see Session document schema.

Example 2: Restrict access to specific managed nodes

You can create an IAM policy that defines which managed nodes that a user is allowed to connect to using Session Manager. For example, the following policy grants a user the permission to start, end, and resume their sessions on three specific nodes. The policy restricts the user from connecting to nodes other than those specified.

Note

For federated users, see Example 4: Allow a user to end only sessions they started.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1:111122223333:instance/
i-1234567890EXAMPLE",
                "arn:aws:ec2:us-east-1:111122223333:instance/i-
abcdefghijEXAMPLE",
                "arn:aws:ec2:us-east-1:111122223333:instance/
i-0e9d8c7b6aEXAMPLE",
                "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
            ]
        },
        {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
       },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:TerminateSession",
                "ssm:ResumeSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        },
        {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
       }
    ]
```

```
}
```

Example 3: Restrict access based on tags

You can restrict access to managed nodes based on specific tags. In the following example, the user is allowed to start and resume sessions (`Effect: Allow, Action: ssm:StartSession, ssm:ResumeSession`) on any managed node (`Resource: arn:aws:ec2:region:987654321098:instance/*`) with the condition that the node is a Finance WebServer (`ssm:resourceTag/Finance: WebServer`). If the user sends a command to a managed node that isn't tagged or that has any tag other than `Finance: WebServer`, the command result will include `AccessDenied`.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1:111122223333:instance/*"
            ],
            "Condition": {
                "StringLike": {
                    "ssm:resourceTag/Finance": [
                        "WebServers"
                    ]
                }
            }
        },
        {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
       },
        {
            "Effect": "Allow",
            "Action": [
```

```
                "ssm:TerminateSession",
                "ssm:ResumeSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession"
            ],
            "Resource": [
                "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
            ]
        }
    ]
}
```

You can create IAM policies that allow a user to start sessions to managed nodes that are tagged with multiple tags. The following policy allows the user to start sessions to managed nodes that have both the specified tags applied to them. If a user sends a command to a managed node that isn't tagged with both of these tags, the command result will include `AccessDenied`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "ssm:StartSession"
         ],
         "Resource":"*",
         "Condition":{
            "StringLike":{
               "ssm:resourceTag/tag-key1":[
                  "tag-value1"
               ],
```

```
                "ssm:resourceTag/tag-key2":[
                   "tag-value2"
                ]
             }
          }
       },
       {
          "Effect": "Allow",
          "Action": ["ssmmessages:OpenDataChannel"],
          "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
        },
       {
             "Effect": "Allow",
             "Action": [
                 "ssm:StartSession"
             ],
             "Resource": [
                 "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
             ]
       }
    ]
}
```

For more information about creating IAM policies, see Managed Policies and Inline Policies in the *IAM User Guide*. For more information about tagging managed nodes, see Tagging your Amazon EC2 resources in the *Amazon EC2 User Guide* (content applies to Windows and Linux managed nodes). For more information about increasing your security posture against unauthorized root-level commands on your managed nodes, see Restricting access to root-level commands through SSM Agent

Example 4: Allow a user to end only sessions they started

Session Manager provides two methods to control which sessions a federated user in your AWS account is allowed to end.

- Use the variable `{aws:userid}` in an AWS Identity and Access Management (IAM) permissions policy. Federated users can end only sessions they started. For unfederated users, use Method 1. For federated users, use Method 2.
- Use tags supplied by AWS tags in an IAM permissions policy. In the policy, you include a condition that allows users to end only sessions that are tagged with specific tags that have been provided

by AWS. This method works for all accounts, including those that use federated IDs to grant access to AWS.

Method 1: Grant TerminateSession privileges using the variable `{aws:username}`

The following IAM policy allows a user to view the IDs of all sessions in your account. However, users can interact with managed nodes only through sessions they started. A user who is assigned the following policy can't connect to or end other users' sessions. The policy uses the variable `{aws:username}` to achieve this.

> **Note**
>
> This method doesn't work for accounts that grant access to AWS using federated IDs.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ssm:DescribeSessions"
            ],
            "Effect": "Allow",
            "Resource": [
                "*"
            ]
        },
        {
            "Action": [
                "ssm:TerminateSession"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:username}-*"
            ]
        }
    ]
}
```

Method 2: Grant TerminateSession privileges using tags supplied by AWS

You can control which sessions that a user can end by including conditional tag key variables in an IAM policy. The condition specifies that the user can only end sessions that are tagged with one or both of these specific tag key variables and a specified value.

When a user in your AWS account starts a session, Session Manager applies two resource tags to the session. The first resource tag is `aws:ssmmessages:target-id`, with which you specify the ID of the target the user is allowed to end. The other resource tag is `aws:ssmmessages:session-id`, with a value in the format of *role-id*:*caller-specified-role-name*.

> **Note**
>
> Session Manager doesn't support custom tags for this IAM access control policy. You must use the resource tags supplied by AWS, described below.

`aws:ssmmessages:target-id`

With this tag key, you include the managed node ID as the value in policy. In the following policy block, the condition statement allows a user to end only the node i-02573cafcfEXAMPLE.

JSON

```
{
     "Version": "2012-10-17",
     "Statement": [
         {
             "Effect": "Allow",
             "Action": [
                "ssm:TerminateSession"
             ],
             "Resource": "*",
             "Condition": {
                 "StringLike": {
                     "ssm:resourceTag/aws:ssmmessages:target-id": [
                        "i-02573cafcfEXAMPLE"
                     ]
                 }
             }
         }
```

```
    ]
}
```

If the user tries to end a session for which they haven't been granted this `TerminateSession` permission, they receive an `AccessDeniedException` error.

`aws:ssmmessages:session-id`

This tag key includes a variable for the session ID as the value in the request to start a session.

The following example demonstrates a policy for cases where the caller type is `User`. The value you supply for `aws:ssmmessages:session-id` is the ID of the user. In this example, `AIDIODR4TAW7CSEXAMPLE` represents the ID of a user in your AWS account. To retrieve the ID for a user in your AWS account, use the IAM command, `get-user`. For information, see get-user in the AWS Identity and Access Management section of the *IAM User Guide*.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
               "ssm:TerminateSession"
            ],
            "Resource": "*",
            "Condition": {
                "StringLike": {
                    "ssm:resourceTag/aws:ssmmessages:session-id": [
                       "AIDIODR4TAW7CSEXAMPLE"
                    ]
                }
            }
        }
    ]
}
```

The following example demonstrates a policy for cases where the caller type is `AssumedRole`. You can use the `{aws:userid}` variable for the value you supply for

`aws:ssmmessages:session-id`. Alternatively, you can hardcode a role ID for the value you supply for `aws:ssmmessages:session-id`. If you hardcode a role ID, you must provide the value in the format *`role-id`*`:`*`caller-specified-role-name`*. For example, `AIDIODR4TAW7CSEXAMPLE:MyRole`.

> **Important**
>
> In order for system tags to be applied, the role ID you supply can contain the following characters only: Unicode letters, 0-9, space, _, ., :, /, =, +, -, @, and \.

To retrieve the role ID for a role in your AWS account, use the `get-caller-identity` command. For information, see get-caller-identity in the AWS CLI Command Reference.

JSON

```
{
     "Version": "2012-10-17",
     "Statement": [
         {
             "Effect": "Allow",
             "Action": [
                "ssm:TerminateSession"
             ],
             "Resource": "*",
             "Condition": {
                 "StringLike": {
                     "ssm:resourceTag/aws:ssmmessages:session-id": [
                        "${aws:userid}*"
                     ]
                 }
             }
         }
     ]
}
```

If a user tries to end a session for which they haven't been granted this `TerminateSession` permission, they receive an `AccessDeniedException` error.

`aws:ssmmessages:target-id` and `aws:ssmmessages:session-id`

You can also create IAM policies that allow a user to end sessions that are tagged with both system tags, as shown in this example.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "ssm:TerminateSession"
         ],
         "Resource":"*",
         "Condition":{
            "StringLike":{
               "ssm:resourceTag/aws:ssmmessages:target-id":[
                  "i-02573cafcfEXAMPLE"
               ],
               "ssm:resourceTag/aws:ssmmessages:session-id":[
                  "${aws:userid}*"
               ]
            }
         }
      }
   ]
}
```

Example 5: Allow full (administrative) access to all sessions

The following IAM policy allows a user to fully interact with all managed nodes and all sessions created by all users for all nodes. It should be granted only to an Administrator who needs full control over your organization's Session Manager activities.

JSON

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Action": [
                "ssm:StartSession",
                "ssm:TerminateSession",
                "ssm:ResumeSession",
                "ssm:DescribeSessions",
                "ssm:GetConnectionStatus"
            ],
            "Effect": "Allow",
            "Resource": [
                "*"
            ]
        },
        {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
       }
    ]
}
```

Step 4: Configure session preferences

Users that have been granted administrative permissions in their AWS Identity and Access Management (IAM) policy can configure session preferences, including the following:

- Turn on Run As support for Linux managed nodes. This makes it possible to start sessions using the credentials of a specified operating system user instead of the credentials of a system-generated `ssm-user` account that AWS Systems Manager Session Manager can create on a managed node.
- Configure Session Manager to use AWS KMS key encryption to provide additional protection to the data transmitted between client machines and managed nodes.
- Configure Session Manager to create and send session history logs to an Amazon Simple Storage Service (Amazon S3) bucket or an Amazon CloudWatch Logs log group. The stored log data can then be used to report on the session connections made to your managed nodes and the commands run on them during the sessions.
- Configure session timeouts. You can use this setting to specify when to end a session after a period of inactivity.

- Configure Session Manager to use configurable shell profiles. These customizable profiles allow you to define preferences within sessions such as shell preferences, environment variables, working directories, and running multiple commands when a session is started.

For more information about the permissions needed to configue Session Manager preferences, see the section called “Grant or deny a user permissions to update Session Manager preferences”.

Topics

For information about using the Systems Manager console to configure options for logging session data, see the following topics:

- Logging session data using Amazon S3 (console)
- Streaming session data using Amazon CloudWatch Logs (console)
- Logging session data using Amazon CloudWatch Logs (console)

Grant or deny a user permissions to update Session Manager preferences

Account preferences are stored as AWS Systems Manager (SSM) documents for each AWS Region. Before a user can update account preferences for sessions in your account, they must be granted the necessary permissions to access the type of SSM document where these preferences are stored. These permissions are granted through an AWS Identity and Access Management (IAM) policy.

Administrator policy to allow preferences to be created and updated

An administrator can have the following policy to create and update preferences at any time. The following policy allows permission to access and update the `SSM-SessionManagerRunShell` document in the us-east-2 account 123456789012.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ssm:CreateDocument",
                "ssm:GetDocument",
                "ssm:UpdateDocument",
                "ssm:DeleteDocument"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
            ]
        }
    ]
}
```

User policy to prevent preferences from being updated

Use the following policy to prevent end users in your account from updating or overriding any Session Manager preferences.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ssm:CreateDocument",
                "ssm:GetDocument",
                "ssm:UpdateDocument",
                "ssm:DeleteDocument"
            ],
            "Effect": "Deny",
            "Resource": [
```

```
                "arn:aws:ssm:us-east-1:111122223333:document/SSM-
SessionManagerRunShell"
            ]
        }
    ]
}
```

Specify an idle session timeout value

Session Manager, a tool in AWS Systems Manager, allows you to specify the amount of time to allow a user to be inactive before the system ends a session. By default, sessions time out after 20 minutes of inactivity. You can modify this setting to specify that a session times out between 1 and 60 minutes of inactivity. Some professional computing security agencies recommend setting idle session timeouts to a maximum of 15 minutes.

To allow idle session timeout (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Specify the amount of time to allow a user to be inactive before a session ends in the **minutes** field under **Idle session timeout**.
5. Choose **Save**.

Specify maximum session duration

Session Manager, a tool in AWS Systems Manager, allows you to specify the maximum duration of a session before it ends. By default, sessions do not have a maximum duration. The value you specify for maximum session duration must be between 1 and 1,440 minutes.

To specify maximum session duration (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.

4. Select the check box next to **Enable maximum session duration**.
5. Specify the maximum duration of session before it ends in the **minutes** field under **Maximum session duration**.
6. Choose **Save**.

Allow configurable shell profiles

By default, sessions on EC2 instances for Linux start using the Bourne shell (sh). However, you might prefer to use another shell like bash. By allowing configurable shell profiles, you can customize preferences within sessions such as shell preferences, environment variables, working directories, and running multiple commands when a session is started.

> **Important**
>
> Systems Manager doesn't check the commands or scripts in your shell profile to see what changes they would make to an instance before they're run. To restrict a user's ability to modify commands or scripts entered in their shell profile, we recommend the following:
>
> - Create a customized Session-type document for your AWS Identity and Access Management (IAM) users and roles. Then modify the IAM policy for these users and roles so the `StartSession` API operation can only use the Session-type document you have created for them. For information see, Create a Session Manager preferences document (command line) and Quickstart end user policies for Session Manager.
> - Modify the IAM policy for your IAM users and roles to deny access to the `UpdateDocument` API operation for the Session-type document resource you create. This allows your users and roles to use the document you created for their session preferences without allowing them to modify any of the settings.

To turn on configurable shell profiles

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Specify the environment variables, shell preferences, or commands you want to run when your session starts in the fields for the applicable operating systems.

5. Choose **Save**.

The following are some example commands that can be added to your shell profile.

Change to the bash shell and change to the /usr directory on Linux instances.

```
exec /bin/bash
cd /usr
```

Output a timestamp and welcome message at the start of a session.

Linux & macOS

```
timestamp=$(date '+%Y-%m-%dT%H:%M:%SZ')
user=$(whoami)
echo $timestamp && echo "Welcome $user"'!'
echo "You have logged in to a production instance. Note that all session activity is
 being logged."
```

Windows

```
$timestamp = (Get-Date).ToString("yyyy-MM-ddTH:mm:ssZ")
$splitName = (whoami).Split("\")
$user = $splitName[1]
Write-Host $timestamp
Write-Host "Welcome $user!"
Write-Host "You have logged in to a production instance. Note that all session
 activity is being logged."
```

View dynamic system activity at the start of a session.

Linux & macOS

```
top
```

Windows

```
while ($true) { Get-Process | Sort-Object -Descending CPU | Select-Object -First 30;
 `
```

```
Start-Sleep -Seconds 2; cls
Write-Host "Handles  NPM(K)    PM(K)      WS(K) VM(M)   CPU(s)     Id ProcessName";
Write-Host "-------  ------    -----      ----- -----   ------     -- -----------"}
```

Turn on Run As support for Linux and macOS managed nodes

By default, Session Manager authenticates connections using the credentials of the system-generated `ssm-user` account that is created on a managed node. (On Linux and macOS machines, this account is added to `/etc/sudoers/`.) If you choose, you can instead authenticate sessions using the credentials of an operating system (OS) user account, or a domain user for instances joined to an Active Directory. In this case, Session Manager verifies that the OS account that you specified exists on the node, or in the domain, before starting the session. If you attempt to start a session using an OS account that doesn't exist on the node, or in the domain, the connection fails.

> **Note**
>
> Session Manager does not support using an operating system's `root` user account to authenticate connections. For sessions that are authenticated using an OS user account, the node's OS-level and directory policies, like login restrictions or system resource usage restrictions, might not apply.

How it works

If you turn on Run As support for sessions, the system checks for access permissions as follows:

1. For the user who is starting the session, has their IAM entity (user or role) been tagged with `SSMSessionRunAs = os user account name`?

   If Yes, does the OS user name exist on the managed node? If it does, start the session. If it doesn't, don't allow a session to start.

   If the IAM entity has *not* been tagged with `SSMSessionRunAs = os user account name`, continue to step 2.
2. If the IAM entity hasn't been tagged with `SSMSessionRunAs = os user account name`, has an OS user name been specified in the AWS account's Session Manager preferences?

   If Yes, does the OS user name exist on the managed node? If it does, start the session. If it doesn't, don't allow a session to start.

> **Note**
>
> When you activate Run As support, it prevents Session Manager from starting sessions using the `ssm-user` account on a managed node. This means that if Session Manager fails to connect using the specified OS user account, it doesn't fall back to connecting using the default method.
> If you activate Run As without specifying an OS account or tagging an IAM entity, and you have not specified an OS account in Session Manager preferences, session connection attempts will fail.

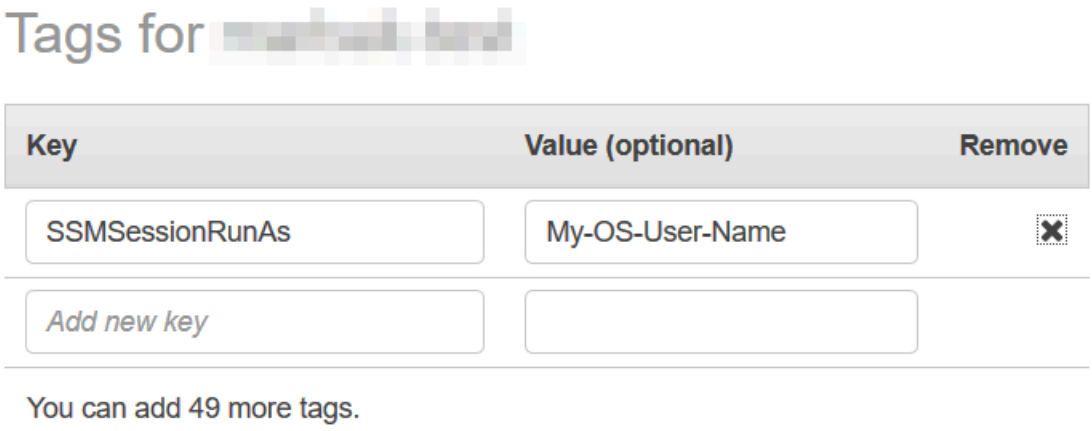
To turn on Run As support for Linux and macOS managed nodes

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Enable Run As support for Linux instances**.
5. Do one of the following:

   - **Option 1**: In the **Operating system user name** field, enter the name of the OS user account that you want to use to start sessions. Using this option, all sessions are run by the same OS user for all users in your AWS account who connect using Session Manager.
   - **Option 2** (Recommended): Choose the **Open the IAM console** link. In the navigation pane, choose either **Users** or **Roles**. Choose the entity (user or role) to add tags to, and then choose the **Tags** tab. Enter `SSMSessionRunAs` for the key name. Enter the name of an OS user account for the key value. Choose **Save changes**.

     Using this option, you can specify unique OS users for different IAM entities if you choose. For more information about tagging IAM entities (users or roles), see Tagging IAM resources in the *IAM User Guide*.

     The following is an example.



6. Choose **Save**.

Turn on KMS key encryption of session data (console)

Use AWS Key Management Service (AWS KMS) to create and manage encryption keys. With AWS KMS, you can control the use of encryption across a wide range of AWS services and in your applications. You can specify that session data transmitted between your managed nodes and the local machines of users in your AWS account is encrypted using KMS key encryption. (This is in addition to the TLS 1.2/1.3 encryption that AWS already provides by default.) To encrypt Session Manager session data, create a *symmetric* KMS key using AWS KMS.

AWS KMS encryption is available for `Standard_Stream`, `InteractiveCommands`, and `NonInteractiveCommands` session types. To use the option to encrypt session data using a key created in AWS KMS, version 2.3.539.0 or later of AWS Systems Manager SSM Agent must be installed on the managed node.

> **Note**
>
> You must allow AWS KMS encryption in order to reset passwords on your managed nodes from the AWS Systems Manager console. For more information, see Reset a password on a managed node.

You can use a key that you created in your AWS account. You can also use a key that was created in a different AWS account. The creator of the key in a different AWS account must provide you with the permissions needed to use the key.

After you turn on KMS key encryption for your session data, both the users who start sessions and the managed nodes that they connect to must have permission to use the key. You provide permission to use the KMS key with Session Manager through AWS Identity and Access Management (IAM) policies. For information, see the following topics:

- Add AWS KMS permissions for users in your account: Sample IAM policies for Session Manager.
- Add AWS KMS permissions for managed nodes in your account: Step 2: Verify or add instance permissions for Session Manager.

For more information about creating and managing KMS keys, see the *AWS Key Management Service Developer Guide*.

For information about using the AWS CLI to turn on KMS key encryption of session data in your account, see Create a Session Manager preferences document (command line) or Update Session Manager preferences (command line).

> **Note**
>
> There is a charge to use KMS keys. For information, see AWS Key Management Service pricing.

To turn on KMS key encryption of session data (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Enable KMS encryption**.
5. Do one of the following:

   - Choose the button next to **Select a KMS key in my current account**, then select a key from the list.

     -or-

Choose the button next to **Enter a KMS key alias or KMS key ARN**. Manually enter a KMS key alias for a key created in your current account, or enter the key Amazon Resource Name (ARN) for a key in another account. The following are examples:

- Key alias: `alias/my-kms-key-alias`
- Key ARN: `arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-12345EXAMPLE`

-or-

Choose **Create new key** to create a new KMS key in your account. After you create the new key, return to the **Preferences** tab and select the key for encrypting session data in your account.

For more information about sharing keys, see Allowing External AWS accounts to Access a key in the *AWS Key Management Service Developer Guide*.

6. Choose **Save**.

Create a Session Manager preferences document (command line)

Use the following procedure to create SSM documents that define your preferences for AWS Systems Manager Session Manager sessions. You can use the document to configure session options including data encryption, session duration, and logging. For example, you can specify whether to store session log data in an Amazon Simple Storage Service (Amazon S3) bucket or Amazon CloudWatch Logs log group. You can create documents that define general preferences for all sessions for an AWS account and AWS Region, or that define preferences for individual sessions.

> **Note**
>
> You can also configure general session preferences by using the Session Manager console.

Documents used to set Session Manager preferences must have a `sessionType` of `Standard_Stream`. For more information about Session documents, see the section called "Session document schema".

For information about using the command line to update existing Session Manager preferences, see Update Session Manager preferences (command line).

For an example of how to create session preferences using AWS CloudFormation, see Create a Systems Manager document for Session Manager preferences in the *AWS CloudFormation User Guide*.

> **Note**
>
> This procedure describes how to create documents for setting Session Manager preferences at the AWS account level. To create documents that will be used for setting session-level preferences, specify a value other than `SSM-SessionManagerRunShell` for the file name related command inputs .
>
> To use your document to set preferences for sessions started from the AWS Command Line Interface (AWS CLI), provide the document name as the `--document-name` parameter value. To set preferences for sessions started from the Session Manager console, you can type or select the name of your document from a list.

To create Session Manager preferences (command line)

1. Create a JSON file on your local machine with a name such as `SessionManagerRunShell.json`, and then paste the following content into it.

```
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": "",
        "s3KeyPrefix": "",
        "s3EncryptionEnabled": true,
        "cloudWatchLogGroupName": "",
        "cloudWatchEncryptionEnabled": true,
        "cloudWatchStreamingEnabled": false,
        "kmsKeyId": "",
        "runAsEnabled": false,
        "runAsDefaultUser": "",
        "idleSessionTimeout": "",
        "maxSessionDuration": "",
        "shellProfile": {
            "windows": "date",
            "linux": "pwd;ls"
        }
```

```
    }
}
```

You can also pass values to your session preferences using parameters instead of hardcoding the values as shown in the following example.

```
{
   "schemaVersion":"1.0",
   "description":"Session Document Parameter Example JSON Template",
   "sessionType":"Standard_Stream",
   "parameters":{
      "s3BucketName":{
         "type":"String",
         "default":""
      },
      "s3KeyPrefix":{
         "type":"String",
         "default":""
      },
      "s3EncryptionEnabled":{
         "type":"Boolean",
         "default":"false"
      },
      "cloudWatchLogGroupName":{
         "type":"String",
         "default":""
      },
      "cloudWatchEncryptionEnabled":{
         "type":"Boolean",
         "default":"false"
      }
   },
   "inputs":{
      "s3BucketName":"{{s3BucketName}}",
      "s3KeyPrefix":"{{s3KeyPrefix}}",
      "s3EncryptionEnabled":"{{s3EncryptionEnabled}}",
      "cloudWatchLogGroupName":"{{cloudWatchLogGroupName}}",
      "cloudWatchEncryptionEnabled":"{{cloudWatchEncryptionEnabled}}",
      "kmsKeyId":""
   }
}
```

2. Specify where you want to send session data. You can specify an S3 bucket name (with an optional prefix) or a CloudWatch Logs log group name. If you want to further encrypt data between local client and managed nodes, provide the KMS key to use for encryption. The following is an example.

```
{
  "schemaVersion": "1.0",
  "description": "Document to hold regional settings for Session Manager",
  "sessionType": "Standard_Stream",
  "inputs": {
    "s3BucketName": "amzn-s3-demo-bucket",
    "s3KeyPrefix": "MyS3Prefix",
    "s3EncryptionEnabled": true,
    "cloudWatchLogGroupName": "MyLogGroupName",
    "cloudWatchEncryptionEnabled": true,
    "cloudWatchStreamingEnabled": false,
    "kmsKeyId": "MyKMSKeyID",
    "runAsEnabled": true,
    "runAsDefaultUser": "MyDefaultRunAsUser",
    "idleSessionTimeout": "20",
    "maxSessionDuration": "60",
    "shellProfile": {
        "windows": "MyCommands",
        "linux": "MyCommands"
    }
  }
}
```

Note

If you don't want to encrypt the session log data, change `true` to `false` for `s3EncryptionEnabled`.

If you aren't sending logs to either an Amazon S3 bucket or a CloudWatch Logs log group, don't want to encrypt active session data, or don't want to turn on Run As support for the sessions in your account, you can delete the lines for those options. Make sure the last line in the `inputs` section doesn't end with a comma.

If you add a KMS key ID to encrypt your session data, both the users who start sessions and the managed nodes that they connect to must have permission to use the key. You provide permission to use the KMS key with Session Manager through IAM policies. For information, see the following topics:

- Add AWS KMS permissions for users in your account: Sample IAM policies for Session Manager
- Add AWS KMS permissions for managed nodes in your account: Step 2: Verify or add instance permissions for Session Manager

3. Save the file.
4. In the directory where you created the JSON file, run the following command.

   Linux & macOS

   ```
   aws ssm create-document \
       --name SSM-SessionManagerRunShell \
       --content "file://SessionManagerRunShell.json" \
       --document-type "Session" \
       --document-format JSON
   ```

   Windows

   ```
   aws ssm create-document ^
       --name SSM-SessionManagerRunShell ^
       --content "file://SessionManagerRunShell.json" ^
       --document-type "Session" ^
       --document-format JSON
   ```

   PowerShell

   ```
   New-SSMDocument `
       -Name "SSM-SessionManagerRunShell" `
       -Content (Get-Content -Raw SessionManagerRunShell.json) `
       -DocumentType "Session" `
       -DocumentFormat JSON
   ```

   If successful, the command returns output similar to the following.

   ```
   {
       "DocumentDescription": {
           "Status": "Creating",
           "Hash": "ce4fd0a2ab9b0fae759004ba603174c3ec2231f21a81db8690a33eb66EXAMPLE",
   ```

```
        "Name": "SSM-SessionManagerRunShell",
        "Tags": [],
        "DocumentType": "Session",
        "PlatformTypes": [
            "Windows",
            "Linux"
        ],
        "DocumentVersion": "1",
        "HashType": "Sha256",
        "CreatedDate": 1547750660.918,
        "Owner": "111122223333",
        "SchemaVersion": "1.0",
        "DefaultVersion": "1",
        "DocumentFormat": "JSON",
        "LatestVersion": "1"
    }
}
```

Update Session Manager preferences (command line)

The following procedure describes how to use your preferred command line tool to make changes to the AWS Systems Manager Session Manager preferences for your AWS account in the selected AWS Region. Use Session Manager preferences to specify options for logging session data in an Amazon Simple Storage Service (Amazon S3) bucket or Amazon CloudWatch Logs log group. You can also use Session Manager preferences to encrypt your session data.

To update Session Manager preferences (command line)

1. Create a JSON file on your local machine with a name such as `SessionManagerRunShell.json`, and then paste the following content into it.

```
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": "",
        "s3KeyPrefix": "",
        "s3EncryptionEnabled": true,
        "cloudWatchLogGroupName": "",
        "cloudWatchEncryptionEnabled": true,
```

```
        "cloudWatchStreamingEnabled": false,
        "kmsKeyId": "",
        "runAsEnabled": true,
        "runAsDefaultUser": "",
        "idleSessionTimeout": "",
        "maxSessionDuration": "",
        "shellProfile": {
            "windows": "date",
            "linux": "pwd;ls"
        }
    }
}
```

2. Specify where you want to send session data. You can specify an S3 bucket name (with an optional prefix) or a CloudWatch Logs log group name. If you want to further encrypt data between local client and managed nodes, provide the AWS KMS key to use for encryption. The following is an example.

```
{
  "schemaVersion": "1.0",
  "description": "Document to hold regional settings for Session Manager",
  "sessionType": "Standard_Stream",
  "inputs": {
    "s3BucketName": "amzn-s3-demo-bucket",
    "s3KeyPrefix": "MyS3Prefix",
    "s3EncryptionEnabled": true,
    "cloudWatchLogGroupName": "MyLogGroupName",
    "cloudWatchEncryptionEnabled": true,
    "cloudWatchStreamingEnabled": false,
    "kmsKeyId": "MyKMSKeyID",
    "runAsEnabled": true,
    "runAsDefaultUser": "MyDefaultRunAsUser",
    "idleSessionTimeout": "20",
    "maxSessionDuration": "60",
    "shellProfile": {
        "windows": "MyCommands",
        "linux": "MyCommands"
    }
  }
}
```

Note

If you don't want to encrypt the session log data, change `true` to `false` for `s3EncryptionEnabled`.
If you aren't sending logs to either an Amazon S3 bucket or a CloudWatch Logs log group, don't want to encrypt active session data, or don't want to turn on Run As support for the sessions in your account, you can delete the lines for those options. Make sure the last line in the `inputs` section doesn't end with a comma.
If you add a KMS key ID to encrypt your session data, both the users who start sessions and the managed nodes that they connect to must have permission to use the key. You provide permission to use the KMS key with Session Manager through AWS Identity and Access Management (IAM) policies. For information, see the following topics:

- Add AWS KMS permissions for users in your account: Sample IAM policies for Session Manager.
- Add AWS KMS permissions for managed nodes in your account: Step 2: Verify or add instance permissions for Session Manager.

3. Save the file.
4. In the directory where you created the JSON file, run the following command.

Linux & macOS

```
aws ssm update-document \
    --name "SSM-SessionManagerRunShell" \
    --content "file://SessionManagerRunShell.json" \
    --document-version "\$LATEST"
```

Windows

```
aws ssm update-document ^
    --name "SSM-SessionManagerRunShell" ^
    --content "file://SessionManagerRunShell.json" ^
    --document-version "$LATEST"
```

PowerShell

```
Update-SSMDocument `
```

```
    -Name "SSM-SessionManagerRunShell" `
    -Content (Get-Content -Raw SessionManagerRunShell.json) `
    -DocumentVersion '$LATEST'
```

If successful, the command returns output similar to the following.

```
{
    "DocumentDescription": {
        "Status": "Updating",
        "Hash": "ce4fd0a2ab9b0fae759004ba603174c3ec2231f21a81db8690a33eb66EXAMPLE",
        "Name": "SSM-SessionManagerRunShell",
        "Tags": [],
        "DocumentType": "Session",
        "PlatformTypes": [
            "Windows",
            "Linux"
        ],
        "DocumentVersion": "2",
        "HashType": "Sha256",
        "CreatedDate": 1537206341.565,
        "Owner": "111122223333",
        "SchemaVersion": "1.0",
        "DefaultVersion": "1",
        "DocumentFormat": "JSON",
        "LatestVersion": "2"
    }
}
```

Step 5: (Optional) Restrict access to commands in a session

You can restrict the commands that a user can run in an AWS Systems Manager Session Manager session by using a custom `Session` type AWS Systems Manager (SSM) document. In the document, you define the command that is run when the user starts a session and the parameters that the user can provide to the command. The `Session` document `schemaVersion` must be 1.0, and the `sessionType` of the document must be `InteractiveCommands`. You can then create AWS Identity and Access Management (IAM) policies that allow users to access only the `Session` documents that you define. For more information about using IAM policies to restrict access to commands in a session, see IAM policy examples for interactive commands.

Documents with the `sessionType` of `InteractiveCommands` are only supported for sessions started from the AWS Command Line Interface (AWS CLI). The user provides the custom document name as the `--document-name` parameter value and provides any command parameter values using the `--parameters` option. For more information about running interactive commands, see Starting a session (interactive and noninteractive commands).

Use following procedure to create a custom `Session` type SSM document that defines the command a user is allowed to run.

Restrict access to commands in a session (console)

To restrict the commands a user can run in a Session Manager session (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Choose **Create command or session**.
4. For **Name**, enter a descriptive name for the document.
5. For **Document type**, choose **Session document**.
6. Enter your document content that defines the command a user can run in a Session Manager session using JSON or YAML, as shown in the following example.

   YAML

```
---
schemaVersion: '1.0'
description: Document to view a log file on a Linux instance
sessionType: InteractiveCommands
parameters:
  logpath:
    type: String
    description: The log file path to read.
    default: "/var/log/amazon/ssm/amazon-ssm-agent.log"
    allowedPattern: "^[a-zA-Z0-9-_/]+(.log)$"
properties:
  linux:
    commands: "tail -f {{ logpath }}"
    runAsElevated: true
```

JSON

```
{
    "schemaVersion": "1.0",
    "description": "Document to view a log file on a Linux instance",
    "sessionType": "InteractiveCommands",
    "parameters": {
        "logpath": {
            "type": "String",
            "description": "The log file path to read.",
            "default": "/var/log/amazon/ssm/amazon-ssm-agent.log",
            "allowedPattern": "^[a-zA-Z0-9-_/]+(.log)$"
        }
    },
    "properties": {
        "linux": {
            "commands": "tail -f {{ logpath }}",
            "runAsElevated": true
        }
    }
}
```

7. Choose **Create document**.

Restrict access to commands in a session (command line)

Before you begin

If you haven't already, install and configure the AWS Command Line Interface (AWS CLI) or the AWS Tools for PowerShell. For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

To restrict the commands a user can run in a Session Manager session (command line)

1. Create a JSON or YAML file for your document content that defines the command a user can run in a Session Manager session, as shown in the following example.

   YAML

```
---
schemaVersion: '1.0'
```

```
description: Document to view a log file on a Linux instance
sessionType: InteractiveCommands
parameters:
  logpath:
    type: String
    description: The log file path to read.
    default: "/var/log/amazon/ssm/amazon-ssm-agent.log"
    allowedPattern: "^[a-zA-Z0-9-_/]+(.log)$"
properties:
  linux:
    commands: "tail -f {{ logpath }}"
    runAsElevated: true
```

JSON

```
{
    "schemaVersion": "1.0",
    "description": "Document to view a log file on a Linux instance",
    "sessionType": "InteractiveCommands",
    "parameters": {
        "logpath": {
            "type": "String",
            "description": "The log file path to read.",
            "default": "/var/log/amazon/ssm/amazon-ssm-agent.log",
            "allowedPattern": "^[a-zA-Z0-9-_/]+(.log)$"
        }
    },
    "properties": {
        "linux": {
            "commands": "tail -f {{ logpath }}",
            "runAsElevated": true
        }
    }
}
```

2. Run the following commands to create an SSM document using your content that defines the command a user can run in a Session Manager session.

   Linux & macOS

```
aws ssm create-document \
    --content file://path/to/file/documentContent.json \
    --name "exampleAllowedSessionDocument" \
```

```
    --document-type "Session"
```

Windows

```
aws ssm create-document ^
    --content file://C:\path\to\file\documentContent.json ^
    --name "exampleAllowedSessionDocument" ^
    --document-type "Session"
```

PowerShell

```
$json = Get-Content -Path "C:\path\to\file\documentContent.json" | Out-String
New-SSMDocument `
    -Content $json `
    -Name "exampleAllowedSessionDocument" `
    -DocumentType "Session"
```

Interactive command parameters and the AWS CLI

There are a variety of ways you can provide interactive command parameters when using the AWS CLI. Depending on the operating system (OS) of your client machine that you use to connect to managed nodes with the AWS CLI, the syntax you provide for commands that contain special or escape characters might differ. The following examples show some of the different ways you can provide command parameters when using the AWS CLI, and how to handle special or escape characters.

Parameters stored in Parameter Store can be referenced in the AWS CLI for your command parameters as shown in the following example.

Linux & macOS

```
aws ssm start-session \
    --target instance-id \
    --document-name MyInteractiveCommandDocument \
    --parameters '{"command":["{{ssm:mycommand}}"]}'
```

Windows

```
aws ssm start-session ^
```

```
    --target instance-id ^
    --document-name MyInteractiveCommandDocument ^
    --parameters '{"command":["{{ssm:mycommand}}"]}'
```

The following example shows how you can use a shorthand syntax with the AWS CLI to pass parameters.

Linux & macOS

```
aws ssm start-session \
    --target instance-id \
    --document-name MyInteractiveCommandDocument \
    --parameters command="ifconfig"
```

Windows

```
aws ssm start-session ^
    --target instance-id ^
    --document-name MyInteractiveCommandDocument ^
    --parameters command="ipconfig"
```

You can also provide parameters in JSON as shown in the following example.

Linux & macOS

```
aws ssm start-session \
    --target instance-id \
    --document-name MyInteractiveCommandDocument \
    --parameters '{"command":["ifconfig"]}'
```

Windows

```
aws ssm start-session ^
    --target instance-id ^
    --document-name MyInteractiveCommandDocument ^
    --parameters '{"command":["ipconfig"]}'
```

Parameters can also be stored in a JSON file and provided to the AWS CLI as shown in the following example. For more information about using AWS CLI parameters from a file, see Loading AWS CLI parameters from a file in the *AWS Command Line Interface User Guide*.

```
{
    "command": [
        "my command"
    ]
}
```

Linux & macOS

```
aws ssm start-session \
    --target instance-id \
    --document-name MyInteractiveCommandDocument \
    --parameters file://complete/path/to/file/parameters.json
```

Windows

```
aws ssm start-session ^
    --target instance-id ^
    --document-name MyInteractiveCommandDocument ^
    --parameters file://complete/path/to/file/parameters.json
```

You can also generate an AWS CLI skeleton from a JSON input file as shown in the following example. For more information about generating AWS CLI skeletons from JSON input files, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the *AWS Command Line Interface User Guide*.

```
{
    "Target": "instance-id",
    "DocumentName": "MyInteractiveCommandDocument",
    "Parameters": {
        "command": [
            "my command"
        ]
    }
}
```

Linux & macOS

```
aws ssm start-session \
    --cli-input-json file://complete/path/to/file/parameters.json
```

Windows

```
aws ssm start-session ^
    --cli-input-json file://complete/path/to/file/parameters.json
```

To escape characters inside quotation marks, you must add additional backslashes to the escape characters as shown in the following example.

Linux & macOS

```
aws ssm start-session \
    --target instance-id \
    --document-name MyInteractiveCommandDocument \
    --parameters '{"command":["printf \"abc\\\\tdef\""]}'
```

Windows

```
aws ssm start-session ^
    --target instance-id ^
    --document-name MyInteractiveCommandDocument ^
    --parameters '{"command":["printf \"abc\\\\tdef\""]}'
```

For information about using quotation marks with command parameters in the AWS CLI, see Using quotation marks with strings in the AWS CLI in the *AWS Command Line Interface User Guide*.

IAM policy examples for interactive commands

You can create IAM policies that allow users to access only the `Session` documents you define. This restricts the commands a user can run in a Session Manager session to only the commands defined in your custom `Session` type SSM documents.

Allow a user to run an interactive command on a single managed node

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"ssm:StartSession",
         "Resource":[
            "arn:aws:ec2:us-east-1:444455556666:instance/i-02573cafcfEXAMPLE",
            "arn:aws:ssm:us-east-1:444455556666:document/allowed-session-
document"
         ]
      },
      {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
         "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
      }
   ]
}
```

Allow a user to run an interactive command on all managed nodes

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"ssm:StartSession",
         "Resource":[
            "arn:aws:ec2:us-east-1:444455556666:instance/*",
            "arn:aws:ssm:us-east-1:444455556666:document/allowed-session-
document"
         ]
      },
      {
         "Effect": "Allow",
         "Action": ["ssmmessages:OpenDataChannel"],
```

```
            "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
        }
    ]
}
```

Allow a user to run multiple interactive commands on all managed nodes

JSON

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Effect":"Allow",
            "Action":"ssm:StartSession",
            "Resource":[
                "arn:aws:ec2:us-east-1:444455556666:instance/*",
                "arn:aws:ssm:us-east-1:444455556666:document/allowed-session-
document",
                "arn:aws:ssm:us-east-1:444455556666:document/allowed-session-
document-2"
            ]
        },
        {
            "Effect": "Allow",
            "Action": ["ssmmessages:OpenDataChannel"],
            "Resource": ["arn:aws:ssm:*:*:session/${aws:userid}-*"]
        }
    ]
}
```

Step 6: (Optional) Use AWS PrivateLink to set up a VPC endpoint for Session Manager

You can further improve the security posture of your managed nodes by configuring AWS Systems Manager to use an interface virtual private cloud (VPC) endpoint. Interface endpoints are powered by AWS PrivateLink, a technology that allows you to privately access Amazon Elastic Compute Cloud (Amazon EC2) and Systems Manager APIs by using private IP addresses.

AWS PrivateLink restricts all network traffic between your managed nodes, Systems Manager, and Amazon EC2 to the Amazon network. (Managed nodes don't have access to the internet.) Also, you don't need an internet gateway, a NAT device, or a virtual private gateway.

For information about creating a VPC endpoint, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

The alternative to using a VPC endpoint is to allow outbound internet access on your managed nodes. In this case, the managed nodes must also allow HTTPS (port 443) outbound traffic to the following endpoints:

- `ec2messages.region.amazonaws.com`
- `ssm.region.amazonaws.com`
- `ssmmessages.region.amazonaws.com`

Systems Manager uses the last of these endpoints, `ssmmessages.region.amazonaws.com`, to make calls from SSM Agent to the Session Manager service in the cloud.

To use optional features like AWS Key Management Service (AWS KMS) encryption, streaming logs to Amazon CloudWatch Logs (CloudWatch Logs), and sending logs to Amazon Simple Storage Service (Amazon S3) you must allow HTTPS (port 443) outbound traffic to the following endpoints:

- `kms.region.amazonaws.com`
- `logs.region.amazonaws.com`
- `s3.region.amazonaws.com`

For more information about required endpoints for Systems Manager, see Reference: ec2messages, ssmmessages, and other API operations.

Step 7: (Optional) Turn on or turn off ssm-user account administrative permissions

Starting with version 2.3.50.0 of AWS Systems Manager SSM Agent, the agent creates a local user account called `ssm-user` and adds it to `/etc/sudoers` (Linux and macOS) or to the Administrators group (Windows). On agent versions earlier than 2.3.612.0, the account is created the first time SSM Agent starts or restarts after installation. On version 2.3.612.0 and later, the `ssm-user` account is created the first time a session is started on a node. This `ssm-user` is the default operating system (OS) user when a AWS Systems Manager Session Manager session is started. SSM Agent version 2.3.612.0 was released on May 8th, 2019.

If you want to prevent Session Manager users from running administrative commands on a node, you can update the `ssm-user` account permissions. You can also restore these permissions after they have been removed.

Topics

Managing ssm-user sudo account permissions on Linux and macOS

Use one of the following procedures to turn on or turn off the ssm-user account sudo permissions on Linux and macOS managed nodes.

Use Run Command to modify ssm-user sudo permissions (console)

- Use the procedure in Running commands from the console with the following values:
  - For **Command document**, choose `AWS-RunShellScript`.
  - To remove sudo access, in the **Command parameters** area, paste the following in the **Commands** box.

```
cd /etc/sudoers.d
echo "#User rules for ssm-user" > ssm-agent-users
```

-or-

To restore sudo access, in the **Command parameters** area, paste the following in the **Commands** box.

```
cd /etc/sudoers.d
echo "ssm-user ALL=(ALL) NOPASSWD:ALL" > ssm-agent-users
```

Use the command line to modify ssm-user sudo permissions (AWS CLI)

1. Connect to the managed node and run the following command.

```
sudo -s
```

2. Change the working directory using the following command.

```
cd /etc/sudoers.d
```

3. Open the file named `ssm-agent-users` for editing.
4. To remove sudo access, delete the following line.

   ```
   ssm-user ALL=(ALL) NOPASSWD:ALL
   ```

   -or-

   To restore sudo access, add the following line.

   ```
   ssm-user ALL=(ALL) NOPASSWD:ALL
   ```

5. Save the file.

Managing ssm-user Administrator account permissions on Windows Server

Use one of the following procedures to turn on or turn off the ssm-user account Administrator permissions on Windows Server managed nodes.

Use Run Command to modify Administrator permissions (console)

- Use the procedure in Running commands from the console with the following values:

  For **Command document**, choose `AWS-RunPowerShellScript`.

  To remove administrative access, in the **Command parameters** area, paste the following in the **Commands** box.

  ```
  net localgroup "Administrators" "ssm-user" /delete
  ```

  -or-

  To restore administrative access, in the **Command parameters** area, paste the following in the **Commands** box.

  ```
  net localgroup "Administrators" "ssm-user" /add
  ```

Use the PowerShell or command prompt window to modify Administrator permissions

1. Connect to the managed node and open the PowerShell or Command Prompt window.

2. To remove administrative access, run the following command.

```
net localgroup "Administrators" "ssm-user" /delete
```

-or-

To restore administrative access, run the following command.

```
net localgroup "Administrators" "ssm-user" /add
```

Use the Windows console to modify Administrator permissions

1. Connect to the managed node and open the PowerShell or Command Prompt window.
2. From the command line, run `lusrmgr.msc` to open the **Local Users and Groups** console.
3. Open the **Users** directory, and then open **ssm-user**.
4. On the **Member Of** tab, do one of the following:
   - To remove administrative access, select **Administrators**, and then choose **Remove**.

     -or-

     To restore administrative access, enter **`Administrators`** in the text box, and then choose **Add**.
5. Choose **OK**.

Step 8: (Optional) Allow and control permissions for SSH connections through Session Manager

You can allow users in your AWS account to use the AWS Command Line Interface (AWS CLI) to establish Secure Shell (SSH) connections to managed nodes using AWS Systems Manager Session Manager. Users who connect using SSH can also copy files between their local machines and managed nodes using Secure Copy Protocol (SCP). You can use this functionality to connect to managed nodes without opening inbound ports or maintaining bastion hosts.

After allowing SSH connections, you can use AWS Identity and Access Management (IAM) policies to explicitly allow or deny users, groups, or roles to make SSH connections using Session Manager.

> **Note**
>
> Logging isn't available for Session Manager sessions that connect through port forwarding or SSH. This is because SSH encrypts all session data, and Session Manager only serves as a tunnel for SSH connections.

Topics

- Allowing SSH connections for Session Manager
- Controlling user permissions for SSH connections through Session Manager

Allowing SSH connections for Session Manager

Use the following steps to allow SSH connections through Session Manager on a managed node.

To allow SSH connections for Session Manager

1. On the managed node to which you want to allow SSH connections, do the following:

   - Ensure that SSH is running on the managed node. (You can close inbound ports on the node.)
   - Ensure that SSM Agent version 2.3.672.0 or later is installed on the managed node.

     For information about installing or updating SSM Agent on a managed node, see the following topics:

     - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server.
     - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
     - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
     - How to install the SSM Agent on hybrid Windows nodes
     - How to install the SSM Agent on hybrid Linux nodes

     > **Note**
     >
     > To use Session Manager with on-premises servers, edge devices, and virtual machines (VMs) that you activated as managed nodes, you must use the advanced-

instances tier. For more information about advanced instances, see Configuring instance tiers.

2. On the local machine from which you want to connect to a managed node using SSH, do the following:

   - Ensure that version 1.1.23.0 or later of the Session Manager plugin is installed.

     For information about installing the Session Manager plugin, see Install the Session Manager plugin for the AWS CLI.

   - Update the SSH configuration file to allow running a proxy command that starts a Session Manager session and transfer all data through the connection.

     Linux and macOS

     Tip

     The SSH configuration file is typically located at `~/.ssh/config`.

     Add the following to the configuration file on the local machine.

```
# SSH over Session Manager
Host i-* mi-*
    ProxyCommand sh -c "aws ssm start-session --target %h --document-name AWS-StartSSHSession --parameters 'portNumber=%p'"
    User ec2-user
```

     Windows

     Tip

     The SSH configuration file is typically located at `C:\Users\<username>\.ssh\config`.

     Add the following to the configuration file on the local machine.

```
# SSH over Session Manager
```

```
Host i-* mi-*
    ProxyCommand C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe "aws
 ssm start-session --target %h --document-name AWS-StartSSHSession --parameters
 portNumber=%p"
```

- Create or verify that you have a Privacy Enhanced Mail certificate (a PEM file), or at minimum a public key, to use when establishing connections to managed nodes. This must be a key that is already associated with the managed node. The permissions of your private key file must be set so that only you can read it. You can use the following command to set the permissions of your private key file so that only you can read it.

  ```
  chmod 400 <my-key-pair>.pem
  ```

  For example, for an Amazon Elastic Compute Cloud (Amazon EC2) instance, the key pair file you created or selected when you created the instance. (You specify the path to the certificate or key as part of the command to start a session. For information about starting a session using SSH, see Starting a session (SSH).)

Controlling user permissions for SSH connections through Session Manager

After you enable SSH connections through Session Manager on a managed node, you can use IAM policies to allow or deny users, groups, or roles the ability to make SSH connections through Session Manager.

To use an IAM policy to allow SSH connections through Session Manager

- Use one of the following options:

  - **Option 1**: Open the IAM console at https://console.aws.amazon.com/iam/.

    In the navigation pane, choose **Policies**, and then update the permissions policy for the user or role you want to allow to start SSH connections through Session Manager.

    For example, add the following element to the Quickstart policy you created in Quickstart end user policies for Session Manager. Replace each *example resource placeholder* with your own information.

    JSON

    ```
    {
    ```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ssm:StartSession",
            "Resource": [
                "arn:aws:ec2:us-east-1:111122223333:instance/instance-id",
                "arn:aws:ssm:*:*:document/AWS-StartSSHSession"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "ssmmessages:OpenDataChannel",
            "Resource": "arn:aws:ssm:*:*:session/${aws:userid}-*"
        }
    ]
}
```

- **Option 2**: Attach an inline policy to a user policy by using the AWS Management Console, the AWS CLI, or the AWS API.

  Using the method of your choice, attach the policy statement in **Option 1** to the policy for an AWS user, group, or role.

  For information, see Adding and Removing IAM Identity Permissions in the *IAM User Guide*.

To use an IAM policy to deny SSH connections through Session Manager

- Use one of the following options:

  - **Option 1**: Open the IAM console at https://console.aws.amazon.com/iam/. In the navigation pane, choose **Policies**, and then update the permissions policy for the user or role to block from starting Session Manager sessions.

    For example, add the following element to the Quickstart policy you created in Quickstart end user policies for Session Manager.

    JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Deny",
            "Action": "ssm:StartSession",
            "Resource": "arn:aws:ssm:*:*:document/AWS-StartSSHSession"
        },
        {
            "Effect": "Allow",
            "Action": "ssmmessages:OpenDataChannel",
            "Resource": "arn:aws:ssm:*:*:session/${aws:userid}-*"
        }
    ]
}
```

- **Option 2**: Attach an inline policy to a user policy by using the AWS Management Console, the AWS CLI, or the AWS API.

  Using the method of your choice, attach the policy statement in **Option 1** to the policy for an AWS user, group, or role.

  For information, see Adding and Removing IAM Identity Permissions in the *IAM User Guide*.

Working with Session Manager

You can use the AWS Systems Manager console, the Amazon Elastic Compute Cloud (Amazon EC2) console, or the AWS Command Line Interface (AWS CLI) to start sessions that connect you to the managed nodes your system administrator has granted you access to using AWS Identity and Access Management (IAM) policies. Depending on your permissions, you can also view information about sessions, resume inactive sessions that haven't timed out, and end sessions. After a session is established, it is not affected by IAM role session duration. For information about limiting session duration with Session Manager, see Specify an idle session timeout value and Specify maximum session duration.

For more information about sessions, see What is a session?

- View session history

Install the Session Manager plugin for the AWS CLI

To initiate Session Manager sessions with your managed nodes by using the AWS Command Line Interface (AWS CLI), you must install the *Session Manager plugin* on your local machine. You can install the plugin on supported versions of Microsoft Windows Server, macOS, Linux, and Ubuntu Server.

> **Note**
>
> To use the Session Manager plugin, you must have AWS CLI version 1.16.12 or later installed on your local machine. For more information, see Installing or updating the latest version of the AWS Command Line Interface.

Topics

Session Manager plugin latest version and release history

Your local machine must be running a supported version of the Session Manager plugin. The current minimum supported version is 1.1.17.0. If you're running an earlier version, your Session Manager operations might not succeed.

To see if you have the latest version, run the following command in the AWS CLI.

> **Note**
>
> The command returns results only if the plugin is located in the default installation directory for your operating system type. You can also check the version in the contents of the `VERSION` file in the directory where you have installed the plugin.

```
session-manager-plugin --version
```

The following table lists all releases of the Session Manager plugin and the features and enhancements included with each version.

> **Important**
>
> We recommend you always run the latest version. The latest version includes enhancements that improve the experience of using the plugin.

Version	Release date	Details
1.2.707.0	February 6, 2025	**Enhancement**: Upgraded the Go version to 1.23 in the Dockerfile. Updated the version configuration step in the README.
1.2.694.0	November 20, 2024	**Bug fix**: Rolled back change that added credentials to OpenDataChannel requests.
1.2.688.0	November 6, 2024	**This version was deprecated on 11/20/2024.** **Enhancements**: • Added credentials to OpenDataChannel requests. • Upgraded the `testify` and `objx` dependent packages.
1.2.677.0	October 10, 2024	**Enhancement**: Added support for passing the plugin version with OpenDataChannel requests.
1.2.650.0	July 02, 2024	**Enhancement**: Upgraded aws-sdk-go to 1.54.10. **Bug fix**: Reformated comments for gofmt check.
1.2.633.0	May 30, 2024	**Enhancement**: Updated the Dockerfile to use an Amazon Elastic Container Registry (Amazon ECR) image.
1.2.553.0	January 10, 2024	**Enhancement**: Upgraded aws-sdk-go and dependent Golang packages.

Version	Release date	Details
1.2.536.0	December 4, 2023	**Enhancement**: Added support for passing a StartSession API response as an environment variable to session-manager-plugin.
1.2.497.0	August 1, 2023	**Enhancement**: Upgraded Go SDK to v1.44.302.
1.2.463.0	March 15, 2023	**Enhancement**: Added Mac with Apple silicon support for Apple Mac (M1) in macOS bundle installer and signed installer.
1.2.398.0	October 14, 2022	**Enhancement**: Support golang version 1.17. Update default session-manager-plugin runner for macOS to use python3. Update import path from SSMCLI to session-manager-plugin.
1.2.339.0	June 16, 2022	**Bug fix**: Fix idle session timeout for port sessions.
1.2.331.0	May 27, 2022	**Bug fix**: Fix port sessions closing prematurely when the local server doesn't connect before timeout.
1.2.323.0	May 19, 2022	**Bug fix**: Disable smux keep alive to use idle session timeout feature.
1.2.312.0	March 31, 2022	**Enhancement**: Supports more output message payload types.
1.2.295.0	January 12, 2022	**Bug fix**: Hung sessions caused by client resending stream data when agent becomes inactive, and incorrect logs for `start_publication` and `pause_publication` messages.
1.2.279.0	October 27, 2021	**Enhancement**: Zip packaging for Windows platform.
1.2.245.0	August 19, 2021	**Enhancement**: Upgrade `aws-sdk-go` to latest version (v1.40.17) to support AWS IAM Identity Center.

Version	Release date	Details
1.2.234.0	July 26, 2021	**Bug fix**: Handle session abruptly terminated scenario in interactive session type.
1.2.205.0	June 10, 2021	**Enhancement**: Added support for signed macOS installer.
1.2.54.0	January 29, 2021	**Enhancement**: Added support for running sessions in NonInteractiveCommands execution mode.
1.2.30.0	November 24, 2020	**Enhancement**: (Port forwarding sessions only) Improved overall performance.
1.2.7.0	October 15, 2020	**Enhancement**: (Port forwarding sessions only) Reduced latency and improved overall performance.
1.1.61.0	April 17, 2020	**Enhancement**: Added ARM support for Linux and Ubuntu Server.
1.1.54.0	January 6, 2020	**Bug fix**: Handle race condition scenario of packets being dropped when the Session Manager plugin isn't ready.
1.1.50.0	November 19, 2019	**Enhancement**: Added support for forwarding a port to a local unix socket.
1.1.35.0	November 7, 2019	**Enhancement**: (Port forwarding sessions only) Send a TerminateSession command to SSM Agent when the local user presses `Ctrl+C`.
1.1.33.0	September 26, 2019	**Enhancement**: (Port forwarding sessions only) Send a disconnect signal to the server when the client drops the TCP connection.
1.1.31.0	September 6, 2019	**Enhancement**: Update to keep port forwarding session open until remote server closes the connection.
1.1.26.0	July 30, 2019	**Enhancement**: Update to limit the rate of data transfer during a session.

Version	Release date	Details
1.1.23.0	July 9, 2019	**Enhancement**: Added support for running SSH sessions using Session Manager.
1.1.17.0	April 4, 2019	**Enhancement**: Added support for further encryption of session data using AWS Key Management Service (AWS KMS).
1.0.37.0	September 20, 2018	**Enhancement**: Bug fix for Windows version.
1.0.0.0	September 11, 2018	Initial release of the Session Manager plugin.

Install the Session Manager plugin on Windows

You can install the Session Manager plugin on Windows Vista or later using the standalone installer.

When updates are released, you must repeat the installation process to get the latest version of the Session Manager plugin.

> **Note**
>
> Note the following information.
>
> - The Session Manager plugin installer needs Administrator rights to install the plugin.
> - For best results, we recommend that you start sessions on Windows clients using Windows PowerShell, version 5 or later. Alternatively, you can use the Command shell in Windows 10. The Session Manager plugin only supports PowerShell and the Command shell. Third-party command line tools might not be compatible with the plugin.

To install the Session Manager plugin using the EXE installer

1. Download the installer using the following URL.

```
https://s3.amazonaws.com/session-manager-downloads/plugin/latest/windows/
SessionManagerPluginSetup.exe
```

Alternatively, you can download a zipped version of the installer using the following URL.

```
https://s3.amazonaws.com/session-manager-downloads/plugin/latest/windows/
SessionManagerPlugin.zip
```

2. Run the downloaded installer, and follow the on-screen instructions. If you downloaded the zipped version of the installer, you must unzip the installer first.

   Leave the install location box blank to install the plugin to the default directory.

   - `%PROGRAMFILES%\Amazon\SessionManagerPlugin\bin\`

3. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.

   > **Note**
   >
   > If Windows is unable to find the executable, you might need to re-open the command prompt or add the installation directory to your PATH environment variable manually. For information, see the troubleshooting topic Session Manager plugin not automatically added to command line path (Windows).

Install the Session Manager plugin on macOS

Choose one of the following topics to install the Session Manager plugin on macOS.

> **Note**
>
> The signed installer is a signed `.pkg` file. The bundled installer uses a `.zip` file. After the file is unzipped, you can install the plugin using the binary.

Install the Session Manager plugin on macOS with the signed installer

This section describes how to install the Session Manager plugin on macOS using the signed installer.

To install the Session Manager plugin using the signed installer (macOS)

1. Download the signed installer.

   x86_64

   ```
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/mac/
   session-manager-plugin.pkg" -o "session-manager-plugin.pkg"
   ```

   Mac with Apple silicon

   ```
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/
   mac_arm64/session-manager-plugin.pkg" -o "session-manager-plugin.pkg"
   ```

2. Run the install commands. If the command fails, verify that the `/usr/local/bin` folder exists. If it doesn't, create it and run the command again.

   ```
   sudo installer -pkg session-manager-plugin.pkg -target /
   sudo ln -s /usr/local/sessionmanagerplugin/bin/session-manager-plugin /usr/local/
   bin/session-manager-plugin
   ```

3. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.

Install the Session Manager plugin on macOS

This section describes how to install the Session Manager plugin on macOS using the bundled installer.

> **Important**
>
> Note the following important information.
>
> - By default, the installer requires sudo access to run, because the script installs the plugin to the `/usr/local/sessionmanagerplugin` system directory. If you don't want to install the plugin using sudo, manually update the installer script to install the plugin to a directory that doesn't require sudo access.
> - The bundled installer doesn't support installing to paths that contain spaces.

To install the Session Manager plugin using the bundled installer (macOS)

1. Download the bundled installer.

   x86_64

   ```
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/mac/
   sessionmanager-bundle.zip" -o "sessionmanager-bundle.zip"
   ```

   Mac with Apple silicon

   ```
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/
   mac_arm64/sessionmanager-bundle.zip" -o "sessionmanager-bundle.zip"
   ```

2. Unzip the package.

   ```
   unzip sessionmanager-bundle.zip
   ```

3. Run the install command.

   ```
   sudo ./sessionmanager-bundle/install -i /usr/local/sessionmanagerplugin -b /usr/
   local/bin/session-manager-plugin
   ```

   Note

   The plugin requires either Python 2.6.5 or later, or Python 3.3 or later. By default, the install script runs under the system default version of Python. If you have installed an alternative version of Python and want to use that to install the Session Manager plugin, run the install script with that version by absolute path to the Python executable. The following is an example.

   ```
   sudo /usr/local/bin/python3.8 sessionmanager-bundle/install -i /usr/local/
   sessionmanagerplugin -b /usr/local/bin/session-manager-plugin
   ```

   The installer installs the Session Manager plugin at `/usr/local/sessionmanagerplugin` and creates the symlink `session-manager-plugin` in the `/usr/local/bin` directory. This eliminates the need to specify the install directory in the user's $PATH variable.

To see an explanation of the `-i` and `-b` options, use the `-h` option.

```
./sessionmanager-bundle/install -h
```

4. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.

> **Note**
>
> To uninstall the plugin, run the following two commands in the order shown.
>
> ```
> sudo rm -rf /usr/local/sessionmanagerplugin
> ```
>
> ```
> sudo rm /usr/local/bin/session-manager-plugin
> ```

Install the Session Manager plugin on Linux

This section includes information about verifying the signature of the Session Manager plugin installer package and installing the plugin on the following Linux distributions:

- Amazon Linux 2
- AL2023
- RHEL
- Debian Server
- Ubuntu Server

Topics

- Verify the signature of the Session Manager plugin
- Install the Session Manager plugin on Amazon Linux 2, Amazon Linux 2023, and Red Hat Enterprise Linux distributions
- Install the Session Manager plugin on Debian Server and Ubuntu Server

Verify the signature of the Session Manager plugin

The Session Manager plugin RPM and Debian installer packages for Linux instances are cryptographically signed. You can use a public key to verify that the plugin binary and package is original and unmodified. If the file is altered or damaged, the verification fails. You can verify the signature of the installer package using the GNU Privacy Guard (GPG) tool. The following information is for Session Manager plugin versions 1.2.707.0 or later.

Complete the following steps to verify the signature of the Session Manager plugin installer package.

Topics

Step 1: Download the Session Manager plugin installer package

Download the Session Manager plugin installer package you want to verify.

Amazon Linux 2, AL2023, and RHEL RPM packages

x86_64

```
curl -o "session-manager-plugin.rpm" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_64bit/session-manager-plugin.rpm"
```

ARM64

```
curl -o "session-manager-plugin.rpm" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_arm64/session-manager-plugin.rpm"
```

Debian Server and Ubuntu Server Deb packages

x86_64

```
curl -o "session-manager-plugin.deb" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/ubuntu_64bit/session-manager-plugin.deb"
```

ARM64

```
curl -o "session-manager-plugin.deb" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/ubuntu_arm64/session-manager-plugin.deb"
```

Step 2: Download the associated signature file

After you download the installer package, download the associated signature file for package verification. To provide an extra layer of protection against unauthorized copying or use of the session-manager-plugin binary file inside the package, we also offer binary signatures, which you can use to validate individual binary files. You can choose to use these binary signatures based on your security needs.

Amazon Linux 2, AL2023, and RHEL signature packages

x86_64

Package:

```
curl -o "session-manager-plugin.rpm.sig" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_64bit/session-manager-plugin.rpm.sig"
```

Binary:

```
curl -o "session-manager-plugin.sig" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_64bit/session-manager-plugin.sig"
```

ARM64

Package:

```
curl -o "session-manager-plugin.rpm.sig" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_arm64/session-manager-plugin.rpm.sig"
```

Binary:

```
curl -o "session-manager-plugin.sig" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_arm64/session-manager-plugin.sig"
```

Debian Server and Ubuntu Server Deb signature packages

x86_64

Package:

```
curl -o "session-manager-plugin.deb.sig" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/ubuntu_64bit/session-manager-plugin.deb.sig"
```

Binary:

```
curl -o "session-manager-plugin.sig" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/ubuntu_64bit/session-manager-plugin.sig"
```

ARM64

Package:

```
curl -o "session-manager-plugin.deb.sig" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/ubuntu_arm64/session-manager-plugin.deb.sig"
```

Binary:

```
curl -o "session-manager-plugin.sig" "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/ubuntu_arm64/session-manager-plugin.sig"
```

Step 3: Install the GPG tool

To verify the signature of the Session Manager plugin, you must have the GNU Privacy Guard (GPG) tool installed on your system. The verification process requires GPG version 2.1 or later. You can check your GPG version by running the following command:

```
gpg --version
```

If your GPG version is older than 2.1, update it before proceeding with the verification process. For most systems, you can update the GPG tool using your package manager. For example, on supported Amazon Linux and RHEL versions, you can use the following commands:

```
sudo yum update
sudo yum install gnupg2
```

On supported Ubuntu Server and Debian Server systems, you can use the following commands:

```
sudo apt-get update
sudo apt-get install gnupg2
```

Ensure you have the required GPG version before continuing with the verification process.

Step 4: Verify the Session Manager plugin installer package on a Linux server

Use the following procedure to verify the Session Manager plugin installer package on a Linux server.

> **Note**
>
> Amazon Linux 2 doesn't support the gpg tool version 2.1 or higher. If the following procedure doesn't work on your Amazon Linux 2 instances, verify the signature on a different platform before installing it on your Amazon Linux 2 instances.

1. Copy the following public key, and save it to a file named session-manager-plugin.gpg.

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

mFIEZ5ERQxMIKoZIzj0DAQcCAwQjuZy+IjFoYg57sLTGhF3aZLBaGpzB+gY6j7Ix
P7NqbpXyjVj8a+dy79gSd64OEaMxUb7vw/jug+CfRXwVGRMNtIBBV1MgU1NNIFNl

AwIbAwIVCAAKCRAsTUr/b2dX7rO1AQCa1kig3lQ78W/QHGU76uHx3XAyv0tfpE9U
oQBCIwFLSgEA3PDHt3lZ+s6m9JLGJsy+Cp5ZFzpiF6RgluR/2gA861M=
```

```
=2DQm
-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring. The returned key value should be 2C4D4AFF6F6757EE.

```
$ gpg --import session-manager-plugin.gpg
gpg: key 2C4D4AFF6F6757EE: public key "AWS SSM Session Manager <session-manager-
plugin-signer@amazon.com> (AWS Systems Manager Session Manager Plugin Linux Signer
 Key)" imported
gpg: Total number processed: 1
gpg:               imported: 1
```

3. Run the following command to verify the fingerprint.

```
gpg --fingerprint 2C4D4AFF6F6757EE
```

The fingerprint for the command output should match the following.

```
7959 6371 24CE 093A D501 D47A 2C4D 4AFF 6F67 57EE
```

```
pub   nistp256 2025-01-22 [SC]
      7959 6371 24CE 093A D501  D47A 2C4D 4AFF 6F67 57EE
uid           [ unknown] AWS SSM Session Manager <session-manager-plugin-
signer@amazon.com> (AWS Systems Manager Session Manager Plugin Linux Signer Key)
```

If the fingerprint doesn't match, don't install the plugin. Contact AWS Support.

4. Verify the installer package signature. Replace the *signature-filename* and *downloaded-plugin-filename* with the values you specified when downloading the signature file and session-manager-plugin, as listed in the table earlier in this topic.

```
gpg --verify signature-filename downloaded-plugin-filename
```

For example, for the x86_64 architecture on Amazon Linux 2, the command is as follows:

```
gpg --verify session-manager-plugin.rpm.sig session-manager-plugin.rpm
```

This command returns output similar to the following.

```
gpg: Signature made Mon Feb 3 20:08:32 2025 UTC gpg: using ECDSA key
 2C4D4AFF6F6757EE
gpg: Good signature from "AWS Systems Manager Session Manager <session-manager-
plugin-signer@amazon.com> (AWS Systems Manager Session Manager Plugin Linux Signer
 Key)" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg: There is no indication that the signature belongs to the owner.
Primary key fingerprint: 7959 6371 24CE 093A D501 D47A 2C4D 4AFF 6F67 57EE
```

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact AWS Support and don't install the package. The warning message about the trust doesn't mean that the signature isn't valid, only that you haven't verified the public key. A key is trusted only if you or someone who you trust has signed it. If the output includes the phrase `Can't check signature: No public key`, verify you downloaded Session Manager plugin with version 1.2.707.0 or later.

Install the Session Manager plugin on Amazon Linux 2, Amazon Linux 2023, and Red Hat Enterprise Linux distributions

Use the following procedure to install the Session Manager plugin on Amazon Linux 2, Amazon Linux 2023 (AL2023), and RHEL distributions.

1. Download and install the Session Manager plugin RPM package.

   x86_64

   On Amazon Linux 2 and RHEL 7, run the following command:

   ```
   sudo yum install -y https://s3.amazonaws.com/session-manager-downloads/plugin/
   latest/linux_64bit/session-manager-plugin.rpm
   ```

   On AL2023 and RHEL 8 and 9, run the following command:

   ```
   sudo dnf install -y https://s3.amazonaws.com/session-manager-downloads/plugin/
   latest/linux_64bit/session-manager-plugin.rpm
   ```

   ARM64

   On Amazon Linux 2 and RHEL 7, run the following command:

```
sudo yum install -y https://s3.amazonaws.com/session-manager-downloads/plugin/
latest/linux_arm64/session-manager-plugin.rpm
```

On AL2023 and RHEL 8 and 9, run the following command:

```
sudo dnf install -y https://s3.amazonaws.com/session-manager-downloads/plugin/
latest/linux_arm64/session-manager-plugin.rpm
```

2. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.

> **Note**
>
> If you want to uninstall the plugin, run `sudo yum erase session-manager-plugin -y`

Install the Session Manager plugin on Debian Server and Ubuntu Server

1. Download the Session Manager plugin deb package.

   x86_64

   ```
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/
   ubuntu_64bit/session-manager-plugin.deb" -o "session-manager-plugin.deb"
   ```

   ARM64

   ```
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/
   ubuntu_arm64/session-manager-plugin.deb" -o "session-manager-plugin.deb"
   ```

2. Run the install command.

   ```
   sudo dpkg -i session-manager-plugin.deb
   ```

3. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.

> **Note**
>
> If you ever want to uninstall the plugin, run `sudo dpkg -r session-manager-plugin`

Verify the Session Manager plugin installation

Run the following commands to verify that the Session Manager plugin installed successfully.

```
session-manager-plugin
```

If the installation was successful, the following message is returned.

```
The Session Manager plugin is installed successfully. Use the AWS CLI to start a
 session.
```

You can also test the installation by running the start-session command in the the AWS Command Line Interface (AWS CLI). In the following command, replace *instance-id* with your own information.

```
aws ssm start-session --target instance-id
```

This command will work only if you have installed and configured the AWS CLI, and if your Session Manager administrator has granted you the necessary IAM permissions to access the target managed node using Session Manager.

Session Manager plugin on GitHub

The source code for Session Manager plugin is available on GitHub so that you can adapt the plugin to meet your needs. We encourage you to submit pull requests for changes that you would like to have included. However, Amazon Web Services doesn't provide support for running modified copies of this software.

(Optional) Turn on Session Manager plugin logging

The Session Manager plugin includes an option to allow logging for sessions that you run. By default, logging is turned off.

If you allow logging, the Session Manager plugin creates log files for both application activity (`session-manager-plugin.log`) and errors (`errors.log`) on your local machine.

Topics

Turn on logging for the Session Manager plugin (Windows)

1. Locate the `seelog.xml.template` file for the plugin.

   The default location is `C:\Program Files\Amazon\SessionManagerPlugin\seelog.xml.template`.
2. Change the name of the file to `seelog.xml`.
3. Open the file and change `minlevel="off"` to `minlevel="info"` or `minlevel="debug"`.

   > **Note**
   >
   > By default, log entries about opening a data channel and reconnecting sessions are recorded at the **INFO** level. Data flow (packets and acknowledgement) entries are recorded at the **DEBUG** level.
4. Change other configuration options you want to modify. Options you can change include:

   - **Debug level**: You can change the debug level from `formatid="fmtinfo"` to `formatid="fmtdebug"`.
   - **Log file options**: You can make changes to the log file options, including where the logs are stored, with the exception of the log file names.

     > **Important**
     >
     > Don't change the file names or logging won't work correctly.

     ```
     <rollingfile type="size" filename="C:\Program Files\Amazon\SessionManagerPlugin
     \Logs\session-manager-plugin.log" maxsize="30000000" maxrolls="5"/>
     <filter levels="error,critical" formatid="fmterror">
     <rollingfile type="size" filename="C:\Program Files\Amazon\SessionManagerPlugin
     \Logs\errors.log" maxsize="10000000" maxrolls="5"/>
     ```
5. Save the file.

Enable logging for the Session Manager plugin (Linux and macOS)

1. Locate the `seelog.xml.template` file for the plugin.

   The default location is `/usr/local/sessionmanagerplugin/seelog.xml.template`.

2. Change the name of the file to `seelog.xml`.

3. Open the file and change `minlevel="off"` to `minlevel="info"` or `minlevel="debug"`.

   > **Note**
   >
   > By default, log entries about opening data channels and reconnecting sessions are recorded at the **INFO** level. Data flow (packets and acknowledgement) entries are recorded at the **DEBUG** level.

4. Change other configuration options you want to modify. Options you can change include:

   - **Debug level**: You can change the debug level from `formatid="fmtinfo"` to `outputs formatid="fmtdebug"`
   - **Log file options**: You can make changes to the log file options, including where the logs are stored, with the exception of the log file names.

     > **Important**
     >
     > Don't change the file names or logging won't work correctly.

     ```
     <rollingfile type="size" filename="/usr/local/sessionmanagerplugin/logs/session-
     manager-plugin.log" maxsize="30000000" maxrolls="5"/>
     <filter levels="error,critical" formatid="fmterror">
     <rollingfile type="size" filename="/usr/local/sessionmanagerplugin/logs/
     errors.log" maxsize="10000000" maxrolls="5"/>
     ```

     > **Important**
     >
     > If you use the specified default directory for storing logs, you must either run session commands using **sudo** or give the directory where the plugin is installed full read

and write permissions. To bypass these restrictions, change the location where logs are stored.

5. Save the file.

Start a session

You can use the AWS Systems Manager console, the Amazon Elastic Compute Cloud (Amazon EC2) console, the AWS Command Line Interface (AWS CLI), or SSH to start a session.

Topics

Starting a session (Systems Manager console)

You can use the AWS Systems Manager console to start a session with a managed node in your account.

> **Note**
>
> Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.

To start a session (Systems Manager console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose **Start session**.

4. (Optional) Enter a session description in the **Reason for session** field.
5. For **Target instances**, choose the option button to the left of the managed node that you want to connect to.

   If the node that you want isn't in the list, or if you select a node and receive a configuration error, see Managed node not available or not configured for Session Manager for troubleshooting steps.
6. Choose **Start session** to launch the session immediately.

   -or-

   Choose **Next** for session options.
7. (Optional) For **Session document**, select the document that you want to run when the session starts. If your document supports runtime parameters, you can enter one or more comma-separated values in each parameter field.
8. Choose **Next**.
9. Choose **Start session**.

After the connection is made, you can run bash commands (Linux and macOS) or PowerShell commands (Windows) as you would through any other connection type.

> **Important**
>
> If you want to allow users to specify a document when starting sessions in the Session Manager console, note the following:
>
> - You must grant users the `ssm:GetDocument` and `ssm:ListDocuments` permissions in their IAM policy. For more information, see Grant access to custom Session documents in the console.
> - The console only supports Session documents that have the `sessionType` defined as `Standard_Stream`. For more information, see Session document schema.

Starting a session (Amazon EC2 console)

You can use the Amazon Elastic Compute Cloud (Amazon EC2) console to start a session with an instance in your account.

> **Note**
>
> If you receive an error that you aren't authorized to perform one or more Systems Manager actions (`ssm:command-name`, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to start sessions from the Amazon EC2 console. If you're an administrator, see Sample IAM policies for Session Manager for more information.

To start a session (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. For **Connection method**, choose **Session Manager**.
5. Choose **Connect**.

After the connection is made, you can run bash commands (Linux and macOS) or PowerShell commands (Windows) as you would through any other connection type.

Starting a session (AWS CLI)

Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see Installing or updating the latest version of the AWS CLI.

Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.

To use the AWS CLI to run session commands, the Session Manager plugin must also be installed on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.

To start a session using the AWS CLI, run the following command replacing *instance-id* with your own information.

```
aws ssm start-session \
    --target instance-id
```

For information about other options you can use with the **start-session** command, see start-session in the AWS Systems Manager section of the AWS CLI Command Reference.

Starting a session (SSH)

To start a Session Manager SSH session, version 2.3.672.0 or later of SSM Agent must be installed on the managed node.

SSH connection requirements

Take note of the following requirements and limitations for session connections using SSH:

- Your target managed node must be configured to support SSH connections. For more information, see (Optional) Allow and control permissions for SSH connections through Session Manager.
- You must connect using the managed node account associated with the Privacy Enhanced Mail (PEM) certificate, not the `ssm-user` account that is used for other types of session connections. For example, on EC2 instances for Linux and macOS, the default user is `ec2-user`. For information about identifying the default user for each instance type, see Get Information About Your Instance in the *Amazon EC2 User Guide*.
- Logging isn't available for Session Manager sessions that connect through port forwarding or SSH. This is because SSH encrypts all session data, and Session Manager only serves as a tunnel for SSH connections.

> **Note**
>
> Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.

To start a session using SSH, run the following command. Replace each *`example resource placeholder`* with your own information.

```
ssh -i /path/my-key-pair.pem username@instance-id
```

Tip

When you start a session using SSH, you can copy local files to the target managed node using the following command format.

```
scp -i /path/my-key-pair.pem /path/ExampleFile.txt username@instance-id:~
```

For information about other options you can use with the **start-session** command, see start-session in the AWS Systems Manager section of the AWS CLI Command Reference.

Starting a session (port forwarding)

To start a Session Manager port forwarding session, version 2.3.672.0 or later of SSM Agent must be installed on the managed node.

Note

Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.
To use the AWS CLI to run session commands, you must install the Session Manager plugin on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.
Depending on your operating system and command line tool, the placement of quotation marks can differ and escape characters might be required.

To start a port forwarding session, run the following command from the CLI. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm start-session \
    --target instance-id \
    --document-name AWS-StartPortForwardingSession \
    --parameters '{"portNumber":["80"], "localPortNumber":["56789"]}'
```

Windows

```
aws ssm start-session ^
    --target instance-id ^
    --document-name AWS-StartPortForwardingSession ^
    --parameters portNumber="3389",localPortNumber="56789"
```

`portNumber` is the remote port on the managed node where you want the session traffic to be redirected. For example, you might specify port 3389 for connecting to a Windows node using the Remote Desktop Protocol (RDP). If you don't specify the `portNumber` parameter, Session Manager uses `80` as the default value.

`localPortNumber` is the port on your local computer where traffic starts, such as 56789. This value is what you enter when connecting to a managed node using a client. For example, **`localhost:56789`**.

For information about other options you can use with the **start-session** command, see start-session in the AWS Systems Manager section of the AWS CLI Command Reference.

For more information about port forwarding sessions, see Port Forwarding Using AWS Systems Manager Session Manager in the *AWS News Blog*.

Starting a session (port forwarding to remote host)

To start a Session Manager port forwarding session to a remote host, version 3.1.1374.0 or later of SSM Agent must be installed on the managed node. The remote host isn't required to be managed by Systems Manager.

> **Note**
>
> Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.
> To use the AWS CLI to run session commands, you must install the Session Manager plugin on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.
> Depending on your operating system and command line tool, the placement of quotation marks can differ and escape characters might be required.

To start a port forwarding session, run the following command from the AWS CLI. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm start-session \
    --target instance-id \
    --document-name AWS-StartPortForwardingSessionToRemoteHost \
    --parameters '{"host":["mydb.example.us-east-2.rds.amazonaws.com"],"portNumber":
["3306"], "localPortNumber":["3306"]}'
```

Windows

```
aws ssm start-session ^
    --target instance-id ^
    --document-name AWS-StartPortForwardingSessionToRemoteHost ^
    --parameters host="mydb.example.us-
east-2.rds.amazonaws.com",portNumber="3306",localPortNumber="3306"
```

The `host` value represents the hostname or IP address of the remote host that you want to connect to. General connectivity and name resolution requirements between the managed node and the remote host still apply.

`portNumber` is the remote port on the managed node where you want the session traffic to be redirected. For example, you might specify port 3389 for connecting to a Windows node using the Remote Desktop Protocol (RDP). If you don't specify the `portNumber` parameter, Session Manager uses `80` as the default value.

`localPortNumber` is the port on your local computer where traffic starts, such as 56789. This value is what you enter when connecting to a managed node using a client. For example, **`localhost:56789`**.

For information about other options you can use with the **start-session** command, see start-session in the AWS Systems Manager section of the AWS CLI Command Reference.

Starting a session with an Amazon ECS task

Session Manager supports starting a port forwarding session with a task inside an Amazon Elastic Container Service (Amazon ECS) cluster. To do so, you must update the task role in IAM to include the following permissions:

JSON

```
{
   "Version": "2012-10-17",
   "Statement": [
       {
       "Effect": "Allow",
       "Action": [
            "ssmmessages:CreateControlChannel",
            "ssmmessages:CreateDataChannel",
            "ssmmessages:OpenControlChannel",
            "ssmmessages:OpenDataChannel"
       ],
      "Resource": "*"
      }
   ]
}
```

To start a port forwarding session with an Amazon ECS task, run the following command from the AWS CLI. Replace each *example resource placeholder* with your own information.

> **Note**
>
> Remove the < and > symbols from the `target` parameter. These symbols are provided for reader clarification only.

Linux & macOS

```
aws ssm start-session \
    --target ecs:<ECS_cluster_name>_<ECS_container_ID>_<container_runtime_ID> \
    --document-name AWS-StartPortForwardingSessionToRemoteHost \
    --parameters '{"host":["URL"],"portNumber":["port_number"], "localPortNumber":
["port_number"]}'
```

Windows

```
aws ssm start-session ^
    --target ecs:<ECS_cluster_name>_<ECS_container_ID>_<container_runtime_ID> ^
```

```
    --document-name AWS-StartPortForwardingSessionToRemoteHost ^
    --parameters host="URL",portNumber="port_number",localPortNumber="port_number"
```

Starting a session (interactive and noninteractive commands)

Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.

To use the AWS CLI to run session commands, the Session Manager plugin must also be installed on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.

To start an interactive command session, run the following command. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm start-session \
    --target instance-id \
    --document-name CustomCommandSessionDocument \
    --parameters '{"logpath":["/var/log/amazon/ssm/amazon-ssm-agent.log"]}'
```

Windows

```
aws ssm start-session ^
    --target instance-id ^
    --document-name CustomCommandSessionDocument ^
    --parameters logpath="/var/log/amazon/ssm/amazon-ssm-agent.log"
```

For information about other options you can use with the **start-session** command, see start-session in the AWS Systems Manager section of the AWS CLI Command Reference.

More info

- Use port forwarding in AWS Systems Manager Session Manager to connect to remote hosts
- Amazon EC2 instance port forwarding with AWS Systems Manager
- Manage AWS Managed Microsoft AD resources with Session Manager port forwarding
- Port Forwarding Using AWS Systems Manager Session Manager on the *AWS News Blog*.

End a session

You can end a session that you started in your account using the AWS Systems Manager console or the AWS Command Line Interface (AWS CLI). When you choose the **Terminate** button for a session in the console or call the TerminateSession API action by using the AWS CLI, Session Manager permanently ends the session and closes the data connection between the Session Manager client and SSM Agent on the managed node. You can't resume a terminated session.

If there is no user activity in an open session for 20 minutes, the idle state triggers a timeout. Session Manager doesn't call `TerminateSession`, but it does close the underlying channel. You can't resume a session closed because of idle timeout.

We recommend always explicitly terminating a session by using the `terminate-session` command, when using the AWS CLI, or the **Terminate** button when using the console. (**Terminate** buttons are located on both the session window and main Session Manager console page.) If you only close a browser or command window, the session remains listed as **Active** in the console for 30 days. When you don't explicitly terminate a session, or when a session times out, any processes that were running on the managed node at the time will continue to run.

Topics

- Ending a session (console)
- Ending a session (AWS CLI)

Ending a session (console)

You can use the AWS Systems Manager console to end a session in your account.

To end a session (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. For **Sessions**, choose the option button to the left of the session you want to end.
4. Choose **Terminate**.

Ending a session (AWS CLI)

To end a session using the AWS CLI, run the following command. Replace *session-id* with your own information.

```
aws ssm terminate-session \
    --session-id session-id
```

For more information about the **terminate-session** command, see terminate-session in the AWS Systems Manager section of the AWS CLI Command Reference.

View session history

You can use the AWS Systems Manager console or the AWS Command Line Interface (AWS CLI) to view information about sessions in your account. In the console, you can view session details such as the following:

- The ID of the session
- Which user connected to a managed node through a session
- The ID of the managed node
- When the session began and ended
- The status of the session
- The location specified for storing session logs (if turned on)

Using the AWS CLI, you can view a list of sessions in your account, but not the additional details that are available in the console.

For information about logging session history information, see Enabling and disabling session logging.

Topics

- Viewing session history (console)
- Viewing session history (AWS CLI)

Viewing session history (console)

You can use the AWS Systems Manager console to view details about the sessions in your account.

To view session history (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Session history** tab.

   -or-

   If the Session Manager home page opens first, choose **Configure Preferences** and then choose the **Session history** tab.

Viewing session history (AWS CLI)

To view a list of sessions in your account using the AWS CLI, run the following command.

```
aws ssm describe-sessions \
    --state History
```

> **Note**
>
> This command returns only results for connections to targets initiated using Session Manager. It doesn't list connections made through other means, such as Remote Desktop Protocol (RDP) or the Secure Shell Protocol (SSH).

For information about other options you can use with the **describe-sessions** command, see describe-sessions in the AWS Systems Manager section of the AWS CLI Command Reference.

Logging session activity

In addition to providing information about current and completed sessions in the Systems Manager console, Session Manager provides you with the ability to log session activity in your AWS account using AWS CloudTrail.

CloudTrail captures session API calls through the Systems Manager console, the AWS Command Line Interface (AWS CLI), and the Systems Manager SDK. You can view the information on the CloudTrail console or store it in a specified Amazon Simple Storage Service (Amazon S3) bucket.

One Amazon S3 bucket is used for all CloudTrail logs for your account. For more information, see Logging AWS Systems Manager API calls with AWS CloudTrail.

> **Note**
>
> For recurring, historical, analytical analysis of your log files, consider querying CloudTrail logs using CloudTrail Lake or a table you maintain. For more information, see Querying AWS CloudTrail logs in the *AWS CloudTrail User Guide*.

Monitoring session activity using Amazon EventBridge (console)

With EventBridge, you can set up rules to detect when changes happen to AWS resources. You can create a rule to detect when a user in your organization starts or ends a session, and then, for example, receive a notification through Amazon SNS about the event.

EventBridge support for Session Manager relies on records of API operations that were recorded by CloudTrail. (You can use CloudTrail integration with EventBridge to respond to most AWS Systems Manager events.) Actions that take place within a session, such as an `exit` command, that don't make an API call aren't detected by EventBridge.

The following steps outline how to initiate notifications through Amazon Simple Notification Service (Amazon SNS) when a Session Manager API event occurs, such as **StartSession**.

To monitor session activity using Amazon EventBridge (console)

1. Create an Amazon SNS topic to use for sending notifications when the Session Manager event occurs that you want to track.

   For more information, see Create a Topic in the *Amazon Simple Notification Service Developer Guide*.
2. Create an EventBridge rule to invoke the Amazon SNS target for the type of Session Manager event you want to track.

   For information about how to create the rule, see Creating Amazon EventBridge rules that react to events in the *Amazon EventBridge User Guide*.

   As you follow the steps to create the rule, make the following selections:

   - For **AWS service**, choose **Systems Manager**.

- For **Event type**, choose **AWS API Call through CloudTrail**.
- Choose **Specific operation(s)**, and then enter the Session Manager command or commands (one at a time) you want to receive notifications for. You can choose **StartSession**, **ResumeSession**, and **TerminateSession**. (EventBridge doesn't support `Get*`, `List*`, and `Describe*` commands.)
- For **Select a target**, choose **SNS topic**. For **Topic**, choose the name of the Amazon SNS topic you created in Step 1.

For more information, see the *Amazon EventBridge User Guide* and the *Amazon Simple Notification Service Getting Started Guide*.

Enabling and disabling session logging

Session logging records information about current and completed sessions in the Systems Manager console. You can also log details about commands run during sessions in your AWS account. Session logging enables you to do the following:

- Create and store session logs for archival purposes.
- Generate a report showing details of every connection made to your managed nodes using Session Manager over the past 30 days.
- Generate notifications for session logging in your AWS account, such as Amazon Simple Notification Service (Amazon SNS) notifications.
- Automatically initiate another action on an AWS resource as the result of actions performed during a session, such as running an AWS Lambda function, starting an AWS CodePipeline pipeline, or running an AWS Systems Manager Run Command document.

Important

Note the following requirements and limitations for Session Manager:

- Session Manager logs the commands you enter and their output during a session depending on your session preferences. To prevent sensitive data, such as passwords, from being viewed in your session logs we recommend using the following commands when entering sensitive data during a session.

Linux & macOS

```
stty -echo; read passwd; stty echo;
```

Windows

```
$Passwd = Read-Host -AsSecureString
```

- If you're using Windows Server 2012 or earlier, the data in your logs might not be formatted optimally. We recommend using Windows Server 2012 R2 and later for optimal log formats.
- If you're using Linux or macOS managed nodes, ensure that the screen utility is installed. If it isn't, your log data might be truncated. On Amazon Linux 2, AL2023 and Ubuntu Server, the screen utility is installed by default. To install screen manually, depending on your version of Linux, run either `sudo yum install screen` or `sudo apt-get install screen`.
- Logging isn't available for Session Manager sessions that connect through port forwarding or SSH. This is because SSH encrypts all session data, and Session Manager only serves as a tunnel for SSH connections.

For more information about the permissions required to use Amazon S3 or Amazon CloudWatch Logs for logging session data, see Creating an IAM role with permissions for Session Manager and Amazon S3 and CloudWatch Logs (console).

Refer to the following topics for more information about logging options for Session Manager.

Topics

- Streaming session data using Amazon CloudWatch Logs (console)
- Logging session data using Amazon S3 (console)
- Logging session data using Amazon CloudWatch Logs (console)
- Configuring session logging to disk
- Adjusting how long the Session Manager temporary log file is stored on disk
- Disabling Session Manager logging in CloudWatch Logs and Amazon S3

Streaming session data using Amazon CloudWatch Logs (console)

You can send a continual stream of session data logs to Amazon CloudWatch Logs. Essential details, such as the commands a user has run in a session, the ID of the user who ran the commands, and timestamps for when the session data is streamed to CloudWatch Logs, are included when streaming session data. When streaming session data, the logs are JSON-formatted to help you integrate with your existing logging solutions. Streaming session data isn't supported for interactive commands.

> **Note**
>
> To stream session data from Windows Server managed nodes, you must have PowerShell 5.1 or later installed. By default, Windows Server 2016 and later have the required PowerShell version installed. However, Windows Server 2012 and 2012 R2 don't have the required PowerShell version installed by default. If you haven't already updated PowerShell on your Windows Server 2012 or 2012 R2 managed nodes, you can do so using Run Command. For information about updating PowerShell using Run Command, see Updating PowerShell using Run Command.

> **Important**
>
> If you have the **PowerShell Transcription** policy setting configured on your Windows Server managed nodes, you won't be able to stream session data.

To stream session data using Amazon CloudWatch Logs (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Enable** under **CloudWatch logging**.
5. Choose the **Stream session logs** option.
6. (Recommended) Select the check box next to **Allow only encrypted CloudWatch log groups**. With this option turned on, log data is encrypted using the server-side encryption

key specified for the log group. If you don't want to encrypt the log data that is sent to CloudWatch Logs, clear the check box. You must also clear the check box if encryption isn't allowed on the log group.

7. For **CloudWatch logs**, to specify the existing CloudWatch Logs log group in your AWS account to upload session logs to, select one of the following:

   - Enter the name of a log group in the text box that has already been created in your account to store session log data.
   - **Browse log groups**: Select a log group that has already been created in your account to store session log data.

8. Choose **Save**.

Logging session data using Amazon S3 (console)

You can choose to store session log data in a specified Amazon Simple Storage Service (Amazon S3) bucket for debugging and troubleshooting purposes. The default option is for logs to be sent to an encrypted Amazon S3 bucket. Encryption is performed using the key specified for the bucket, either an AWS KMS key or an Amazon S3 Server-Side Encryption (SSE) key (AES-256).

> ⚠ **Important**
>
> When you use virtual hosted–style buckets with Secure Sockets Layer (SSL), the SSL wildcard certificate only matches buckets that don't contain periods. To work around this, use HTTP or write your own certificate verification logic. We recommend that you don't use periods (".") in bucket names when using virtual hosted–style buckets.

Amazon S3 bucket encryption

In order to send logs to your Amazon S3 bucket with encryption, encryption must be allowed on the bucket. For more information about Amazon S3 bucket encryption, see Amazon S3 Default Encryption for S3 Buckets.

Customer managed key

If you're using a KMS key that you manage yourself to encrypt your bucket, then the IAM instance profile attached to your instances must have explicit permissions to read the key. If you use an AWS

managed key, the instance doesn't require this explicit permission. For more information about providing the instance profile with access to use the key, see Allows Key Users to Use the key in the *AWS Key Management Service Developer Guide*.

Follow these steps to configure Session Manager to store session logs in an Amazon S3 bucket.

> **Note**
>
> You can also use the AWS CLI to specify or change the Amazon S3 bucket that session data is sent to. For information, see Update Session Manager preferences (command line).

To log session data using Amazon S3 (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Enable** under **S3 logging**.
5. (Recommended) Select the check box next to **Allow only encrypted S3 buckets**. With this option turned on, log data is encrypted using the server-side encryption key specified for the bucket. If you don't want to encrypt the log data that is sent to Amazon S3, clear the check box. You must also clear the check box if encryption isn't allowed on the S3 bucket.
6. For **S3 bucket name**, select one of the following:

   > **Note**
   >
   > We recommend that you don't use periods (".") in bucket names when using virtual hosted–style buckets. For more information about Amazon S3 bucket-naming conventions, see Bucket Restrictions and Limitations in the *Amazon Simple Storage Service User Guide*.

   - **Choose a bucket name from the list**: Select an Amazon S3 bucket that has already been created in your account to store session log data.
   - **Enter a bucket name in the text box**: Enter the name of an Amazon S3 bucket that has already been created in your account to store session log data.

7. (Optional) For **S3 key prefix**, enter the name of an existing or new folder to store logs in the selected bucket.
8. Choose **Save**.

For more information about working with Amazon S3 and Amazon S3 buckets, see the *Amazon Simple Storage Service User Guide* and the *Amazon Simple Storage Service User Guide*.

Logging session data using Amazon CloudWatch Logs (console)

With Amazon CloudWatch Logs, you can monitor, store, and access log files from various AWS services. You can send session log data to a CloudWatch Logs log group for debugging and troubleshooting purposes. The default option is for log data to be sent with encryption using your KMS key, but you can send the data to your log group with or without encryption.

Follow these steps to configure AWS Systems Manager Session Manager to send session log data to a CloudWatch Logs log group at the end of your sessions.

> **Note**
>
> You can also use the AWS CLI to specify or change the CloudWatch Logs log group that session data is sent to. For information, see Update Session Manager preferences (command line).

To log session data using Amazon CloudWatch Logs (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Enable** under **CloudWatch logging**.
5. Choose the **Upload session logs** option.
6. (Recommended) Select the check box next to **Allow only encrypted CloudWatch log groups**. With this option turned on, log data is encrypted using the server-side encryption key specified for the log group. If you don't want to encrypt the log data that is sent to CloudWatch Logs, clear the check box. You must also clear the check box if encryption isn't allowed on the log group.

7. For **CloudWatch logs**, to specify the existing CloudWatch Logs log group in your AWS account to upload session logs to, select one of the following:

   - **Choose a log group from the list**: Select a log group that has already been created in your account to store session log data.
   - **Enter a log group name in the text box**: Enter the name of a log group that has already been created in your account to store session log data.

8. Choose **Save**.

For more information about working with CloudWatch Logs, see the *Amazon CloudWatch Logs User Guide*.

Configuring session logging to disk

After you enable Session Manager logging to CloudWatch or Amazon S3, all commands executed during a session (and the resulting output from those commands) are logged to a temporary file on the disk of the target instance. The temporary file is named `ipcTempFile.log`.

The `ipcTempFile.log` is controlled by the `SessionLogsDestination` parameter in the SSM Agent configuration file. This parameter accepts the following values:

- **disk**: If you specify this parameter and session logging to CloudWatch or Amazon S3 are *enabled*, SSM Agent creates the `ipcTempFile.log` temporary log file and logs session commands and output to disk. Session Manager uploads this log to either CloudWatch or S3 during or after the session, depending on the logging configuration. The log is then deleted according to the duration specified for the SSM Agent `SessionLogsRetentionDurationHours` configuration parameter.

  If you specify this parameter and session logging to CloudWatch and Amazon S3 are *disabled*, SSM Agent still logs command history and output in the `ipcTempFile.log` file. The file will be deleted according to the duration specified for the SSM Agent `SessionLogsRetentionDurationHours` configuration parameter.
- **none**: If you specify this parameter and session logging to CloudWatch or Amazon S3 are *enabled*, logging to disk works exactly as it does as if you'd specified the `disk` parameter. SSM Agent requires the temporary file when session logging to CloudWatch or Amazon S3 are enabled.

If you specify this parameter and session logging to CloudWatch or Amazon S3 are *disabled*, SSM Agent doesn't create the `ipcTempFile.log` file.

Use the following procedure to enable or disable creating the `ipcTempFile.log` temporary log file to disk when a session is stared.

To enable or disable creating the Session Manager temporary log file to disk

1. Either install SSM Agent on your instance or upgrade to version 3.2.2086 or higher. For information about how to check the agent version number, see Checking the SSM Agent version number. For information about how to manually install the agent, locate the procedure for your operating system in the following sections:
   - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
   - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
   - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server
2. Connect to your instance and locate the `amazon-ssm-agent.json` file in the following location.
   - **Linux**: /etc/amazon/ssm/
   - **macOS**: /opt/aws/ssm/
   - **Windows Server**: C:\Program Files\Amazon\SSM

   If the file `amazon-ssm-agent.json` doesn't exist, copy the contents of the `amazon-ssm-agent.json.template` to a new file in the same directory. Name the new file `amazon-ssm-agent.json`.
3. Specify either none or `disk` for the `SessionLogsDestination` parameter. Save your changes.
4. Restart SSM Agent.

If you specified `disk` for the `SessionLogsDestination` parameter, you can verify that SSM Agent creates the temporary log file by starting a new session and then locating the `ipcTempFile.log` in the following location:

- **Linux**: /var/lib/amazon/ssm/*target ID*/session/orchestration/*session ID*/Standard_Stream/ipcTempFile.log
- **macOS**: /opt/aws/ssm/data/*target ID*/session/orchestration/*session ID*/Standard_Stream/ipcTempFile.log
- **Windows Server**: C:\ProgramData\Amazon\SSM\InstanceData*target ID*\session\orchestration*session ID*\Standard_Stream\ipcTempFile.log

> **Note**
>
> By default, the temporary log file is saved on the instance for 14 days.

If you want to update the `SessionLogsDestination` parameter across multiple instances, we recommend you create an SSM Document that specifies the new configuration. You can then use Systems Manager Run Command to implement the change on your instances. For more information, see Writing your own AWS Systems Manager documents (blog) and Running commands on managed nodes.

Adjusting how long the Session Manager temporary log file is stored on disk

After you enable Session Manager logging to CloudWatch or Amazon S3, all commands executed during a session (and the resulting output from those commands) are logged to a temporary file on the disk of the target instance. The temporary file is named `ipcTempFile.log`. During a session, or after it is completed, Session Manager uploads this temporary log to either CloudWatch or S3. The temporary log is then deleted according to the duration specified for the SSM Agent `SessionLogsRetentionDurationHours` configuration parameter. By default, the temporary log file is saved on the instance for 14 days in the following location:

- **Linux**: /var/lib/amazon/ssm/*target ID*/session/orchestration/*session ID*/Standard_Stream/ipcTempFile.log
- **macOS**: /opt/aws/ssm/data/*target ID*/session/orchestration/*session ID*/Standard_Stream/ipcTempFile.log
- **Windows Server**: C:\ProgramData\Amazon\SSM\InstanceData*target ID*\session\orchestration*session ID*\Standard_Stream\ipcTempFile.log

Use the following procedure to adjust how long the Session Manager temporary log file is stored on disk.

To adjust how long the `ipcTempFile.log` file is stored on disk

1. Connect to your instance and locate the `amazon-ssm-agent.json` file in the following location.

   - **Linux**: /etc/amazon/ssm/
   - **macOS**: /opt/aws/ssm/
   - **Windows Server**: C:\Program Files\Amazon\SSM

   If the file `amazon-ssm-agent.json` doesn't exist, copy the contents of the `amazon-ssm-agent.json.template` to a new file in the same directory. Name the new file `amazon-ssm-agent.json`.
2. Change the value of `SessionLogsRetentionDurationHours` to the desired number of hours. If `SessionLogsRetentionDurationHours` is set to 0, the temporary log file is created during the session and deleted when the session is completed. This setting should ensure the log file doesn't persist after the session ends.
3. Save your changes.
4. Restart SSM Agent.

Disabling Session Manager logging in CloudWatch Logs and Amazon S3

You can use the Systems Manager console or AWS CLI to disable session logging in your account.

To disable session logging (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. To disable CloudWatch logging, in the **CloudWatch logging** section, clear the **Enable** checkbox.
5. To disable S3 logging, in the **S3 logging** section, clear the **Enable** checkbox.
6. Choose **Save**.

To disable session logging (AWS CLI)

To disable session logging using the AWS CLI, follow the instructions in Update Session Manager preferences (command line).

In your JSON file, ensure that the `s3BucketName` and `cloudWatchLogGroupName` inputs contain no values. For example:

```
"inputs": {
        "s3BucketName": "",
        ...
        "cloudWatchLogGroupName": "",
        ...
    }
```

Alternatively, to disable logging, you can remove all `S3*` and `cloudWatch*` inputs from your JSON file.

> **Note**
>
> Depending on your configuration, after you disable CloudWatch or S3, a temporary log file might still be generated to disk by SSM Agent. For information about how to disable logging to disk, see Configuring session logging to disk.

Session document schema

The following information describes the schema elements of a Session document. AWS Systems Manager Session Manager uses Session documents to determine which type of session to start, such as a standard session, a port forwarding session, or a session to run an interactive command.

schemaVersion

The schema version of the Session document. Session documents only support version 1.0.

Type: String

Required: Yes

description

A description you specify for the Session document. For example, "Document to start port forwarding session with Session Manager".

Type: String

Required: No

sessionType

The type of session the Session document is used to establish.

Type: String

Required: Yes

Valid values: `InteractiveCommands` | `NonInteractiveCommands` | `Port` | `Standard_Stream`

inputs

The session preferences to use for sessions established using this Session document. This element is required for Session documents that are used to create `Standard_Stream` sessions.

Type: StringMap

Required: No

s3BucketName

The Amazon Simple Storage Service (Amazon S3) bucket you want to send session logs to at the end of your sessions.

Type: String

Required: No

s3KeyPrefix

The prefix to use when sending logs to the Amazon S3 bucket you specified in the `s3BucketName` input. For more information about using a shared prefix with objects stored in Amazon S3, see How do I use folders in an S3 bucket? in the *Amazon Simple Storage Service User Guide*.

Type: String

Required: No

s3EncryptionEnabled

If set to `true`, the Amazon S3 bucket you specified in the `s3BucketName` input must be encrypted.

Type: Boolean

Required: Yes

cloudWatchLogGroupName

The name of the Amazon CloudWatch Logs (CloudWatch Logs) group you want to send session logs to at the end of your sessions.

Type: String

Required: No

cloudWatchEncryptionEnabled

If set to `true`, the log group you specified in the `cloudWatchLogGroupName` input must be encrypted.

Type: Boolean

Required: Yes

cloudWatchStreamingEnabled

If set to `true`, a continual stream of session data logs are sent to the log group you specified in the `cloudWatchLogGroupName` input. If set to `false`, session logs are sent to the log group you specified in the `cloudWatchLogGroupName` input at the end of your sessions.

Type: Boolean

Required: Yes

kmsKeyId

The ID of the AWS KMS key you want to use to further encrypt data between your local client machines and the Amazon Elastic Compute Cloud (Amazon EC2) managed nodes you connect to.

Type: String

Required: No

runAsEnabled

If set to `true`, you must specify a user account that exists on the managed nodes you will be connecting to in the `runAsDefaultUser` input. Otherwise, sessions will fail to start. By default, sessions are started using the `ssm-user` account created by the AWS Systems Manager SSM Agent. The Run As feature is only supported for connecting to Linux and macOS managed nodes.

Type: Boolean

Required: Yes

runAsDefaultUser

The name of the user account to start sessions with on Linux and macOS managed nodes when the `runAsEnabled` input is set to `true`. The user account you specify for this input must exist on the managed nodes you will be connecting to; otherwise, sessions will fail to start.

Type: String

Required: No

idleSessionTimeout

The amount of time of inactivity you want to allow before a session ends. This input is measured in minutes.

Type: String

Valid values: 1-60

Required: No

maxSessionDuration

The maximum amount of time you want to allow before a session ends. This input is measured in minutes.

Type: String

Valid values: 1-1440

Required: No

shellProfile

The preferences you specify per operating system to apply within sessions such as shell preferences, environment variables, working directories, and running multiple commands when a session is started.

Type: StringMap

Required: No

windows

The shell preferences, environment variables, working directories, and commands you specify for sessions on Windows Server managed nodes.

Type: String

Required: No

linux

The shell preferences, environment variables, working directories, and commands you specify for sessions on Linux and macOS managed nodes.

Type: String

Required: No

parameters

An object that defines the parameters the document accepts. For more information about defining document parameters, see **parameters** in the Top-level data elements. For parameters that you reference often, we recommend that you store those parameters in Systems Manager Parameter Store and then reference them. You can reference `String` and `StringList` Parameter Store parameters in this section of a document. You can't reference `SecureString` Parameter Store parameters in this section of a document. You can reference a Parameter Store parameter using the following format.

```
{{ssm:parameter-name}}
```

For more information about Parameter Store, see AWS Systems Manager Parameter Store.

Type: StringMap

Required: No

properties

An object whose values you specify that are used in the `StartSession` API operation.

For Session documents that are used for `InteractiveCommands` sessions, the properties object includes the commands to run on the operating systems you specify. You can also determine whether commands are run as `root` using the `runAsElevated` boolean property. For more information, see Restrict access to commands in a session.

For Session documents that are used for `Port` sessions, the properties object contains the port number where traffic should be redirected to. For an example, see the `Port` type Session document example later in this topic.

Type: StringMap

Required: No

`Standard_Stream` type Session document example

YAML

```
---
schemaVersion: '1.0'
description: Document to hold regional settings for Session Manager
sessionType: Standard_Stream
inputs:
  s3BucketName: ''
  s3KeyPrefix: ''
  s3EncryptionEnabled: true
  cloudWatchLogGroupName: ''
  cloudWatchEncryptionEnabled: true
  cloudWatchStreamingEnabled: true
  kmsKeyId: ''
```

```
  runAsEnabled: true
  runAsDefaultUser: ''
  idleSessionTimeout: '20'
  maxSessionDuration: '60'
  shellProfile:
    windows: ''
    linux: ''
```

JSON

```
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": "",
        "s3KeyPrefix": "",
        "s3EncryptionEnabled": true,
        "cloudWatchLogGroupName": "",
        "cloudWatchEncryptionEnabled": true,
        "cloudWatchStreamingEnabled": true,
        "kmsKeyId": "",
        "runAsEnabled": true,
        "runAsDefaultUser": "",
        "idleSessionTimeout": "20",
        "maxSessionDuration": "60",
        "shellProfile": {
            "windows": "date",
            "linux": "pwd;ls"
        }
    }
}
```

`InteractiveCommands` type Session document example

YAML

```
---
schemaVersion: '1.0'
description: Document to view a log file on a Linux instance
sessionType: InteractiveCommands
parameters:
```

```
  logpath:
    type: String
    description: The log file path to read.
    default: "/var/log/amazon/ssm/amazon-ssm-agent.log"
    allowedPattern: "^[a-zA-Z0-9-_/]+(.log)$"
properties:
  linux:
    commands: "tail -f {{ logpath }}"
    runAsElevated: true
```

JSON

```
{
    "schemaVersion": "1.0",
    "description": "Document to view a log file on a Linux instance",
    "sessionType": "InteractiveCommands",
    "parameters": {
        "logpath": {
            "type": "String",
            "description": "The log file path to read.",
            "default": "/var/log/amazon/ssm/amazon-ssm-agent.log",
            "allowedPattern": "^[a-zA-Z0-9-_/]+(.log)$"
        }
    },
    "properties": {
        "linux": {
            "commands": "tail -f {{ logpath }}",
            "runAsElevated": true
        }
    }
}
```

`Port` type Session document example

YAML

```
---
schemaVersion: '1.0'
description: Document to open given port connection over Session Manager
sessionType: Port
parameters:
  paramExample:
```

```
    type: string
    description: document parameter
properties:
  portNumber: anyPortNumber
```

JSON

```
{
    "schemaVersion": "1.0",
    "description": "Document to open given port connection over Session Manager",
    "sessionType": "Port",
    "parameters": {
        "paramExample": {
            "type": "string",
            "description": "document parameter"
        }
    },
    "properties": {
        "portNumber": "anyPortNumber"
    }
}
```

Session document example with special characters

YAML

```
---
schemaVersion: '1.0'
description: Example document with quotation marks
sessionType: InteractiveCommands
parameters:
  Test:
    type: String
    description: Test Input
    maxChars: 32
properties:
  windows:
    commands: |
        $Test = '{{ Test }}'
        $myVariable = \"Computer name is $env:COMPUTERNAME\"
        Write-Host "Test variable: $myVariable`.`nInput parameter: $Test"
    runAsElevated: false
```

JSON

```
{
   "schemaVersion":"1.0",
   "description":"Test document with quotation marks",
   "sessionType":"InteractiveCommands",
   "parameters":{
      "Test":{
         "type":"String",
         "description":"Test Input",
         "maxChars":32
      }
   },
   "properties":{
      "windows":{
         "commands":[
            "$Test = '{{ Test }}'",
            "$myVariable = \\\"Computer name is $env:COMPUTERNAME\\\"",
            "Write-Host \"Test variable: $myVariable`.`nInput parameter: $Test\""
         ],
         "runAsElevated":false
      }
   }
}
```

Troubleshooting Session Manager

Use the following information to help you troubleshoot problems with AWS Systems Manager Session Manager.

Topics

- AccessDeniedException when calling the TerminateSession operation
- Document process failed unexpectedly: document worker timed out
- Session Manager can't connect from the Amazon EC2 console
- No permission to start a session
- SSM Agent not online
- No permission to change session preferences
- Managed node not available or not configured for Session Manager

- Session Manager plugin not found
- Session Manager plugin not automatically added to command line path (Windows)
- Session Manager plugin becomes unresponsive
- TargetNotConnected
- Blank screen displays after starting a session
- Managed node becomes unresponsive during long running sessions
- An error occurred (InvalidDocument) when calling the StartSession operation

AccessDeniedException when calling the TerminateSession operation

Problem: When attempting to terminate a session, Systems Manager returns the following error:

```
An error occurred (AccessDeniedException) when calling the TerminateSession operation:
User: <user_arn> is not authorized to perform: ssm:TerminateSession on resource:
<ssm_session_arn> because no identity-based policy allows the ssm:TerminateSession
 action.
```

Solution A: Confirm that the latest version of the Session Manager plugin is installed on the node

Enter the following command in the terminal and press Enter.

```
session-manager-plugin --version
```

Solution B: Install or reinstall the latest version of the plugin

For more information, see Install the Session Manager plugin for the AWS CLI.

Solution C: Attempt to reestablish a connection to the node

Verify that the node is responding to requests. Try reestablishing the session. Or, if necessary, open the Amazon EC2 console and verify the status of the instance is running.

Document process failed unexpectedly: document worker timed out

Problem: When starting a session to a Linux host, Systems Manager returns the following error:

```
document process failed unexpectedly: document worker timed out,
```

```
check [ssm-document-worker]/[ssm-session-worker] log for crash reason
```

If you configured SSM Agent logging, as described in Viewing SSM Agent logs, you can view more details in the debugging log. For this issue, Session Manager shows the following log entry:

```
failed to create channel: too many open files
```

This error typically indicates that there are too many Session Manager worker processes running and the underlying operating system reached a limit. You have two options for resolving this issue.

Solution A: Increase the operating system file notification limit

You can increase the limit by running the following command from a separate Linux host. This command uses Systems Manager Run Command. The specified value increases `max_user_instances` to 8192. This value is considerably higher than the default value of 128, but it won't strain host resources:

```
aws ssm send-command --document-name AWS-RunShellScript \
--instance-id i-02573cafcfEXAMPLE  --parameters \
"commands=sudo sysctl fs.inotify.max_user_instances=8192"
```

Solution B: Decrease the file notifications used by Session Manager in the target host

Run the following command from a separate Linux host to list sessions running on the target host:

```
aws ssm describe-sessions --state Active --filters key=Target,value=i-02573cafcfEXAMPLE
```

Review the command output to identify sessions that are no longer needed. You can terminate those session by running the following command from a separate Linux host:

```
aws ssm terminate-session –session-id session ID
```

Optionally, once there are no more sessions running on the remote server, you can free additional resources by running the following command from a separate Linux host. This command terminates all Session Manager processes running on the remote host, and consequently all sessions to the remote host. Before you run this command, verify there are no ongoing sessions you would like to keep:

```
aws ssm send-command --document-name AWS-RunShellScript \
            --instance-id i-02573cafcfEXAMPLE --parameters \
'{"commands":["sudo kill $(ps aux | grep ssm-session-worker | grep -v grep | awk
 '"'"'{print $2}'"'"')"]}'
```

Session Manager can't connect from the Amazon EC2 console

Problem: After creating a new instance, the **Connect** button > **Session Manager** tab in the Amazon Elastic Compute Cloud (Amazon EC2) console doesn't give you the option to connect.

Solution A: Create an instance profile: If you haven't already done so (as instructed by the information on the **Session Manager** tab in the EC2 console), create an AWS Identity and Access Management (IAM) instance profile by using Quick Setup. Quick Setup is a tool in AWS Systems Manager.

Session Manager requires an IAM instance profile to connect to your instance. You can create an instance profile and assign it to your instance by creating a host management configuration with Quick Setup. A *host management configuration* creates an instance profile with the required permissions and assigns it to your instance. A host management configuration also enables other Systems Manager tools and creates IAM roles for running those tools. There is no charge to use Quick Setup or the tools enabled by the host management configuration. Open Quick Setup and create a host management configuration.

> **Important**
>
> After you create the host management configuration, Amazon EC2 can take several minutes to register the change and refresh the **Session Manager** tab. If the tab doesn't show you a **Connect** button after two minutes, reboot your instance. After it reboots, if you still don't see the option to connect, open Quick Setup and verify you have only one host management configuration. If there are two, delete the older configuration and wait a few minutes.

If you still can't connect after creating a host management configuration, or if you receive an error, including an error about SSM Agent, see one of the following solutions:

- Solution B: No error, but still can't connect
- Solution C: Error about missing SSM Agent

Solution B: No error, but still can't connect

If you created the host management configuration, waited several minutes before trying to connect, and still can't connect, then you might need to manually apply the host management configuration to your instance. Use the following procedure to update a Quick Setup host management configuration and apply changes to an instance.

To update a host management configuration using Quick Setup

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. In the **Configurations** list, choose the **Host Management** configuration you created.
4. Choose **Actions**, and then choose **Edit configuration**.
5. Near the bottom of the **Targets** section, under **Choose how you want to target instances**, choose **Manual**.
6. In the **Instances** section, choose the instance you created.
7. Choose **Update**.

Wait a few minutes for EC2 to refresh the **Session Manager** tab. If you still can't connect or if you receive an error, review the remaining solutions for this issue.

Solution C: Error about missing SSM Agent

If you weren't able to create a host management configuration by using Quick Setup, or if you received an error about SSM Agent not being installed, you may need to manually install SSM Agent on your instance. SSM Agent is Amazon software that enables Systems Manager to connect to your instance by using Session Manager. SSM Agent is installed by default on most Amazon Machine Images (AMIs). If your instance was created from a non-standard AMI or an older AMI, you might have to manually install the agent. For the procedure to install SSM Agent, see the following topic that corresponds to your instance operating system.

- Windows Server
- macOS
- AlmaLinux
- Amazon Linux 2 and AL2023
- Debian Server

- Oracle Linux
- Red Hat Enterprise Linux
- Rocky Linux
- Ubuntu Server

For issues with SSM Agent, see Troubleshooting SSM Agent.

No permission to start a session

Problem: You try to start a session, but the system tells you that you don't have the necessary permissions.

- **Solution**: A system administrator hasn't granted you AWS Identity and Access Management (IAM) policy permissions for starting Session Manager sessions. For information, see Control user session access to instances.

SSM Agent not online

Problem: You see a message on the Amazon EC2 instance **Session Manager** tab that states: "SSM Agent is not online. The SSM Agent was unable to connect to a Systems Manager endpoint to register itself with the service."

Solution: SSM Agent is Amazon software that runs on Amazon EC2 instances so that Session Manager can connect to them. If you see this error, SSM Agent is unable to establish a connection with the Systems Manager endpoint. Possible sources of the problem could be firewall restrictions, routing problems, or lack of internet connectivity. To resolve this issue, investigate network connectivity problems. For more information, see Troubleshooting SSM Agent and Troubleshooting managed node availability. For information about Systems Manager endpoints, see AWS Systems Manager endpoints and quotas in the AWS General Reference.

No permission to change session preferences

Problem: You try to update global session preferences for your organization, but the system tells you that you don't have the necessary permissions.

- **Solution**: A system administrator hasn't granted you IAM policy permissions for setting Session Manager preferences. For information, see Grant or deny a user permissions to update Session Manager preferences.

Managed node not available or not configured for Session Manager

Problem 1: You want to start a session on the **Start a session** console page, but a managed node isn't in the list.

- **Solution A**: The managed node you want to connect to might not have been configured for AWS Systems Manager. For more information, see Setting up Systems Manager unified console for an organization.

  > **Note**
  >
  > If AWS Systems Manager SSM Agent is already running on a managed node when you attach the IAM instance profile, you might need to restart the agent before the instance is listed on the **Start a session** console page.

- **Solution B**: The proxy configuration you applied to the SSM Agent on your managed node might be incorrect. If the proxy configuration is incorrect, the managed node won't be able to reach the needed service endpoints, or the node might report as a different operating system to Systems Manager. For more information, see Configuring SSM Agent to use a proxy on Linux nodes and Configure SSM Agent to use a proxy for Windows Server instances.

Problem 2: A managed node you want to connect is in the list on the **Start a session** console page, but the page reports that "The instance you selected isn't configured to use Session Manager."

- **Solution A**: The managed node has been configured for use with the Systems Manager service, but the IAM instance profile attached to the node might not include permissions for the Session Manager tool. For information, see Verify or Create an IAM Instance Profile with Session Manager Permissions.
- **Solution B**: The managed node isn't running a version of SSM Agent that supports Session Manager. Update SSM Agent on the node to version 2.3.68.0 or later.

  Update SSM Agent manually on a managed node by following the steps in Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server, Manually installing and uninstalling SSM Agent on EC2 instances for Linux, or Manually installing and uninstalling SSM Agent on EC2 instances for macOS, depending on the operating system.

Alternatively, use the Run Command document `AWS-UpdateSSMAgent` to update the agent version on one or more managed nodes at a time. For information, see Updating the SSM Agent using Run Command.

> **Tip**
>
> To always keep your agent up to date, we recommend updating SSM Agent to the latest version on an automated schedule that you define using either of the following methods:
>
> - Run `AWS-UpdateSSMAgent` as part of a State Manager association. For information, see Walkthrough: Automatically update SSM Agent with the AWS CLI.
> - Run `AWS-UpdateSSMAgent` as part of a maintenance window. For information about working with maintenance windows, see Create and manage maintenance windows using the console and Tutorial: Create and configure a maintenance window using the AWS CLI.

- **Solution C**: The managed node can't reach the requisite service endpoints. You can improve the security posture of your managed nodes by using interface endpoints powered by AWS PrivateLink to connect to Systems Manager endpoints. The alternative to using interface endpoints is to allow outbound internet access on your managed nodes. For more information, see Use PrivateLink to set up a VPC endpoint for Session Manager.
- **Solution D**: The managed node has limited available CPU or memory resources. Although your managed node might otherwise be functional, if the node doesn't have enough available resources, you can't establish a session. For more information, see Troubleshooting an Unreachable Instance.

Session Manager plugin not found

To use the AWS CLI to run session commands, the Session Manager plugin must also be installed on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.

Session Manager plugin not automatically added to command line path (Windows)

When you install the Session Manager plugin on Windows, the `session-manager-plugin` executable should be automatically added to your operating system's PATH environment variable. If the command failed after you ran it to check whether the Session Manager plugin installed correctly (`aws ssm start-session --target` *`instance-id`*), you might need to set it manually using the following procedure.

To modify your PATH variable (Windows)

1. Press the Windows key and enter **`environment variables`**.
2. Choose **Edit environment variables for your account**.
3. Choose **PATH** and then choose **Edit**.
4. Add paths to the **Variable value** field, separated by semicolons, as shown in this example: *`C:\existing\path`*;***`C:\new\path`***

   `C:\existing\path` represents the value already in the field. ***`C:\new\path`*** represents the path you want to add, as shown in the following example.

   - **64-bit machines**: `C:\Program Files\Amazon\SessionManagerPlugin\bin\`
5. Choose **OK** twice to apply the new settings.
6. Close any running command prompts and re-open.

Session Manager plugin becomes unresponsive

During a port forwarding session, traffic might stop forwarding if you have antivirus software installed on your local machine. In some cases, antivirus software interferes with the Session Manager plugin causing process deadlocks. To resolve this issue, allow or exclude the Session Manager plugin from the antivirus software. For information about the default installation path for the Session Manager plugin, see Install the Session Manager plugin for the AWS CLI.

TargetNotConnected

Problem: You try to start a session, but the system returns the error message, "An error occurred (TargetNotConnected) when calling the StartSession operation: *`InstanceID`* isn't connected."

- **Solution A**: This error is returned when the specified target managed node for the session isn't fully configured for use with Session Manager. For information, see Setting up Session Manager.
- **Solution B**: This error is also returned if you attempt to start a session on a managed node that is located in a different AWS account or AWS Region.

Blank screen displays after starting a session

Problem: You start a session and Session Manager displays a blank screen.

- **Solution A**: This issue can occur when the root volume on the managed node is full. Due to lack of disk space, SSM Agent on the node stops working. To resolve this issue, use Amazon CloudWatch to collect metrics and logs from the operating systems. For information, see Collect metrics, logs, and traces with the CloudWatch agent in the *Amazon CloudWatch User Guide*.
- **Solution B**: A blank screen might display if you accessed the console using a link that includes a mismatched endpoint and Region pair. For example, in the following console URL, `us-west-2` is the specified endpoint, but `us-west-1` is the specified AWS Region.

```
https://us-west-2.console.aws.amazon.com/systems-manager/session-manager/sessions?
region=us-west-1
```

- **Solution C**: The managed node is connecting to Systems Manager using VPC endpoints, and your Session Manager preferences write session output to an Amazon S3 bucket or Amazon CloudWatch Logs log group, but an `s3` gateway endpoint or `logs` interface endpoint doesn't exist in the VPC. An `s3` endpoint in the format **`com.amazonaws.`*`region`*`.s3`** is required if your managed nodes are connecting to Systems Manager using VPC endpoints, and your Session Manager preferences write session output to an Amazon S3 bucket. Alternatively, a `logs` endpoint in the format **`com.amazonaws.`*`region`*`.logs`** is required if your managed nodes are connecting to Systems Manager using VPC endpoints, and your Session Manager preferences write session output to a CloudWatch Logs log group. For more information, see Creating VPC endpoints for Systems Manager.
- **Solution D**: The log group or Amazon S3 bucket you specified in your session preferences has been deleted. To resolve this issue, update your session preferences with a valid log group or S3 bucket.
- **Solution E**: The log group or Amazon S3 bucket you specified in your session preferences isn't encrypted, but you have set the `cloudWatchEncryptionEnabled` or `s3EncryptionEnabled` input to `true`. To resolve this issue, update your session preferences with a log group or Amazon S3 bucket that is encrypted, or set the `cloudWatchEncryptionEnabled` or `s3EncryptionEnabled` input to `false`. This scenario is only applicable to customers who create session preferences using command line tools.

Managed node becomes unresponsive during long running sessions

Problem: Your managed node becomes unresponsive or crashes during a long running session.

Solution: Decrease the SSM Agent log retention duration for Session Manager.

To decrease the SSM Agent log retention duration for sessions

1. Locate the `amazon-ssm-agent.json.template` in the `/etc/amazon/ssm/` directory for Linux, or `C:\Program Files\Amazon\SSM` for Windows.
2. Copy the contents of the `amazon-ssm-agent.json.template` to a new file in the same directory named `amazon-ssm-agent.json`.
3. Decrease the default value of the `SessionLogsRetentionDurationHours` value in the `SSM` property, and save the file.
4. Restart the SSM Agent.

An error occurred (InvalidDocument) when calling the StartSession operation

Problem: You receive the following error when starting a session by using the AWS CLI.

```
An error occurred (InvalidDocument) when calling the StartSession operation: Document
 type: 'Command' is not supported. Only type: 'Session' is supported for Session
 Manager.
```

Solution: The SSM document you specified for the `--document-name` parameter isn't a *Session* document. Use the following procedure to view a list of Session documents in the AWS Management Console.

To view a list of Session documents

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the **Categories** list, choose **Session documents**.

AWS Systems Manager State Manager

State Manager, a tool in AWS Systems Manager, is a secure and scalable configuration management service that automates the process of keeping your managed nodes and other AWS resources in a state that you define. To get started with State Manager, open the Systems Manager console. In the navigation pane, choose **State Manager**.

> **Note**
>
> State Manager and Maintenance Windows can perform some similar types of updates on your managed nodes. Which one you choose depends on whether you need to automate system compliance or perform high-priority, time-sensitive tasks during periods you specify.
> For more information, see Choosing between State Manager and Maintenance Windows.

How can State Manager benefit my organization?

By using pre-configured Systems Manager documents (SSM documents), State Manager offers the following benefits for managing your nodes:

- Bootstrap nodes with specific software at start-up.
- Download and update agents on a defined schedule, including the SSM Agent.
- Configure network settings.
- Join nodes to a Microsoft Active Directory domain.
- Run scripts on Linux, macOS, and Windows Server managed nodes throughout their lifecycle.

To manage configuration drift across other AWS resources, you can use Automation, a tool in Systems Manager, with State Manager to perform the following types of tasks:

- Attach a Systems Manager role to Amazon Elastic Compute Cloud (Amazon EC2) instances to make them *managed nodes*.
- Enforce desired ingress and egress rules for a security group.
- Create or delete Amazon DynamoDB backups.
- Create or delete Amazon Elastic Block Store (Amazon EBS) snapshots.
- Turn off read and write permissions on Amazon Simple Storage Service (Amazon S3) buckets.
- Start, restart, or stop managed nodes and Amazon Relational Database Service (Amazon RDS) instances.
- Apply patches to Linux, macOS, and Window AMIs.

For information about using State Manager with Automation runbooks, see Scheduling automations with State Manager associations.

Who should use State Manager?

State Manager is appropriate for any AWS customer that wants to improve the management and governance of their AWS resources and reduce configuration drift.

What are the features of State Manager?

Key features of State Manager include the following:

- **State Manager associations**

  A State Manager *association* is a configuration that you assign to your AWS resources. The configuration defines the state that you want to maintain on your resources. For example, an association can specify that antivirus software must be installed and running on a managed node, or that certain ports must be closed.

  An association specifies a schedule for when to apply the configuration and the targets for the association. For example, an association for antivirus software might run once a day on all managed nodes in an AWS account. If the software isn't installed on a node, then the association could instruct State Manager to install it. If the software is installed, but the service isn't running, then the association could instruct State Manager to start the service.
- **Flexible scheduling options**

  State Manager offers the following options for scheduling when an association runs:

  - **Immediate or delayed processing**

    When you create an association, by default, the system immediately runs it on the specified resources. After the initial run, the association runs in intervals according to the schedule that you defined.

    You can instruct State Manager not to run an association immediately by using the **Apply association only at the next specified Cron interval** option in the console or the `ApplyOnlyAtCronInterval` parameter from the command line.
  - **Cron and rate expressions**

    When you create an association, you specify a schedule for when State Manager applies the configuration. State Manager supports most standard cron and rate expressions for scheduling when an association runs. State Manager also supports cron expressions that include a day of

the week and the number sign (#) to designate the *n*th day of a month to run an association and the (L) sign to indicate the last *X* day of the month.

> **Note**
>
> State Manager doesn't currently support specifying months in cron expressions for associations.

To further control when an association runs, for example if you want to run an association two days after patch Tuesday, you can specify an offset. An *offset* defines how many days to wait after the scheduled day to run an association.

For information about building cron and rate expressions, see Reference: Cron and rate expressions for Systems Manager.

- **Multiple targeting options**

  An association also specifies the targets for the association. State Manager supports targeting AWS resources by using tags, AWS Resource Groups, individual node IDs, or all managed nodes in the current AWS Region and AWS account.

- **Amazon S3 support**

  Store the command output from association runs in an Amazon S3 bucket of your choice. For more information, see Working with associations in Systems Manager.

- **EventBridge support**

  This Systems Manager tool is supported as both an *event* type and a *target* type in Amazon EventBridge rules. For information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

Is there a charge to use State Manager?

State Manager is available at no additional charge.

Understanding how State Manager works

State Manager, a tool in AWS Systems Manager, is a secure and scalable service that automates the process of keeping managed nodes in a hybrid and multicloud infrastructure in a state that you define.

Here's how State Manager works:

1. Determine the state you want to apply to your AWS resources.

Do you want to guarantee that your managed nodes are configured with specific applications, such as antivirus or malware applications? Do you want to automate the process of updating the SSM Agent or other AWS packages such as `AWSPVDriver`? Do you need to guarantee that specific ports are closed or open? To get started with State Manager, determine the state that you want to apply to your AWS resources. The state that you want to apply determines which SSM document you use to create a State Manager association.

A State Manager *association* is a configuration that you assign to your AWS resources. The configuration defines the state that you want to maintain on your resources. For example, an association can specify that antivirus software must be installed and running on a managed node, or that certain ports must be closed.

An association specifies a schedule for when to apply the configuration and the targets for the association. For example, an association for antivirus software might run once a day on all managed nodes in an AWS account. If the software isn't installed on a node, then the

association could instruct State Manager to install it. If the software is installed, but the service isn't running, then the association could instruct State Manager to start the service.

2. Determine if a preconfigured SSM document can help you create the desired state on your AWS resources.

Systems Manager includes dozens of preconfigured SSM documents that you can use to create an association. Preconfigured documents are ready to perform common tasks like installing applications, configuring Amazon CloudWatch, running AWS Systems Manager automations, running PowerShell and Shell scripts, and joining managed nodes to a directory service domain for Active Directory.

You can view all SSM documents in the Systems Manager console. Choose the name of a document to learn more about each one. Here are two examples: `AWS-ConfigureAWSPackage` and `AWS-InstallApplication`.

3. Create an association.

You can create an association by using the Systems Manager console, the AWS Command Line Interface (AWS CLI), AWS Tools for Windows PowerShell (Tools for Windows PowerShell), or the Systems Manager API. When you create an association, you specify the following information:

- A name for the association.
- The parameters for the SSM document (for example, the path to the application to install or the script to run on the nodes).
- Targets for the association. You can target managed nodes by specifying tags, by choosing individual node IDs, or by choosing a group in AWS Resource Groups. You can also target *all* managed nodes in the current AWS Region and AWS account. If your targets include more than 1,000 nodes, the system uses an hourly throttling mechanism. This means you might see inaccuracies in your status aggregation count since the aggregation process runs hourly and only when the execution status for a node changes.
- A schedule for when or how often to apply the state. You can specify a cron or rate expression. For more information about creating schedules by using cron and rate expressions, see Cron and rate expressions for associations.

> **Note**
>
> State Manager doesn't currently support specifying months in cron expressions for associations.

When you run the command to create the association, Systems Manager binds the information you specified (schedule, targets, SSM document, and parameters) to the targeted resources. The status of the association initially shows "Pending" as the system attempts to reach all targets and *immediately* apply the state specified in the association.

> **Note**
>
> If you create a new association that is scheduled to run while an earlier association is still running, the earlier association times out and the new association runs.

Systems Manager reports the status of the request to create associations on the resources. You can view status details in the console or (for managed nodes) by using the DescribeInstanceAssociationsStatus API operation. If you choose to write the output of the command to Amazon Simple Storage Service (Amazon S3) when you create an association, you can also view the output in the Amazon S3 bucket you specified.

For more information, see Working with associations in Systems Manager.

> **Note**
>
> API operations that are initiated by the SSM document during an association run are not logged in AWS CloudTrail.

4. Monitor and update.

After you create the association, State Manager reapplies the configuration according to the schedule that you defined in the association. You can view the status of your associations on the State Manager page in the console or by directly calling the association ID generated by Systems Manager when you created the association. For more information, see Viewing association histories. You can update your association documents and reapply them as necessary. You can also create multiple versions of an association. For more information, see Editing and creating a new version of an association.

Understanding when associations are applied to resources

When you create an association, you specify an SSM document that defines the configuration, a list of target resources, and a schedule for applying the configuration. By default, State Manager

runs the association when you create it and then according to your schedule. State Manager also attempts to run the association in the following situations:

- **Association edit** – State Manager runs the association after a user edits and saves their changes to any of the following association fields: `DOCUMENT_VERSION`, `PARAMETERS`, `SCHEDULE_EXPRESSION`, `OUTPUT_S3_LOCATION`.
- **Document edit** – State Manager runs the association after a user edits and saves changes to the SSM document that defines the association's configuration state. Specifically, the association runs after the following edits to the document:
  - A user specifies a new `$DEFAULT` document version and the association was created using the `$DEFAULT` version.
  - A user updates a document and the association was created using the `$LATEST` version.
  - A user deletes the document that was specified when the association was created.
- **Manual start** – State Manager runs the association when initiated by the user from either the Systems Manager console or programmatically.
- **Target changes** – State Manager runs the association after any of the following activity occurs on a target node:
  - A managed node comes online for the first time.
  - A managed node comes online after missing a scheduled association run.
  - A managed node comes online after being stopped for more than 30 days.

> **Note**
>
> State Manager doesn't monitor documents or packages used in associations across AWS accounts. If you update a document or package in one account, the update won't cause the association to run in the second account. You must manually run the association in the second account.

Preventing associations from running when a target changes

In some cases, you might not want an association to run when a target that consists of managed nodes changes, but only according to its specified schedule.

> **Note**
>
> Running an Automation runbook incurs a cost. If an association with an Automation runbook targets all instances in your account and you regularly launch a large number of instances, the runbook is run on each of the instances when it launches. This can lead to elevated automation charges.

To prevent an association from running when the targets for that association change, select the **Apply association only at the next specified cron interval check box**. This check box is located in the **Specify schedule** area of the **Create association** and **Edit association** pages.

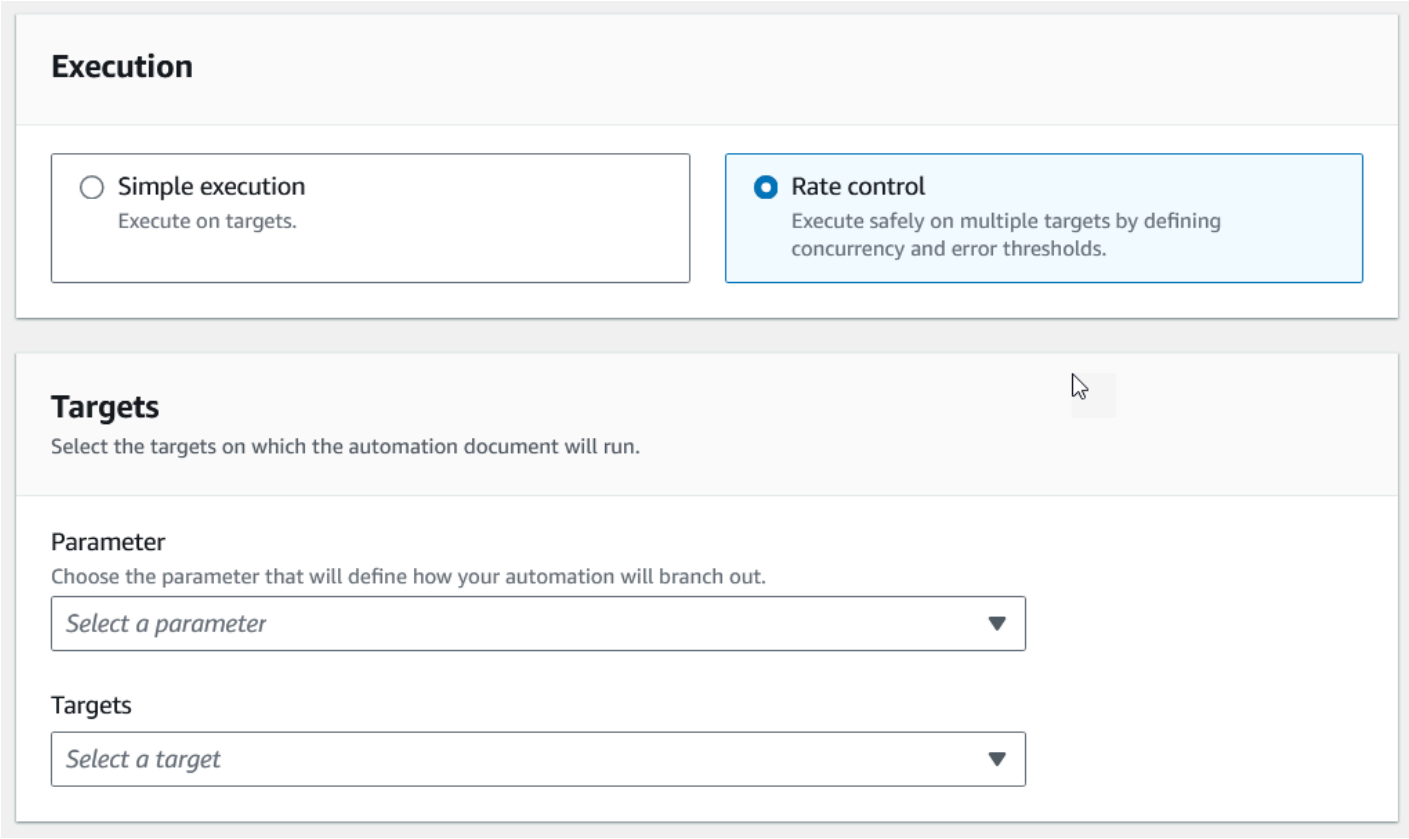
This option applies to associations that incorporate either an Automation runbook or an SSM document.

About target updates with Automation runbooks

In order for associations that are created with Automation runbooks to be applied when new target nodes are detected, the following conditions must be true:

- The association must have been created by a Quick Setup configuration. Quick Setup is a tool in AWS Systems Manager. Associations created by other processes are not currently supported.
- The Automation runbook must explicitly target the resource type `AWS::EC2::Instance` or `AWS::SSM::ManagedInstance`.
- The association must specify both parameters and targets.

  In the console, the **Parameter** and **Targets** fields are displayed when you choose a rate control execution.



When you use the CreateAssociation, CreateAssociationBatch, or UpdateAssociation API actions, you can specify these values using the `AutomationTargetParameterName` and `Targets` inputs. In each of these API actions, you can also prevent the association from running each time a target changes by setting the `ApplyOnlyAtCronInterval` parameter to `true`.

For information about using the console to control when associations run, including details for avoiding unexpectedly high costs for Automation executions, see Understanding when associations are applied to resources.

Working with associations in Systems Manager

This section describes how to create and manage State Manager associations by using the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), and AWS Tools for PowerShell.

Topics

- Understanding targets and rate controls in State Manager associations
- Creating associations

- Editing and creating a new version of an association

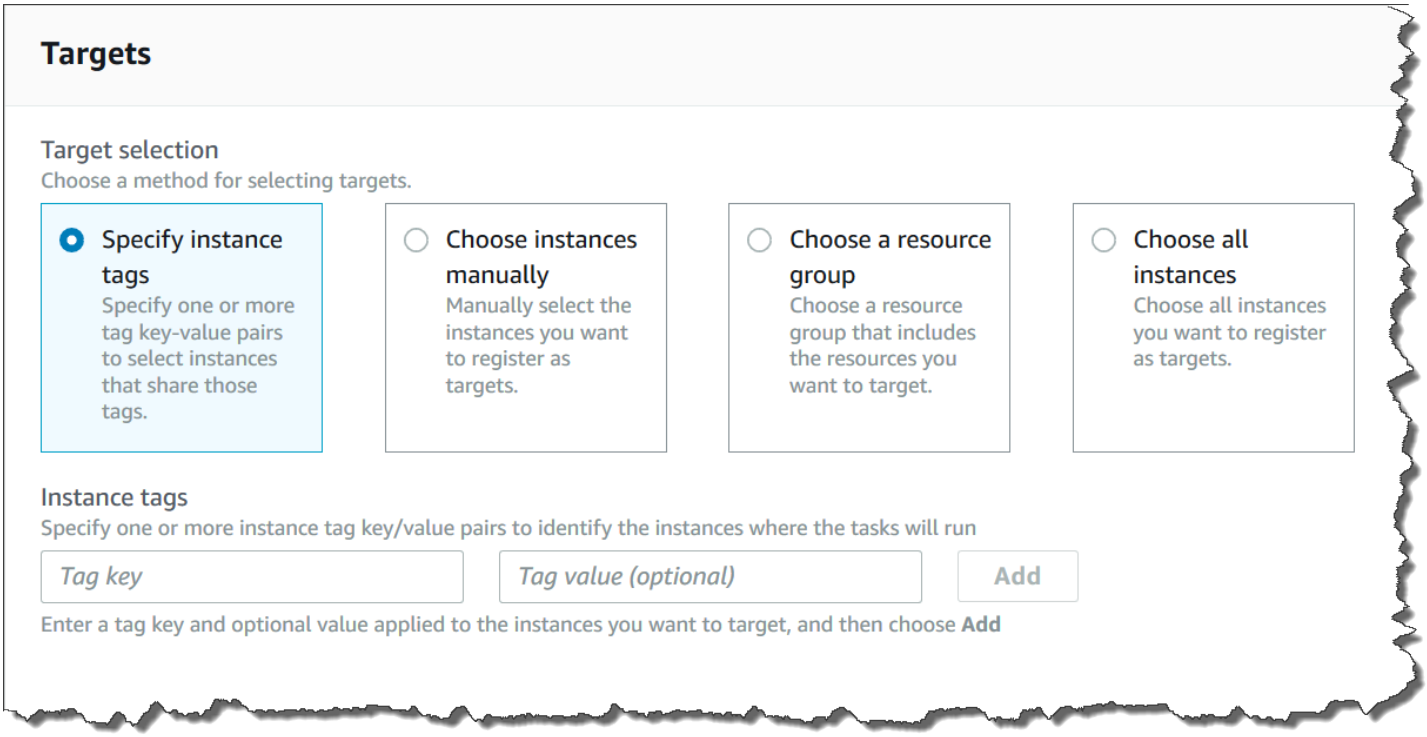
- Working with associations using IAM

Understanding targets and rate controls in State Manager associations

This topic describes State Manager features that help you deploy an association to dozens or hundreds of nodes while controlling the number of nodes that run the association at the scheduled time. State Manager is a tool in AWS Systems Manager.

Using targets

When you create a State Manager association, you choose which nodes to configure with the association in the **Targets** section of the Systems Manager console, as shown here.



If you create an association by using a command line tool such as the AWS Command Line Interface (AWS CLI), then you specify the `targets` parameter. Targeting nodes allows you to configure tens, hundreds, or thousands of nodes with an association without having to specify or choose individual node IDs.

Each managed node can be targeted by a maximum of 20 associations.

State Manager includes the following target options when creating an association.

Specify tags

Use this option to specify a tag key and (optionally) a tag value assigned to your nodes. When you run the request, the system locates and attempts to create the association on all nodes that match the specified tag key and value. If you specified multiple tag values, the association targets any node with at least one of those tag values. When the system initially creates the association, it runs the association. After this initial run, the system runs the association according to the schedule you specified.

If you create new nodes and assign the specified tag key and value to those nodes, the system automatically applies the association, runs it immediately, and then runs it according to the schedule. This applies when the association uses a Command or Policy document and doesn't apply if the association uses an Automation runbook. If you delete the specified tags from a node, the system no longer runs the association on those nodes.

> **Note**
>
> If you use Automation runbooks with State Manager and the tagging limitation prevents you from achieving a specific goal, consider using Automation runbooks with Amazon EventBridge. For more information, see Run automations based on EventBridge events. For more information about using runbooks with State Manager, see Scheduling automations with State Manager associations.

As a best practice, we recommend using tags when creating associations that use a Command or Policy document. We also recommend using tags when creating associations to run Auto Scaling groups. For more information, see Running Auto Scaling groups with associations.

> **Note**
>
> Note the following information.
>
> - When creating an association in the AWS Management Console that targets nodes by using tags, you can specify only one tag key for an automation association and five tag keys for a command association. *All* tag keys specified in the association must be

currently assigned to the node. If they aren't, State Manager fails to target the node for an association.

- If you want to use the console *and* you want to target your nodes by using more than one tag key for an automation association and five tag keys for a command association, assign the tag keys to an AWS Resource Groups group and add the nodes to it. You can then choose the **Resource Group** option in the **Targets** list when you create the State Manager association.
- You can specify a maximum of five tag keys by using the AWS CLI. If you use the AWS CLI, *all* tag keys specified in the `create-association` command must be currently assigned to the node. If they aren't, State Manager fails to target the node for an association.

Choose nodes manually

Use this option to manually select the nodes where you want to create the association. The **Instances** pane displays all Systems Manager managed nodes in the current AWS account and AWS Region. You can manually select as many nodes as you want. When the system initially creates the association, it runs the association. After this initial run, the system runs the association according to the schedule you specified.

> **Note**
>
> If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

Choose a resource group

Use this option to create an association on all nodes returned by an AWS Resource Groups tag-based or AWS CloudFormation stack-based query.

Below are details about targeting resource groups for an association.

- If you add new nodes to a group, the system automatically maps the nodes to the association that targets the resource group. The system applies the association to the nodes when it discovers the change. After this initial run, the system runs the association according to the schedule you specified.

- If you create an association that targets a resource group and the `AWS::SSM::ManagedInstance` resource type was specified for that group, then by design, the association runs on both Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 nodes in a hybrid and multicloud environment.

  The converse is also true. If you create an association that targets a resource group and the `AWS::EC2::Instance` resource type was specified for that group, then by design, the association runs on both non-EC2 nodes in a hybrid and multicloud environment and (Amazon EC2) instances.
- If you create an association that targets a resource group, the resource group must not have more than five tag keys assigned to it or more than five values specified for any one tag key. If either of these conditions applies to the tags and keys assigned to your resource group, the association fails to run and returns an `InvalidTarget` error.
- If you create an association that targets a resource group using tags, you can't choose the **(empty value)** option for the tag value.
- If you delete a resource group, all instances in that group no longer run the association. As a best practice, delete associations targeting the group.
- At most you can target a single resource group for an association. Multiple or nested groups aren't supported.
- After you create an association, State Manager periodically updates the association with information about resources in the Resource Group. If you add new resources to a Resource Group, the schedule for when the system applies the association to the new resources depends on several factors. You can determine the status of the association in the State Manager page of the Systems Manager console.

> **Warning**
>
> An AWS Identity and Access Management (IAM) user, group, or role with permission to create an association that targets a resource group of Amazon EC2 instances automatically has root-level control of all instances in the group. Only trusted administrators should be permitted to create associations.

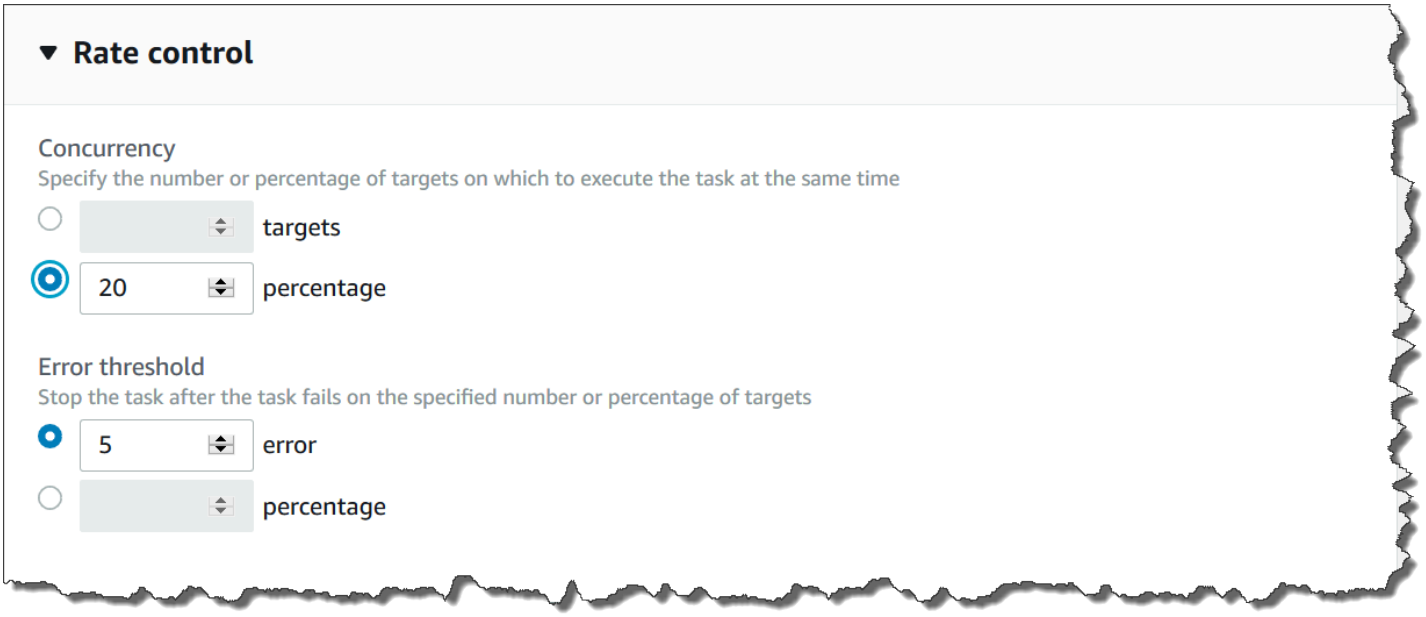
For more information about Resource Groups, see What Is AWS Resource Groups? in the *AWS Resource Groups User Guide*.

Choose all nodes

Use this option to target all nodes in the current AWS account and AWS Region. When you run the request, the system locates and attempts to create the association on all nodes in the current AWS account and AWS Region. When the system initially creates the association, it runs the association. After this initial run, the system runs the association according to the schedule you specified. If you create new nodes, the system automatically applies the association, runs it immediately, and then runs it according to the schedule.

Using rate controls

You can control the execution of an association on your nodes by specifying a concurrency value and an error threshold. The concurrency value specifies how many nodes can run the association simultaneously. An error threshold specifies how many association executions can fail before Systems Manager sends a command to each node configured with that association to stop running the association. The command stops the association from running until the next scheduled execution. The concurrency and error threshold features are collectively called *rate controls*.



Concurrency

Concurrency helps to limit the impact on your nodes by allowing you to specify that only a certain number of nodes can process an association at one time. You can specify either an absolute number of nodes, for example 20, or a percentage of the target set of nodes, for example 10%.

State Manager concurrency has the following restrictions and limitations:

- If you choose to create an association by using targets, but you don't specify a concurrency value, then State Manager automatically enforces a maximum concurrency of 50 nodes.
- If new nodes that match the target criteria come online while an association that uses concurrency is running, then the new nodes run the association if the concurrency value isn't exceeded. If the concurrency value is exceeded, then the nodes are ignored during the current association execution interval. The nodes run the association during the next scheduled interval while conforming to the concurrency requirements.
- If you update an association that uses concurrency, and one or more nodes are processing that association when it's updated, then any node that is running the association is allowed to complete. Those associations that haven't started are stopped. After running associations complete, all target nodes immediately run the association again because it was updated. When the association runs again, the concurrency value is enforced.

Error thresholds

An error threshold specifies how many association executions are allowed to fail before Systems Manager sends a command to each node configured with that association. The command stops the association from running until the next scheduled execution. You can specify either an absolute number of errors, for example 10, or a percentage of the target set, for example 10%.

If you specify an absolute number of three errors, for example, State Manager sends the stop command when the fourth error is returned. If you specify 0, then State Manager sends the stop command after the first error result is returned.

If you specify an error threshold of 10% for 50 associations, then State Manager sends the stop command when the sixth error is returned. Associations that are already running when an error threshold is reached are allowed to complete, but some of these associations might fail. To ensure that there aren't more errors than the number specified for the error threshold, set the **Concurrency** value to 1 so that associations proceed one at a time.

State Manager error thresholds have the following restrictions and limitations:

- Error thresholds are enforced for the current interval.
- Information about each error, including step-level details, is recorded in the association history.
- If you choose to create an association by using targets, but you don't specify an error threshold, then State Manager automatically enforces a threshold of 100% failures.

Creating associations

State Manager, a tool in AWS Systems Manager, helps you keep your AWS resources in a state that you define and reduce configuration drift. To do this, State Manager uses associations. An *association* is a configuration that you assign to your AWS resources. The configuration defines the state that you want to maintain on your resources. For example, an association can specify that antivirus software must be installed and running on a managed node, or that certain ports must be closed.

An association specifies a schedule for when to apply the configuration and the targets for the association. For example, an association for antivirus software might run once a day on all managed nodes in an AWS account. If the software isn't installed on a node, then the association could instruct State Manager to install it. If the software is installed, but the service isn't running, then the association could instruct State Manager to start the service.

> **Warning**
>
> When you create an association, you can choose an AWS resource group of managed nodes as the target for the association. If an AWS Identity and Access Management (IAM) user, group, or role has permission to create an association that targets a resource group of managed nodes, then that user, group, or role automatically has root-level control of all nodes in the group. Permit only trusted administrators to create associations.

Association targets and rate controls

An association specifies which managed nodes, or targets, should receive the association. State Manager includes several features to help you target your managed nodes and control how the association is deployed to those targets. For more information about targets and rate controls, see Understanding targets and rate controls in State Manager associations.

Tagging associations

You can assign tags to an association when you create it by using a command line tool such as the AWS CLI or AWS Tools for PowerShell. Adding tags to an association by using the Systems Manager console isn't supported.

Running associations

By default, State Manager runs an association immediately after you create it, and then according to the schedule that you've defined.

The system also runs associations according to the following rules:

- State Manager attempts to run the association on all specified or targeted nodes during an interval.
- If an association doesn't run during an interval (because, for example, a concurrency value limited the number of nodes that could process the association at one time), then State Manager attempts to run the association during the next interval.
- State Manager runs the association after changes to the association's configuration, target nodes, documents, or parameters. For more information, see Understanding when associations are applied to resources
- State Manager records history for all skipped intervals. You can view the history on the **Execution History** tab.

Scheduling associations

You can schedule associations to run at basic intervals such as *every 10 hours*, or you can create more advanced schedules using custom cron and rate expressions. You can also prevent associations from running when you first create them.

Using cron and rate expressions to schedule association runs

In addition to standard cron and rate expressions, State Manager also supports cron expressions that include a day of the week and the number sign (#) to designate the *n*th day of a month to run an association. Here is an example that runs a cron schedule on the third Tuesday of every month at 23:30 UTC:

```
cron(30 23 ? * TUE#3 *)
```

Here is an example that runs on the second Thursday of every month at midnight UTC:

```
cron(0 0 ? * THU#2 *)
```

State Manager also supports the (L) sign to indicate the last *X* day of the month. Here is an example that runs a cron schedule on the last Tuesday of every month at midnight UTC:

```
cron(0 0 ? * 3L *)
```

To further control when an association runs, for example if you want to run an association two days after patch Tuesday, you can specify an offset. An *offset* defines how many days to wait after the scheduled day to run an association. For example, if you specified a cron schedule of `cron(0 0 ? * THU#2 *)`, you could specify the number `3` in the **Schedule offset** field to run the association each Sunday after the second Thursday of the month.

> **Note**
>
> To use offsets, you must either select **Apply association only at the next specified Cron interval** in the console or specify the `ApplyOnlyAtCronInterval` parameter from the command line. When either of these options are activated, State Manager doesn't run the association immediately after you create it.

For more information about cron and rate expressions, see Reference: Cron and rate expressions for Systems Manager.

Create an association (console)

The following procedure describes how to use the Systems Manager console to create a State Manager association.

> **Note**
>
> Note the following information.
>
> - This procedure describes how to create an association that uses either a `Command` or a `Policy` document to target managed nodes. For information about creating an association that uses an Automation runbook to target nodes or other types of AWS resources, see Scheduling automations with State Manager associations.
> - When creating an association, you can specify a maximum of five tag keys by using the AWS Management Console. *All* tag keys specified for the association must be currently assigned to the node. If they aren't, State Manager fails to target the node for the association.

To create a State Manager association

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Choose **Create association**.
4. In the **Name** field, specify a name.
5. In the **Document** list, choose the option next to a document name. Note the document type. This procedure applies to `Command` and `Policy` documents. For information about creating an association that uses an Automation runbook, see Scheduling automations with State Manager associations.

   > **Important**
   >
   > State Manager doesn't support running associations that use a new version of a document if that document is shared from another account. State Manager always runs the `default` version of a document if shared from another account, even though the Systems Manager console shows that a new version was processed. If you want to run an association using a new version of a document shared from another account, you must set the document version to `default`.

6. For **Parameters**, specify the required input parameters.
7. (Optional) Choose a CloudWatch alarm to apply to your association for monitoring.

   > **Note**
   >
   > Note the following information about this step.
   >
   > - The alarms list displays a maximum of 100 alarms. If you don't see your alarm in the list, use the AWS Command Line Interface to create the association. For more information, see Create an association (command line).
   > - To attach a CloudWatch alarm to your command, the IAM principal that creates the association must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms.

- If your alarm activates, any pending command invocations or automations do not run.

8. For **Targets**, choose an option. For information about using targets, see Understanding targets and rate controls in State Manager associations.

> **Note**
>
> In order for associations that are created with Automation runbooks to be applied when new target nodes are detected, certain conditions must be met. For information, see About target updates with Automation runbooks.

9. In the **Specify schedule** section, choose either **On Schedule** or **No schedule**. If you choose **On Schedule**, use the buttons provided to create a cron or rate schedule for the association.

   If you don't want the association to run immediately after you create it, choose **Apply association only at the next specified Cron interval**.

10. (Optional) In the **Schedule offset** field, specify a number between 1 and 6.
11. In the **Advanced options** section use **Compliance severity** to choose a severity level for the association and use **Change Calendars** to choose a change calendar for the association.

    Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you indicate here. For more information, see About State Manager association compliance.

    The change calendar determines when the association runs. If the calendar is closed, the association isn't applied. If the calendar is open, the association runs accordingly. For more information, see AWS Systems Manager Change Calendar.

12. In the **Rate control** section, choose options to control how the association runs on multiple nodes. For more information about using rate controls, see Understanding targets and rate controls in State Manager associations.

    In the **Concurrency** section, choose an option:

    - Choose **targets** to enter an absolute number of targets that can run the association simultaneously.
    - Choose **percentage** to enter a percentage of the target set that can run the association simultaneously.

In the **Error threshold** section, choose an option:

- Choose **errors** to enter an absolute number of errors that are allowed before State Manager stops running associations on additional targets.
- Choose **percentage** to enter a percentage of errors that are allowed before State Manager stops running associations on additional targets.

13. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

Following are the minimal permissions required to turn on Amazon S3 output for an association. You can further restrict access by attaching IAM policies to users or roles within an account. At minimum, an Amazon EC2 instance profile should have an IAM role with the `AmazonSSMManagedInstanceCore` managed policy and the following inline policy.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetObject",
                "s3:PutObjectAcl"
            ],
```

```
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

For minimal permissions, the Amazon S3 bucket you export to must have the default settings defined by the Amazon S3 console. For more information about creating Amazon S3 buckets, see Creating a bucket in the *Amazon S3 User Guide*.

> **Note**
>
> API operations that are initiated by the SSM document during an association run are not logged in AWS CloudTrail.

14. Choose **Create Association**.

> **Note**
>
> If you delete the association you created, the association no longer runs on any targets of that association.

Create an association (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows Server) or Tools for PowerShell to create a State Manager association. This section includes several examples that show how to use targets and rate controls. Targets and rate controls allow you to assign an association to dozens or hundreds of nodes while controlling the execution of those associations. For more information about targets and rate controls, see Understanding targets and rate controls in State Manager associations.

> **Important**
>
> This procedure describes how to create an association that uses either a `Command` or a `Policy` document to target managed nodes. For information about creating an association that uses an Automation runbook to target nodes or other types of AWS resources, see Scheduling automations with State Manager associations.

Before you begin

The `targets` parameter is an array of search criteria that targets nodes using a `Key`,`Value` combination that you specify. If you plan to create an association on dozens or hundreds of node by using the `targets` parameter, review the following targeting options before you begin the procedure.

Target specific nodes by specifying IDs

```
--targets Key=InstanceIds,Values=instance-id-1,instance-id-2,instance-id-3
```

```
--targets
 Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE,i-07782c72faEXAMPLE
```

Target instances by using tags

```
--targets Key=tag:tag-key,Values=tag-value-1,tag-value-2,tag-value-3
```

```
--targets Key=tag:Environment,Values=Development,Test,Pre-production
```

Target nodes by using AWS Resource Groups

```
--targets Key=resource-groups:Name,Values=resource-group-name
```

```
--targets Key=resource-groups:Name,Values=WindowsInstancesGroup
```

Target all instances in the current AWS account and AWS Region

```
--targets Key=InstanceIds,Values=*
```

Note

Note the following information.

- State Manager doesn't support running associations that use a new version of a document if that document is shared from another account. State Manager always runs

the `default` version of a document if shared from another account, even though the Systems Manager console shows that a new version was processed. If you want to run an association using a new version of a document shared form another account, you must set the document version to `default`.

- State Manager doesn't support the `IncludeChildOrganizationUnits` parameter for TargetLocation.
- You can specify a maximum of five tag keys by using the AWS CLI. If you use the AWS CLI, *all* tag keys specified in the `create-association` command must be currently assigned to the node. If they aren't, State Manager fails to target the node for an association.
- When you create an association, you specify when the schedule runs. Specify the schedule by using a cron or rate expression. For more information about cron and rate expressions, see Cron and rate expressions for associations.
- In order for associations that are created with Automation runbooks to be applied when new target nodes are detected, certain conditions must be met. For information, see About target updates with Automation runbooks.

To create an association

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Use the following format to create a command that creates a State Manager association. Replace each *`example resource placeholder`* with your own information.

   Linux & macOS

```
aws ssm create-association \
    --name document_name \
    --document-version version_of_document_applied \
    --instance-id instances_to_apply_association_on \
    --parameters (if any) \
    --targets target_options \
    --schedule-expression "cron_or_rate_expression" \
    --apply-only-at-cron-interval required_parameter_for_schedule_offsets \
    --schedule-offset number_between_1_and_6 \
```

```
    --output-location s3_bucket_to_store_output_details \
    --association-name association_name \
    --max-errors a_number_of_errors_or_a_percentage_of_target_set \
    --max-concurrency a_number_of_instances_or_a_percentage_of_target_set \
    --compliance-severity severity_level \
    --calendar-names change_calendar_names \
    --target-locations aws_region_or_account \
    --tags "Key=tag_key,Value=tag_value"
```

Windows

```
aws ssm create-association ^
    --name document_name ^
    --document-version version_of_document_applied ^
    --instance-id instances_to_apply_association_on ^
    --parameters (if any) ^
    --targets target_options ^
    --schedule-expression "cron_or_rate_expression" ^
    --apply-only-at-cron-interval required_parameter_for_schedule_offsets ^
    --schedule-offset number_between_1_and_6 ^
    --output-location s3_bucket_to_store_output_details ^
    --association-name association_name ^
    --max-errors a_number_of_errors_or_a_percentage_of_target_set ^
    --max-concurrency a_number_of_instances_or_a_percentage_of_target_set ^
    --compliance-severity severity_level ^
    --calendar-names change_calendar_names ^
    --target-locations aws_region_or_account ^
    --tags "Key=tag_key,Value=tag_value"
```

PowerShell

```
New-SSMAssociation `
    -Name document_name `
    -DocumentVersion version_of_document_applied `
    -InstanceId instances_to_apply_association_on `
    -Parameters (if any) `
    -Target target_options `
    -ScheduleExpression "cron_or_rate_expression" `
    -ApplyOnlyAtCronInterval required_parameter_for_schedule_offsets `
    -ScheduleOffSet number_between_1_and_6 `
    -OutputLocation s3_bucket_to_store_output_details `
    -AssociationName association_name `
    -MaxError  a_number_of_errors_or_a_percentage_of_target_set
```

```
    -MaxConcurrency a_number_of_instances_or_a_percentage_of_target_set `
    -ComplianceSeverity severity_level `
    -CalendarNames change_calendar_names `
    -TargetLocations aws_region_or_account `
    -Tags "Key=tag_key,Value=tag_value"
```

The following example creates an association on nodes tagged with `"Environment,Linux"`. The association uses the `AWS-UpdateSSMAgent` document to update the SSM Agent on the targeted nodes at 2:00 UTC every Sunday morning. This association runs simultaneously on 10 nodes maximum at any given time. Also, this association stops running on more nodes for a particular execution interval if the error count exceeds 5. For compliance reporting, this association is assigned a severity level of Medium.

Linux & macOS

```
aws ssm create-association \
  --association-name Update_SSM_Agent_Linux \
  --targets Key=tag:Environment,Values=Linux \
  --name AWS-UpdateSSMAgent  \
  --compliance-severity "MEDIUM" \
  --schedule-expression "cron(0 2 ? * SUN *)" \
  --max-errors "5" \
  --max-concurrency "10"
```

Windows

```
aws ssm create-association ^
  --association-name Update_SSM_Agent_Linux ^
  --targets Key=tag:Environment,Values=Linux ^
  --name AWS-UpdateSSMAgent  ^
  --compliance-severity "MEDIUM" ^
  --schedule-expression "cron(0 2 ? * SUN *)" ^
  --max-errors "5" ^
  --max-concurrency "10"
```

PowerShell

```
New-SSMAssociation `
  -AssociationName Update_SSM_Agent_Linux `
  -Name AWS-UpdateSSMAgent `
```

```
  -Target @{
      "Key"="tag:Environment"
      "Values"="Linux"
    } `
  -ComplianceSeverity MEDIUM `
  -ScheduleExpression "cron(0 2 ? * SUN *)" `
  -MaxConcurrency 10 `
  -MaxError 5
```

The following example targets node IDs by specifying a wildcard value (*). This allows Systems Manager to create an association on *all* nodes in the current AWS account and AWS Region. This association runs simultaneously on 10 nodes maximum at any given time. Also, this association stops running on more nodes for a particular execution interval if the error count exceeds 5. For compliance reporting, this association is assigned a severity level of Medium. This association uses a schedule offset, which means it runs two days after the specified cron schedule. It also includes the `ApplyOnlyAtCronInterval` parameter, which is required to use the schedule offset and which means the association won't run immediately after it is created.

Linux & macOS

```
aws ssm create-association \
  --association-name Update_SSM_Agent_Linux \
  --name "AWS-UpdateSSMAgent" \
  --targets "Key=instanceids,Values=*" \
  --compliance-severity "MEDIUM" \
  --schedule-expression "cron(0 2 ? * SUN#2 *)" \
  --apply-only-at-cron-interval \
  --schedule-offset 2 \
  --max-errors "5" \
  --max-concurrency "10" \
```

Windows

```
aws ssm create-association ^
  --association-name Update_SSM_Agent_Linux ^
  --name "AWS-UpdateSSMAgent" ^
  --targets "Key=instanceids,Values=*" ^
  --compliance-severity "MEDIUM" ^
```

```
  --schedule-expression "cron(0 2 ? * SUN#2 *)" ^
  --apply-only-at-cron-interval ^
  --schedule-offset 2 ^
  --max-errors "5" ^
  --max-concurrency "10" ^
  --apply-only-at-cron-interval
```

PowerShell

```
New-SSMAssociation `
  -AssociationName Update_SSM_Agent_All `
  -Name AWS-UpdateSSMAgent `
  -Target @{
      "Key"="InstanceIds"
      "Values"="*"
    } `
  -ScheduleExpression "cron(0 2 ? * SUN#2 *)" `
  -ApplyOnlyAtCronInterval `
  -ScheduleOffset 2 `
  -MaxConcurrency 10 `
  -MaxError 5 `
  -ComplianceSeverity MEDIUM `
  -ApplyOnlyAtCronInterval
```

The following example creates an association on nodes in Resource Groups. The group is named "HR-Department". The association uses the `AWS-UpdateSSMAgent` document to update SSM Agent on the targeted nodes at 2:00 UTC every Sunday morning. This association runs simultaneously on 10 nodes maximum at any given time. Also, this association stops running on more nodes for a particular execution interval if the error count exceeds 5. For compliance reporting, this association is assigned a severity level of Medium. This association runs at the specified cron schedule. It doesn't run immediately after the association is created.

Linux & macOS

```
aws ssm create-association \
  --association-name Update_SSM_Agent_Linux \
  --targets Key=resource-groups:Name,Values=HR-Department \
  --name AWS-UpdateSSMAgent  \
  --compliance-severity "MEDIUM" \
  --schedule-expression "cron(0 2 ? * SUN *)" \
```

```
  --max-errors "5" \
  --max-concurrency "10" \
  --apply-only-at-cron-interval
```

Windows

```
aws ssm create-association ^
  --association-name Update_SSM_Agent_Linux ^
  --targets Key=resource-groups:Name,Values=HR-Department ^
  --name AWS-UpdateSSMAgent  ^
  --compliance-severity "MEDIUM" ^
  --schedule-expression "cron(0 2 ? * SUN *)" ^
  --max-errors "5" ^
  --max-concurrency "10" ^
  --apply-only-at-cron-interval
```

PowerShell

```
New-SSMAssociation `
  -AssociationName Update_SSM_Agent_Linux `
  -Name AWS-UpdateSSMAgent `
  -Target @{
      "Key"="resource-groups:Name"
      "Values"="HR-Department"
    } `
  -ScheduleExpression "cron(0 2 ? * SUN *)" `
  -MaxConcurrency 10 `
  -MaxError 5 `
  -ComplianceSeverity MEDIUM `
  -ApplyOnlyAtCronInterval
```

The following example creates an association that runs on nodes tagged with a specific node ID. The association uses the SSM Agent document to update SSM Agent on the targeted nodes once when the change calendar is open. The association checks the calendar state when it runs. If the calendar is closed at launch time and the association is only run once, it won't run again because the association run window has passed. If the calendar is open, the association runs accordingly.

> **Note**
>
> If you add new nodes to the tags or resource groups that an association acts on when the change calendar is closed, the association is applied to those nodes once the change calendar opens.

Linux & macOS

```
aws ssm create-association \
  --association-name CalendarAssociation \
  --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f" \
  --name AWS-UpdateSSMAgent  \
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1" \
  --schedule-expression "rate(1day)"
```

Windows

```
aws ssm create-association ^
  --association-name CalendarAssociation ^
  --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f" ^
  --name AWS-UpdateSSMAgent  ^
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1" ^
  --schedule-expression "rate(1day)"
```

PowerShell

```
New-SSMAssociation `
  -AssociationName CalendarAssociation `
  -Target @{
      "Key"="tag:instanceids"
      "Values"="i-0cb2b964d3e14fd9f"
    } `
  -Name AWS-UpdateSSMAgent `
  -CalendarNames "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1" `
  -ScheduleExpression "rate(1day)"
```

The following example creates an association that runs on nodes tagged with a specific node ID. The association uses the SSM Agent document to update SSM Agent on the targeted nodes on the targeted nodes at 2:00 AM every Sunday. This association runs only at the specified cron schedule when the change calendar is open. When the association is created, it checks the calendar state. If the calendar is closed, the association isn't applied. When the interval to apply the association starts at 2:00 AM on Sunday, the association checks to see if the calendar is open. If the calendar is open, the association runs accordingly.

> **Note**
>
> If you add new nodes to the tags or resource groups that an association acts on when the change calendar is closed, the association is applied to those nodes once the change calendar opens.

Linux & macOS

```
aws ssm create-association \
  --association-name MultiCalendarAssociation \
  --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f" \
  --name AWS-UpdateSSMAgent  \
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
 "arn:aws:ssm:us-east-2:123456789012:document/testCalendar2" \
  --schedule-expression "cron(0 2 ? * SUN *)"
```

Windows

```
aws ssm create-association ^
  --association-name MultiCalendarAssociation ^
  --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f" ^
  --name AWS-UpdateSSMAgent  ^
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
 "arn:aws:ssm:us-east-2:123456789012:document/testCalendar2" ^
  --schedule-expression "cron(0 2 ? * SUN *)"
```

PowerShell

```
New-SSMAssociation `
```

```
  -AssociationName MultiCalendarAssociation `
  -Name AWS-UpdateSSMAgent `
  -Target @{
      "Key"="tag:instanceids"
      "Values"="i-0cb2b964d3e14fd9f"
    } `
  -CalendarNames "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
"arn:aws:ssm:us-east-2:123456789012:document/testCalendar2" `
  -ScheduleExpression "cron(0 2 ? * SUN *)"
```

Note

If you delete the association you created, the association no longer runs on any targets of that association. Also, if you specified the `apply-only-at-cron-interval` parameter, you can reset this option. To do so, specify the `no-apply-only-at-cron-interval` parameter when you update the association from the command line. This parameter forces the association to run immediately after updating the association and according to the interval specified.

Editing and creating a new version of an association

You can edit a State Manager association to specify a new name, schedule, severity level, targets, or other values. For associations based on SSM Command-type documents, you can also choose to write the output of the command to an Amazon Simple Storage Service (Amazon S3) bucket. After you edit an association, State Manager creates a new version. You can view different versions after editing, as described in the following procedures.

Note

In order for associations that are created with Automation runbooks to be applied when new target nodes are detected, certain conditions must be met. For information, see About target updates with Automation runbooks.

The following procedures describe how to edit and create a new version of an association using the Systems Manager console, AWS Command Line Interface (AWS CLI), and AWS Tools for PowerShell (Tools for PowerShell).

Important

State Manager doesn't support running associations that use a new version of a document if that document is shared from another account. State Manager always runs the `default` version of a document if shared from another account, even though the Systems Manager console shows that a new version was processed. If you want to run an association using a new version of a document shared form another account, you must set the document version to `default`.

Edit an association (console)

The following procedure describes how to use the Systems Manager console to edit and create a new version of an association.

Note

For associations that use SSM Command documents, not Automation runbooks, this procedure requires that you have write access to an existing Amazon S3 bucket. If you haven't used Amazon S3 before, be aware that you will incur charges for using Amazon S3. For information about how to create a bucket, see Create a Bucket.

To edit a State Manager association

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Choose an existing association, and then choose **Edit**.
4. Reconfigure the association to meet your current requirements.

   For information about association options with `Command` and `Policy` documents, see Creating associations. For information about association options with Automation runbooks, see Scheduling automations with State Manager associations.
5. Choose **Save Changes**.

6. (Optional) To view association information, in the **Associations** page, choose the name of the association you edited, and then choose the **Versions** tab. The system lists each version of the association you created and edited.
7. (Optional) To view output for associations based on SSM Command documents, do the following:

   a. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

   b. Choose the name of the Amazon S3 bucket you specified for storing command output, and then choose the folder named with the ID of the node that ran the association. (If you chose to store output in a folder in the bucket, open it first.)

   c. Drill down several levels, through the `awsrunPowerShell` folder, to the `stdout` file.

   d. Choose **Open** or **Download** to view the host name.

Edit an association (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows Server) or AWS Tools for PowerShell to edit and create a new version of an association.

To edit a State Manager association

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Use the following format to create a command to edit and create a new version of an existing State Manager association. Replace each *`example resource placeholder`* with your own information.

   > **Important**
   >
   > When you call `update-association`, the system drops all optional parameters from the request and overwrites the association with null values for those parameters. This is by design. You must specify all optional parameters in the call, even if you are not changing the parameters. This includes the `--name` parameter. Before calling this action, we recommend that you call the `describe-association` operation and make a note of all optional parameters required for your `update-association` call.

Linux & macOS

```
aws ssm update-association \
    --name document_name \
    --document-version version_of_document_applied \
    --instance-id instances_to_apply_association_on \
    --parameters (if any) \
    --targets target_options \
    --schedule-expression "cron_or_rate_expression" \
    --schedule-offset "number_between_1_and_6" \
    --output-location s3_bucket_to_store_output_details \
    --association-name association_name \
    --max-errors a_number_of_errors_or_a_percentage_of_target_set \
    --max-concurrency a_number_of_instances_or_a_percentage_of_target_set \
    --compliance-severity severity_level \
    --calendar-names change_calendar_names \
    --target-locations aws_region_or_account
```

Windows

```
aws ssm update-association ^
    --name document_name ^
    --document-version version_of_document_applied ^
    --instance-id instances_to_apply_association_on ^
    --parameters (if any) ^
    --targets target_options ^
    --schedule-expression "cron_or_rate_expression" ^
    --schedule-offset "number_between_1_and_6" ^
    --output-location s3_bucket_to_store_output_details ^
    --association-name association_name ^
    --max-errors a_number_of_errors_or_a_percentage_of_target_set ^
    --max-concurrency a_number_of_instances_or_a_percentage_of_target_set ^
    --compliance-severity severity_level ^
    --calendar-names change_calendar_names ^
    --target-locations aws_region_or_account
```

PowerShell

```
Update-SSMAssociation `
    -Name document_name `
    -DocumentVersion version_of_document_applied `
```

```
    -InstanceId instances_to_apply_association_on `
    -Parameters (if any) `
    -Target target_options `
    -ScheduleExpression "cron_or_rate_expression" `
    -ScheduleOffset "number_between_1_and_6" `
    -OutputLocation s3_bucket_to_store_output_details `
    -AssociationName association_name `
    -MaxError  a_number_of_errors_or_a_percentage_of_target_set
    -MaxConcurrency a_number_of_instances_or_a_percentage_of_target_set `
    -ComplianceSeverity severity_level `
    -CalendarNames change_calendar_names `
    -TargetLocations aws_region_or_account
```

The following example updates an existing association to change the name to `TestHostnameAssociation2`. The new association version runs every hour and writes the output of commands to the specified Amazon S3 bucket.

Linux & macOS

```
aws ssm update-association \
  --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE \
  --association-name TestHostnameAssociation2 \
  --parameters commands="echo Association" \
  --output-location S3Location='{OutputS3Region=us-
east-1,OutputS3BucketName=amzn-s3-demo-bucket,OutputS3KeyPrefix=logs}' \
  --schedule-expression "cron(0 */1 * * ? *)"
```

Windows

```
aws ssm update-association ^
  --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE ^
  --association-name TestHostnameAssociation2 ^
  --parameters commands="echo Association" ^
  --output-location S3Location='{OutputS3Region=us-
east-1,OutputS3BucketName=amzn-s3-demo-bucket,OutputS3KeyPrefix=logs}' ^
  --schedule-expression "cron(0 */1 * * ? *)"
```

PowerShell

```
Update-SSMAssociation `
  -AssociationId b85ccafe-9f02-4812-9b81-01234EXAMPLE `
```

```
  -AssociationName TestHostnameAssociation2 `
  -Parameter @{"commands"="echo Association"} `
  -S3Location_OutputS3BucketName amzn-s3-demo-bucket `
  -S3Location_OutputS3KeyPrefix logs `
  -S3Location_OutputS3Region us-east-1 `
  -ScheduleExpression "cron(0 */1 * * ? *)"
```

The following example updates an existing association to change the name to `CalendarAssociation`. The new association runs when the calendar is open and writes command output to the specified Amazon S3 bucket.

Linux & macOS

```
aws ssm update-association \
  --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE \
  --association-name CalendarAssociation \
  --parameters commands="echo Association" \
  --output-location S3Location='{OutputS3Region=us-
east-1,OutputS3BucketName=amzn-s3-demo-bucket,OutputS3KeyPrefix=logs}' \
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar2"
```

Windows

```
aws ssm update-association ^
  --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE ^
  --association-name CalendarAssociation ^
  --parameters commands="echo Association" ^
  --output-location S3Location='{OutputS3Region=us-
east-1,OutputS3BucketName=amzn-s3-demo-bucket,OutputS3KeyPrefix=logs}' ^
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar2"
```

PowerShell

```
Update-SSMAssociation `
  -AssociationId b85ccafe-9f02-4812-9b81-01234EXAMPLE `
  -AssociationName CalendarAssociation `
  -AssociationName OneTimeAssociation `
  -Parameter @{"commands"="echo Association"} `
  -S3Location_OutputS3BucketName amzn-s3-demo-bucket `
  -CalendarNames "arn:aws:ssm:us-east-1:123456789012:document/testCalendar2"
```

The following example updates an existing association to change the name to `MultiCalendarAssociation`. The new association runs when the calendars are open and writes command output to the specified Amazon S3 bucket.

Linux & macOS

```
aws ssm update-association \
  --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE \
  --association-name MultiCalendarAssociation \
  --parameters commands="echo Association" \
  --output-location S3Location='{OutputS3Region=us-
east-1,OutputS3BucketName=amzn-s3-demo-bucket,OutputS3KeyPrefix=logs}' \
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
 "arn:aws:ssm:us-east-2:123456789012:document/testCalendar2"
```

Windows

```
aws ssm update-association ^
  --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE ^
  --association-name MultiCalendarAssociation ^
  --parameters commands="echo Association" ^
  --output-location S3Location='{OutputS3Region=us-
east-1,OutputS3BucketName=amzn-s3-demo-bucket,OutputS3KeyPrefix=logs}' ^
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
 "arn:aws:ssm:us-east-2:123456789012:document/testCalendar2"
```

PowerShell

```
Update-SSMAssociation `
  -AssociationId b85ccafe-9f02-4812-9b81-01234EXAMPLE `
  -AssociationName MultiCalendarAssociation `
  -Parameter @{"commands"="echo Association"} `
  -S3Location_OutputS3BucketName amzn-s3-demo-bucket `
  -CalendarNames "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
 "arn:aws:ssm:us-east-2:123456789012:document/testCalendar2"
```

3. To view the new version of the association, run the following command.

Linux & macOS

```
aws ssm describe-association \
  --association-id b85ccafe-9f02-4812-9b81-01234EXAMPLE
```

Windows

```
aws ssm describe-association ^
  --association-id b85ccafe-9f02-4812-9b81-01234EXAMPLE
```

PowerShell

```
Get-SSMAssociation `
  -AssociationId b85ccafe-9f02-4812-9b81-01234EXAMPLE | Select-Object *
```

The system returns information like the following.

Linux & macOS

```
{
    "AssociationDescription": {
        "ScheduleExpression": "cron(0 */1 * * ? *)",
        "OutputLocation": {

```

Deleting associations

Use the following procedure to delete an association by using the AWS Systems Manager console.

To delete an association

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Select an association and then choose **Delete**.

You can delete multiple associations in a single operation by running an automation from the AWS Systems Manager console. When you select multiple associations for deletion, State Manager launches the automation runbook start page with the association IDs entered as input parameter values.

To delete multiple associations in a single operation

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Select each association that you want to delete and then choose **Delete**.
4. (Optional) In the **Additional input parameters** area, select the Amazon Resource Name (ARN) for the *assume role* that you want the automation to use while running. To create a new assume role, choose **Create**.
5. Choose **Submit**.

Running Auto Scaling groups with associations

The best practice when using associations to run Auto Scaling groups is to use tag targets. Not using tags might cause you to reach the association limit.

If all nodes are tagged with the same key and value, you only need one association to run your Auto Scaling group. The following procedure describes how to create such an association.

To create an association that runs Auto Scaling groups

1. Ensure all nodes in the Auto Scaling group are tagged with the same key and value. For more instructions on tagging nodes, see Tagging Auto Scaling groups and instances in the *AWS Auto Scaling User Guide*.
2. Create an association by using the procedure in Working with associations in Systems Manager.

   If you're working in the console, choose **Specify instance tags** in the **Targets** field. For **Instance tags**, enter the **Tag** key and value for your Auto Scaling group.

   If you're using the AWS Command Line Interface (AWS CLI), specify `--targets Key=tag:tag-key,Values=tag-value` where the key and value match what you tagged your nodes with.

Viewing association histories

You can view all executions for a specific association ID by using the DescribeAssociationExecutions API operation. Use this operation to see the status, detailed status, results, last execution time, and more information for a State Manager association. State Manager is a tool in AWS Systems Manager. This API operation also includes filters to help you locate associations according to the criteria you specify. For example, you can specify an exact date and time, and use a GREATER_THAN filter to view executions processed after the specified date and time.

If, for example, an association execution failed, you can drill down into the details of a specific execution by using the DescribeAssociationExecutionTargets API operation. This operation shows you the resources, such as node IDs, where the association ran and the various association statuses. You can then see which resource or node failed to run an association. With the resource ID you can then view the command execution details to see which step in a command failed.

The examples in this section also include information about how to use the StartAssociationsOnce API operation to run an association once at the time of creation. You can use this API operation when you investigate failed association executions. If you see that an association failed, you can make a change on the resource, and then immediately run the association to see if the change on the resource allows the association to run successfully.

> **Note**
>
> API operations that are initiated by the SSM document during an association run are not logged in AWS CloudTrail.

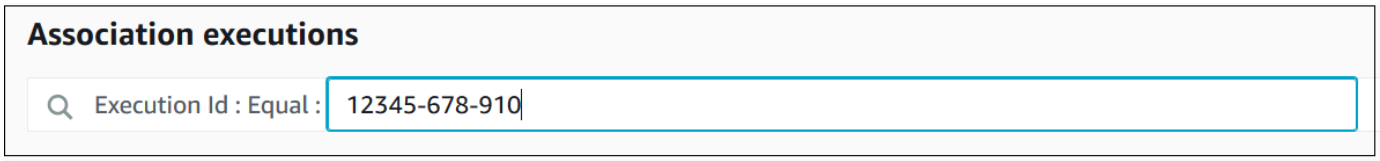
Viewing association histories (console)

Use the following procedure to view the execution history for a specific association ID and then view execution details for one or more resources.

To view execution history for a specific association ID

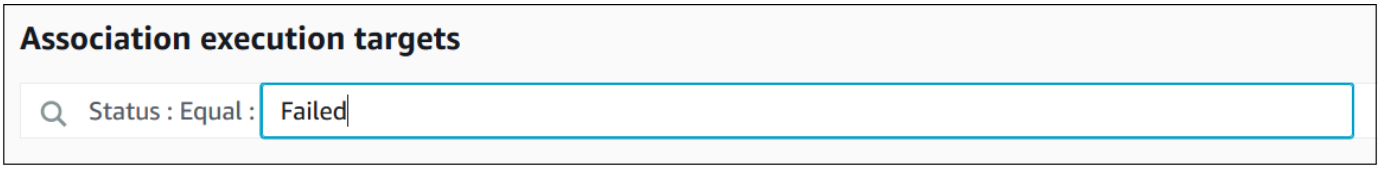
1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Choose **State Manager**.
3. In the **Association id** field, choose an association for which you want to view the history.
4. Choose the **View details** button.
5. Choose the **Execution history** tab.
6. Choose an association for which you want to view resource-level execution details. For example, choose an association that shows a status of **Failed**. You can then view the execution details for the nodes that failed to run the association.

   Use the search box filters to locate the execution for which you want to view details.

7. Choose an execution ID. The **Association execution targets** page opens. This page shows all the resources that ran the association.
8. Choose a resource ID to view specific information about that resource.

   Use the search box filters to locate the resource for which you want to view details.

9. If you're investigating an association that failed to run, you can use the **Apply association now** button to run an association once at the time of creation. After you made changes on the resource where the association failed to run, choose the **Association ID** link in the navigation breadcrumb.
10. Choose the **Apply association now** button. After the execution is complete, verify that the association execution succeeded.

Viewing association histories (command line)

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) (on Linux or Windows Server) or AWS Tools for PowerShell to view the execution history for a specific association ID. Following this, the procedure describes how to view execution details for one or more resources.

To view execution history for a specific association ID

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.
2. Run the following command to view a list of executions for a specific association ID.

   Linux & macOS

```
aws ssm describe-association-executions \
  --association-id ID \
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN
```

> **Note**
>
> This command includes a filter to limit the results to only those executions that occurred after a specific date and time. If you want to view all executions for a specific association ID, remove the `--filters` parameter and `Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN` value.

Windows

```
aws ssm describe-association-executions ^
  --association-id ID ^
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN
```

Note

This command includes a filter to limit the results to only those executions that occurred after a specific date and time. If you want to view all executions for a specific association ID, remove the `--filters` parameter and `Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN` value.

PowerShell

```
Get-SSMAssociationExecution `
  -AssociationId ID `
  -Filter
 @{"Key"="CreatedTime";"Value"="2019-06-01T19:15:38.372Z";"Type"="GREATER_THAN"}
```

Note

This command includes a filter to limit the results to only those executions that occurred after a specific date and time. If you want to view all executions for a specific association ID, remove the `-Filter` parameter and `@{"Key"="CreatedTime";"Value"="2019-06-01T19:15:38.372Z";"Type"="GREAT` value.

The system returns information like the following.

Linux & macOS

```
{
   "AssociationExecutions":[
```

```
      {
         "Status":"Success",
         "DetailedStatus":"Success",

ExecutionId           : ecec60fa-6bb0-4d26-98c7-140308EXAMPLE
LastExecutionDate     : 1/1/0001 12:00:00 AM
ResourceCountByStatus : {Success=1}
Status                : Success
```

You can limit the results by using one or more filters. The following example returns all associations that were run before a specific date and time.

Linux & macOS

```
aws ssm describe-association-executions \
  --association-id ID \
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=LESS_THAN
```

Windows

```
aws ssm describe-association-executions ^
  --association-id ID ^
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=LESS_THAN
```

PowerShell

```
Get-SSMAssociationExecution `
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE `
  -Filter
 @{"Key"="CreatedTime";"Value"="2019-06-01T19:15:38.372Z";"Type"="LESS_THAN"}
```

The following returns all associations that were *successfully* run after a specific date and time.

Linux & macOS

```
aws ssm describe-association-executions \
  --association-id ID \
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN
 Key=Status,Value=Success,Type=EQUAL
```

Windows

```
aws ssm describe-association-executions ^
  --association-id ID ^
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN
 Key=Status,Value=Success,Type=EQUAL
```

PowerShell

```
Get-SSMAssociationExecution `
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE `
  -Filter @{
      "Key"="CreatedTime";
      "Value"="2019-06-01T19:15:38.372Z";
      "Type"="GREATER_THAN"
    },
    @{
      "Key"="Status";
      "Value"="Success";
      "Type"="EQUAL"
    }
```

3. Run the following command to view all targets where the specific execution ran.

Linux & macOS

```
aws ssm describe-association-execution-targets \
  --association-id ID \
  --execution-id ID
```

Windows

```
aws ssm describe-association-execution-targets ^
  --association-id ID ^
  --execution-id ID
```

PowerShell

```
Get-SSMAssociationExecutionTarget `
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE `
  -ExecutionId 76a5a04f-caf6-490c-b448-92c02EXAMPLE
```

You can limit the results by using one or more filters. The following example returns information about all targets where the specific association failed to run.

Linux & macOS

```
aws ssm describe-association-execution-targets \
  --association-id ID \
  --execution-id ID \
  --filters Key=Status,Value="Failed"
```

Windows

```
aws ssm describe-association-execution-targets ^
  --association-id ID ^
  --execution-id ID ^
  --filters Key=Status,Value="Failed"
```

PowerShell

```
Get-SSMAssociationExecutionTarget `
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE `
  -ExecutionId 76a5a04f-caf6-490c-b448-92c02EXAMPLE `
  -Filter @{
      "Key"="Status";
      "Value"="Failed"
    }
```

The following example returns information about a specific managed node where an association failed to run.

Linux & macOS

```
aws ssm describe-association-execution-targets \
  --association-id ID \
  --execution-id ID \
  --filters Key=Status,Value=Failed Key=ResourceId,Value="i-02573cafcfEXAMPLE"
 Key=ResourceType,Value=ManagedInstance
```

Windows

```
aws ssm describe-association-execution-targets ^
  --association-id ID ^
```

```
  --execution-id ID ^
  --filters Key=Status,Value=Failed Key=ResourceId,Value="i-02573cafcfEXAMPLE"
 Key=ResourceType,Value=ManagedInstance
```

PowerShell

```
Get-SSMAssociationExecutionTarget `
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE `
  -ExecutionId 76a5a04f-caf6-490c-b448-92c02EXAMPLE `
  -Filter @{
      "Key"="Status";
      "Value"="Success"
    },
    @{
      "Key"="ResourceId";
      "Value"="i-02573cafcfEXAMPLE"
    },
    @{
      "Key"="ResourceType";
      "Value"="ManagedInstance"
    }
```

4. If you're investigating an association that failed to run, you can use the StartAssociationsOnce API operation to run an association immediately and only one time. After you change the resource where the association failed to run, run the following command to run the association immediately and only one time.

   Linux & macOS

   ```
   aws ssm start-associations-once \
     --association-id ID
   ```

   Windows

   ```
   aws ssm start-associations-once ^
     --association-id ID
   ```

   PowerShell

   ```
   Start-SSMAssociationsOnce `
     -AssociationId ID
   ```

Working with associations using IAM

State Manager, a tool in AWS Systems Manager, uses targets to choose which instances you configure your associations with. Originally, associations were created by specifying a document name (`Name`) and instance ID (`InstanceId`). This created an association between a document and an instance or managed node. Associations used to be identified by these parameters. These parameters are now deprecated, but they're still supported. The resources `instance` and `managed-instance` were added as resources to actions with `Name` and `InstanceId`.

AWS Identity and Access Management (IAM) policy enforcement behavior depends on the type of resource specified. Resources for State Manager operations are only enforced based on the passed-in request. State Manager doesn't perform a deep check for the properties of resources in your account. A request is only validated against policy resources if the request parameter contains the specified policy resources. For example, if you specify an instance in the resource block, the policy is enforced if the request uses the `InstanceId` parameter. The `Targets` parameter for each resource in the account isn't checked for that `InstanceId`.

Following are some cases with confusing behavior:

- DescribeAssociation, DeleteAssociation, and UpdateAssociation use `instance`, `managed-instance`, and `document` resources to specify the deprecated way of referring to associations. This includes all associations created with the deprecated `InstanceId` parameter.
- CreateAssociation, CreateAssociationBatch, and UpdateAssociation use `instance` and `managed-instance` resources to specify the deprecated way of referring to associations. This includes all associations created with the deprecated `InstanceId` parameter. The `document` resource type is part of the deprecated way of referring to associations and is an actual property of an association. This means you can construct IAM policies with `Allow` or `Deny` permissions for both `Create` and `Update` actions based on document name.

For more information about using IAM policies with Systems Manager, see Identity and access management for AWS Systems Manager or Actions, resources, and condition keys for AWS Systems Manager in the *Service Authorization Reference*.

Creating associations that run MOF files

You can run Managed Object Format (MOF) files to enforce a target state on Windows Server managed nodes with State Manager, a tool in AWS Systems Manager, by using the `AWS-ApplyDSCMofs` SSM document. The `AWS-ApplyDSCMofs` document has two execution modes.

With the first mode, you can configure the association to scan and report if the managed nodes are in the desired state defined in the specified MOF files. In the second mode, you can run the MOF files and change the configuration of your nodes based on the resources and their values defined in the MOF files. The `AWS-ApplyDSCMofs` document allows you to download and run MOF configuration files from Amazon Simple Storage Service (Amazon S3), a local share, or from a secure website with an HTTPS domain.

State Manager logs and reports the status of each MOF file execution during each association run. State Manager also reports the output of each MOF file execution as a compliance event which you can view on the AWS Systems Manager Compliance page.

MOF file execution is built on Windows PowerShell Desired State Configuration (PowerShell DSC). PowerShell DSC is a declarative platform used for configuration, deployment, and management of Windows systems. PowerShell DSC allows administrators to describe, in simple text documents called DSC configurations, how they want a server to be configured. A PowerShell DSC configuration is a specialized PowerShell script that states what to do, but not how to do it. Running the configuration produces a MOF file. The MOF file can be applied to one or more servers to achieve the desired configuration for those servers. PowerShell DSC resources do the actual work of enforcing configuration. For more information, see Windows PowerShell Desired State Configuration Overview.

Topics

Using Amazon S3 to store artifacts

If you're using Amazon S3 to store PowerShell modules, MOF files, compliance reports, or status reports, then the AWS Identity and Access Management (IAM) role used by AWS Systems Manager SSM Agent must have `GetObject` and `ListBucket` permissions on the bucket. If you

don't provide these permissions, the system returns an *Access Denied* error. Below is important information about storing artifacts in Amazon S3.

- If the bucket is in a different AWS account, create a bucket resource policy that grants the account (or the IAM role) `GetObject` and `ListBucket` permissions.
- If you want to use custom DSC resources, you can download these resources from an Amazon S3 bucket. You can also install them automatically from the PowerShell gallery.
- If you're using Amazon S3 as a module source, upload the module as a Zip file in the following case-sensitive format: *`ModuleName_ModuleVersion`*.zip. For example: MyModule_1.0.0.zip.
- All files must be in the bucket root. Folder structures aren't supported.

Resolving credentials in MOF files

Credentials are resolved by using AWS Secrets Manager or AWS Systems Manager Parameter Store. This allows you to set up automatic credential rotation. This also allows DSC to automatically propagate credentials to your servers without redeploying MOFs.

To use an AWS Secrets Manager secret in a configuration, create a PSCredential object where the Username is the SecretId or SecretARN of the secret containing the credential. You can specify any value for the password. The value is ignored. Following is an example.

```
Configuration MyConfig
{
   $ss = ConvertTo-SecureString -String 'a_string' -AsPlaintext -Force
   $credential = New-Object PSCredential('a_secret_or_ARN', $ss)

    Node localhost
    {
       File file_name
       {
           DestinationPath = 'C:\MyFile.txt'
           SourcePath = '\\FileServer\Share\MyFile.txt'
           Credential = $credential
       }
    }
}
```

Compile your MOF using the PsAllowPlaintextPassword setting in configuration data. This is OK because the credential only contains a label.

In Secrets Manager, ensure that the node has GetSecretValue access in an IAM Managed Policy, and optionally in the Secret Resource Policy if one exists. To work with DSC, the secret must be in the following format.

```
{ 'Username': 'a_name', 'Password': 'a_password' }
```

The secret can have other properties (for example, properties used for rotation), but it must at least have the username and password properties.

We recommended that you use a multi-user rotation method, where you have two different usernames and passwords, and the rotation AWS Lambda function flips between them. This method allows you to have multiple active accounts while eliminating the risk of locking out a user during rotation.

Using tokens in MOF files

Tokens give you the ability to modify resource property values *after* the MOF has been compiled. This allows you to reuse common MOF files on multiple servers that require similar configurations.

Token substitution only works for Resource Properties of type `String`. However, if your resource has a nested CIM node property, it also resolves tokens from `String` properties in that CIM node. You can't use token substitution for numerals or arrays.

For example, consider a scenario where you're using the xComputerManagement resource and you want to rename the computer using DSC. Normally you would need a dedicated MOF file for that machine. However, with token support, you can create a single MOF file and apply it to all your nodes. In the `ComputerName` property, instead of hardcoding the computer name into the MOF, you can use an Instance Tag type token. The value is resolved during MOF parsing. See the following example.

```
Configuration MyConfig
{
    xComputer Computer
    {
        ComputerName = '{tag:ComputerName}'
    }
}
```

You then set a tag on either the managed node in the Systems Manager console, or an Amazon Elastic Compute Cloud (Amazon EC2) tag in the Amazon EC2 console. When you run the document, the script substitutes the {tag:ComputerName} token for the value of the instance tag.

You can also combine multiple tags into a single property, as shown in the following example.

```
Configuration MyConfig
{
    File MyFile
    {
        DestinationPath = '{env:TMP}\{tag:ComputerName}'
        Type = 'Directory'
    }
}
```

There are five different types of tokens you can use:

- **tag**: Amazon EC2 or managed node tags.
- **tagb64**: This is the same as tag, but the system use base64 to decode the value. This allows you to use special characters in tag values.
- **env**: Resolves Environment variables.
- **ssm**: Parameter Store values. Only String and Secure String types are supported.
- **tagssm**: This is the same as tag, but if the tag isn't set on the node, the system tries to resolve the value from a Systems Manager parameter with the same name. This is useful in situations when you want a 'default global value' but you want to be able to override it on a single node (for example, one-box deployments).

Here is a Parameter Store example that uses the `ssm` token type.

```
File MyFile
{
    DestinationPath = "C:\ProgramData\ConnectionData.txt"
    Content = "{ssm:%servicePath%/ConnectionData}"
}
```

Tokens play an important role in reducing redundant code by making MOF files generic and reusable. If you can avoid server-specific MOF file, then there's no need for a MOF building service. A MOF building service increases costs, slows provisioning time, and increases the risk of

configuration drift between grouped nodes due to differing module versions being installed on the build server when their MOFs were compiled.

Prerequisites for creating associations that run MOF files

Before you create an association that runs MOF files, verify that your managed nodes have the following prerequisites installed:

- Windows PowerShell version 5.0 or later. For more information, see Windows PowerShell System Requirements on Microsoft.com.
- AWS Tools for Windows PowerShell version 3.3.261.0 or later.
- SSM Agent version 2.2 or later.

Creating an association that runs MOF files

To create an association that runs MOF files

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Choose **State Manager**, and then choose **Create association**.
4. In the **Name** field, specify a name. This is optional, but recommended. A name can help you understand the purpose of the association when you created it. Spaces aren't allowed in the name.
5. In the **Document** list, choose **`AWS-ApplyDSCMofs`**.
6. In the **Parameters** section, specify your choices for the required and optional input parameters.

    a. **Mofs To Apply**: Specify one or more MOF files to run when this association runs. Use commas to separate a list of MOF files. Systems Manager iterates through the list of MOF files and runs them in the order specified by the comma separated list.

    - An Amazon S3 bucket name. Bucket names must use lowercase letters. Specify this information by using the following format.

```
s3:amzn-s3-demo-bucket:MOF_file_name.mof
```

If you want to specify an AWS Region, then use the following format.

```
s3:bucket_Region:amzn-s3-demo-bucket:MOF_file_name.mof
```

- A secure website. Specify this information by using the following format.

```
https://domain_name/MOF_file_name.mof
```

Here is an example.

```
https://www.example.com/TestMOF.mof
```

- A file system on a local share. Specify this information by using the following format.

```
\server_name\shared_folder_name\MOF_file_name.mof
```

Here is an example.

```
\StateManagerAssociationsBox\MOFs_folder\MyMof.mof
```

b. **Service Path**: (Optional) A service path is either an Amazon S3 bucket prefix where you want to write reports and status information. Or, a service path is a path for Parameter Store parameter-based tags. When resolving parameter-based tags, the system uses {ssm:%servicePath%/*parameter_name*} to inject the servicePath value into the parameter name. For example, if your service path is "WebServers/Production" then the systems resolves the parameter as: WebServers/Production/*parameter_name*. This is useful for when you're running multiple environments in the same account.

c. **Report Bucket Name**: (Optional) Enter the name of an Amazon S3 bucket where you want to write compliance data. Reports are saved in this bucket in JSON format.

> **Note**
>
> You can prefix the bucket name with a Region where the bucket is located. Here's an example: us-west-2:MyMOFBucket. If you're using a proxy for Amazon S3 endpoints in a specific Region that doesn't include us-east-1, prefix the bucket name with a Region. If the bucket name isn't prefixed, it automatically discovers the bucket Region by using the us-east-1 endpoint.

d. **Mof Operation Mode**: Choose State Manager behavior when running the **`AWS-ApplyDSCMofs`** association:

- **Apply**: Correct node configurations that aren't compliant.
- **ReportOnly**: Don't correct node configurations, but instead log all compliance data and report nodes that aren't compliant.

e. **Status Bucket Name**: (Optional) Enter the name of an Amazon S3 bucket where you want to write MOF execution status information. These status reports are singleton summaries of the most recent compliance run of a node. This means that the report is overwritten the next time the association runs MOF files.

> **Note**
>
> You can prefix the bucket name with a Region where the bucket is located. Here's an example: `us-west-2:amzn-s3-demo-bucket`. If you're using a proxy for Amazon S3 endpoints in a specific Region that doesn't include us-east-1, prefix the bucket name with a Region. If the bucket name isn't prefixed, it automatically discovers the bucket Region using the us-east-1 endpoint.

f. **Module Source Bucket Name**: (Optional) Enter the name of an Amazon S3 bucket that contains PowerShell module files. If you specify **None**, choose **True** for the next option, **Allow PS Gallery Module Source**.

> **Note**
>
> You can prefix the bucket name with a Region where the bucket is located. Here's an example: `us-west-2:amzn-s3-demo-bucket`. If you're using a proxy for Amazon S3 endpoints in a specific Region that doesn't include us-east-1, prefix the bucket name with a Region. If the bucket name isn't prefixed, it automatically discovers the bucket Region using the us-east-1 endpoint.

g. **Allow PS Gallery Module Source**: (Optional) Choose **True** to download PowerShell modules from https://www.powershellgallery.com/. If you choose **False**, specify a source for the previous option, **ModuleSourceBucketName**.

h. **Proxy Uri**: (Optional) Use this option to download MOF files from a proxy server.

i. **Reboot Behavior**: (Optional) Specify one of the following reboot behaviors if your MOF file execution requires rebooting:

- **AfterMof**: Reboots the node after all MOF executions are complete. Even if multiple MOF executions request reboots, the system waits until all MOF executions are complete to reboot.
- **Immediately**: Reboots the node whenever a MOF execution requests it. If running multiple MOF files that request reboots, then the nodes are rebooted multiple times.
- **Never**: Nodes aren't rebooted, even if the MOF execution explicitly requests a reboot.

j. **Use Computer Name For Reporting**: (Optional) Turn on this option to use the name of the computer when reporting compliance information. The default value is **false**, which means that the system uses the node ID when reporting compliance information.

k. **Turn on Verbose Logging**: (Optional) We recommend that you turn on verbose logging when deploying MOF files for the first time.

> **Important**
>
> When allowed, verbose logging writes more data to your Amazon S3 bucket than standard association execution logging. This might result in slower performance and higher storage charges for Amazon S3. To mitigate storage size issues, we recommend that you turn on lifecycle policies on your Amazon S3 bucket. For more information, see How Do I Create a Lifecycle Policy for an S3 Bucket? in the *Amazon Simple Storage Service User Guide*.

l. **Turn on Debug Logging**: (Optional) We recommend that you turn on debug logging to troubleshoot MOF failures. We also recommend that you deactivate this option for normal use.

> **Important**
>
> When allowed, debug logging writes more data to your Amazon S3 bucket than standard association execution logging. This might result in slower performance and higher storage charges for Amazon S3. To mitigate storage size issues, we recommend that you turn on lifecycle policies on your Amazon S3 bucket. For more information, see How Do I Create a Lifecycle Policy for an S3 Bucket? in the *Amazon Simple Storage Service User Guide*.

m. **Compliance Type**: (Optional) Specify the compliance type to use when reporting compliance information. The default compliance type is **Custom:DSC**. If you create

multiple associations that run MOF files, then be sure to specify a different compliance type for each association. If you don't, each additional association that uses **Custom:DSC** overwrites the existing compliance data.

n. **Pre Reboot Script**: (Optional) Specify a script to run if the configuration has indicated that a reboot is necessary. The script runs before the reboot. The script must be a single line. Separate additional lines by using semicolons.

7. In the **Targets** section, choose either **Specifying tags** or **Manually Selecting Instance**. If you choose to target resources by using tags, then enter a tag key and a tag value in the fields provided. For more information about using targets, see Understanding targets and rate controls in State Manager associations.

8. In the **Specify schedule** section, choose either **On Schedule** or **No schedule**. If you choose **On Schedule**, then use the buttons provided to create a cron or rate schedule for the association.

9. In the **Advanced options** section:

   - In **Compliance severity**, choose a severity level for the association. Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you indicate here. For more information, see About State Manager association compliance.

10. In the **Rate control** section, configure options for running State Manager associations across of fleet of managed nodes. For more information about these options, see Understanding targets and rate controls in State Manager associations.

    In the **Concurrency** section, choose an option:

    - Choose **targets** to enter an absolute number of targets that can run the association simultaneously.
    - Choose **percentage** to enter a percentage of the target set that can run the association simultaneously.

    In the **Error threshold** section, choose an option:

    - Choose **errors** to enter an absolute number of errors allowed before State Manager stops running associations on additional targets.
    - Choose **percentage** to enter a percentage of errors allowed before State Manager stops running associations on additional targets.

11. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

12. Choose **Create Association**.

State Manager creates and immediately runs the association on the specified nodes or targets. After the initial execution, the association runs in intervals according to the schedule that you defined and according to the following rules:

- State Manager runs associations on nodes that are online when the interval starts and skips offline nodes.
- State Manager attempts to run the association on all configured nodes during an interval.
- If an association isn't run during an interval (because, for example, a concurrency value limited the number of nodes that could process the association at one time), then State Manager attempts to run the association during the next interval.
- State Manager records history for all skipped intervals. You can view the history on the **Execution History** tab.

> **Note**
>
> The `AWS-ApplyDSCMofs` is a Systems Manager Command document. This means that you can also run this document by using Run Command, a tool in AWS Systems Manager. For more information, see AWS Systems Manager Run Command.

Troubleshooting issues when creating associations that run MOF files

This section includes information to help you troubleshoot issues creating associations that run MOF files.

Turn on enhanced logging

As a first step to troubleshooting, turn on enhanced logging. More specifically, do the following:

1. Verify that the association is configured to write command output to either Amazon S3 or Amazon CloudWatch Logs (CloudWatch).
2. Set the **Enable Verbose Logging** parameter to True.
3. Set the **Enable Debug Logging** parameter to True.

With verbose and debug logging turned on, the **Stdout** output file includes details about the script execution. This output file can help you identify where the script failed. The **Stderr** output file contains errors that occurred during the script execution.

Common problems when creating associations that run MOF files

This section includes information about common problems that can occur when creating associations that run MOF files and steps to troubleshoot these issues.

My MOF wasn't applied

If State Manager failed to apply the association to your nodes, then start by reviewing the **Stderr** output file. This file can help you understand the root cause of the issue. Also, verify the following:

- The node has the required access permissions to all MOF-related Amazon S3 buckets. Specifically:
  - **s3:GetObject permissions**: This is required for MOF files in private Amazon S3 buckets and custom modules in Amazon S3 buckets.
  - **s3:PutObject permission**: This is required to write compliance reports and compliance status to Amazon S3 buckets.
- If you're using tags, then ensure that the node has the required IAM policy. Using tags requires the instance IAM role to have a policy allowing the `ec2:DescribeInstances` and `ssm:ListTagsForResource` actions.
- Ensure that the node has the expected tags or SSM parameters assigned.
- Ensure that the tags or SSM parameters aren't misspelled.

- Try applying the MOF locally on the node to make sure there isn't an issue with the MOF file itself.

My MOF seemed to fail, but the Systems Manager execution was successful

If the `AWS-ApplyDSCMofs` document successfully ran, then the Systems Manager execution status shows **Success**. This status doesn't reflect the compliance status of your node against the configuration requirements in the MOF file. To view the compliance status of your nodes, view the compliance reports. You can view a JSON report in the Amazon S3 Report Bucket. This applies to Run Command and State Manager executions. Also, for State Manager, you can view compliance details on the Systems Manager Compliance page.

Stderr states: Name resolution failure attempting to reach service

This error indicates that the script can't reach a remote service. Most likely, the script can't reach Amazon S3. This issue most often occurs when the script attempts to write compliance reports or compliance status to the Amazon S3 bucket supplied in the document parameters. Typically, this error occurs when a computing environment uses a firewall or transparent proxy that includes an allow list. To resolve this issue:

- Use Region-specific bucket syntax for all Amazon S3 bucket parameters. For example, the **Mofs to Apply** parameter should be formatted as follows:

  s3:*bucket-region*:*amzn-s3-demo-bucket*:*mof-file-name*.mof.

  Here is an example: `s3:us-west-2:amzn-s3-demo-bucket:my-mof.mof`

  The Report, Status, and Module Source bucket names should be formatted as follows.

  bucket-region:*amzn-s3-demo-bucket*. Here is an example: `us-west-1:amzn-s3-demo-bucket;`
- If Region-specific syntax doesn't fix the problem, then make sure that the targeted nodes can access Amazon S3 in the desired Region. To verify this:
  1. Find the endpoint name for Amazon S3 in the appropriate Amazon S3 Region. For information, see Amazon S3 Service Endpoints in the *Amazon Web Services General Reference*.
  2. Log on to the target node and run the following ping command.

     ```
     ping s3.s3-region.amazonaws.com
     ```

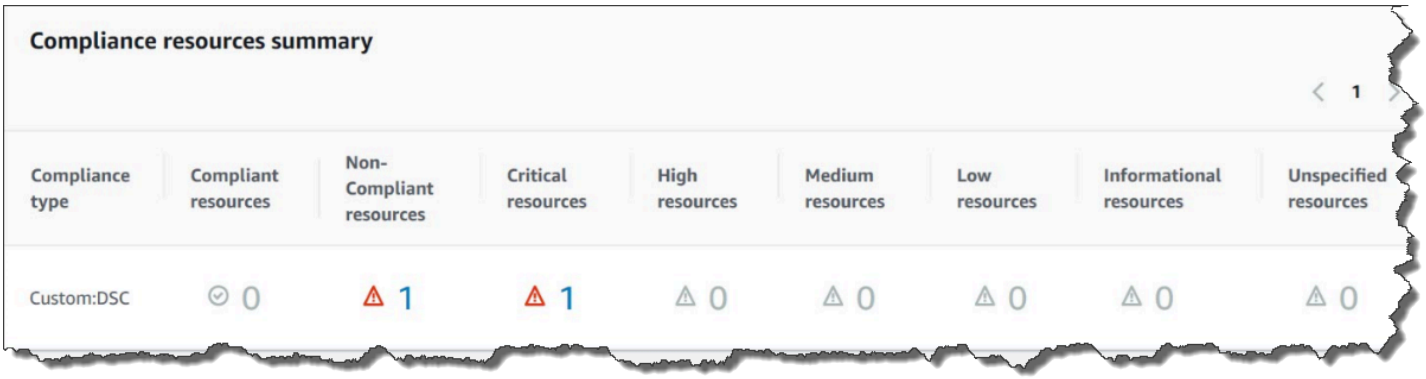
If the ping failed, it means that either Amazon S3 is down, or a firewall/transparent proxy is blocking access to the Amazon S3 Region, or the node can't access the internet.

Viewing DSC resource compliance details

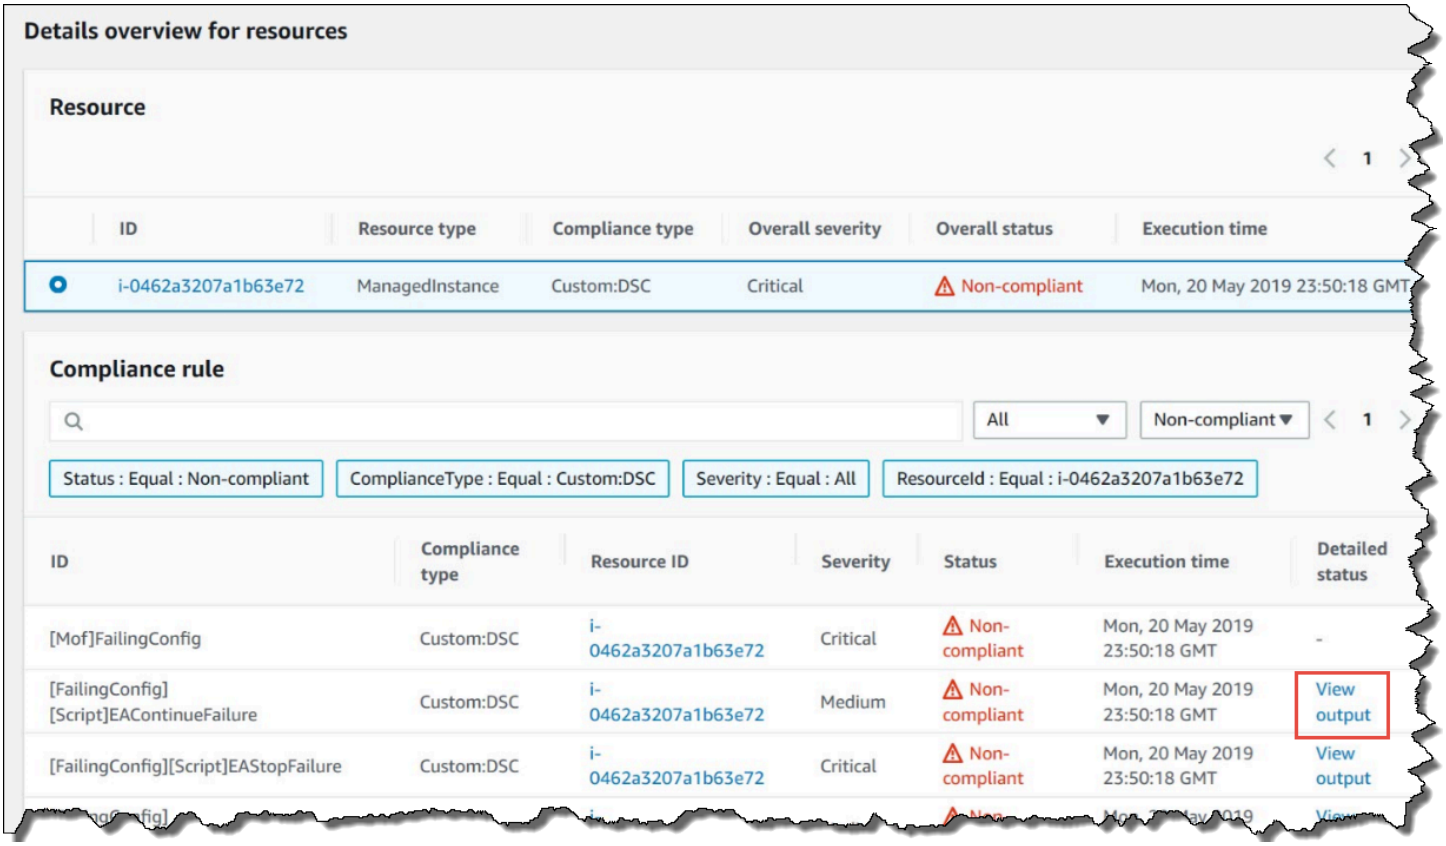
Systems Manager captures compliance information about DSC resource failures in the Amazon S3 **Status Bucket** you specified when you ran the `AWS-ApplyDSCMofs` document. Searching for information about DSC resource failures in an Amazon S3 bucket can be time consuming. Instead, you can view this information in the Systems Manager **Compliance** page.

The **Compliance resources summary** section displays a count of resources that failed. In the following example, the **ComplianceType** is **Custom:DSC** and one resource is noncompliant.

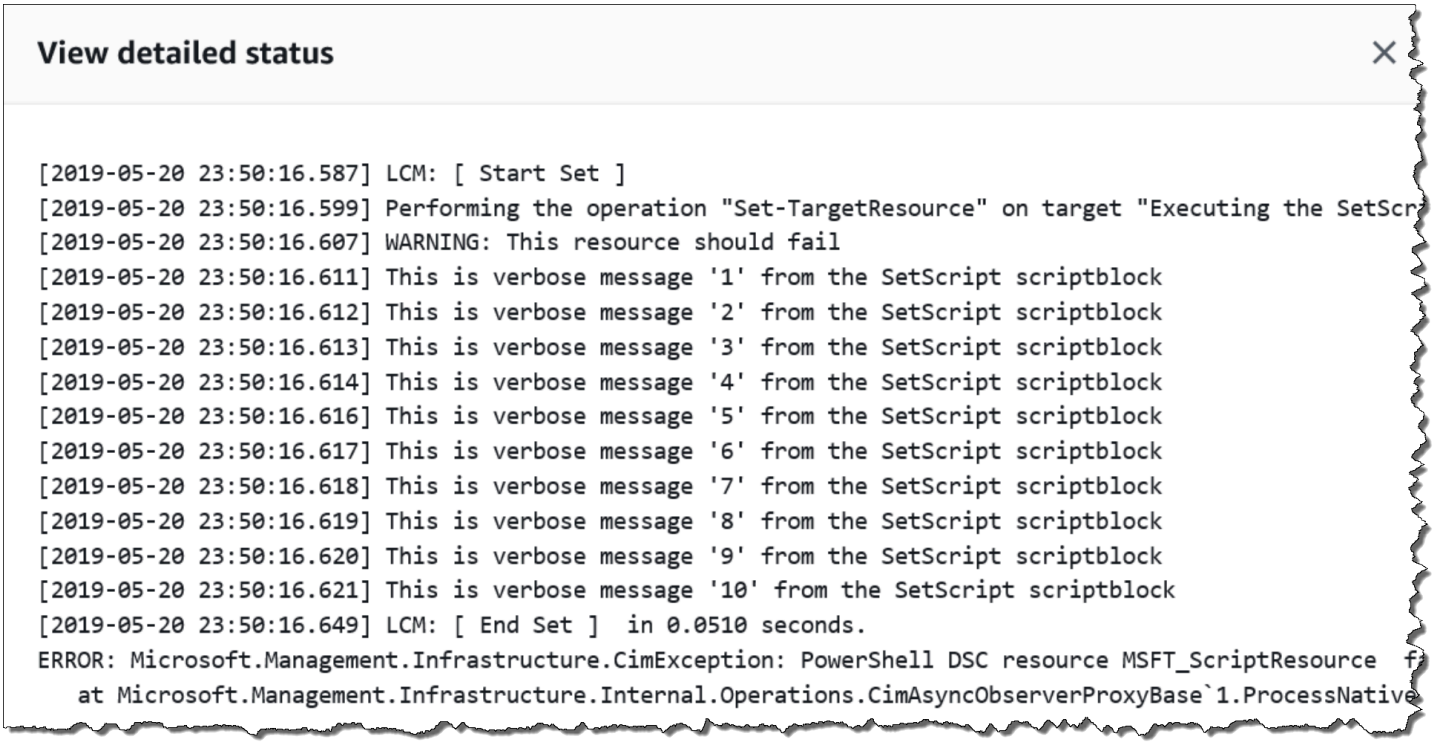
> **Note**
>
> Custom:DSC is the default **ComplianceType** value in the `AWS-ApplyDSCMofs` document. This value is customizable.



The **Details overview for resources** section displays information about the AWS resource with the noncompliant DSC resource. This section also includes the MOF name, script execution steps, and (when applicable) a **View output** link to view detailed status information.



The **View output** link displays the last 4,000 characters of the detailed status. Systems Manager starts with the exception as the first element, and then scans back through the verbose messages and prepends as many as it can until it reaches the 4,000 character quota. This process displays the log messages that were output before the exception was thrown, which are the most relevant messages for troubleshooting.



For information about how to view compliance information, see AWS Systems Manager Compliance.

Situations that affect compliance reporting

If the State Manager association fails, then no compliance data is reported. More specifically, if a MOF fails to process, then Systems Manager doesn't report any compliance items because the associations fails. For example, if Systems Manager attempts to download a MOF from an Amazon S3 bucket that the node doesn't have permission to access, then the association fails and no compliance data is reported.

If a resource in a second MOF fails, then Systems Manager *does* report compliance data. For example, if a MOF tries to create a file on a drive that doesn't exist, then Systems Manager reports compliance because the `AWS-ApplyDSCMofs` document is able to process completely, which means the association successfully runs.

Creating associations that run Ansible playbooks

You can create State Manager associations that run Ansible playbooks by using the `AWS-ApplyAnsiblePlaybooks` SSM document. State Manager is a tool in AWS Systems Manager. This document offers the following benefits for running playbooks:

- Support for running complex playbooks
- Support for downloading playbooks from GitHub and Amazon Simple Storage Service (Amazon S3)
- Support for compressed playbook structure
- Enhanced logging
- Ability to specify which playbook to run when playbooks are bundled

> **Note**
>
> Systems Manager includes two SSM documents that allow you to create State Manager associations that run Ansible playbooks: `AWS-RunAnsiblePlaybook` and `AWS-ApplyAnsiblePlaybooks`. The `AWS-RunAnsiblePlaybook` document is deprecated. It remains available in Systems Manager for legacy purposes. We recommend that you use the `AWS-ApplyAnsiblePlaybooks` document because of the enhancements described here.
>
> Associations that run Ansible playbooks aren't supported on macOS.

Support for running complex playbooks

The `AWS-ApplyAnsiblePlaybooks` document supports bundled, complex playbooks because it copies the entire file structure to a local directory before executing the specified main playbook. You can provide source playbooks in Zip files or in a directory structure. The Zip file or directory can be stored in GitHub or Amazon S3.

Support for downloading playbooks from GitHub

The `AWS-ApplyAnsiblePlaybooks` document uses the `aws:downloadContent` plugin to download playbook files. Files can be stored in GitHub in a single file or as a combined set of playbook files. To download content from GitHub, specify information about your GitHub repository in JSON format. Here is an example.

```
{
   "owner":"TestUser",
   "repository":"GitHubTest",
   "path":"scripts/python/test-script",
   "getOptions":"branch:master",
   "tokenInfo":"{{ssm-secure:secure-string-token}}"
```

```
}
```

Support for downloading playbooks from Amazon S3

You can also store and download Ansible playbooks in Amazon S3 as either a single .zip file or a directory structure. To download content from Amazon S3, specify the path to the file. Here are two examples.

Example 1: Download a specific playbook file

```
{
   "path":"https://s3.amazonaws.com/amzn-s3-demo-bucket/playbook.yml"
}
```

Example 2: Download the contents of a directory

```
{
   "path":"https://s3.amazonaws.com/amzn-s3-demo-bucket/ansible/webservers/"
}
```

> **Important**
>
> If you specify Amazon S3, then the AWS Identity and Access Management (IAM) instance profile on your managed nodes must include permissions for the S3 bucket. For more information, see Configure instance permissions required for Systems Manager.

Support for compressed playbook structure

The `AWS-ApplyAnsiblePlaybooks` document allows you to run compressed .zip files in the downloaded bundle. The document checks if the downloaded files contain a compressed file in .zip format. If a .zip is found, the document automatically decompresses the file and then runs the specified Ansible automation.

Enhanced logging

The `AWS-ApplyAnsiblePlaybooks` document includes an optional parameter for specifying different levels of logging. Specify -v for low verbosity, -vv or –vvv for medium verbosity, and -vvvv for debug level logging. These options directly map to Ansible verbosity options.

Ability to specify which playbook to run when playbooks are bundled

The `AWS-ApplyAnsiblePlaybooks` document includes a required parameter for specifying which playbook to run when multiple playbooks are bundled. This option provides flexibility for running playbooks to support different use cases.

Understanding installed dependencies

If you specify **True** for the **InstallDependencies** parameter, then Systems Manager verifies that your nodes have the following dependencies installed:

- **Ubuntu Server/Debian Server**: Apt-get (Package Management), Python 3, Ansible, Unzip
- **Amazon Linux** supported versions: Ansible
- **RHEL**: Python 3, Ansible, Unzip

If one or more of these dependencies aren't found, then Systems Manager automatically installs them.

Create an association that runs Ansible playbooks (console)

The following procedure describes how to use the Systems Manager console to create a State Manager association that runs Ansible playbooks by using the `AWS-ApplyAnsiblePlaybooks` document.

To create an association that runs Ansible playbooks (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Choose **State Manager**, and then choose **Create association**.
4. For **Name**, specify a name that helps you remember the purpose of the association.
5. In the **Document** list, choose **`AWS-ApplyAnsiblePlaybooks`**.
6. In the **Parameters** section, for **Source Type**, choose either **GitHub** or **S3**.

   GitHub

   If you choose **GitHub**, enter repository information in the following format.

   ```
   {
   ```

```
   "owner":"user_name",
   "repository":"name",
   "path":"path_to_directory_or_playbook_to_download",
   "getOptions":"branch:branch_name",
   "tokenInfo":"{{(Optional)_token_information}}"
}
```

S3

If you choose **S3**, enter path information in the following format.

```
{
   "path":"https://s3.amazonaws.com/path_to_directory_or_playbook_to_download"
}
```

7. For **Install Dependencies**, choose an option.
8. (Optional) For **Playbook File**, enter a file name. If a Zip file contains the playbook, specify a relative path to the Zip file.
9. (Optional) For **Extra Variables**, enter variables that you want State Manager to send to Ansible at runtime.
10. (Optional) For **Check**, choose an option.
11. (Optional) For **Verbose**, choose an option.
12. For **Targets**, choose an option. For information about using targets, see Understanding targets and rate controls in State Manager associations.
13. In the **Specify schedule** section, choose either **On schedule** or **No schedule**. If you choose **On schedule**, then use the buttons provided to create a cron or rate schedule for the association.
14. In the **Advanced options** section, for **Compliance severity**, choose a severity level for the association. Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you indicate here. For more information, see About State Manager association compliance.
15. In the **Rate control** section, configure options to run State Manager associations across a fleet of managed nodes. For information about using rate controls, see Understanding targets and rate controls in State Manager associations.

    In the **Concurrency** section, choose an option:

    - Choose **targets** to enter an absolute number of targets that can run the association simultaneously.

- Choose **percentage** to enter a percentage of the target set that can run the association simultaneously.

In the **Error threshold** section, choose an option:

- Choose **errors** to enter an absolute number of errors that are allowed before State Manager stops running associations on additional targets.
- Choose **percentage** to enter a percentage of errors that are allowed before State Manager stops running associations on additional targets.

16. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

17. Choose **Create Association**.

> **Note**
>
> If you use tags to create an association on one or more target nodes, and then you remove the tags from a node, that node no longer runs the association. The node is disassociated from the State Manager document.

Create an association that runs Ansible playbooks (CLI)

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) to create a State Manager association that runs Ansible playbooks by using the `AWS-ApplyAnsiblePlaybooks` document.

To create an association that runs Ansible playbooks (CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Run one of the following commands to create an association that runs Ansible playbooks by targeting nodes using tags. Replace each *example resource placeholder* with your own information. Command (A) specifies GitHub as the source type. Command (B) specifies Amazon S3 as the source type.

   (A) GitHub source

   Linux & macOS

```
aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" \
    --targets Key=tag:TagKey,Values=TagValue \
    --parameters '{"SourceType":["GitHub"],"SourceInfo":
["{\"owner\":\"owner_name\", \"repository\": \"name\",
 \"getOptions\": \"branch:master\"}"],"InstallDependencies":
["True_or_False"],"PlaybookFile":["file_name.yml"],"ExtraVariables":["key/
value_pairs_separated_by_a_space"],"Check":["True_or_False"],"Verbose":["-v,-
vv,-vvv, or -vvvv"],"TimeoutSeconds":["3600"]}' \
    --association-name "name" \
    --schedule-expression "cron_or_rate_expression"
```

   Windows

```
aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" ^
    --targets Key=tag:TagKey,Values=TagValue ^
    --parameters '{"SourceType":["GitHub"],"SourceInfo":
["{\"owner\":\"owner_name\", \"repository\": \"name\",
 \"getOptions\": \"branch:master\"}"],"InstallDependencies":
["True_or_False"],"PlaybookFile":["file_name.yml"],"ExtraVariables":["key/
value_pairs_separated_by_a_space"],"Check":["True_or_False"],"Verbose":["-v,-
vv,-vvv, or -vvvv"], "TimeoutSeconds":["3600"]}' ^
    --association-name "name" ^
    --schedule-expression "cron_or_rate_expression"
```

   Here is an example.

```
aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" \
    --targets "Key=tag:OS,Values=Linux" \
    --parameters '{"SourceType":["GitHub"],"SourceInfo":["{\"owner\":
\"ansibleDocumentTest\", \"repository\": \"Ansible\", \"getOptions\":
 \"branch:master\"}"],"InstallDependencies":["True"],"PlaybookFile":["hello-world-
playbook.yml"],"ExtraVariables":["SSM=True"],"Check":["False"],"Verbose":["-v"]}' \
    --association-name "AnsibleAssociation" \
    --schedule-expression "cron(0 2 ? * SUN *)"
```

(B) S3 source

Linux & macOS

```
aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" \
    --targets Key=tag:TagKey,Values=TagValue \
    --parameters '{"SourceType":["S3"],"SourceInfo":["{\"path\":\"https://
s3.amazonaws.com/
path_to_Zip_file,_directory,_or_playbook_to_download\"}"],"InstallDependencies":
["True_or_False"],"PlaybookFile":["file_name.yml"],"ExtraVariables":["key/
value_pairs_separated_by_a_space"],"Check":["True_or_False"],"Verbose":["-v,-
vv,-vvv, or -vvvv"]}' \
    --association-name "name" \
    --schedule-expression "cron_or_rate_expression"
```

Windows

```
aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" ^
    --targets Key=tag:TagKey,Values=TagValue ^
    --parameters '{"SourceType":["S3"],"SourceInfo":["{\"path\":\"https://
s3.amazonaws.com/
path_to_Zip_file,_directory,_or_playbook_to_download\"}"],"InstallDependencies":
["True_or_False"],"PlaybookFile":["file_name.yml"],"ExtraVariables":["key/
value_pairs_separated_by_a_space"],"Check":["True_or_False"],"Verbose":["-v,-
vv,-vvv, or -vvvv"]}' ^
    --association-name "name" ^
    --schedule-expression "cron_or_rate_expression"
```

Here is an example.

```
aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" \
```

```
    --targets "Key=tag:OS,Values=Linux" \
    --parameters '{"SourceType":["S3"],"SourceInfo":["{\"path\":\"https://
s3.amazonaws.com/amzn-s3-demo-bucket/playbook.yml\"}"],"InstallDependencies":
["True"],"PlaybookFile":["playbook.yml"],"ExtraVariables":["SSM=True"],"Check":
["False"],"Verbose":["-v"]}' \
    --association-name "AnsibleAssociation" \
    --schedule-expression "cron(0 2 ? * SUN *)"
```

> **Note**
>
> State Manager associations don't support all cron and rate expressions. For more information about creating cron and rate expressions for associations, see Reference: Cron and rate expressions for Systems Manager.

The system attempts to create the association on the nodes and immediately apply the state.

3. Run the following command to view an updated status of the association you just created.

```
aws ssm describe-association --association-id "ID"
```

Creating associations that run Chef recipes

You can create State Manager associations that run Chef recipes by using the `AWS-ApplyChefRecipes` SSM document. State Manager is a tool in AWS Systems Manager. You can target Linux-based Systems Manager managed nodes with the `AWS-ApplyChefRecipes` SSM document. This document offers the following benefits for running Chef recipes:

- Supports multiple releases of Chef (Chef 11 through Chef 18).
- Automatically installs the Chef client software on target nodes.
- Optionally runs Systems Manager compliance checks on target nodes, and stores the results of compliance checks in an Amazon Simple Storage Service (Amazon S3) bucket.
- Runs multiple cookbooks and recipes in a single run of the document.
- Optionally runs recipes in `why-run` mode, to show which recipes change on target nodes without making changes.
- Optionally applies custom JSON attributes to `chef-client` runs.

- Optionally applies custom JSON attributes from a source file that is stored at a location that you specify.

You can use Git, GitHub, HTTP, or Amazon S3 buckets as download sources for Chef cookbooks and recipes that you specify in an `AWS-ApplyChefRecipes` document.

> **Note**
>
> Associations that run Chef recipes aren't supported on macOS.

Getting started

Before you create an `AWS-ApplyChefRecipes` document, prepare your Chef cookbooks and cookbook repository. If you don't already have a Chef cookbook that you want to use, you can get started by using a test `HelloWorld` cookbook that AWS has prepared for you. The `AWS-ApplyChefRecipes` document already points to this cookbook by default. Your cookbooks should be set up similarly to the following directory structure. In the following example, `jenkins` and `nginx` are examples of Chef cookbooks that are available in the Chef Supermarket on the Chef website.

Though AWS can't officially support cookbooks on the Chef Supermarket website, many of them work with the `AWS-ApplyChefRecipes` document. The following are examples of criteria to determine when you're testing a community cookbook:

- The cookbook should support the Linux-based operating systems of the Systems Manager managed nodes that you're targeting.
- The cookbook should be valid for the Chef client version (Chef 11 through Chef 18) that you use.
- The cookbook is compatible with Chef Infra Client, and, doesn't require a Chef server.

Verify that you can reach the `Chef.io` website, so that any cookbooks you specify in your run list can be installed when the Systems Manager document (SSM document) runs. Using a nested `cookbooks` folder is supported, but not required; you can store cookbooks directly under the root level.

```
<Top-level directory, or the top level of the archive file (ZIP or tgz or tar.gz)>
    ### cookbooks (optional level)
```

```
        ### jenkins
        #   ### metadata.rb
        #   ### recipes
        ### nginx
            ### metadata.rb
            ### recipes
```

Important

Before you create a State Manager association that runs Chef recipes, be aware that the document run installs the Chef client software on your Systems Manager managed nodes, unless you set the value of **Chef client version** to None. This operation uses an installation script from Chef to install Chef components on your behalf. Before you run an `AWS-ApplyChefRecipes` document, be sure your enterprise can comply with any applicable legal requirements, including license terms applicable to the use of Chef software. For more information, see the Chef website.

Systems Manager can deliver compliance reports to an S3 bucket, the Systems Manager console, or make compliance results available in response to Systems Manager API commands. To run Systems Manager compliance reports, the instance profile attached to Systems Manager managed nodes must have permissions to write to the S3 bucket. The instance profile must have permissions to use the Systems Manager `PutComplianceItem` API. For more information about Systems Manager compliance, see AWS Systems Manager Compliance.

Logging the document run

When you run a Systems Manager document (SSM document) by using a State Manager association, you can configure the association to choose the output of the document run, and you can send the output to Amazon S3 or Amazon CloudWatch Logs (CloudWatch Logs). To help ease troubleshooting when an association has finished running, verify that the association is configured to write command output to either an Amazon S3 bucket or CloudWatch Logs. For more information, see Working with associations in Systems Manager.

Applying JSON attributes to targets when running a recipe

You can specify JSON attributes for your Chef client to apply to target nodes during an association run. When setting up the association, you can provide raw JSON or provide the path to a JSON file stored in Amazon S3.

Use JSON attributes when you want to customize how the recipe is run without having to modify the recipe itself, for example:

- **Overriding a small number of attributes**

  Use custom JSON to avoid having to maintain multiple versions of a recipe to accommodate minor differences.

- **Providing variable values**

  Use custom JSON to specify values that may change from run-to-run. For example, if your Chef cookbooks configure a third-party application that accepts payments, you might use custom JSON to specify the payment endpoint URL.

Specifying attributes in raw JSON

The following is an example of the format you can use to specify custom JSON attributes for your Chef recipe.

```
{"filepath":"/tmp/example.txt", "content":"Hello, World!"}
```

Specifying a path to a JSON file

The following is an example of the format you can use to specify the path to custom JSON attributes for your Chef recipe.

```
{"sourceType":"s3", "sourceInfo":"someS3URL1"}, {"sourceType":"s3",
 "sourceInfo":"someS3URL2"}
```

Use Git as a cookbook source

The `AWS-ApplyChefRecipes` document uses the aws:downloadContent plugin to download Chef cookbooks. To download content from Git, specify information about your Git repository in JSON format as in the following example. Replace each *`example-resource-placeholder`* with your own information.

```
{
   "repository":"GitCookbookRepository",
   "privateSSHKey":"{{ssm-secure:ssh-key-secure-string-parameter}}",
   "skipHostKeyChecking":"false",
```

```
    "getOptions":"branch:refs/head/main",
    "username":"{{ssm-secure:username-secure-string-parameter}}",
    "password":"{{ssm-secure:password-secure-string-parameter}}"
}
```

Use GitHub as a cookbook source

The `AWS-ApplyChefRecipes` document uses the aws:downloadContent plugin to download cookbooks. To download content from GitHub, specify information about your GitHub repository in JSON format as in the following example. Replace each *example-resource-placeholder* with your own information.

```
{
    "owner":"TestUser",
    "repository":"GitHubCookbookRepository",
    "path":"cookbooks/HelloWorld",
    "getOptions":"branch:refs/head/main",
    "tokenInfo":"{{ssm-secure:token-secure-string-parameter}}"
}
```

Use HTTP as a cookbook source

You can store Chef cookbooks at a custom HTTP location as either a single `.zip` or `tar.gz` file, or a directory structure. To download content from HTTP, specify the path to the file or directory in JSON format as in the following example. Replace each *example-resource-placeholder* with your own information.

```
{
    "url":"https://my.website.com/chef-cookbooks/HelloWorld.zip",
    "allowInsecureDownload":"false",
    "authMethod":"Basic",
    "username":"{{ssm-secure:username-secure-string-parameter}}",
    "password":"{{ssm-secure:password-secure-string-parameter}}"
}
```

Use Amazon S3 as a cookbook source

You can also store and download Chef cookbooks in Amazon S3 as either a single `.zip` or `tar.gz` file, or a directory structure. To download content from Amazon S3, specify the path to the file in JSON format as in the following examples. Replace each *example-resource-placeholder* with your own information.

Example 1: Download a specific cookbook

```
{
   "path":"https://s3.amazonaws.com/chef-cookbooks/HelloWorld.zip"
}
```

Example 2: Download the contents of a directory

```
{
   "path":"https://s3.amazonaws.com/chef-cookbooks-test/HelloWorld"
}
```

> **Important**
>
> If you specify Amazon S3, the AWS Identity and Access Management (IAM) instance profile on your managed nodes must be configured with the `AmazonS3ReadOnlyAccess` policy. For more information, see Configure instance permissions required for Systems Manager.

Create an association that runs Chef recipes (console)

The following procedure describes how to use the Systems Manager console to create a State Manager association that runs Chef cookbooks by using the `AWS-ApplyChefRecipes` document.

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Choose **State Manager**, and then choose **Create association**.
4. For **Name**, enter a name that helps you remember the purpose of the association.
5. In the **Document** list, choose **`AWS-ApplyChefRecipes`**.
6. In **Parameters**, for **Source Type**, select either **Git**, **GitHub**, **HTTP**, or **S3**.
7. For **Source info**, enter cookbook source information using the appropriate format for the **Source Type** that you selected in step 6. For more information, see the following topics:
   - the section called “Use Git as a cookbook source”
   - the section called “Use GitHub as a cookbook source”

- the section called “Use HTTP as a cookbook source”
- the section called “Use Amazon S3 as a cookbook source”

8. In **Run list**, list the recipes that you want to run in the following format, separating each recipe with a comma as shown. Don't include a space after the comma. Replace each *example-resource-placeholder* with your own information.

```
recipe[cookbook-name1::recipe-name],recipe[cookbook-name2::recipe-name]
```

9. (Optional) Specify custom JSON attributes that you want the Chef client to pass to your target nodes.

   a. In **JSON attributes content**, add any attributes that you want the Chef client to pass to your target nodes.

   b. In **JSON attributes sources**, add the paths to any attributes that you want the Chef client to pass to your target nodes.

   For more information, see the section called “Applying JSON attributes to targets when running a recipe”.

10. For **Chef client version**, specify a Chef version. Valid values are 11 through 18, or None. If you specify a number between 11 18 (inclusive), Systems Manager installs the correct Chef client version on your target nodes. If you specify None, Systems Manager doesn't install the Chef client on target nodes before running the document's recipes.

11. (Optional) For **Chef client arguments**, specify additional arguments that are supported for the version of Chef you're using. To learn more about supported arguments, run `chef-client -h` on a node that is running the Chef client.

12. (Optional) Turn on **Why-run** to show changes made to target nodes if the recipes are run, without actually changing target nodes.

13. For **Compliance severity**, choose the severity of Systems Manager Compliance results that you want reported. Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you specify. Compliance reports are stored in an S3 bucket that you specify as the value of the **Compliance report bucket** parameter (step 14). For more information about Compliance, see Learn details about Compliance in this guide.

    Compliance scans measure drift between configuration that is specified in your Chef recipes and node resources. Valid values are `Critical`, `High`, `Medium`, `Low`, `Informational`, `Unspecified`, or None. To skip compliance reporting, choose None.

14. For **Compliance type**, specify the compliance type for which you want results reported. Valid values are `Association` for State Manager associations, or `Custom:`*`custom-type`*. The default value is `Custom:Chef`.
15. For **Compliance report bucket**, enter the name of an S3 bucket in which to store information about every Chef run performed by this document, including resource configuration and Compliance results.
16. In **Rate control**, configure options to run State Manager associations across a fleet of managed nodes. For information about using rate controls, see Understanding targets and rate controls in State Manager associations.

    In **Concurrency**, choose an option:

    - Choose **targets** to enter an absolute number of targets that can run the association simultaneously.
    - Choose **percentage** to enter a percentage of the target set that can run the association simultaneously.

    In **Error threshold**, choose an option:

    - Choose **errors** to enter an absolute number of errors that are allowed before State Manager stops running associations on additional targets.
    - Choose **percentage** to enter a percentage of errors that are allowed before State Manager stops running associations on additional targets.
17. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

    > **Note**
    >
    > The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.
18. Choose **Create Association**.

Create an association that runs Chef recipes (CLI)

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) to create a State Manager association that runs Chef cookbooks by using the `AWS-ApplyChefRecipes` document.

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Run one of the following commands to create an association that runs Chef cookbooks on target nodes that have the specified tags. Use the command that is appropriate for your cookbook source type and operating system. Replace each *example-resource-placeholder* with your own information.

   a. **Git source**

   Linux & macOS

```
aws ssm create-association --name "AWS-ApplyChefRecipes" \
    --targets Key=tag:TagKey,Values=TagValue \
    --parameters '{"SourceType":["Git"],"SourceInfo":["{\"repository\":
\"repository-name\", \"getOptions\": \"branch:branch-name\", \"username
\": \"{{ ssm-secure:username-secure-string-parameter }}\", \"password\":
 \"{{ ssm-secure:password-secure-string-parameter }}\"}"], "RunList":
["{\"recipe[cookbook-name-1::recipe-name]\", \"recipe[cookbook-
name-2::recipe-name]\"}"], "JsonAttributesContent": ["{custom-json-
content}"], "JsonAttributesSources": "{\"sourceType\":\"s3\", \"sourceInfo
\":\"s3-bucket-endpoint-1\"}, {\"sourceType\":\"s3\", \"sourceInfo\":
\"s3-bucket-endpoint-2\"}", "ChefClientVersion": ["version-number"],
 "ChefClientArguments":["{chef-client-arguments}"], "WhyRun": boolean,
 "ComplianceSeverity": ["severity-value"], "ComplianceType":
 ["Custom:Chef"], "ComplianceReportBucket": ["s3-bucket-name"]}' \
    --association-name "name" \
    --schedule-expression "cron-or-rate-expression"
```

   Windows

```
aws ssm create-association --name "AWS-ApplyChefRecipes" ^
    --targets Key=tag:TagKey,Values=TagValue ^
    --parameters '{"SourceType":["Git"],"SourceInfo":["{\"repository\":
\"repository-name\", \"getOptions\": \"branch:branch-name\", \"username
```

```
\": \"{{ ssm-secure:username-secure-string-parameter }}\", \"password\":
 \"{{ ssm-secure:password-secure-string-parameter }}\"}"], "RunList":
["{\"recipe[cookbook-name-1::recipe-name]\", \"recipe[cookbook-
name-2::recipe-name]\"}"], "JsonAttributesContent": ["{custom-json}"],
 "JsonAttributesSources": "{\"sourceType\":\"s3\", \"sourceInfo\":
\"s3-bucket-endpoint-1\"}, {\"sourceType\":\"s3\", \"sourceInfo\":
\"s3-bucket-endpoint-2\"}", "ChefClientVersion": ["version-number"],
 "ChefClientArguments":["{chef-client-arguments}"], "WhyRun": boolean,
 "ComplianceSeverity": ["severity-value"], "ComplianceType":
 ["Custom:Chef"], "ComplianceReportBucket": ["s3-bucket-name"]}' ^
    --association-name "name" ^
    --schedule-expression "cron-or-rate-expression"
```

b. **GitHub source**

Linux & macOS

```
aws ssm create-association --name "AWS-ApplyChefRecipes" \
    --targets Key=tag:TagKey,Values=TagValue \
    --parameters '{"SourceType":["GitHub"],"SourceInfo":["{\"owner\":
\"owner-name\", \"repository\": \"name\", \"path\": \"path-to-directory-
or-cookbook-to-download\", \"getOptions\": \"branch:branch-name\"}"],
 "RunList":["{\"recipe[cookbook-name-1::recipe-name]\", \"recipe[cookbook-
name-2::recipe-name]\"}"], "JsonAttributesContent": ["{custom-json}"],
 "ChefClientVersion": ["version-number"], "ChefClientArguments":["{chef-
client-arguments}"], "WhyRun": boolean, "ComplianceSeverity": ["severity-
value"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": ["s3-
bucket-name"]}' \
    --association-name "name" \
    --schedule-expression "cron-or-rate-expression"
```

Windows

```
aws ssm create-association --name "AWS-ApplyChefRecipes" ^
    --targets Key=tag:TagKey,Values=TagValue \
    --parameters '{"SourceType":["GitHub"],"SourceInfo":["{\"owner\":
\"owner-name\", \"repository\": \"name\", \"path\": \"path-to-directory-
or-cookbook-to-download\", \"getOptions\": \"branch:branch-name\"}"],
 "RunList":["{\"recipe[cookbook-name-1::recipe-name]\", \"recipe[cookbook-
name-2::recipe-name]\"}"], "JsonAttributesContent": ["{custom-json}"],
 "ChefClientVersion": ["version-number"], "ChefClientArguments":["{chef-
client-arguments}"], "WhyRun": boolean, "ComplianceSeverity": ["severity-
```

```
value"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": ["s3-
bucket-name"]}' ^
    --association-name "name" ^
    --schedule-expression "cron-or-rate-expression"
```

Here is an example.

Linux & macOS

```
aws ssm create-association --name "AWS-ApplyChefRecipes" \
    --targets Key=tag:OS,Values=Linux \
    --parameters '{"SourceType":["GitHub"],"SourceInfo":["{\"owner
\":\"ChefRecipeTest\", \"repository\": \"ChefCookbooks\", \"path
\": \"cookbooks/HelloWorld\", \"getOptions\": \"branch:master
\"}"], "RunList":["{\"recipe[HelloWorld::HelloWorldRecipe]\",
 \"recipe[HelloWorld::InstallApp]\"}"], "JsonAttributesContent":
 ["{\"state\": \"visible\",\"colors\": {\"foreground\": \"light-blue
\",\"background\": \"dark-gray\"}}"], "ChefClientVersion": ["14"],
 "ChefClientArguments":["{--fips}"], "WhyRun": false, "ComplianceSeverity":
 ["Medium"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket":
 ["ChefComplianceResultsBucket"]}' \
    --association-name "MyChefAssociation" \
    --schedule-expression "cron(0 2 ? * SUN *)"
```

Windows

```
aws ssm create-association --name "AWS-ApplyChefRecipes" ^
    --targets Key=tag:OS,Values=Linux ^
    --parameters '{"SourceType":["GitHub"],"SourceInfo":["{\"owner
\":\"ChefRecipeTest\", \"repository\": \"ChefCookbooks\", \"path
\": \"cookbooks/HelloWorld\", \"getOptions\": \"branch:master
\"}"], "RunList":["{\"recipe[HelloWorld::HelloWorldRecipe]\",
 \"recipe[HelloWorld::InstallApp]\"}"], "JsonAttributesContent":
 ["{\"state\": \"visible\",\"colors\": {\"foreground\": \"light-blue
\",\"background\": \"dark-gray\"}}"], "ChefClientVersion": ["14"],
 "ChefClientArguments":["{--fips}"], "WhyRun": false, "ComplianceSeverity":
 ["Medium"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket":
 ["ChefComplianceResultsBucket"]}' ^
    --association-name "MyChefAssociation" ^
    --schedule-expression "cron(0 2 ? * SUN *)"
```

c. **HTTP source**

Linux & macOS

```
aws ssm create-association --name "AWS-ApplyChefRecipes" \
    --targets Key=tag:TagKey,Values=TagValue \
    --parameters '{"SourceType":["HTTP"],"SourceInfo":["{\"url\":\"url-
to-zip-file|directory|cookbook\", \"authMethod\": \"auth-method\",
 \"username\": \"{{ ssm-secure:username-secure-string-parameter }}\",
 \"password\": \"{{ ssm-secure:password-secure-string-parameter }}\"}"],
 "RunList":["{\"recipe[cookbook-name-1::recipe-name]\", \"recipe[cookbook-
name-2::recipe-name]\"}"], "JsonAttributesContent": ["{custom-json-
content}"], "JsonAttributesSources": "{\"sourceType\":\"s3\", \"sourceInfo
\":\"s3-bucket-endpoint-1\"}, {\"sourceType\":\"s3\", \"sourceInfo\":
\"s3-bucket-endpoint-2\"}", "ChefClientVersion": ["version-number"],
 "ChefClientArguments":["{chef-client-arguments}"], "WhyRun": boolean,

```

d. **Amazon S3 source**

Linux & macOS

```
aws ssm create-association --name "AWS-ApplyChefRecipes" \
    --targets Key=tag:TagKey,Values=TagValue \
    --parameters '{"SourceType":["S3"],"SourceInfo":["{\"path\":\"https://
s3.amazonaws.com/path_to_Zip_file,_directory,_or_cookbook_to_download\"}"],
 "RunList":["{\"recipe[cookbook_name1::recipe_name]\",
 \"recipe[cookbook_name2::recipe_name]\"}"], "JsonAttributesContent":
 ["{Custom_JSON}"], "ChefClientVersion": ["version_number"],
 "ChefClientArguments":["{chef_client_arguments}"], "WhyRun": true_or_false,
 "ComplianceSeverity": ["severity_value"], "ComplianceType":
 ["Custom:Chef"], "ComplianceReportBucket": ["amzn-s3-demo-bucket"]}' \
    --association-name "name" \
    --schedule-expression "cron_or_rate_expression"
```

Windows

```
aws ssm create-association --name "AWS-ApplyChefRecipes" ^
    --targets Key=tag:TagKey,Values=TagValue ^
    --parameters '{"SourceType":["S3"],"SourceInfo":["{\"path\":\"https://
s3.amazonaws.com/path_to_Zip_file,_directory,_or_cookbook_to_download\"}"],
 "RunList":["{\"recipe[cookbook_name1::recipe_name]\",
 \"recipe[cookbook_name2::recipe_name]\"}"], "JsonAttributesContent":
 ["{Custom_JSON}"], "ChefClientVersion": ["version_number"],
 "ChefClientArguments":["{chef_client_arguments}"], "WhyRun": true_or_false,
 "ComplianceSeverity": ["severity_value"], "ComplianceType":
 ["Custom:Chef"], "ComplianceReportBucket": ["amzn-s3-demo-bucket"]}' ^
    --association-name "name" ^
    --schedule-expression "cron_or_rate_expression"
```

Here is an example.

Linux & macOS

```
aws ssm create-association --name "AWS-ApplyChefRecipes" \
    --targets "Key=tag:OS,Values= Linux" \
    --parameters '{"SourceType":["S3"],"SourceInfo":["{\"path
\":\"https://s3.amazonaws.com/amzn-s3-demo-bucket/HelloWorld
\"}"], "RunList":["{\"recipe[HelloWorld::HelloWorldRecipe]\",
 \"recipe[HelloWorld::InstallApp]\"}"], "JsonAttributesContent":
```

```
 ["{\"state\": \"visible\",\"colors\": {\"foreground\": \"light-blue
\",\"background\": \"dark-gray\"}}"], "ChefClientVersion": ["14"],
 "ChefClientArguments":["{--fips}"], "WhyRun": false, "ComplianceSeverity":
 ["Medium"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket":
 ["ChefComplianceResultsBucket"]}' \
    --association-name "name" \
    --schedule-expression "cron(0 2 ? * SUN *)"
```

Windows

```
aws ssm create-association --name "AWS-ApplyChefRecipes" ^
    --targets "Key=tag:OS,Values= Linux" ^
    --parameters '{"SourceType":["S3"],"SourceInfo":["{\"path
\":\"https://s3.amazonaws.com/amzn-s3-demo-bucket/HelloWorld
\"}"], "RunList":["{\"recipe[HelloWorld::HelloWorldRecipe]\",
 \"recipe[HelloWorld::InstallApp]\"}"], "JsonAttributesContent":
 ["{\"state\": \"visible\",\"colors\": {\"foreground\": \"light-blue
\",\"background\": \"dark-gray\"}}"], "ChefClientVersion": ["14"],
 "ChefClientArguments":["{--fips}"], "WhyRun": false, "ComplianceSeverity":
 ["Medium"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket":
 ["ChefComplianceResultsBucket"]}' ^
    --association-name "name" ^
    --schedule-expression "cron(0 2 ? * SUN *)"
```

The system creates the association, and unless your specified cron or rate expression prevents it, the system runs the association on the target nodes.

> **Note**
>
> State Manager associations don't support all cron and rate expressions. For more information about creating cron and rate expressions for associations, see Reference: Cron and rate expressions for Systems Manager.

3. Run the following command to view the status of the association you just created.

```
aws ssm describe-association --association-id "ID"
```

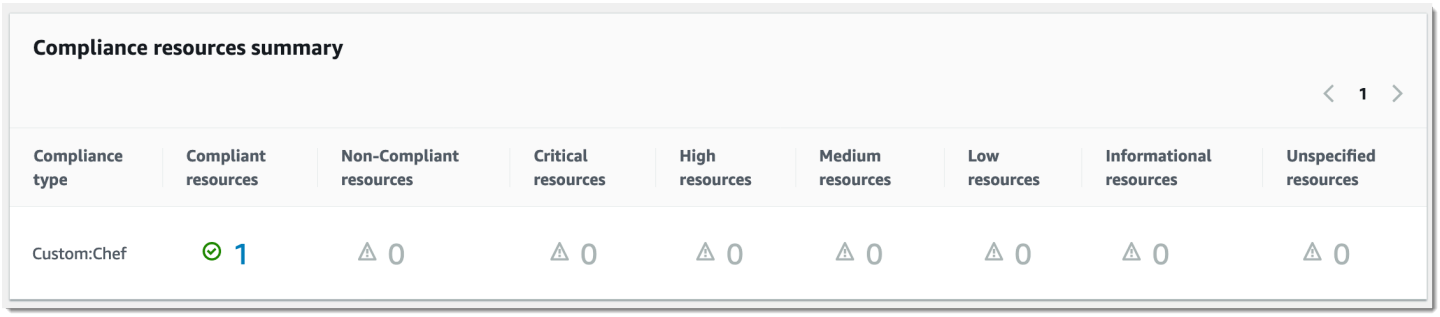
Viewing Chef resource compliance details

Systems Manager captures compliance information about Chef-managed resources in the Amazon S3 **Compliance report bucket** value that you specified when you ran the `AWS-ApplyChefRecipes` document. Searching for information about Chef resource failures in an S3 bucket can be time consuming. Instead, you can view this information on the Systems Manager **Compliance** page.

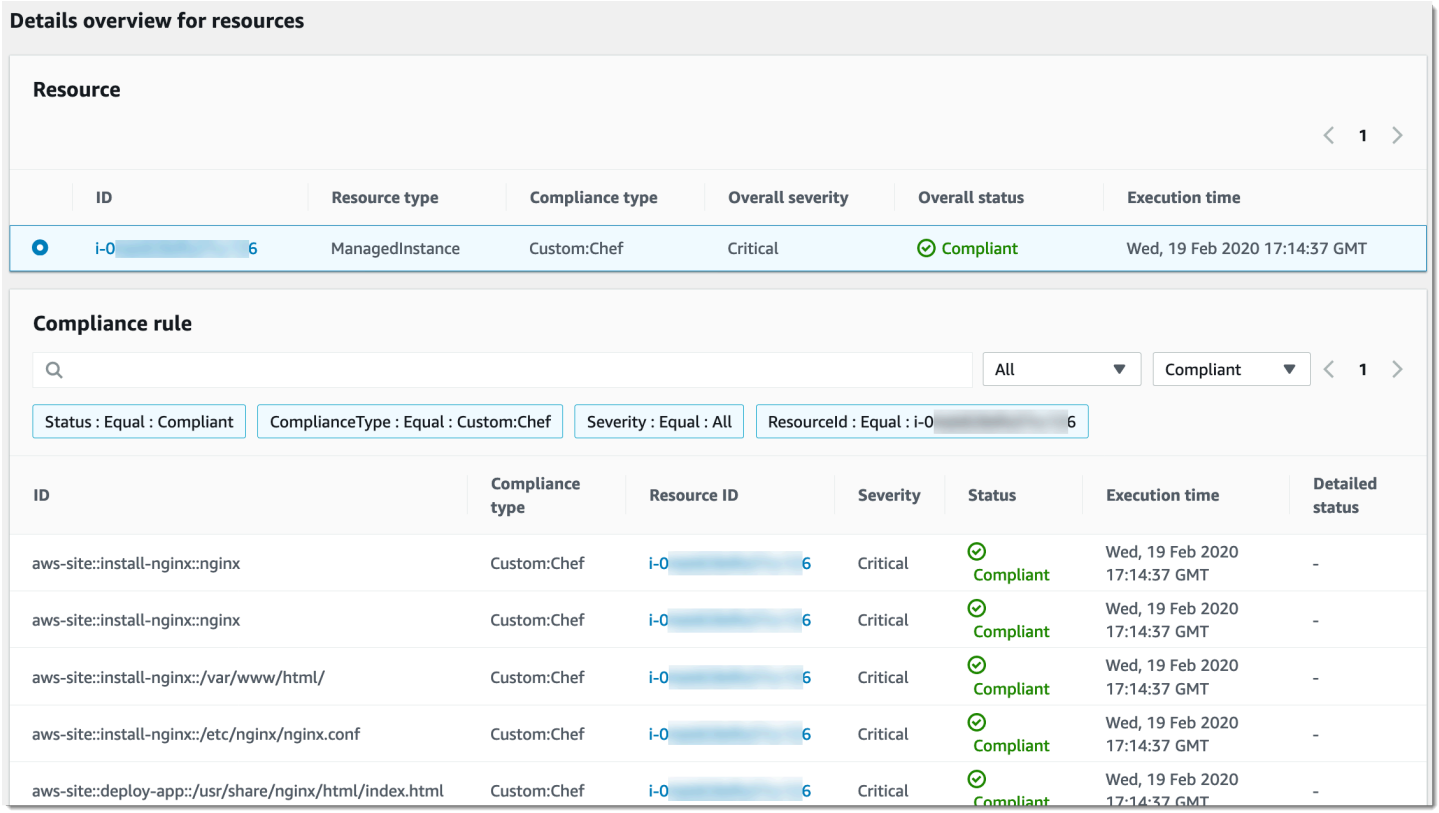
A Systems Manager Compliance scan collects information about resources on your managed nodes that were created or checked in the most recent Chef run. The resources can include files, directories, `systemd` services, `yum` packages, templated files, `gem` packages, and dependent cookbooks, among others.

The **Compliance resources summary** section displays a count of resources that failed. In the following example, the **ComplianceType** is **Custom:Chef** and one resource is noncompliant.

> **Note**
>
> `Custom:Chef` is the default **ComplianceType** value in the `AWS-ApplyChefRecipes` document. This value is customizable.



The **Details overview for resources** section shows information about the AWS resource that isn't in compliance. This section also includes the Chef resource type against which compliance was run, severity of issue, compliance status, and links to more information when applicable.



View output shows the last 4,000 characters of the detailed status. Systems Manager starts with the exception as the first element, finds verbose messages, and shows them until it reaches the 4,000 character quota. This process displays the log messages that were output before the exception was thrown, which are the most relevant messages for troubleshooting.

For information about how to view compliance information, see AWS Systems Manager Compliance.

> **Important**
>
> If the State Manager association fails, no compliance data is reported. For example, if Systems Manager attempts to download a Chef cookbook from an S3 bucket that the node doesn't have permission to access, the association fails, and Systems Manager reports no compliance data.

Walkthrough: Automatically update SSM Agent with the AWS CLI

The following procedure walks you through the process of creating a State Manager association using the AWS Command Line Interface. The association automatically updates the SSM Agent

according to a schedule that you specify. For more information about SSM Agent, see Working with SSM Agent. To customize the update schedule for SSM Agent using the console, see Automatically updating SSM Agent.

To be notified about SSM Agent updates, subscribe to the SSM Agent Release Notes page on GitHub.

Before you begin

Before you complete the following procedure, verify that you have at least one running Amazon Elastic Compute Cloud (Amazon EC2) instance for Linux, macOS, or Windows Server that is configured for Systems Manager. For more information, see Setting up managed nodes for AWS Systems Manager.

If you create an association by using either the AWS CLI or AWS Tools for Windows PowerShell, use the `--Targets` parameter to target instances, as shown in the following example. Don't use the `--InstanceID` parameter. The `--InstanceID` parameter is a legacy parameter.

To create an association for automatically updating SSM Agent

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command to create an association by targeting instances using Amazon Elastic Compute Cloud (Amazon EC2) tags. Replace each *example resource placeholder* with your own information. The `Schedule` parameter sets a schedule to run the association every Sunday morning at 2:00 a.m. (UTC).

   State Manager associations don't support all cron and rate expressions. For more information about creating cron and rate expressions for associations, see Reference: Cron and rate expressions for Systems Manager.

   Linux & macOS

   ```
   aws ssm create-association \
   --targets Key=tag:tag_key,Values=tag_value \
   --name AWS-UpdateSSMAgent \
   --schedule-expression "cron(0 2 ? * SUN *)"
   ```

Windows

```
aws ssm create-association ^
--targets Key=tag:tag_key,Values=tag_value ^
--name AWS-UpdateSSMAgent ^
--schedule-expression "cron(0 2 ? * SUN *)"
```

You can target multiple instances by specifying instances IDs in a comma-separated list.

Linux & macOS

```
aws ssm create-association \
--targets Key=instanceids,Values=instance_ID,instance_ID,instance_ID \
--name AWS-UpdateSSMAgent \
--schedule-expression "cron(0 2 ? * SUN *)"
```

Windows

```
aws ssm create-association ^
--targets Key=instanceids,Values=instance_ID,instance_ID,instance_ID ^
--name AWS-UpdateSSMAgent ^
--schedule-expression "cron(0 2 ? * SUN *)"
```

You can specify the version of the SSM Agent you want to update to.

Linux & macOS

```
aws ssm create-association \
--targets Key=instanceids,Values=instance_ID,instance_ID,instance_ID \
--name AWS-UpdateSSMAgent \
--schedule-expression "cron(0 2 ? * SUN *)" \
--parameters version=ssm_agent_version_number
```

Windows

```
aws ssm create-association ^
--targets Key=instanceids,Values=instance_ID,instance_ID,instance_ID ^
--name AWS-UpdateSSMAgent ^
```

```
--schedule-expression "cron(0 2 ? * SUN *)" ^
--parameters version=ssm_agent_version_number
```

The system returns information like the following.

```
{
    "AssociationDescription": {
        "ScheduleExpression": "cron(0 2 ? * SUN *)",
        "Name": "AWS-UpdateSSMAgent",
        "Overview": {
            "Status": "Pending",
            "DetailedStatus": "Creating"
        },
        "AssociationId": "123.............",
        "DocumentVersion": "$DEFAULT",
        "LastUpdateAssociationDate": 1504034257.98,
        "Date": 1504034257.98,
        "AssociationVersion": "1",
        "Targets": [
            {
                "Values": [
                    "TagValue"
                ],
                "Key": "tag:TagKey"
            }
        ]
    }
}
```

The system attempts to create the association on the instance(s) and applies the state following creation. The association status shows `Pending`.

3. Run the following command to view an updated status of the association you created.

```
aws ssm list-associations
```

If your instances *aren't* running the most recent version of the SSM Agent, the status shows `Failed`. When a new version of SSM Agent is published, the association automatically installs the new agent, and the status shows `Success`.

Walkthrough: Automatically update PV drivers on EC2 instances for Windows Server

Amazon Windows Server Amazon Machine Images (AMIs) contain a set of drivers to permit access to virtualized hardware. These drivers are used by Amazon Elastic Compute Cloud (Amazon EC2) to map instance store and Amazon Elastic Block Store (Amazon EBS) volumes to their devices. We recommend that you install the latest drivers to improve stability and performance of your EC2 instances for Windows Server. For more information about PV drivers, see AWS PV Drivers.

The following walkthrough shows you how to configure a State Manager association to automatically download and install new AWS PV drivers when the drivers become available. State Manager is a tool in AWS Systems Manager.

Before you begin

Before you complete the following procedure, verify that you have at least one Amazon EC2 instance for Windows Server running that is configured for Systems Manager. For more information, see Setting up managed nodes for AWS Systems Manager.

To create a State Manager association that automatically updates PV drivers

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**.
3. Choose **Create association**.
4. In the **Name** field, enter a descriptive name for the association.
5. In the **Document** list, choose `AWS-ConfigureAWSPackage`.
6. In the **Parameters** area, do the following:

   - For **Action**, choose **Install**.
   - For **Installation type**, choose **Uninstall and reinstall**.

     > **Note**
     >
     > In-place upgrades are not supported for this package. It must be uninstalled and reinstalled.

   - For **Name**, enter **`AWSPVDriver`**.

You don't need to enter anything for **Version** and **Additional Arguments**.

7. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

> **Tip**
>
> If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

> **Note**
>
> If you choose to target instances by using tags, and you specify tags that map to Linux instances, the association succeeds on the Windows Server instance but fails on the Linux instances. The overall status of the association shows **Failed**.

8. In the **Specify schedule** area, choose whether to run the association on a schedule that you configure, or just once. Updated PV drivers are released a several times a year, so you can schedule the association to run once a month, if you want.
9. In the **Advanced options** area, for **Compliance severity**, choose a severity level for the association. Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you indicate here. For more information, see About State Manager association compliance.
10. For **Rate control**:

- For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

> **Note**
>
> If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

11. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

12. (Optional) In the **CloudWatch alarm** section, for **Alarm name**, choose a CloudWatch alarm to apply to your association for monitoring.

> **Note**
>
> Note the following information about this step.
>
> - The alarms list displays a maximum of 100 alarms. If you don't see your alarm in the list, use the AWS Command Line Interface to create the association. For more information, see Create an association (command line).
> - To attach a CloudWatch alarm to your command, the IAM principal that creates the association must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms.
> - If your alarm activates, any pending command invocations or automations do not run.

13. Choose **Create association**, and then choose **Close**. The system attempts to create the association on the instances and immediately apply the state.

If you created the association on one or more Amazon EC2 instances for Windows Server, the status changes to **Success**. If your instances aren't configured for Systems Manager, or if you inadvertently targeted Linux instances, the status shows **Failed**.

If the status is **Failed**, choose the association ID, choose the **Resources** tab, and then verify that the association was successfully created on your EC2 instances for Windows Server. If EC2 instances for Windows Server show a status of **Failed**, verify that the SSM Agent is running on the instance, and verify that the instance is configured with an AWS Identity and Access Management (IAM) role for Systems Manager. For more information, see Setting up Systems Manager unified console for an organization.

AWS Systems Manager change management tools

AWS Systems Manager provides the following tools for making changes to your AWS resources.

Topics

AWS Systems Manager Automation

Automation, a tool in AWS Systems Manager, simplifies common maintenance, deployment, and remediation tasks for AWS services like Amazon Elastic Compute Cloud (Amazon EC2), Amazon Relational Database Service (Amazon RDS), Amazon Redshift, Amazon Simple Storage Service (Amazon S3), and many more. To get started with Automation, open the Systems Manager console. In the navigation pane, choose **Automation**.

Automation helps you to build automated solutions to deploy, configure, and manage AWS resources at scale. With Automation, you have granular control over the concurrency of your automations. This means you can specify how many resources to target concurrently, and how many errors can occur before an automation is stopped.

To help you get started with Automation, AWS develops and maintains several pre-defined runbooks. Depending on your use case, you can use these pre-defined runbooks that perform a variety of tasks, or create your own custom runbooks that might better suit your needs. To monitor the progress and status of your automations, you can use the Systems Manager Automation console, or your preferred command line tool. Automation also integrates with Amazon EventBridge to help you build event-driven architecture at scale.

> **Note**
>
> For customers who are new to Systems Manager Automation as of August 14, 2025, the Automation free tier is not available. For customers already using Automation, the free tier of service ends on December 31, 2025. For information about current service costs, see AWS Systems Manager pricing.

How can Automation benefit my organization?

Automation offers these benefits:

- **Scripting support in runbook content**

  Using the `aws:executeScript` action, you can run custom Python and PowerShell functions directly from your runbooks. This provides you greater flexibility in creating your custom runbooks because you can complete various tasks that other Automation actions don't support. You also have greater control over the logic of the runbook. For an example of how this action can be used and how it can help to improve an existing automated solution, see Authoring Automation runbooks.

- **Run automations across multiple AWS accounts and AWS Regions from a centralized location**

  Administrators can run automations on resources across multiple accounts and Regions from the Systems Manager console.

- **Enhanced operations security**

  Administrators have a centralized place to grant and revoke access to runbooks. Using only AWS Identity and Access Management (IAM) policies, you can control which individual users or groups in your organization can use Automation and which runbooks they can access.

- **Automate common IT tasks**

Automating common tasks can help improve operational efficiency, enforce organizational standards, and reduce operator errors. For example, you can use the `AWS-UpdateCloudFormationStackWithApproval` runbook to update resources that were deployed by using an AWS CloudFormation template. The update applies a new template. You can configure the Automation to request approval by one or more users before the update begins.

- **Safely perform disruptive tasks in bulk**

  Automation includes features, like rate controls, that allow you to control the deployment of an automation across your fleet by specifying a concurrency value and an error threshold. For more information about working with rate controls, see Run automated operations at scale.

- **Streamline complex tasks**

  Automation provides pre-defined runbooks that streamline complex and time-consuming tasks such as creating golden Amazon Machine Images (AMIs). For example, you can use the `AWS-UpdateLinuxAmi` and `AWS-UpdateWindowsAmi` runbooks to create golden AMIs from a source AMI. Using these runbooks, you can run custom scripts before and after updates are applied. You can also include or exclude specific software packages from being installed. For examples of how to use these runbooks, see Tutorials.

- **Define constraints for inputs**

  You can define constraints in custom runbooks to limit the values that Automation will accept for a particular input parameter. For example, `allowedPattern` will only accept values for an input parameter that match the regular expression you define. If you specify `allowedValues` for an input parameter, only the values you've specified in the runbook are accepted.

- **Log automation action output to Amazon CloudWatch Logs**

  To meet operational or security requirements in your organization, you might need to provide a record of the scripts run during a runbook. With CloudWatch Logs, you can monitor, store, and access log files from various AWS services. You can send output from the `aws:executeScript` action to a CloudWatch Logs log group for debugging and troubleshooting purposes. Log data can be sent to your log group with or without AWS KMS encryption using your KMS key. For more information, see Logging Automation action output with CloudWatch Logs.

- **Amazon EventBridge integration**

Automation is supported as a *target* type in Amazon EventBridge rules. This means you can trigger runbooks by using events. For more information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

- **Share organizational best practices**

  You can define best practices for resource management, operations tasks, and more in runbooks that you share across accounts and Regions.

Who should use Automation?

- Any AWS customer who wants to improve their operational efficiency at scale, reduce errors associated with manual intervention, and reduce time to resolution of common issues.
- Infrastructure experts who want to automate deployment and configuration tasks.
- Administrators who want to reliably resolve common issues, improve troubleshooting efficiency, and reduce repetitive operations.
- Users who want to automate a task they normally perform manually.

What is an automation?

An *automation* consists of all of the tasks that are defined in a runbook, and are performed by the Automation service. Automation uses the following components to run automations.

Concept	Details
Automation runbook	A Systems Manager Automation runbook defines the automation (the actions that Systems Manager performs on your managed nodes and AWS resources). Automation includes several pre-defined runbooks that you can use to perform common tasks like restarting one or more Amazon EC2 instances or creating an Amazon Machine Image (AMI). You can create your own runbooks as well. Runbooks use YAML or JSON, and they include

Concept	Details
	steps and parameters that you specify. Steps run in sequential order. For more information, see Creating your own runbooks. Runbooks are Systems Manager documents of type `Automation` , as opposed to `Command`, `Policy`, `Session` documents. Runbooks support schema version 0.3. Command documents use schema version 1.2, 2.0, or 2.2. Policy documents use schema version 2.0 or later.
Automation action	The automation defined in a runbook includes one or more steps. Each step is associated with a particular action. The action determines the inputs, behavior, and outputs of the step. Steps are defined in the `mainSteps` section of your runbook. Automation supports 20 distinct action types. For more information, see the Systems Manager Automation actions reference.

Concept	Details
Automation quota	Each AWS account can run 100 automations simultaneously. This includes child automatio ns (automations that are started by another automation), and rate control automations. If you attempt to run more automations than this, Systems Manager adds the additional automations to a queue and displays a status of Pending. This quota can be adjusted using adaptive concurrency. For more informati on, see Allowing Automation to adapt to your concurrency needs.For more informati on about running automations, see Run an automated operation powered by Systems Manager Automation.
Automation queue quota	If you attempt to run more automations than the concurrent automation limit, subsequen t automations are added to a queue. Each AWS account can queue 5,000 automations. When an automation is complete (or reaches a terminal state), the first automation in the queue is started.
Rate control automation quota	Each AWS account can run 25 rate control automations simultaneously. If you attempt to run more rate control automations than the concurrent rate control automation limit, Systems Manager adds the subsequent rate control automations to a queue and displays a status of Pending. For more information about running rate control automations, see Run automated operations at scale.

Concept	Details
Rate control automation queue quota	If you attempt to run more automations than the concurrent rate control automation limit, subsequent automations are added to a queue. Each AWS account can queue 1,000 rate control automations. When an automatio n is complete (or reaches a terminal state), the first automation in the queue is started.

Topics

Setting up Automation

To set up Automation, a tool in AWS Systems Manager, you must verify user access to the Automation service and situationally configure roles so that the service can perform actions on

your resources. We also recommend that you opt in to the adaptive concurrency mode in your Automation preferences. Adaptive concurrency automatically scales your automation quota to meet your needs. For more information, see Allowing Automation to adapt to your concurrency needs.

To ensure proper access to AWS Systems Manager Automation, review the following user and service role requirements.

Verifying user access for runbooks

Verify that you have permission to use runbooks. If your user, group, or role is assigned administrator permissions, then you have access to Systems Manager Automation. If you don't have administrator permissions, then an administrator must give you permission by assigning the `AmazonSSMFullAccess` managed policy, or a policy that provides comparable permissions, to your user, group, or role.

> **Important**
>
> The IAM policy `AmazonSSMFullAccess` grants permissions to Systems Manager actions. However, some runbooks require permissions to other services, such as the runbook `AWS-ReleaseElasticIP`, which requires IAM permissions for `ec2:ReleaseAddress`. Therefore, you must review the actions taken in a runbook to ensure your user, group, or role is assigned the necessary permissions to perform the actions included in the runbook.

Configuring a service role (assume role) access for automations

Automations can be initiated under the context of a service role (or *assume role*). This allows the service to perform actions on your behalf. If you don't specify an assume role, Automation uses the context of the user who invoked the automation.

However, the following situations require that you specify a service role for Automation:

- When you want to restrict a user's permissions on a resource, but you want the user to run an automation that requires elevated permissions. In this scenario, you can create a service role with elevated permissions and allow the user to run the automation.
- When you create a Systems Manager State Manager association that runs a runbook.
- When you have operations that you expect to run longer than 12 hours.

- When you're running a runbook not owned by Amazon that uses the `aws:executeScript` action to call an AWS API operation or to act on an AWS resource. For information, see Permissions for using runbooks.

If you need to create a service role for Automation, you can use one of the following methods.

Topics

Create service roles for Automation by using AWS CloudFormation

You can create a service role for Automation, a tool in AWS Systems Manager, from an AWS CloudFormation template. After you create the service role, you can specify the service role in runbooks using the parameter `AutomationAssumeRole`.

Create the service role using AWS CloudFormation

Use the following procedure to create the required AWS Identity and Access Management (IAM) role for Systems Manager Automation by using AWS CloudFormation.

To create the required IAM role

1. Download and unzip the `AWS-SystemsManager-AutomationServiceRole.zip` file. This file includes the `AWS-SystemsManager-AutomationServiceRole.yaml` AWS CloudFormation template file.
2. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. Choose **Create Stack**.
4. In the **Specify template** section, choose **Upload a template file**.
5. Choose **Browse**, and then choose the `AWS-SystemsManager-AutomationServiceRole.yaml` AWS CloudFormation template file.
6. Choose **Next**.

7. On the **Specify stack details** page, in the **Stack name** field, enter a name.
8. On the **Configure stack options** page, you don't need to make any selections. Choose **Next**.
9. On the **Review** page, scroll down and choose the **I acknowledge that AWS CloudFormation might create IAM resources** option.
10. Choose **Create**.

CloudFormation shows the **CREATE_IN_PROGRESS** status for approximately three minutes. The status changes to **CREATE_COMPLETE** after the stack is created and your roles are ready to use.

> **Important**
>
> If you run an automation workflow that invokes other services by using an AWS Identity and Access Management (IAM) service role, be aware that the service role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (`AWS-*` runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom Automation runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:createStack`, or `aws:copyImage` actions, configure the service role with permission to invoke those services. You can give permissions to other AWS services by adding an IAM inline policy to the role. For more information, see (Optional) Add an Automation inline policy or customer managed policy to invoke other AWS services.

Copy role information for Automation

Use the following procedure to copy information about the Automation service role from the AWS CloudFormation console. You must specify these roles when you use a runbook.

> **Note**
>
> You don't need to copy role information using this procedure if you run the `AWS-UpdateLinuxAmi` or `AWS-UpdateWindowsAmi` runbooks. These runbooks already have the required roles specified as default values. The roles specified in these runbooks use IAM managed policies.

To copy the role names

1. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Select the Automation **Stack name** you created in the previous procedure.
3. Choose the **Resources** tab.
4. Choose the **Physical ID** link for **AutomationServiceRole**. The IAM console opens to a summary of the Automation service role.
5. Copy the Amazon Resource Name (ARN) next to **Role ARN**. The ARN is similar to the following: `arn:aws:iam::12345678:role/AutomationServiceRole`
6. Paste the ARN into a text file to use later.

You have finished configuring the service role for Automation. You can now use the Automation service role ARN in your runbooks.

Create the service roles for Automation using the console

If you need to create a service role for Automation, a tool in AWS Systems Manager, complete the following tasks. For more information about when a service role is required for Automation, see Setting up Automation.

Tasks

- Task 1: Create a service role for Automation
- Task 2: Attach the iam:PassRole policy to your Automation role

Task 1: Create a service role for Automation

Use the following procedure to create a service role (or *assume role*) for Systems Manager Automation.

> **Note**
>
> You can also use this role in runbooks, such as the `AWS-CreateManagedLinuxInstance` runbook. Using this role, or the Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role, in runbooks allows Automation to perform actions in your environment, such as launch new instances and perform actions on your behalf.

To create an IAM role and allow Automation to assume it

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. Under **Select type of trusted entity**, choose **AWS service**.
4. In the **Choose a use case** section, choose **Systems Manager**, and then choose **Next: Permissions**.
5. On the **Attached permissions policy** page, search for the **AmazonSSMAutomationRole** policy, choose it, and then choose **Next: Review**.
6. On the **Review** page, enter a name in the **Role name** box, and then enter a description.
7. Choose **Create role**. The system returns you to the **Roles** page.
8. On the **Roles** page, choose the role you just created to open the **Summary** page. Note the **Role Name** and **Role ARN**. You will specify the role ARN when you attach the **iam:PassRole** policy to your IAM account in the next procedure. You can also specify the role name and the ARN in runbooks.

> **Note**
>
> The `AmazonSSMAutomationRole` policy assigns the Automation role permission to a subset of AWS Lambda functions within your account. These functions begin with "Automation". If you plan to use Automation with Lambda functions, the Lambda ARN must use the following format:
> `"arn:aws:lambda:*:*:function:Automation*"`
> If you have existing Lambda functions whose ARNs don't use this format, then you must also attach an additional Lambda policy to your automation role, such as the **AWSLambdaRole** policy. The additional policy or role must provide broader access to Lambda functions within the AWS account.

After creating your service role, we recommend editing the trust policy to help prevent the cross-service confused deputy problem. The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another

customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies to limit the permissions that Automation gives another service to the resource. If the `aws:SourceArn` value doesn't contain the account ID, such as an Amazon S3 bucket ARN, you must use both global condition context keys to limit permissions. If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use. The value of `aws:SourceArn` must be the ARN for automation executions. If you don't know the full ARN of the resource or if you're specifying multiple resources, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. For example, `arn:aws:ssm:*:123456789012:automation-execution/*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys for Automation to prevent the confused deputy problem.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "ssm.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        },
        "ArnLike": {
          "aws:SourceArn": "arn:aws:ssm:*:123456789012:automation-execution/*"
```

```
        }
      }
    }
  ]
}
```

To modify the role's trust policy

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. In the list of roles in your account, choose the name of your Automation service role.
4. Choose the **Trust relationships** tab, and then choose **Edit trust relationship**.
5. Edit the trust policy using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys for Automation to prevent the confused deputy problem.
6. Choose **Update Trust Policy** to save your changes.

(Optional) Add an Automation inline policy or customer managed policy to invoke other AWS services

If you run an automation that invokes other AWS services by using an IAM service role, the service role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (`AWS-*` runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:CreateStack`, or `aws:copyImage` actions, to name a few, then you must configure the service role with permission to invoke those services. You can give permissions to other AWS services by adding an IAM inline policy or customer managed policy to the role.

To embed an inline policy for a service role (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. In the list, choose the name of the role that you want to edit.
4. Choose the **Permissions** tab.

5. In the **Add permissions** dropdown, choose **Attach policies** or **Create inline policy**.
6. If you choose **Attach policies**, select the check box next to the policy you want to add and choose **Add permissions**.
7. If you choose **Create inline policy**, choose the **JSON** tab.
8. Enter a JSON Policy document for the AWS services you want to invoke. Here are two example JSON Policy documents.

Amazon S3 PutObject and GetObject Example

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Amazon EC2 CreateSnapshot and DescribeSnapShots Example

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"ec2:CreateSnapshot",
         "Resource":"*"
      },
      {
```

```
            "Effect":"Allow",
            "Action":"ec2:DescribeSnapshots",
            "Resource":"*"
        }
    ]
}
```

For details about the IAM policy language, see IAM JSON Policy Reference in the *IAM User Guide*.

9. When you're finished, choose **Review policy**. The Policy Validator reports any syntax errors.
10. On the **Review policy** page, enter a **Name** for the policy that you're creating. Review the policy **Summary** to see the permissions that are granted by your policy. Then choose **Create policy** to save your work.
11. After you create an inline policy, it's automatically embedded in your role.

Task 2: Attach the iam:PassRole policy to your Automation role

Use the following procedure to attach the `iam:PassRole` policy to your Automation service role. This allows the Automation service to pass the role to other services or Systems Manager tools when running automations.

To attach the iam:PassRole policy to your Automation role

1. In the **Summary** page for the role you just created, choose the **Permissions** tab.
2. Choose **Add inline policy**.
3. On the **Create policy** page, choose the **Visual editor** tab.
4. Choose **Service**, and then choose **IAM**.
5. Choose **Select actions**.
6. In the **Filter actions** text box, type **`PassRole`**, and then choose the **PassRole** option.
7. Choose **Resources**. Verify that **Specific** is selected, and then choose **Add ARN**.
8. In the **Specify ARN for role** field, paste the Automation role ARN that you copied at the end of Task 1. The system populates the **Account** and **Role name with path** fields.

> **Note**
>
> If you want the Automation service role to attach an IAM instance profile role to an EC2 instance, then you must add the ARN of the IAM instance profile role. This allows the Automation service role to pass the IAM instance profile role to the target EC2 instance.

9. Choose **Add**.
10. Choose **Review policy**.
11. On the **Review Policy** page, enter a name and then choose **Create Policy**.

Allowing Automation to adapt to your concurrency needs

By default, Automation allows you to run up to 100 concurrent automations at a time. Automation also provides an optional setting that you can use to adjust your concurrency automation quota automatically. With this setting, your concurrency automation quota can accommodate up to 500 concurrent automations, depending on available resources.

> **Note**
>
> If your automation calls API operations, adaptively scaling to your targets can result in throttling exceptions. If recurring throttling exceptions occur when running automations with adaptive concurrency turned on, you might have to request quota increases for the API operation if available.

To turn on adaptive concurrency using the AWS Management Console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Enable adaptive concurrency**.
5. Choose **Save**.

To turn on adaptive concurrency using the command line

- Open the AWS CLI or Tools for Windows PowerShell and run the following command to turn on adaptive concurrency for your account in the requesting Region.

  Linux & macOS

  ```
  aws ssm update-service-setting \
      --setting-id /ssm/automation/enable-adaptive-concurrency \
      --setting-value True
  ```

  Windows

  ```
  aws ssm update-service-setting ^
      --setting-id /ssm/automation/enable-adaptive-concurrency ^
      --setting-value True
  ```

  PowerShell

  ```
  Update-SSMServiceSetting `
      -SettingId "/ssm/automation/enable-adaptive-concurrency" `
      -SettingValue "True"
  ```

Configuring automatic retry for throttled operations

There is a limit on the number of concurrent automation executions that can run in each account. Attempting to run several automations concurrently in an account can lead to throttling issues. You can use the automatic throttling retry capability to configure retry behavior for throttled automation steps.

Automatic throttling retry for automation actions provides a more resilient execution environment for high-scale operations. The throttling retry capability supports all automation actions except for `aws:executeScript`.

The throttling retry setting works in addition to the existing `maxAttempts` step property. When both are configured, the system first attempts throttling retries within the specified time limit, then applies the `maxAttempts` setting if the step continues to fail.

To configure throttling retry using the AWS Management Console

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. In the **Throttling retry time limit** field, enter a value between 0 and 3600 seconds. This specifies the maximum time that the system retries a step that is throttled.
5. Choose **Save**.

To configure throttling retry using the command line

- Open the AWS CLI or Tools for Windows PowerShell and run the following command to configure throttling retry for your account in the requesting Region.

  Linux & macOS

  ```
  aws ssm update-service-setting \
      --setting-id /ssm/automation/throttling-retry-time-limit \
      --setting-value 3600
  ```

  Windows

  ```
  aws ssm update-service-setting ^
      --setting-id /ssm/automation/throttling-retry-time-limit ^
      --setting-value 3600
  ```

  PowerShell

  ```
  Update-SSMServiceSetting `
      -SettingId "/ssm/automation/throttling-retry-time-limit" `
      -SettingValue "3600"
  ```

Implement change controls for Automation

By default, Automation allows you to use runbooks without date and time constraints. By integrating Automation with Change Calendar, you can implement change controls to all

automations in your AWS account. With this setting, AWS Identity and Access Management (IAM) principals in your account can only run automations during the time periods allowed by your change calendar. To learn more about working with Change Calendar, see Working with Change Calendar.

To turn on change controls (console)

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Turn on Change Calendar integration**.
5. In the **Choose a change calendar** dropdown list, choose the change calendar that you want Automation to follow.
6. Choose **Save**.

Run an automated operation powered by Systems Manager Automation

When you run an automation, by default, the automation runs in the context of the user who initiated the automation. This means, for example, if your user has administrator permissions, then the automation runs with administrator permissions and full access to the resources being configured by the automation. As a security best practice, we recommend that you run automation by using an IAM service role that is known in this case as an *assume* role that is configured with the AmazonSSMAutomationRole managed policy. You might need to add additional IAM policies to your assume role to use various runbooks. Using an IAM service role to run automation is called *delegated administration*.

When you use a service role, the automation is allowed to run against the AWS resources, but the user who ran the automation has restricted access (or no access) to those resources. For example, you can configure a service role and use it with Automation to restart one or more Amazon Elastic Compute Cloud (Amazon EC2) instances. Automation is a tool in AWS Systems Manager. The automation restarts the instances, but the service role doesn't give the user permission to access those instances.

You can specify a service role at runtime when you run an automation, or you can create custom runbooks and specify the service role directly in the runbook. If you specify a service role, either at runtime or in a runbook, then the service runs in the context of the specified service role. If you

don't specify a service role, then the system creates a temporary session in the context of the user and runs the automation.

> **Note**
>
> You must specify a service role for automation that you expect to run longer than 12 hours. If you start a long-running automation in the context of a user, the user's temporary session expires after 12 hours.

Delegated administration ensures elevated security and control of your AWS resources. It also allows an enhanced auditing experience because actions are being performed against your resources by a central service role instead of multiple IAM accounts.

Before you begin

Before you complete the following procedures, you must create the IAM service role and configure a trust relationship for Automation, a tool in AWS Systems Manager. For more information, see Task 1: Create a service role for Automation.

The following procedures describe how to use the Systems Manager console or your preferred command line tool to run a simple automation.

Running a simple automation (console)

The following procedure describes how to use the Systems Manager console to run a simple automation.

To run a simple automation

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

> **Note**
>
> You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:
   - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
   - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
   - **1 (Default)** – Choose this option to run the first version of the document, which is the default.
5. Choose **Next**.
6. In the **Execution Mode** section, choose **Simple execution**.
7. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.
8. (Optional) Choose a CloudWatch alarm to apply to your automation for monitoring. To attach a CloudWatch alarm to your automation, the IAM principal that starts the automation must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms. Note that if your alarm activates, the automation is stopped. If you use AWS CloudTrail, you will see the API call in your trail.
9. Choose **Execute**.

The console displays the status of the automation. If the automation fails to run, see Troubleshooting Systems Manager Automation.

After an automation execution completes, you can rerun the execution with the same or modified parameters. For more information, see Rerunning automation executions.

Running a simple automation (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to run a simple automation.

To run a simple automation

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Run the following command to start a simple automation. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm start-automation-execution \
       --document-name runbook name \
       --parameters runbook parameters
   ```

   Windows

   ```
   aws ssm start-automation-execution ^
       --document-name runbook name ^
       --parameters runbook parameters
   ```

   PowerShell

   ```
   Start-SSMAutomationExecution `
     -DocumentName runbook name `
     -Parameter runbook parameters
   ```

   Here is an example using the runbook `AWS-RestartEC2Instance` to restart the specified EC2 instance.

   Linux & macOS

   ```
   aws ssm start-automation-execution \
       --document-name "AWS-RestartEC2Instance" \
       --parameters "InstanceId=i-02573cafcfEXAMPLE"
   ```

   Windows

   ```
   aws ssm start-automation-execution ^
   ```

```
    --document-name "AWS-RestartEC2Instance" ^
    --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

PowerShell

```
Start-SSMAutomationExecution `
  -DocumentName AWS-RestartEC2Instance `
  -Parameter @{"InstanceId"="i-02573cafcfEXAMPLE"}
```

The system returns information like the following.

Linux & macOS

```
{
    "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0123456789ab"
}
```

Windows

```
{
    "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0123456789ab"
}
```

PowerShell

```
4105a4fc-f944-11e6-9d32-0123456789ab
```

3. Run the following command to retrieve the status of the automation.

Linux & macOS

```
aws ssm describe-automation-executions \
    --filter "Key=ExecutionId,Values=4105a4fc-f944-11e6-9d32-0123456789ab"
```

Windows

```
aws ssm describe-automation-executions ^
    --filter "Key=ExecutionId,Values=4105a4fc-f944-11e6-9d32-0123456789ab"
```

PowerShell

```
Get-SSMAutomationExecutionList | `
  Where {$_.AutomationExecutionId -eq "4105a4fc-f944-11e6-9d32-0123456789ab"}
```

The system returns information like the following.

Linux & macOS

```
{
    "AutomationExecutionMetadataList": [
        {
            "AutomationExecutionStatus": "InProgress",
            "CurrentStepName": "stopInstances",
            "Outputs": {},
            "DocumentName": "AWS-RestartEC2Instance",
            "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0123456789ab",
            "DocumentVersion": "1",
            "ResolvedTargets": {
                "ParameterValues": [],
                "Truncated": false
            },
            "AutomationType": "Local",
            "Mode": "Auto",
            "ExecutionStartTime": 1564600648.159,
            "CurrentAction": "aws:changeInstanceState",
            "ExecutedBy": "arn:aws:sts::123456789012:assumed-role/Administrator/
Admin",
            "LogFile": "",
            "Targets": []
        }
    ]
}
```

Windows

```
{
    "AutomationExecutionMetadataList": [
        {
            "AutomationExecutionStatus": "InProgress",
            "CurrentStepName": "stopInstances",
```

```
            "Outputs": {},
            "DocumentName": "AWS-RestartEC2Instance",
            "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0123456789ab",
            "DocumentVersion": "1",
            "ResolvedTargets": {
                "ParameterValues": [],
                "Truncated": false
            },
            "AutomationType": "Local",
            "Mode": "Auto",
            "ExecutionStartTime": 1564600648.159,
            "CurrentAction": "aws:changeInstanceState",
            "ExecutedBy": "arn:aws:sts::123456789012:assumed-role/Administrator/
Admin",
            "LogFile": "",
            "Targets": []
        }
    ]
}
```

PowerShell

```

Targets                     : {}
```

Rerunning automation executions

You can rerun AWS Systems Manager automation executions to repeat tasks with either identical or modified parameters. The rerun capability allows you to efficiently replicate automation executions without manually recreating automation configurations, reducing operational overhead and potential configuration errors.

When you rerun an automation execution, Systems Manager preserves the original runbook parameters, Amazon CloudWatch alarms, and tags from the previous execution. The system creates a new execution with a new execution ID and updated timestamps. You can rerun any type of automation execution, including simple executions, rate control executions, cross-account and cross-region executions, and manual executions.

Rerun an automation execution (console)

The following procedures describe how to use the Systems Manager console to rerun an automation execution.

To rerun an automation execution from the Automation home page

Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.

1. In the navigation pane, choose **Automation**.
2. In the executions list, select the execution that you want to rerun.
3. Choose **Rerun execution**.
4. On the **Execute automation document** page, review the pre-populated parameters, execution mode, and target configuration from the original execution.
5. (Optional) Modify any parameters, targets, or other settings as needed for your rerun.
6. Choose **Execute** to start the rerun with a new execution ID.

To rerun an automation execution from the execution details page

Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.

1. In the navigation pane, choose **Automation**.
2. Choose the execution ID of the automation that you want to rerun.
3. On the execution details page, choose **Rerun execution**.
4. On the **Execute automation document** page, review the pre-populated parameters, execution mode, and target configuration from the original execution.
5. (Optional) Modify any parameters, targets, or other settings as needed for your rerun.
6. Choose **Execute** to start the rerun with a new execution ID.

To copy an automation execution to a new execution

Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.

1. In the navigation pane, choose **Automation**.
2. Choose the execution ID of the automation that you want to copy.
3. On the execution details page, choose **Actions**, and then choose **Copy to new**.
4. On the **Execute automation document** page, review the pre-populated parameters, execution mode, and target configuration from the original execution.
5. (Optional) Modify any parameters, targets, or other settings as needed for your new execution.
6. Choose **Execute** to start the new execution.

Run an automation that requires approvals

The following procedures describe how to use the AWS Systems Manager console and AWS Command Line Interface (AWS CLI) to run an automation with approvals using simple execution. The automation uses the automation action `aws:approve`, which temporarily pauses the automation until the designated principals either approve or deny the action. The automation runs in the context of the current user. This means that you don't need to configure additional IAM permissions as long as you have permission to use the runbook, and any actions called by the runbook. If you have administrator permissions in IAM, then you already have permission to use this runbook.

Before you begin

In addition to the standard inputs required by the runbook, the `aws:approve` action requires the following two parameters:

- A list of approvers. The list of approvers must contain at least one approver in the form of a user name or a user ARN. If multiple approvers are provided, a corresponding minimum approval count must also be specified within the runbook.
- An Amazon Simple Notification Service (Amazon SNS) topic ARN. The Amazon SNS topic name must start with `Automation`.

This procedure assumes that you have already created an Amazon SNS topic, which is required to deliver the approval request. For information, see Create a Topic in the *Amazon Simple Notification Service Developer Guide*.

Running an automation with approvers (console)

To run an automation with approvers

The following procedure describes how to use the Systems Manager console to run an automation with approvers.

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

   > **Note**
   >
   > You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:

   - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
   - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.

- **1 (Default)** – Choose this option to run the first version of the document, which is the default.

5. Choose **Next**.
6. On the **Execute automation document** page, choose **Simple execution**.
7. In the **Input parameters** section, specify the required input parameters.

   For example, if you chose the **`AWS-StartEC2InstanceWithApproval`** runbook, then you must specify or choose instance IDs for the **InstanceId** parameter.
8. In the **Approvers** section, specify the user names or user ARNs of approvers for the automation action.
9. In the **SNSTopicARN** section, specify the SNS topic ARN to use for sending approval notification. The SNS topic name must start with **Automation**.
10. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list. If you're targeting more than 100 accounts and Regions, you must specify the `AWS-SystemsManager-AutomationAdministrationRole`.
11. Choose **Execute automation**.

The specified approver receives an Amazon SNS notification with details to approve or reject the automation. This approval action is valid for 7 days from the date of issue and can be issued using the Systems Manager console or the AWS Command Line Interface (AWS CLI).

If you chose to approve the automation, the automation continues to run the steps included in the specified runbook. The console displays the status of the automation. If the automation fails to run, see Troubleshooting Systems Manager Automation.

To approve or deny an automation

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**, and then select the automation that was run in the previous procedure.
3. Choose **Actions** and then choose **Approve/Deny**.
4. Choose to **Approve** or **Deny** and optionally provide a comment.
5. Choose **Submit**.

Running an automation with approvers (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to run an automation with approvers.

To run an automation with approvers

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Run the following command to run an automation with approvers. Replace each *example resource placeholder* with your own information. In the document name section, specify a runbook that includes the automation action, `aws:approve`.

   For `Approvers`, specify the user names or user ARNs of approvers for the action. For `SNSTopic`, specify the SNS topic ARN to use to send approval notification. The Amazon SNS topic name must start with `Automation`.

   > **Note**
   >
   > The specific names of the parameter values for approvers and the SNS topic depend on the values specified within the runbook you choose.

   Linux & macOS

   ```
   aws ssm start-automation-execution \
       --document-name "AWS-StartEC2InstanceWithApproval" \
       --parameters
    "InstanceId=i-02573cafcfEXAMPLE,Approvers=arn:aws:iam::123456789012:role/
   Administrator,SNSTopicArn=arn:aws:sns:region:123456789012:AutomationApproval"
   ```

   Windows

   ```
   aws ssm start-automation-execution ^
       --document-name "AWS-StartEC2InstanceWithApproval" ^
   ```

```
    --parameters
 "InstanceId=i-02573cafcfEXAMPLE,Approvers=arn:aws:iam::123456789012:role/
Administrator,SNSTopicArn=arn:aws:sns:region:123456789012:AutomationApproval"
```

PowerShell

```
Start-SSMAutomationExecution `
    -DocumentName AWS-StartEC2InstanceWithApproval `
    -Parameters @{
        "InstanceId"="i-02573cafcfEXAMPLE"
        "Approvers"="arn:aws:iam::123456789012:role/Administrator"
        "SNSTopicArn"="arn:aws:sns:region:123456789012:AutomationApproval"
    }
```

The system returns information like the following.

Linux & macOS

```
{
    "AutomationExecutionId": "df325c6d-b1b1-4aa0-8003-6cb7338213c6"
}
```

Windows

```
{
    "AutomationExecutionId": "df325c6d-b1b1-4aa0-8003-6cb7338213c6"
}
```

PowerShell

```
df325c6d-b1b1-4aa0-8003-6cb7338213c6
```

To approve an automation

- Run the following command to approve an automation. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm send-automation-signal \
    --automation-execution-id "df325c6d-b1b1-4aa0-8003-6cb7338213c6" \
    --signal-type "Approve" \
    --payload "Comment=your comments"
```

Windows

```
aws ssm send-automation-signal ^
    --automation-execution-id "df325c6d-b1b1-4aa0-8003-6cb7338213c6" ^
    --signal-type "Approve" ^
    --payload "Comment=your comments"
```

PowerShell

```
Send-SSMAutomationSignal `
    -AutomationExecutionId df325c6d-b1b1-4aa0-8003-6cb7338213c6 `
    -SignalType Approve `
    -Payload @{"Comment"="your comments"}
```

There is no output if the command succeeds.

To deny an automation

- Run the following command to deny an automation. Replace each *example resource placeholder* with your own information.

  Linux & macOS

  ```
  aws ssm send-automation-signal \
      --automation-execution-id "df325c6d-b1b1-4aa0-8003-6cb7338213c6" \
      --signal-type "Deny" \
      --payload "Comment=your comments"
  ```

  Windows

  ```
  aws ssm send-automation-signal ^
  ```

```
    --automation-execution-id "df325c6d-b1b1-4aa0-8003-6cb7338213c6" ^
    --signal-type "Deny" ^
    --payload "Comment=your comments"
```

PowerShell

```
Send-SSMAutomationSignal `
    -AutomationExecutionId df325c6d-b1b1-4aa0-8003-6cb7338213c6 `
    -SignalType Deny `
    -Payload @{"Comment"="your comments"}
```

There is no output if the command succeeds.

Run automated operations at scale

With AWS Systems Manager Automation, you can run automations on a fleet of AWS resources by using *targets*. Additionally, you can control the deployment of the automation across your fleet by specifying a concurrency value and an error threshold. The concurrency and error threshold features are collectively called *rate controls*. The concurrency value determines how many resources are allowed to run the automation simultaneously. Automation also provides an adaptive concurrency mode you can opt in to. Adaptive concurrency automatically scales your automation quota from 100 concurrently running automations up to 500. An error threshold determines how many automations are allowed to fail before Systems Manager stops sending the automation to other resources.

For more information about concurrency and error thresholds, see Control automations at scale. For more information about targets, see Mapping targets for an automation.

The following procedures show you how to turn on adaptive concurrency, and how to run an automation with targets and rate controls by using the Systems Manager console and AWS Command Line Interface (AWS CLI).

Running an automation with targets and rate controls (console)

The following procedure describes how to use the Systems Manager console to run an automation with targets and rate controls.

To run an automation with targets and rate controls

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

   > **Note**
   >
   > You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:

   - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
   - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
   - **1 (Default)** – Choose this option to run the first version of the document, which is the default.

5. Choose **Next**.
6. In the **Execution Mode** section, choose **Rate Control**. You must use this mode or **Multi-account and Region** if you want to use targets and rate controls.
7. In the **Targets** section, choose how you want to target the AWS resources where you want to run the Automation. These options are required.

   a. Use the **Parameter** list to choose a parameter. The items in the **Parameter** list are determined by the parameters in the Automation runbook that you selected at the start of this procedure. By choosing a parameter you define the type of resource on which the Automation workflow runs.

   b. Use the **Targets** list to choose how you want to target resources.

i. If you chose to target resources by using parameter values, then enter the parameter value for the parameter you chose in the **Input parameters** section.

ii. If you chose to target resources by using AWS Resource Groups, then choose the name of the group from the **Resource Group** list.

iii. If you chose to target resources by using tags, then enter the tag key and (optionally) the tag value in the fields provided. Choose **Add**.

iv. If you want to run an Automation runbook on all instances in the current AWS account and AWS Region, then choose **All instances**.

8. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.

> **Note**
>
> You might not need to choose some of the options in the **Input parameters** section. This is because you targeted resources by using tags or a resource group. For example, if you chose the `AWS-RestartEC2Instance` runbook, then you don't need to specify or choose instance IDs in the **Input parameters** section. The Automation execution locates the instances to restart by using the tags or resource group you specified.

9. Use the options in the **Rate control** section to restrict the number of AWS resources that can run the Automation within each account-Region pair.

   In the **Concurrency** section, choose an option:

   - Choose **targets** to enter an absolute number of targets that can run the Automation workflow simultaneously.
   - Choose **percentage** to enter a percentage of the target set that can run the Automation workflow simultaneously.

10. In the **Error threshold** section, choose an option:

    - Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the workflow to other resources.
    - Choose **percentage** to enter a percentage of errors allowed before Automation stops sending the workflow to other resources.

11. (Optional) Choose a CloudWatch alarm to apply to your automation for monitoring. To attach a CloudWatch alarm to your automation, the IAM principal that starts the automation must

have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms. Note that if your alarm activates, the automation is stopped. If you use AWS CloudTrail, you will see the API call in your trail.

12. Choose **Execute**.

To view automations started by your rate control automation, in the navigation pane, choose Automation, and then select **Show child automations**.

After an automation execution completes, you can rerun the execution with the same or modified parameters. For more information, see Rerunning automation executions.

Running an automation with targets and rate controls (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to run an automation with targets and rate controls.

To run an automation with targets and rate controls

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Run the following command to view a list of documents.

   Linux & macOS

   ```
   aws ssm list-documents
   ```

   Windows

   ```
   aws ssm list-documents
   ```

   PowerShell

   ```
   Get-SSMDocumentList
   ```

   Note the name of the runbook that you want to use.

3. Run the following command to view details about the runbook. Replace the *runbook name* with the name of the runbook whose details you want to view. Also, note a parameter name (for example, `InstanceId`) that you want to use for the `--target-parameter-name` option. This parameter determines the type of resource on which the automation runs.

   Linux & macOS

   ```
   aws ssm describe-document \
       --name runbook name
   ```

   Windows

   ```
   aws ssm describe-document ^
       --name runbook name
   ```

   PowerShell

   ```
   Get-SSMDocumentDescription `
       -Name runbook name
   ```

4. Create a command that uses the targets and rate control options you want to run. Replace each *example resource placeholder* with your own information.

   Targeting using tags

   Linux & macOS

   ```
   aws ssm start-automation-execution \
       --document-name runbook name \
       --targets Key=tag:key name,Values=value \
       --target-parameter-name parameter name \
       --parameters "input parameter name=input parameter value,input parameter 2
    name=input parameter 2 value" \
       --max-concurrency 10 \
       --max-errors 25%
   ```

   Windows

   ```
   aws ssm start-automation-execution ^
       --document-name runbook name ^
   ```

```
    --targets Key=tag:key name,Values=value ^
    --target-parameter-name parameter name ^
    --parameters "input parameter name=input parameter value,input parameter 2
 name=input parameter 2 value" ^
    --max-concurrency 10 ^
    --max-errors 25%
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "tag:key name"
$Targets.Values = "value"

Start-SSMAutomationExecution `
    DocumentName "runbook name" `
    -Targets $Targets `
    -TargetParameterName "parameter name" `
    -Parameter @{"input parameter name"="input parameter value";"input parameter
 2 name"="input parameter 2 value"} `
    -MaxConcurrency "10" `
    -MaxError "25%"
```

Targeting using parameter values

Linux & macOS

```
aws ssm start-automation-execution \
    --document-name runbook name \
    --targets Key=ParameterValues,Values=value,value 2,value 3 \
    --target-parameter-name parameter name \
    --parameters "input parameter name=input parameter value" \
    --max-concurrency 10 \
    --max-errors 25%
```

Windows

```
aws ssm start-automation-execution ^
    --document-name runbook name ^
    --targets Key=ParameterValues,Values=value,value 2,value 3 ^
    --target-parameter-name parameter name ^
    --parameters "input parameter name=input parameter value" ^
```

```
    --max-concurrency 10 ^
    --max-errors 25%
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ParameterValues"
$Targets.Values = "value","value 2","value 3"

Start-SSMAutomationExecution `
    -DocumentName "runbook name" `
    -Targets $Targets `
    -TargetParameterName "parameter name" `
    -Parameter @{"input parameter name"="input parameter value"} `
    -MaxConcurrency "10" `
    -MaxError "25%"
```

Targeting using AWS Resource Groups

Linux & macOS

```
aws ssm start-automation-execution \
    --document-name runbook name \
    --targets Key=ResourceGroup,Values=Resource group nname \
    --target-parameter-name parameter name \
    --parameters "input parameter name=input parameter value" \
    --max-concurrency 10 \
    --max-errors 25%
```

Windows

```
aws ssm start-automation-execution ^
    --document-name runbook name ^
    --targets Key=ResourceGroup,Values=Resource group name ^
    --target-parameter-name parameter name ^
    --parameters "input parameter name=input parameter value" ^
    --max-concurrency 10 ^
    --max-errors 25%
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "Resource group name"

Start-SSMAutomationExecution `
    -DocumentName "runbook name" `
    -Targets $Targets `
    -TargetParameterName "parameter name" `
    -Parameter @{"input parameter name"="input parameter value"} `
    -MaxConcurrency "10" `
    -MaxError "25%"
```

Targeting all Amazon EC2 instances in the current AWS account and AWS Region

Linux & macOS

```
aws ssm start-automation-execution \
    --document-name runbook name \
    --targets "Key=AWS::EC2::Instance,Values=*"  \
    --target-parameter-name instanceId \
    --parameters "input parameter name=input parameter value" \
    --max-concurrency 10 \
    --max-errors 25%
```

Windows

```
aws ssm start-automation-execution ^
    --document-name runbook name ^
    --targets Key=AWS::EC2::Instance,Values=* ^
    --target-parameter-name instanceId ^
    --parameters "input parameter name=input parameter value" ^
    --max-concurrency 10 ^
    --max-errors 25%
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "AWS::EC2::Instance"
```

```
$Targets.Values = "*"

Start-SSMAutomationExecution `
    -DocumentName "runbook name" `
    -Targets $Targets `
    -TargetParameterName "instanceId" `
    -Parameter @{"input parameter name"="input parameter value"} `
    -MaxConcurrency "10" `
    -MaxError "25%"
```

The command returns an execution ID. Copy this ID to the clipboard. You can use this ID to view the status of the automation.

Linux & macOS

```
{
    "AutomationExecutionId": "a4a3c0e9-7efd-462a-8594-01234EXAMPLE"
}
```

Windows

```
{
    "AutomationExecutionId": "a4a3c0e9-7efd-462a-8594-01234EXAMPLE"
}
```

PowerShell

```
a4a3c0e9-7efd-462a-8594-01234EXAMPLE
```

5. Run the following command to view the automation. Replace each *automation execution ID* with your own information.

   Linux & macOS

   ```
   aws ssm describe-automation-executions \
       --filter Key=ExecutionId,Values=automation execution ID
   ```

   Windows

   ```
   aws ssm describe-automation-executions ^
   ```

```
    --filter Key=ExecutionId,Values=automation execution ID
```

PowerShell

```
Get-SSMAutomationExecutionList | `
    Where {$_.AutomationExecutionId -eq "automation execution ID"}
```

6. To view details about the automation progress, run the following command. Replace each *automation execution ID* with your own information.

   Linux & macOS

   ```
   aws ssm get-automation-execution \
       --automation-execution-id automation execution ID
   ```

   Windows

   ```
   aws ssm get-automation-execution ^
       --automation-execution-id automation execution ID
   ```

   PowerShell

   ```
   Get-SSMAutomationExecution `
       -AutomationExecutionId automation execution ID
   ```

   The system returns information like the following.

   Linux & macOS

   ```
   {
       "AutomationExecution": {
           "StepExecutionsTruncated": false,
           "AutomationExecutionStatus": "Success",

Note

You can also monitor the status of the automation in the console. In the **Automation executions** list, choose the automation you just ran and then choose the **Execution steps** tab. This tab shows the status of the automation actions.

Mapping targets for an automation

Use the `Targets` parameter to quickly define which resources are targeted by an automation. For example, if you want to run an automation that restarts your managed instances, then instead of manually selecting dozens of instance IDs in the console or typing them in a command, you can target instances by specifying Amazon Elastic Compute Cloud (Amazon EC2) tags with the `Targets` parameter.

When you run an automation that uses a target, AWS Systems Manager creates a child automation for each target. For example, if you target Amazon Elastic Block Store (Amazon EBS) volumes by specifying tags, and those tags resolve to 100 Amazon EBS volumes, then Systems Manager creates 100 child automations. The parent automation is complete when all child automations reach a final state.

> **Note**
>
> Any `input parameters` that you specify at runtime (either in the **Input parameters** section of the console or by using the `parameters` option from the command line) are automatically processed by all child automations.

You can target resources for an automation by using tags, Resource Groups,and parameter values. Additionally, you can use the `TargetMaps` option to target multiple parameter values from the command line or a file. The following section describes each of these targeting options in more detail.

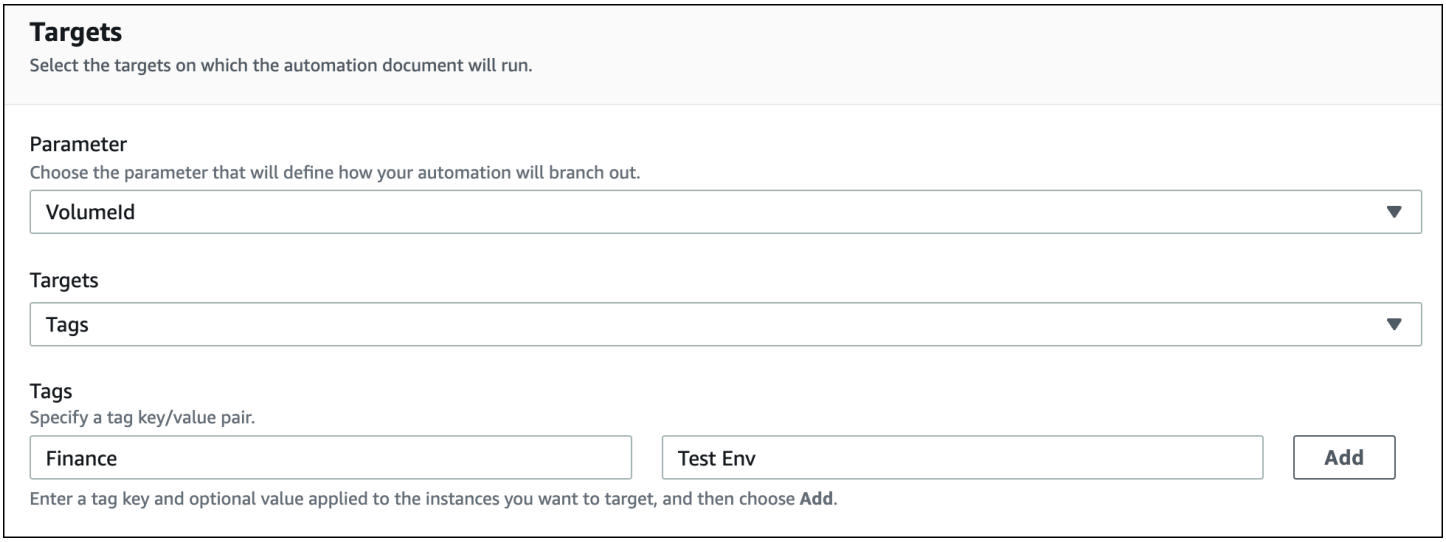
Targeting a tag

You can specify a single tag as the target of an automation. Many AWS resources support tags, including Amazon Elastic Compute Cloud (Amazon EC2) and Amazon Relational Database Service (Amazon RDS) instances, Amazon Elastic Block Store (Amazon EBS) volumes and snapshots, Resource Groups,and Amazon Simple Storage Service (Amazon S3) buckets, to name a few. You can quickly run automation on your AWS resources by targeting a tag. A tag is a key-value pair, such as Operating_System:Linux or Department:Finance. If you assign a specific name to a resource, then you can also use the word "Name" as a key, and the name of the resource as the value.

When you specify a tag as the target for an automation, you also specify a target parameter. The target parameter uses the `TargetParameterName` option. By choosing a target parameter, you define the type of resource on which the automation runs. The target parameter you specify

with the tag must be a valid parameter defined in the runbook. For example, if you want to target dozens of EC2 instances by using tags, then choose the `InstanceId` target parameter. By choosing this parameter, you define *instances* as the resource type for the automation. When creating a custom runbook you must specify the **Target type** as `/AWS::EC2::Instance` to ensure only instances are used. Otherwise, all resources with the same tag will be targeted. When targeting instances with a tag, terminated instances might be included.

The following screenshot uses the `AWS-DetachEBSVolume` runbook. The logical target parameter is `VolumeId`.



The `AWS-DetachEBSVolume` runbook also includes a special property called **Target type**, which is set to `/AWS::EC2::Volume`. This means that if the tag-key pair `Finance:TestEnv` returns different types of resources (for example, EC2 instances, Amazon EBS volumes, Amazon EBS snapshots) then only Amazon EBS volumes will be used.

Important

Target parameter names are case sensitive. If you run automations by using either the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell, then you must enter the target parameter name exactly as it's defined in the runbook. If you don't, the system returns an `InvalidAutomationExecutionParametersException` error. You can use the DescribeDocument API operation to see information about the available target parameters in a specific runbook. Following is an example AWS CLI command that provides information about the `AWS-DeleteSnapshot` document.

```
aws ssm describe-document \
```

```
    --name AWS-DeleteSnapshot
```

Here are some example AWS CLI commands that target resources by using a tag.

Example 1: Targeting a tag using a key-value pair to restart Amazon EC2 instances

This example restarts all Amazon EC2 instances that are tagged with a key of *Department* and a value of *HumanResources*. The target parameter uses the *InstanceId* parameter from the runbook. The example uses an additional parameter to run the automation by using an Automation service role (also called an *assume role*).

```
aws ssm start-automation-execution \
    --document-name AWS-RestartEC2Instance \
    --targets Key=tag:Department,Values=HumanResources \
    --target-parameter-name InstanceId \
    --parameters "AutomationAssumeRole=arn:aws:iam::111122223333:role/
AutomationServiceRole"
```

Example 2: Targeting a tag using a key-value pair to delete Amazon EBS snapshots

The following example uses the `AWS-DeleteSnapshot` runbook to delete all snapshots with a key of *Name* and a value of *January2018Backups*. The target parameter uses the *VolumeId* parameter.

```
aws ssm start-automation-execution \
    --document-name AWS-DeleteSnapshot \
    --targets Key=tag:Name,Values=January2018Backups \
    --target-parameter-name VolumeId
```

Targeting AWS Resource Groups

You can specify a single AWS resource group as the target of an automation. Systems Manager creates a child automation for every object in the target Resource Group.

For example, say that one of your Resource Groups is named PatchedAMIs. This Resource Group includes a list of 25 Windows Amazon Machine Images (AMIs) that are routinely patched. If you run an automation that uses the `AWS-CreateManagedWindowsInstance` runbook and target this Resource Group, then Systems Manager creates a child automation for each of the 25 AMIs. This means, that by targeting the PatchedAMIs Resource Group, the automation creates 25 instances

from a list of patched AMIs. The parent automation is complete when all child automations complete processing or reach a final state.

The following AWS CLI command applies to the PatchAMIs Resource Group example. The command takes the *AmiId* parameter for the `--target-parameter-name` option. The command doesn't include an additional parameter defining which type of instance to create from each AMI. The `AWS-CreateManagedWindowsInstance` runbook defaults to the t2.medium instance type, so this command would create 25 t2.medium Amazon EC2 instances for Windows Server.

```
aws ssm start-automation-execution \
    --document-name AWS-CreateManagedWindowsInstance \
    --targets Key=ResourceGroup,Values=PatchedAMIs  \
    --target-parameter-name AmiId
```

The following console example uses a Resource Group called t2-micro-instances.

Targeting parameter values

You can also target a parameter value. You enter `ParameterValues` as the key and then enter the specific resource value where you want the automation to run. If you specify multiple values, Systems Manager runs a child automation on each value specified.

For example, say that your runbook includes an **InstanceID** parameter. If you target the values of the **InstanceID** parameter when you run the Automation, then Systems Manager runs a child automation for each instance ID value specified. The parent automation is complete when the automation finishes running each specified instance, or if the automation fails. You can target a maximum of 50 parameter values.

The following example uses the `AWS-CreateImage` runbook. The target parameter name specified is *InstanceId*. The key uses *ParameterValues*. The values are two Amazon EC2 instance IDs. This command creates an automation for each instance, which produces an AMI from each instance.

```
aws ssm start-automation-execution
    --document-name AWS-CreateImage \
    --target-parameter-name InstanceId \
    --targets Key=ParameterValues,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE
```

> **Note**
>
> `AutomationAssumeRole` isn't a valid parameter. Don't choose this item when running automation that target a parameter value.

Targeting parameter value maps

The `TargetMaps` option expands your ability to target `ParameterValues`. You can enter an array of parameter values by using `TargetMaps` at the command line. You can specify a maximum of 50 parameter values at the command line. If you want to run commands that specify more than 50 parameter values, then you can enter the values in a JSON file. You can then call the file from the command line.

> **Note**
>
> The `TargetMaps` option isn't supported in the console.

Use the following format to specify multiple parameter values by using the `TargetMaps` option in a command. Replace each *`example resource placeholder`* with your own information.

```
aws ssm start-automation-execution \
    --document-name runbook name \
    --target-maps “parameter=value, parameter 2=value, parameter 3=value”  “parameter
 4=value, parameter 5=value, parameter 6=value”
```

If you want to enter more than 50 parameter values for the `TargetMaps` option, then specify the values in a file by using the following JSON format. Using a JSON file also improves readability when providing multiple parameter values.

```
[

    {“parameter”: "value", “parameter 2”: "value", “parameter 3”: "value"},

    {“parameter 4”: "value", “parameter 5”: "value", "parameter 6": "value"}

]
```

Save the file with a .json file extension. You can call the file by using the following command. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \
    --document-name runbook name \
    --parameters input parameters \
    --target-maps path to file/file name.json
```

You can also download the file from an Amazon Simple Storage Service (Amazon S3) bucket, as long as you have permission to read data from the bucket. Use the following command format. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \
    --document-name runbook name \
    --target-maps http://amzn-s3-demo-bucket.s3.amazonaws.com/file_name.json
```

Here is an example scenario to help you understand the `TargetMaps` option. In this scenario, a user wants to create Amazon EC2 instances of different types from different AMIs. To perform this task, the user creates a runbook named AMI_Testing. This runbook defines two input parameters: `instanceType` and `imageId`.

```
{
  "description": "AMI Testing",
  "schemaVersion": "0.3",
  "assumeRole": "{{assumeRole}}",
  "parameters": {
    "assumeRole": {
      "type": "String",
```

```
      "description": "Role under which to run the automation",
      "default": ""
    },
    "instanceType": {
      "type": "String",
      "description": "Type of EC2 Instance to launch for this test"
    },
    "imageId": {
      "type": "String",
      "description": "Source AMI id from which to run instance"
    }
  },
  "mainSteps": [
    {
      "name": "runInstances",
      "action": "aws:runInstances",
      "maxAttempts": 1,
      "onFailure": "Abort",
      "inputs": {
        "ImageId": "{{imageId}}",
        "InstanceType": "{{instanceType}}",
        "MinInstanceCount": 1,
        "MaxInstanceCount": 1
      }
    }
  ],
  "outputs": [
    "runInstances.InstanceIds"
  ]
}
```

The user then specifies the following target parameter values in a file named `AMI_instance_types.json`.

```
[
  {
    "instanceType" : ["t2.micro"],
    "imageId" : ["ami-b70554c8"]
  },
  {
    "instanceType" : ["t2.small"],
    "imageId" : ["ami-b70554c8"]
  },
```

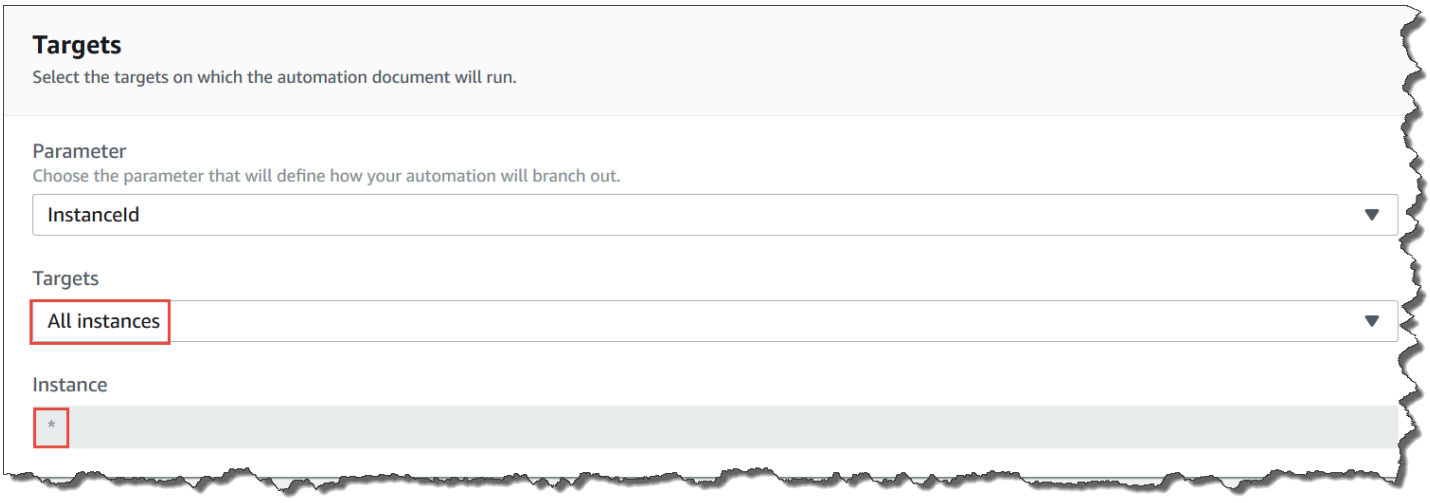
```
  {
    "instanceType" : ["t2.medium"],
    "imageId" : ["ami-cfe4b2b0"]
  },
  {
    "instanceType" : ["t2.medium"],
    "imageId" : ["ami-cfe4b2b0"]
  },
  {
    "instanceType" : ["t2.medium"],
    "imageId" : ["ami-cfe4b2b0"]
  }
]
```

The user can run the automation and create the five EC2 instances defined in `AMI_instance_types.json` by running the following command.

```
aws ssm start-automation-execution \
    --document-name AMI_Testing \
    --target-parameter-name imageId \
    --target-maps file:///home/TestUser/workspace/runinstances/AMI_instance_types.json
```

Targeting all Amazon EC2 instances

You can run an automation on all Amazon EC2 instances in the current AWS account and AWS Region by choosing **All instances** in the **Targets** list. For example, if you want to restart all Amazon EC2 instances your AWS account and the current AWS Region, you can choose the **`AWS-RestartEC2Instance`** runbook and then choose **All instances** from the **Targets** list.



After you choose **All instances**, Systems Manager populates the **Instance** field with an asterisk (*) and makes the field unavailable for changes (the field is grayed out). Systems Manager also makes the **InstanceId** field in the **Input parameters** field unavailable for changes. Making these fields unavailable for changes is expected behavior if you choose to target all instances.

Control automations at scale

You can control the deployment of an automation across a fleet of AWS resources by specifying a concurrency value and an error threshold. Concurrency and error threshold are collectively called *rate controls*.

Concurrency

Use Concurrency to specify how many resources are allowed to run an automation simultaneously. Concurrency helps to limit the impact or downtime on your resources when processing an automation. You can specify either an absolute number of resources, for example 20, or a percentage of the target set, for example 10%.

The queueing system delivers the automation to a single resource and waits until the initial invocation is complete before sending the automation to two more resources. The system exponentially sends the automation to more resources until the concurrency value is met.

Error thresholds

Use an error threshold to specify how many automations are allowed to fail before AWS Systems Manager stops sending the automation to other resources. You can specify either an absolute number of errors, for example 10, or a percentage of the target set, for example 10%.

If you specify an absolute number of 3 errors, for example, the system stops running the automation when the fourth error is received. If you specify 0, then the system stops running the automation on additional targets after the first error result is returned.

If you send an automation to, for example, 50 instances and set the error threshold to 10%, then the system stops sending the command to additional instances when the fifth error is received. Invocations that are already running an automation when an error threshold is reached are allowed to be completed, but some of these automations might fail as well. If you need to ensure that there won't be more errors than the number specified for the error threshold, then set the **Concurrency** value to 1 so that automations proceed one at a time.

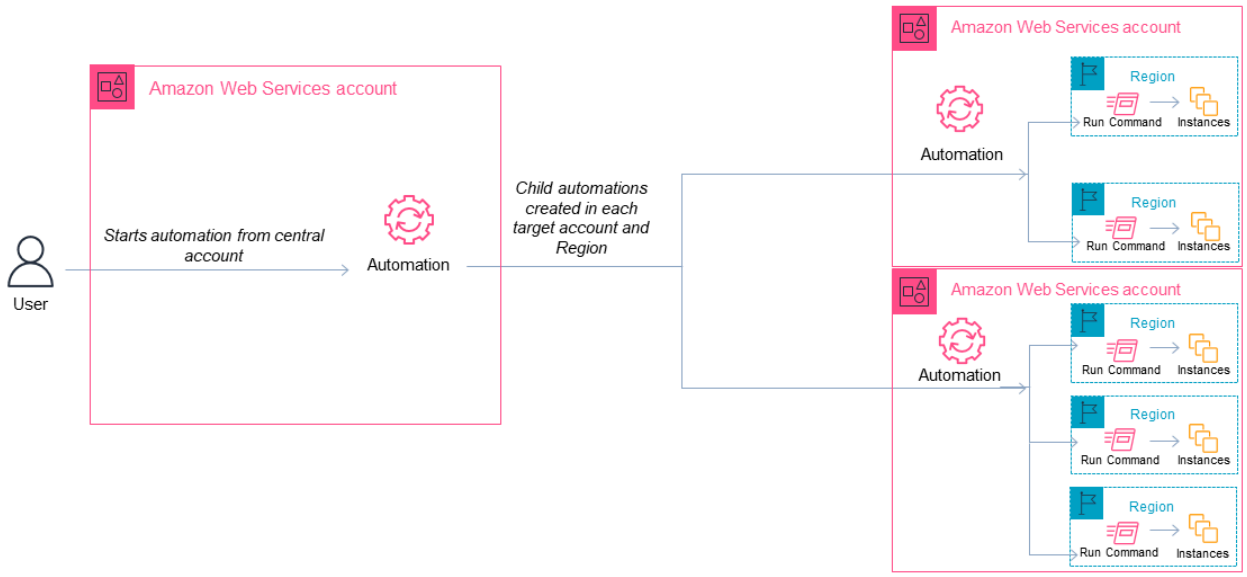
Running automations in multiple AWS Regions and accounts

You can run AWS Systems Manager automations across multiple AWS Regions and AWS accounts or AWS Organizations organizational units (OUs) from a central account. Automation is a tool in AWS Systems Manager. Running automations in multiple Regions and accounts or OUs reduces the time required to administer your AWS resources while enhancing the security of your computing environment.

For example, you can do the following by using automation runbooks:

- Implement patching and security updates centrally.
- Remediate compliance drift on VPC configurations or Amazon S3 bucket policies.
- Manage resources, such as Amazon Elastic Compute Cloud (Amazon EC2) EC2 instances, at scale.

The following diagram shows an example of a user who is running the `AWS-RestartEC2Instances` runbook in multiple Regions and accounts from a central account. The automation locates the instances by using the specified tags in the targeted Regions and accounts.



Choose a central account for Automation

If you want to run automations across OUs, the central account must have permissions to list all of the accounts in the OUs. This is only possible from a delegated administrator account, or the management account of the organization. We recommend that you follow AWS Organizations best practices and use a delegated administrator account. For more information about AWS Organizations best practices, see Best practices for the management account in the *AWS Organizations User Guide*. To create a delegated administrator account for Systems Manager, you can use the `register-delegated-administrator` command with the AWS CLI as shown in the following example.

```
aws organizations register-delegated-administrator \
    --account-id delegated admin account ID \
    --service-principal ssm.amazonaws.com
```

If you want to run automations across multiple accounts that are not managed by AWS Organizations, we recommend creating a dedicated account for automation management. Running all cross-account automations from a dedicated account simplifies IAM permissions management, troubleshooting efforts, and creates a layer of separation between operations and administration. This approach is also recommended if you use AWS Organizations, but only want to target individual accounts and not OUs.

How running automations works

Running automations across multiple Regions and accounts or OUs works as follows:

1. Sign in to the account that you want to configure as the Automation central account.
2. Use the Setting up management account permissions for multi-Region and multi-account automation procedure in this topic to create the following IAM roles:
   - **`AWS-SystemsManager-AutomationAdministrationRole`** - This role gives the user permission to run automations in multiple accounts and OUs.
   - **`AWS-SystemsManager-AutomationExecutionRole`** - This role gives the user permission to run automations in the targeted accounts.
3. Choose the runbook, Regions, and accounts or OUs where you want to run the automation.

> **Note**
>
> Be sure that the target OU contains the desired accounts. If you choose a custom runbook, the runbook must be shared with all of the target accounts. For information

about sharing runbooks, see Sharing SSM documents. For information about using shared runbooks, see Using shared SSM documents.

4. Run the automation.

> **Note**
>
> When running automations across multiple Regions, accounts, or OUs, the automation you run from the primary account starts child automations in each of the target accounts. The automation in the primary account contains `aws:executeAutomation` steps for each of the target accounts.

5. Use the GetAutomationExecution, DescribeAutomationStepExecutions, and DescribeAutomationExecutions API operations from the AWS Systems Manager console or the AWS CLI to monitor automation progress. The output of the steps for the automation in your primary account will be the `AutomationExecutionId` of the child automations. To view the output of the child automations created in your target accounts, be sure to specify the appropriate account, Region, and `AutomationExecutionId` in your request.

Setting up management account permissions for multi-Region and multi-account automation

Use the following procedure to create the required IAM roles for Systems Manager Automation multi-Region and multi-account automation by using AWS CloudFormation. This procedure describes how to create the **`AWS-SystemsManager-AutomationAdministrationRole`** role. You only need to create this role in the Automation central account. This procedure also describes how to create the **`AWS-SystemsManager-AutomationExecutionRole`** role. You must create this role in *every* account that you want to target to run multi-Region and multi-account automations. We recommend using AWS CloudFormation StackSets to create the **`AWS-SystemsManager-AutomationExecutionRole`** role in the accounts you want to target to run multi-Region and multi-account automations.

To create the required IAM administration role for multi-Region and multi-account automations by using AWS CloudFormation

1. Download and unzip the `AWS-SystemsManager-AutomationAdministrationRole.zip`. Or, if your accounts are managed by AWS Organizations `AWS-SystemsManager-AutomationAdministrationRole (org).zip`. This file contains the `AWS-`

SystemsManager-AutomationAdministrationRole.yaml AWS CloudFormation template file.

2. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. Choose **Create stack**.
4. In the **Specify template** section, choose **Upload a template**.
5. Choose **Choose file**, and then choose the AWS-SystemsManager-AutomationAdministrationRole.yaml AWS CloudFormation template file.
6. Choose **Next**.
7. On the **Specify stack details** page, in the **Stack name** field, enter a name.
8. Choose **Next**.
9. On the **Configure stack options** page, enter values for any options you want to use. Choose **Next**.
10. On the **Review** page, scroll down and choose the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** option.
11. Choose **Create stack**.

AWS CloudFormation shows the **CREATE_IN_PROGRESS** status for approximately three minutes. The status changes to **CREATE_COMPLETE**.

You must repeat the following procedure in *every* account that you want to target to run multi-Region and multi-account automations.

To create the required IAM automation role for multi-Region and multi-account automations by using AWS CloudFormation

1. Download the AWS-SystemsManager-AutomationExecutionRole.zip. Or, if your accounts are managed by AWS Organizations AWS-SystemsManager-AutomationExecutionRole (org).zip. This file contains the AWS-SystemsManager-AutomationExecutionRole.yaml AWS CloudFormation template file.
2. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. Choose **Create stack**.
4. In the **Specify template** section, choose **Upload a template**.
5. Choose **Choose file**, and then choose the AWS-SystemsManager-AutomationExecutionRole.yaml AWS CloudFormation template file.

6. Choose **Next**.
7. On the **Specify stack details** page, in the **Stack name** field, enter a name.
8. In the **Parameters** section, in the **AdminAccountId** field, enter the ID for the Automation central account.
9. If you are setting up this role for an AWS Organizations environment, there is another field in the section called **OrganizationID**. Enter the ID of your AWS organization.
10. Choose **Next**.
11. On the **Configure stack options** page, enter values for any options you want to use. Choose **Next**.
12. On the **Review** page, scroll down and choose the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** option.
13. Choose **Create stack**.

AWS CloudFormation shows the **CREATE_IN_PROGRESS** status for approximately three minutes. The status changes to **CREATE_COMPLETE**.

Run an automation in multiple Regions and accounts (console)

The following procedure describes how to use the Systems Manager console to run an automation in multiple Regions and accounts from the Automation management account.

Before you begin

Before you complete the following procedure, note the following information:

- The user or role you use to run a multi-Region or multi-account automation must have the `iam:PassRole` permission for the `AWS-SystemsManager-AutomationAdministrationRole` role.
- AWS account IDs or OUs where you want to run the automation.
- Regions supported by Systems Manager where you want to run the automation.
- The tag key and the tag value, or the name of the resource group, where you want to run the automation.

To run an automation in multiple Regions and accounts

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

   > **Note**
   >
   > You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:

   - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
   - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
   - **1 (Default)** – Choose this option to run the first version of the document, which is the default.

5. Choose **Next**.
6. On the **Execute automation document** page, choose **Multi-account and Region**.
7. In the **Target accounts and Regions** section, use the **Accounts, organizational units (OUs), and roots** field to specify the different AWS accounts or AWS organizational units (OUs) where you want to run the automation. Separate multiple accounts or OUs with a comma.

   a. (Optional) Select the **Include child OUs** checkbox to include all child organizational units within the specified OUs.

   b. (Optional) In the **Exclude accounts and organizational units (OUs)** field, enter a comma-separated list of account IDs and OU IDs that you want to exclude from the expanded entities entered above.

8. Use the **Regions** list to choose one or more Regions where you want to run the automation.

9. Use the **Multi-Region and account rate control** options to restrict the automation to a limited number of accounts running in a limited number of Regions. These options don't restrict the number of AWS resources that can run the automations.

    a. In the **Location (account-Region pair) concurrency** section, choose an option to restrict the number of automations that can run in multiple accounts and Regions at the same time. For example, if you choose to run an automation in five (5) AWS accounts, which are located in four (4) AWS Regions, then Systems Manager runs automations in a total of 20 account-Region pairs. You can use this option to specify an absolute number, such as **2**, so that the automation only runs in two account-Region pairs at the same time. Or you can specify a percentage of the account-Region pairs that can run at the same time. For example, with 20 account-Region pairs, if you specify 20%, then the automation simultaneously runs in a maximum of five (5) account-Region pairs.

    - Choose **targets** to enter an absolute number of account-Region pairs that can run the automation simultaneously.
    - Choose **percent** to enter a percentage of the total number of account-Region pairs that can run the automation simultaneously.

    b. In the **Error threshold** section, choose an option:

    - Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the automation to other resources.
    - Choose **percent** to enter a percentage of errors allowed before Automation stops sending the automation to other resources.

10. In the **Targets** section, choose how you want to target the AWS resources where you want to run the Automation. These options are required.

    a. Use the **Parameter** list to choose a parameter. The items in the **Parameter** list are determined by the parameters in the Automation runbook that you selected at the start of this procedure. By choosing a parameter you define the type of resource on which the Automation workflow runs.

    b. Use the **Targets** list to choose how you want to target resources.

        i. If you chose to target resources by using parameter values, then enter the parameter value for the parameter you chose in the **Input parameters** section.

        ii. If you chose to target resources by using AWS Resource Groups, then choose the name of the group from the **Resource Group** list.

iii. If you chose to target resources by using tags, then enter the tag key and (optionally) the tag value in the fields provided. Choose **Add**.

iv. If you want to run an Automation runbook on all instances in the current AWS account and AWS Region, then choose **All instances**.

11. In the **Input parameters** section, specify the required inputs. Choose the `AWS-SystemsManager-AutomationAdministrationRole` IAM service role from the **AutomationAssumeRole** list.

> **Note**
>
> You might not need to choose some of the options in the **Input parameters** section. This is because you targeted resources in multiple Regions and accounts by using tags or a resource group. For example, if you chose the `AWS-RestartEC2Instance` runbook, then you don't need to specify or choose instance IDs in the **Input parameters** section. The automation locates the instances to restart by using the tags you specified.

12. (Optional) Choose a CloudWatch alarm to apply to your automation for monitoring. To attach a CloudWatch alarm to your automation, the IAM principal that starts the automation must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms. Note that if your alarm activates, the automation is cancelled and any `0nCancel` steps you have defined run. If you use AWS CloudTrail, you will see the API call in your trail.

13. Use the options in the **Rate control** section to restrict the number of AWS resources that can run the Automation within each account-Region pair.

    In the **Concurrency** section, choose an option:

    - Choose **targets** to enter an absolute number of targets that can run the Automation workflow simultaneously.
    - Choose **percentage** to enter a percentage of the target set that can run the Automation workflow simultaneously.

14. In the **Error threshold** section, choose an option:

    - Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the workflow to other resources.

- Choose **percentage** to enter a percentage of errors allowed before Automation stops sending the workflow to other resources.

15. Choose **Execute**.

After an automation execution completes, you can rerun the execution with the same or modified parameters. For more information, see Rerunning automation executions.

Run an automation in multiple Regions and accounts (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to run an automation in multiple Regions and accounts from the Automation management account.

Before you begin

Before you complete the following procedure, note the following information:

- AWS account IDs or OUs where you want to run the automation.
- Regions supported by Systems Manager where you want to run the automation.
- The tag key and the tag value, or the name of the resource group, where you want to run the automation.

To run an automation in multiple Regions and accounts

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Use the following format to create a command to run an automation in multiple Regions and accounts. Replace each *example resource placeholder* with your own information.

   Linux & macOS

```
aws ssm start-automation-execution \
        --document-name runbook name \
        --parameters AutomationAssumeRole=arn:aws:iam::management account
 ID:role/AWS-SystemsManager-AutomationAdministrationRole \
        --target-parameter-name parameter name \
        --targets Key=tag key,Values=value \
```

```
        --target-locations Accounts=account ID,account ID
 2,Regions=Region,Region 2,ExecutionRoleName=AWS-SystemsManager-
AutomationExecutionRole
```

Windows

```
aws ssm start-automation-execution ^
        --document-name runbook name ^
        --parameters AutomationAssumeRole=arn:aws:iam::management account
 ID:role/AWS-SystemsManager-AutomationAdministrationRole ^
        --target-parameter-name parameter name ^
        --targets Key=tag key,Values=value ^
        --target-locations Accounts=account ID,account ID
 2,Regions=Region,Region 2,ExecutionRoleName=AWS-SystemsManager-
AutomationExecutionRole
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
    $Targets.Key = "tag key"
    $Targets.Values = "value"

    Start-SSMAutomationExecution `
        -DocumentName "runbook name" `
        -Parameter @{
        "AutomationAssumeRole"="arn:aws:iam::management account ID:role/AWS-
SystemsManager-AutomationAdministrationRole" } `
        -TargetParameterName "parameter name" `
        -Target $Targets `
        -TargetLocation @{
        "Accounts"="account ID","account ID 2";
        "Regions"="Region","Region 2";
        "ExecutionRoleName"="AWS-SystemsManager-AutomationExecutionRole" }
```

Examples: Running an automation in multiple Regions and accounts

The following are examples demonstrating how to use the AWS CLI and PowerShell to run automations in multiple accounts and Regions with a single command.

Example 1: This example restarts EC2 instances in three Regions across an entire AWS Organizations organization. This is achieved by targeting the root ID of the organization, and including child OUs.

Linux & macOS

```
aws ssm start-automation-execution \
        --document-name "AWS-RestartEC2Instance" \
        --target-parameter-name InstanceId \
        --targets '[{"Key":"AWS::EC2::Instance","Values":["*"]}]' \
        --target-locations '[{
            "Accounts": ["r-example"],
            "IncludeChildOrganizationUnits": true,
            "Regions": ["us-east-1", "us-east-2", "us-west-2"]
        }]'
```

Windows

```
aws ssm start-automation-execution \
        --document-name "AWS-RestartEC2Instance" ^
        --target-parameter-name InstanceId ^
        --targets '[{"Key":"AWS::EC2::Instance","Values":["*"]}]' ^
        --target-locations '[{
            "Accounts": ["r-example"],
            "IncludeChildOrganizationUnits": true,
            "Regions": ["us-east-1", "us-east-2", "us-west-2"]
        }]'
```

PowerShell

```
Start-SSMAutomationExecution `
        -DocumentName "AWS-RestartEC2Instance" `
        -TargetParameterName "InstanceId" `
        -Targets '[{"Key":"AWS::EC2::Instance","Values":["*"]}]'
        -TargetLocation @{
            "Accounts"="r-example";
            "Regions"="us-east-1", "us-east-2", "us-west-2";
            "IncludeChildOrganizationUnits"=true}
```

Example 2: This example restarts specific EC2 instances in different accounts and Regions.

> **Note**
>
> The `TargetLocationMaxConcurrency` option is available using the AWS CLI and AWS SDKs.

Linux & macOS

```
aws ssm start-automation-execution \
        --document-name "AWS-RestartEC2Instance" \
        --target-parameter-name InstanceId \
        --target-locations '[{
            "Accounts": ["123456789012"],
            "Targets": [{
                "Key":"ParameterValues",
                "Values":["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]
            }],
            "TargetLocationMaxConcurrency": "100%",
            "Regions": ["us-east-1"]
        }, {
            "Accounts": ["987654321098"],
            "Targets": [{
                "Key":"ParameterValues",
                "Values":["i-07782c72faEXAMPLE"]
            }],
            "TargetLocationMaxConcurrency": "100%",
            "Regions": ["us-east-2"]
        }]'
```

Windows

```
aws ssm start-automation-execution ^
        --document-name "AWS-RestartEC2Instance" ^
        --target-parameter-name InstanceId ^
        --target-locations '[{
            "Accounts": ["123456789012"],
            "Targets": [{
                "Key":"ParameterValues",
                "Values":["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]
            }],
            "TargetLocationMaxConcurrency": "100%",
```

```
            "Regions": ["us-east-1"]
        }, {
            "Accounts": ["987654321098"],
            "Targets": [{
                "Key":"ParameterValues",
                "Values":["i-07782c72faEXAMPLE"]
            }],
            "TargetLocationMaxConcurrency": "100%",
            "Regions": ["us-east-2"]
        }]'
```

PowerShell

```
Start-SSMAutomationExecution `
        -DocumentName "AWS-RestartEC2Instance" `
        -TargetParameterName "InstanceId" `
        -Targets '[{"Key":"AWS::EC2::Instance","Values":["*"]}]'
        -TargetLocation @({
            "Accounts"="123456789012",
            "Targets"= @{
                "Key":"ParameterValues",
                "Values":["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]
            },
            "TargetLocationMaxConcurrency"="100%",
            "Regions"=["us-east-1"]
        }, {
            "Accounts"="987654321098",
            "Targets": @{
                "Key":"ParameterValues",
                "Values":["i-07782c72faEXAMPLE"]
            },
            "TargetLocationMaxConcurrency": "100%",
            "Regions"=["us-east-2"]
        })
```

Example 3: This example demonstrates specifying multiple AWS accounts and Regions where the automation should run using the `--target-locations-url` option. The value for this option must be a JSON file in a publicly accessible presigned Amazon S3 URL.

> **Note**
>
> `--target-locations-url` is available when using the AWS CLI and AWS SDKs.

Linux & macOS

```
aws ssm start-automation-execution \
    --document-name "MyCustomAutomationRunbook" \
    --target-locations-url "https://amzn-s3-demo-bucket.s3.amazonaws.com/target-
locations.json"
```

Windows

```
aws ssm start-automation-execution ^
    --document-name "MyCustomAutomationRunbook" ^
    --target-locations-url "https://amzn-s3-demo-bucket.s3.amazonaws.com/target-
locations.json"
```

PowerShell

```
Start-SSMAutomationExecution `
    -DocumentName "MyCustomAutomationRunbook" `
    -TargetLocationsUrl "https://amzn-s3-demo-bucket.s3.amazonaws.com/target-
locations.json"
```

Sample content for the JSON file:

```
[
{
        "Accounts": [ "123456789012", "987654321098", "456789123012" ],
        "ExcludeAccounts": [ "111222333444", "999888444666" ],
        "ExecutionRoleName": "MyAutomationExecutionRole",
        "IncludeChildOrganizationUnits": true,
        "Regions": [ "us-east-1", "us-west-2", "ap-south-1", "ap-northeast-1" ],
        "Targets": ["Key": "AWS::EC2::Instance", "Values": ["i-2"]],
        "TargetLocationMaxConcurrency": "50%",
        "TargetLocationMaxErrors": "10",
        "TargetsMaxConcurrency": "20",
```

```
        "TargetsMaxErrors": "12"
 }
]
```

Example 4: This example restarts EC2 instances in the 123456789012 and 987654321098 accounts, which are located in the us-east-2 and us-west-1 Regions. The instances must be tagged with the tag key-pair value Env-PROD.

Linux & macOS

```
aws ssm start-automation-execution \
        --document-name AWS-RestartEC2Instance \
        --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole \
        --target-parameter-name InstanceId \
        --targets Key=tag:Env,Values=PROD \
        --target-locations Accounts=123456789012,987654321098,Regions=us-
east-2,us-west-1,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

Windows

```
aws ssm start-automation-execution ^
        --document-name AWS-RestartEC2Instance ^
        --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole ^
        --target-parameter-name InstanceId ^
        --targets Key=tag:Env,Values=PROD ^
        --target-locations Accounts=123456789012,987654321098,Regions=us-
east-2,us-west-1,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
    $Targets.Key = "tag:Env"
    $Targets.Values = "PROD"

    Start-SSMAutomationExecution `
        -DocumentName "AWS-RestartEC2Instance" `
        -Parameter @{
        "AutomationAssumeRole"="arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole" } `
```

```
        -TargetParameterName "InstanceId" `
        -Target $Targets `
        -TargetLocation @{
        "Accounts"="123456789012","987654321098";
        "Regions"="us-east-2","us-west-1";
        "ExecutionRoleName"="AWS-SystemsManager-AutomationExecutionRole" }
```

Example 5: This example restarts EC2 instances in the 123456789012 and 987654321098 accounts, which are located in the `eu-central-1` Region. The instances must be members of the `prod-instances` AWS resource group.

Linux & macOS

```
aws ssm start-automation-execution \
        --document-name AWS-RestartEC2Instance \
        --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole \
        --target-parameter-name InstanceId \
        --targets Key=ResourceGroup,Values=prod-instances \
        --target-locations Accounts=123456789012,987654321098,Regions=eu-
central-1,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

Windows

```
aws ssm start-automation-execution ^
        --document-name AWS-RestartEC2Instance ^
        --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole ^
        --target-parameter-name InstanceId ^
        --targets Key=ResourceGroup,Values=prod-instances ^
        --target-locations Accounts=123456789012,987654321098,Regions=eu-
central-1,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
    $Targets.Key = "ResourceGroup"
    $Targets.Values = "prod-instances"

    Start-SSMAutomationExecution `
        -DocumentName "AWS-RestartEC2Instance" `
```

```
        -Parameter @{
        "AutomationAssumeRole"="arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole" } `
        -TargetParameterName "InstanceId" `
        -Target $Targets `
        -TargetLocation @{
        "Accounts"="123456789012","987654321098";
        "Regions"="eu-central-1";
        "ExecutionRoleName"="AWS-SystemsManager-AutomationExecutionRole" }
```

Example 6: This example restarts EC2 instances in the `ou-1a2b3c-4d5e6c` AWS organizational unit (OU). The instances are located in the `us-west-1` and `us-west-2` Regions. The instances must be members of the `WebServices` AWS resource group.

Linux & macOS

```
aws ssm start-automation-execution \
        --document-name AWS-RestartEC2Instance \
        --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole \
        --target-parameter-name InstanceId \
        --targets Key=ResourceGroup,Values=WebServices \
        --target-locations Accounts=ou-1a2b3c-4d5e6c,Regions=us-west-1,us-
west-2,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

Windows

```
aws ssm start-automation-execution ^
        --document-name AWS-RestartEC2Instance ^
        --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole ^
        --target-parameter-name InstanceId ^
        --targets Key=ResourceGroup,Values=WebServices ^
        --target-locations Accounts=ou-1a2b3c-4d5e6c,Regions=us-west-1,us-
west-2,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
    $Targets.Key = "ResourceGroup"
    $Targets.Values = "WebServices"
```

```
    Start-SSMAutomationExecution `
        -DocumentName "AWS-RestartEC2Instance" `
        -Parameter @{
        "AutomationAssumeRole"="arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole" } `
        -TargetParameterName "InstanceId" `
        -Target $Targets `
        -TargetLocation @{
        "Accounts"="ou-1a2b3c-4d5e6c";
        "Regions"="us-west-1";
        "ExecutionRoleName"="AWS-SystemsManager-AutomationExecutionRole" }
```

The system returns information similar to the following.

Linux & macOS

```
{
        "AutomationExecutionId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
    }
```

Windows

```
{
        "AutomationExecutionId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
    }
```

PowerShell

```
4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

3. Run the following command to view details for the automation. Replace *automation execution ID* with your own information.

Linux & macOS

```
aws ssm describe-automation-executions \
        --filters Key=ExecutionId,Values=automation execution ID
```

Windows

```
aws ssm describe-automation-executions ^
        --filters Key=ExecutionId,Values=automation execution ID
```

PowerShell

```
Get-SSMAutomationExecutionList | `
        Where {$_.AutomationExecutionId -eq "automation execution ID"}
```

4. Run the following command to view details about the automation progress.

Linux & macOS

```
aws ssm get-automation-execution \
        --automation-execution-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

Windows

```
aws ssm get-automation-execution ^
        --automation-execution-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

PowerShell

```
Get-SSMAutomationExecution `
        -AutomationExecutionId a4a3c0e9-7efd-462a-8594-01234EXAMPLE
```

> **Note**
>
> You can also monitor the status of the automation in the console. In the **Automation executions** list, choose the automation you just ran and then choose the **Execution steps** tab. This tab shows the status of the automation actions.

More info

Centralized multi-account and multi-Region patching with AWS Systems Manager Automation

Run automations based on EventBridge events

You can start an automation by specifying a runbook as the target of an Amazon EventBridge event. You can start automations according to a schedule, or when a specific AWS system event occurs. For example, let's say you create a runbook named *BootStrapInstances* that installs software on an instance when an instance starts. To specify the *BootStrapInstances* runbook (and corresponding automation) as a target of an EventBridge event, you first create a new EventBridge rule. (Here's an example rule: **Service name**: EC2, **Event Type**: EC2 Instance State-change Notification, **Specific state(s)**: running, **Any instance**.) Then you use the following procedures to specify the *BootStrapInstances* runbook as the target of the event using the EventBridge console and AWS Command Line Interface (AWS CLI). When a new instance starts, the system runs the automation and installs software.

For information about creating runbooks, see Creating your own runbooks.

Creating an EventBridge event that uses a runbook (console)

Use the following procedure to configure a runbook as the target of a EventBridge event.

To configure a runbook as a target of a EventBridge event rule

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule.

   A rule can't have the same name as another rule in the same Region and on the same event bus.
5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own AWS account, select **default**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
6. Choose how the rule is triggered.

To create a rule based on...	Do this...
Event	a. For **Rule type**, choose **Rule with an event pattern**. b. Choose **Next**. c. For **Event source**, choose **AWS events or EventBridge partner events**. d. In the **Event pattern** section, do one of the following: • To use a template to create your event pattern, choose **Event pattern form** and choose **Event source**, **AWS service**, and **Event type**. If you choose **All Events** as the event type, all events emitted by the AWS service will match the rule. To customize the template, choose **Custom pattern (JSON editor)** and make your changes. • To use a custom event pattern, choose **Custom pattern (JSON editor)** and create your event pattern.

To create a rule based on...	Do this...
Schedule	a. For **Rule type**, choose **Schedule**. b. Choose **Next**. c. For **Schedule pattern**, do one of the following: • To use a cron expression to define the schedule, choose **A fine-grained schedule that runs at a specific time, such as 8:00 a.m. PST on the first Monday of every month** and enter the cron expression. • To use a rate expression to define the schedule, choose **A schedule that runs at a regular rate, such as every 10 minutes** and enter the rate expression.

7. Choose **Next**.
8. For **Target types**, choose **AWS service**.
9. For **Select a target**, choose **Systems Manager Automation**.
10. For **Document**, choose a runbook to use when your target is invoked.
11. In the **Configure automation parameter(s)** section, either keep the default parameter values (if available) or enter your own values.

> **Note**
>
> To create a target, you must specify a value for each required parameter. If you don't, the system creates the rule, but the rule won't run.

12. For many target types, EventBridge needs permissions to send events to the target. In these cases, EventBridge can create the IAM role needed for your rule to run. Do one of the following:

    - To create an IAM role automatically, choose **Create a new role for this specific resource**.
    - To use an IAM role that you created earlier, choose **Use existing role** and select the existing role from the dropdown. Note that you might need to update the trust policy for your IAM role to include EventBridge. The following is an example:

    JSON

    ```
    {
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "",
                "Effect": "Allow",
                "Principal": {
                    "Service": [
                        "events.amazonaws.com",
                        "ssm.amazonaws.com"
                    ]
                },
                "Action": "sts:AssumeRole"
            }
        ]
    }
    ```

13. Choose **Next**.
14. (Optional) Enter one or more tags for the rule. For more information, see Tagging Your Amazon EventBridge Resources in the *Amazon EventBridge User Guide*.
15. Choose **Next**.

16. Review the details of the rule and choose **Create rule**.

Create an EventBridge event that uses a runbook (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to create an EventBridge event rule and configure a runbook as the target.

To configure a runbook as a target of an EventBridge event rule

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Create a command to specify a new EventBridge event rule. Replace each *example resource placeholder* with your own information.

   Triggers based on a schedule

   Linux & macOS

   ```
   aws events put-rule \
   --name "rule name" \
   --schedule-expression "cron or rate expression"
   ```

   Windows

   ```
   aws events put-rule ^
   --name "rule name" ^
   --schedule-expression "cron or rate expression"
   ```

   PowerShell

   ```
   Write-CWERule `
   -Name "rule name" `
   -ScheduleExpression "cron or rate expression"
   ```

   The following example creates an EventBridge event rule that starts every day at 9:00 AM (UTC).

Linux & macOS

```
aws events put-rule \
--name "DailyAutomationRule" \
--schedule-expression "cron(0 9 * * ? *)"
```

Windows

```
aws events put-rule ^
--name "DailyAutomationRule" ^
--schedule-expression "cron(0 9 * * ? *)"
```

PowerShell

```
Write-CWERule `
-Name "DailyAutomationRule" `
-ScheduleExpression "cron(0 9 * * ? *)"
```

Triggers based on an event

Linux & macOS

```
aws events put-rule \
--name "rule name" \
--event-pattern "{\"source\":[\"aws.service\"],\"detail-type\":[\"service event
 detail type\"]}"
```

Windows

```
aws events put-rule ^
--name "rule name" ^
--event-pattern "{\"source\":[\"aws.service\"],\"detail-type\":[\"service event
 detail type\"]}"
```

PowerShell

```
Write-CWERule `
-Name "rule name" `
```

```
-EventPattern '{"source":["aws.service"],"detail-type":["service event detail
 type"]}'
```

The following example creates an EventBridge event rule that starts when any EC2 instance in the Region changes state.

Linux & macOS

```
aws events put-rule \
--name "EC2InstanceStateChanges" \
--event-pattern "{\"source\":[\"aws.ec2\"],\"detail-type\":[\"EC2 Instance
 State-change Notification\"]}"
```

Windows

```
aws events put-rule ^
--name "EC2InstanceStateChanges" ^
--event-pattern "{\"source\":[\"aws.ec2\"],\"detail-type\":[\"EC2 Instance
 State-change Notification\"]}"
```

PowerShell

```
Write-CWERule `
-Name "EC2InstanceStateChanges" `
-EventPattern '{"source":["aws.ec2"],"detail-type":["EC2 Instance State-change
 Notification"]}'
```

The command returns details for the new EventBridge rule similar to the following.

Linux & macOS

```
{
"RuleArn": "arn:aws:events:us-east-1:123456789012:rule/automationrule"
}
```

Windows

```
{
"RuleArn": "arn:aws:events:us-east-1:123456789012:rule/automationrule"
```

```
}
```

PowerShell

```
arn:aws:events:us-east-1:123456789012:rule/EC2InstanceStateChanges
```

3. Create a command to specify a runbook as a target of the EventBridge event rule you created in step 2. Replace each *example resource placeholder* with your own information.

   Linux & macOS

```
aws events put-targets \
--rule rule name \
--targets '{"Arn": " arn:aws:ssm:region:account ID:automation-definition/runbook
 name","Input":"{\"Message\":[\"{\\\"Key\\\":\\\"key name\\\",\\\"Values\\\":[\\
\"value\\\"]}\"]}","Id": "target ID","RoleArn": "arn:aws:iam::123456789012:role/
service-role/EventBridge service role"}'
```

   Windows

```
aws events put-targets ^
--rule rule name ^
--targets '{"Arn": "arn:aws:ssm:region:account ID:automation-definition/runbook
 name","Input":"{\"Message\":[\"{\\\"Key\\\":\\\"key name\\\",\\\"Values\\\":[\\
\"value\\\"]}\"]}","Id": "target ID","RoleArn": "arn:aws:iam::123456789012:role/
service-role/EventBridge service role"}'
```

   PowerShell

```
$Target = New-Object Amazon.CloudWatchEvents.Model.Target
$Target.Id = "target ID"
$Target.Arn = "arn:aws:ssm:region:account ID:automation-definition/runbook name"
$Target.RoleArn = "arn:aws:iam::123456789012:role/service-role/EventBridge
 service role"
$Target.Input = '{"input parameter":["value"],"AutomationAssumeRole":
["arn:aws:iam::123456789012:role/AutomationServiceRole"]}'

Write-CWETarget `
-Rule "rule name" `
-Target $Target
```

The following example creates an EventBridge event target that starts the specified instance ID using the runbook `AWS-StartEC2Instance`.

Linux & macOS

```
aws events put-targets \
--rule DailyAutomationRule \
--targets '{"Arn": "arn:aws:ssm:region:*:automation-definition/AWS-
StartEC2Instance","Input":"{\"InstanceId\":[\"i-02573cafcfEXAMPLE\"],
\"AutomationAssumeRole\":[\"arn:aws:iam::123456789012:role/AutomationServiceRole
\"]}","Id": "Target1","RoleArn": "arn:aws:iam::123456789012:role/service-role/
AWS_Events_Invoke_Start_Automation_Execution_1213609520"}'
```

Windows

```
aws events put-targets ^
--rule DailyAutomationRule ^
--targets '{"Arn": "arn:aws:ssm:region:*:automation-definition/AWS-
StartEC2Instance","Input":"{\"InstanceId\":[\"i-02573cafcfEXAMPLE\"],
\"AutomationAssumeRole\":[\"arn:aws:iam::123456789012:role/AutomationServiceRole
\"]}","Id": "Target1","RoleArn": "arn:aws:iam::123456789012:role/service-role/
AWS_Events_Invoke_Start_Automation_Execution_1213609520"}'
```

PowerShell

```
$Target = New-Object Amazon.CloudWatchEvents.Model.Target
$Target.Id = "Target1"
$Target.Arn = "arn:aws:ssm:region:*:automation-definition/AWS-StartEC2Instance"
$Target.RoleArn = "arn:aws:iam::123456789012:role/service-role/
AWS_Events_Invoke_Start_Automation_Execution_1213609520"
$Target.Input = '{"InstanceId":["i-02573cafcfEXAMPLE"],"AutomationAssumeRole":
["arn:aws:iam::123456789012:role/AutomationServiceRole"]}'

Write-CWETarget `
-Rule "DailyAutomationRule" `
-Target $Target
```

The system returns information like the following.

Linux & macOS

```
{
"FailedEntries": [],
"FailedEntryCount": 0
}
```

Windows

```
{
"FailedEntries": [],
"FailedEntryCount": 0
}
```

PowerShell

There is no output if the command succeeds for PowerShell.

Run an automation step by step

The following procedures describe how to use the AWS Systems Manager console and AWS Command Line Interface (AWS CLI) to run an automation using the manual execution mode. By using the manual execution mode, the automation starts in a *Waiting* status and pauses in the *Waiting* status between each step. This allows you to control when the automation proceeds, which is useful if you need to review the result of a step before continuing.

The automation runs in the context of the current user. This means that you don't need to configure additional IAM permissions as long as you have permission to use the runbook, and any actions called by the runbook. If you have administrator permissions in IAM, then you already have permission to run this automation.

Running an automation step by step (console)

The following procedure shows how to use the Systems Manager console to manually run an automation step by step.

To run an automation step by step

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

   > **Note**
   >
   > You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:

   - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
   - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
   - **1 (Default)** – Choose this option to run the first version of the document, which is the default.

5. Choose **Next**.
6. In the **Execution Mode** section, choose **Manual execution**.
7. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.
8. Choose **Execute**.
9. Choose **Execute this step** when you're ready to start the first step of the automation. The automation proceeds with step one and pauses before running any subsequent steps specified in the runbook you chose in step 3 of this procedure. If the runbook has multiple steps, you must select **Execute this step** for each step for the automation to proceed. Each time you choose **Execute this step** the action runs.

> **Note**
>
> The console displays the status of the automation. If the automation fails to run a step, see Troubleshooting Systems Manager Automation.

10. After you complete all steps specified in the runbook, choose **Complete and view results** to finish the automation and view the results.

After an automation execution completes, you can rerun the execution with the same or modified parameters. For more information, see Rerunning automation executions.

Running an automation step by step (command line)

The following procedure describes how to use the AWS CLI (on Linux, macOS, or Windows) or AWS Tools for PowerShell to manually run an automation step by step.

To run an automation step by step

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Run the following command to start a manual automation. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm start-automation-execution \
       --document-name runbook name \
       --mode Interactive \
       --parameters runbook parameters
   ```

   Windows

   ```
   aws ssm start-automation-execution ^
       --document-name runbook name ^
       --mode Interactive ^
       --parameters runbook parameters
   ```

PowerShell

```
Start-SSMAutomationExecution `
    -DocumentName runbook name `
    -Mode Interactive `
    -Parameter runbook parameters
```

Here is an example using the runbook `AWS-RestartEC2Instance` to restart the specified EC2 instance.

Linux & macOS

```
aws ssm start-automation-execution \
    --document-name "AWS-RestartEC2Instance" \
    --mode Interactive \
    --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

Windows

```
aws ssm start-automation-execution ^
    --document-name "AWS-RestartEC2Instance" ^
    --mode Interactive ^
    --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

PowerShell

```
Start-SSMAutomationExecution `
    -DocumentName AWS-RestartEC2Instance `
    -Mode Interactive
    -Parameter @{"InstanceId"="i-02573cafcfEXAMPLE"}
```

The system returns information like the following.

Linux & macOS

```
{
    "AutomationExecutionId": "ba9cd881-1b36-4d31-a698-0123456789ab"
}
```

Windows

```
{
    "AutomationExecutionId": "ba9cd881-1b36-4d31-a698-0123456789ab"
}
```

PowerShell

```
ba9cd881-1b36-4d31-a698-0123456789ab
```

3. Run the following command when you're ready to start the first step of the automation. Replace each *example resource placeholder* with your own information. The automation proceeds with step one and pauses before running any subsequent steps specified in the runbook you chose in step 1 of this procedure. If the runbook has multiple steps, you must run the following command for each step for the automation to proceed.

   Linux & macOS

   ```
   aws ssm send-automation-signal \
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab \
       --signal-type StartStep \
       --payload StepName="stopInstances"
   ```

   Windows

   ```
   aws ssm send-automation-signal ^
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab ^
       --signal-type StartStep ^
       --payload StepName="stopInstances"
   ```

   PowerShell

   ```
   Send-SSMAutomationSignal `
       -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab `
       -SignalType StartStep
       -Payload @{"StepName"="stopInstances"}
   ```

   There is no output if the command succeeds.

4. Run the following command to retrieve the status of each step execution in the automation.

   Linux & macOS

   ```
   aws ssm describe-automation-step-executions \
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab
   ```

   Windows

   ```
   aws ssm describe-automation-step-executions ^
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab
   ```

   PowerShell

   ```
   Get-SSMAutomationStepExecution `
       -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab
   ```

   The system returns information like the following.

   Linux & macOS

   ```
   {
       "StepExecutions": [
           {
               "StepName": "stopInstances",
               "Action": "aws:changeInstanceState",
               "ExecutionStartTime": 1557167178.42,
               "ExecutionEndTime": 1557167220.617,
               "StepStatus": "Success",
               "Inputs": {
                   "DesiredState": "\"stopped\"",
                   "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
               },
               "Outputs": {
                   "InstanceStates": [
                       "stopped"
                   ]
               },
               "StepExecutionId": "654243ba-71e3-4771-b04f-0123456789ab",
               "OverriddenParameters": {},
               "ValidNextSteps": [
   ```

```
                "startInstances"
            ]
        },
        {
            "StepName": "startInstances",
            "Action": "aws:changeInstanceState",
            "ExecutionStartTime": 1557167273.754,
            "ExecutionEndTime": 1557167480.73,
            "StepStatus": "Success",
            "Inputs": {
                "DesiredState": "\"running\"",
                "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
            },
            "Outputs": {
                "InstanceStates": [
                    "running"
                ]
            },
            "StepExecutionId": "8a4a1e0d-dc3e-4039-a599-0123456789ab",
            "OverriddenParameters": {}
        }
    ]
}
```

Windows

```
{
    "StepExecutions": [
        {
            "StepName": "stopInstances",
            "Action": "aws:changeInstanceState",
            "ExecutionStartTime": 1557167178.42,
            "ExecutionEndTime": 1557167220.617,
            "StepStatus": "Success",
            "Inputs": {
                "DesiredState": "\"stopped\"",
                "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
            },
            "Outputs": {
                "InstanceStates": [
                    "stopped"
                ]
            },
```

```
            "StepExecutionId": "654243ba-71e3-4771-b04f-0123456789ab",
            "OverriddenParameters": {},
            "ValidNextSteps": [
                "startInstances"
            ]
        },
        {
            "StepName": "startInstances",
            "Action": "aws:changeInstanceState",
            "ExecutionStartTime": 1557167273.754,
            "ExecutionEndTime": 1557167480.73,
            "StepStatus": "Success",
            "Inputs": {
                "DesiredState": "\"running\"",
                "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
            },
            "Outputs": {
                "InstanceStates": [
                    "running"
                ]
            },
            "StepExecutionId": "8a4a1e0d-dc3e-4039-a599-0123456789ab",
            "OverriddenParameters": {}
        }
    ]
}
```

PowerShell

```
Action: aws:changeInstanceState
ExecutionEndTime     : 5/6/2019 19:45:46
ExecutionStartTime   : 5/6/2019 19:45:03

StepStatus           : Success
TimeoutSeconds       : 0
ValidNextSteps       : {startInstances}
```

5. Run the following command to complete the automation after all steps specified within the chosen runbook have finished. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm stop-automation-execution \
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab \
       --type Complete
   ```

   Windows

   ```
   aws ssm stop-automation-execution ^
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab ^
       --type Complete
   ```

   PowerShell

   ```
   Stop-SSMAutomationExecution `
       -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab `
       -Type Complete
   ```

   There is no output if the command succeeds.

Scheduling automations with State Manager associations

You can start an automation by creating a State Manager association with a runbook. State Manager is a tool in AWS Systems Manager. By creating a State Manager association with a runbook, you can target different types of AWS resources. For example, you can create associations that enforce a desired state on an AWS resource, including the following:

- Attach a Systems Manager role to Amazon Elastic Compute Cloud (Amazon EC2) instances to make them *managed instances*.
- Enforce desired ingress and egress rules for a security group.
- Create or delete Amazon DynamoDB backups.
- Create or delete Amazon Elastic Block Store (Amazon EBS) snapshots.
- Turn off read and write permissions on Amazon Simple Storage Service (Amazon S3) buckets.
- Start, restart, or stop managed instances and Amazon Relational Database Service (Amazon RDS) instances.
- Apply patches to Linux, macOS, and Window AMIs.

Use the following procedures to create a State Manager association that runs an automation using the AWS Systems Manager console and AWS Command Line Interface (AWS CLI). For general information about associations and information about creating an association that uses an SSM `Command` document or `Policy` document, see Creating associations.

Before you begin

Be aware of the following important details before you run an automation by using State Manager:

- Before you can create an association that uses a runbook, verify that you configured permissions for Automation, a tool in AWS Systems Manager. For more information, see Setting up Automation.
- State Manager associations that use runbooks contribute to the maximum number of concurrently running automations in your AWS account. You can have a maximum of 100 concurrent automations running. For information, see Systems Manager service quotas in the *Amazon Web Services General Reference*.
- When running an automation, State Manager does not log the API operations initiated by the automation in AWS CloudTrail.
- Systems Manager automatically creates a service-linked role so that State Manager has permission to call Systems Manager Automation API operations. If you want, you can create the service-linked role yourself by running the following command from the AWS CLI or AWS Tools for PowerShell.

  Linux & macOS

```
aws iam create-service-linked-role \
```

```
--aws-service-name ssm.amazonaws.com
```

Windows

```
aws iam create-service-linked-role ^
--aws-service-name ssm.amazonaws.com
```

PowerShell

```
New-IAMServiceLinkedRole `
-AWSServiceName ssm.amazonaws.com
```

For more information about service-linked roles, see Using service-linked roles for Systems Manager.

Creating an association that runs an automation (console)

The following procedure describes how to use the Systems Manager console to create a State Manager association that runs an automation.

To create a State Manager association that runs an automation

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **State Manager**, and then choose **Create association**.
3. In the **Name** field, specify a name. This is optional, but recommended.
4. In the **Document** list, choose a runbook. Use the Search bar to filter on **Document type : Equal : Automation** runbooks. To view more runbooks, use the numbers to the right of the Search bar.

   > **Note**
   >
   > You can view information about a runbook by choosing the runbook name.

5. Choose **Simple execution** to run the automation on one or more targets by specifying the resource ID for those targets. Choose **Rate control** to run the automation across a fleet of AWS resources by specifying a targeting option such as tags or AWS Resource Groups. You can also

control the operation of the automation across your resources by specifying concurrency and error thresholds.

If you chose **Rate control**, the **Targets** section is displayed.

6. In the **Targets** section, choose a method for targeting resources.

   a. (Required) In the **Parameter** list, choose a parameter. The items in the **Parameter** list are determined by the parameters in the runbook that you selected at the start of this procedure. By choosing a parameter, you define the type of resource on which the automation runs.

   b. (Required) In the **Targets** list, choose a method for targeting the resources.

      - **Resource Group**: Choose the name of the group from the **Resource Group** list. For more information about targeting AWS Resource Groups in runbooks, see Targeting AWS Resource Groups.
      - **Tags**: Enter the tag key and (optionally) the tag value in the fields provided. Choose **Add**. For more information about targeting tags in runbooks, see Targeting a tag.
      - **Parameter Values**: Enter values in the **Input parameters** section. If you specify multiple values, Systems Manager runs a child automation on each value specified.

        For example, say that your runbook includes an **InstanceID** parameter. If you target the values of the **InstanceID** parameter when you run the automation, then Systems Manager runs a child automation for each instance ID value specified. The parent automation is complete when the automation finishes running each specified instance, or if the automation fails. You can target a maximum of 50 parameter values. For more information about targeting parameter values in runbooks, see Targeting parameter values.

7. In the **Input parameters** section, specify the required input parameters.

   If you chose to target resources by using tags or a resource group, then you might not need to choose some of the options in the **Input parameters** section. For example, if you chose the `AWS-RestartEC2Instance` runbook, and you chose to target instances by using tags, then you don't need to specify or choose instance IDs in the **Input parameters** section. The automation locates the instances to restart by using the tags you specified.

> **Important**
>
> You must specify a role ARN in the **AutomationAssumeRole** field. State Manager uses the assume role to call AWS services specified in the runbook and run Automation associations on your behalf.

8. In the **Specify schedule** section, choose **On Schedule** if you want to run the association at regular intervals. If you choose this option, then use the options provided to create the schedule using Cron or Rate expressions. For more information about Cron and Rate expressions for State Manager, see Cron and rate expressions for associations.

   > **Note**
   >
   > Rate expressions are the preferred scheduling mechanism for State Manager associations that use runbooks. Rate expressions allow more flexibility for running associations in the event that you reach the maximum number of concurrently running automations. With a rate schedule, Systems Manager can retry the automation shortly after receiving notification that concurrent automations have reached their maximum and have been throttled.

   Choose **No schedule** if you want to run the association one time.

9. (Optional) In the **Rate Control** section, choose **Concurrency** and **Error threshold** options to control the automation deployment across your AWS resources.

   a. In the **Concurrency** section, choose an option:

      - Choose **targets** to enter an absolute number of targets that can run the automation simultaneously.
      - Choose **percentage** to enter a percentage of the target set that can run the automation simultaneously.

   b. In the **Error threshold** section, choose an option:

      - Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the automation to other resources.

- Choose **percentage** to enter a percentage of errors allowed before Automation stops sending the automation to other resources.

For more information about using targets and rate controls with Automation, see Run automated operations at scale.

10. Choose **Create Association**.

> **Important**
>
> When you create an association, the association immediately runs against the specified targets. The association then runs based on the cron or rate expression you chose. If you chose **No schedule**, the association doesn't run again.

Creating an association that runs an automation (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows Server) or AWS Tools for PowerShell to create a State Manager association that runs an automation.

Before you begin

Before you complete the following procedure, make sure you have created an IAM service role that contains the permissions necessary to run the runbook, and configured a trust relationship for Automation, a tool in AWS Systems Manager. For more information, see Task 1: Create a service role for Automation.

To create an association that runs an automation

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Run the following command to view a list of documents.

   Linux & macOS

   ```
   aws ssm list-documents
   ```

Windows

```
aws ssm list-documents
```

PowerShell

```
Get-SSMDocumentList
```

Note the name of the runbook that you want to use for the association.

3. Run the following command to view details about the runbook. In the following command, replace *runbook name* with your own information.

   Linux & macOS

   ```
   aws ssm describe-document \
   --name runbook name
   ```

   Note a parameter name (for example, `InstanceId`) that you want to use for the `--automation-target-parameter-name` option. This parameter determines the type of resource on which the automation runs.

   Windows

   ```
   aws ssm describe-document ^
   --name runbook name
   ```

   Note a parameter name (for example, `InstanceId`) that you want to use for the `--automation-target-parameter-name` option. This parameter determines the type of resource on which the automation runs.

   PowerShell

   ```
   Get-SSMDocumentDescription `
   -Name runbook name
   ```

   Note a parameter name (for example, `InstanceId`) that you want to use for the `AutomationTargetParameterName` option. This parameter determines the type of resource on which the automation runs.

4. Create a command that runs an automation using a State Manager association. Replace each *example resource placeholder* with your own information.

   Targeting using tags

   Linux & macOS

   ```
   aws ssm create-association \
   --association-name association name \
   --targets Key=tag:key name,Values=value \
   --name runbook name \
   --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
   RunbookAssumeRole \
   --automation-target-parameter-name target parameter \
   --schedule "cron or rate expression"
   ```

   Note

   If you create an association by using the AWS CLI, use the `--targets` parameter to target instances for the association. Don't use the `--instance-id` parameter. The `--instance-id` parameter is a legacy parameter.

   Windows

   ```
   aws ssm create-association ^
   --association-name association name ^
   --targets Key=tag:key name,Values=value ^
   --name runbook name ^
   --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
   RunbookAssumeRole ^
   --automation-target-parameter-name target parameter ^
   --schedule "cron or rate expression"
   ```

   Note

   If you create an association by using the AWS CLI, use the `--targets` parameter to target instances for the association. Don't use the `--instance-id` parameter. The `--instance-id` parameter is a legacy parameter.

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "tag:key name"
$Targets.Values = "value"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws:iam::123456789012:role/RunbookAssumeRole" } `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

Note

If you create an association by using the AWS Tools for PowerShell, use the `Target` parameter to target instances for the association. Don't use the `InstanceId` parameter. The `InstanceId` parameter is a legacy parameter.

Targeting using parameter values

Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ParameterValues,Values=value,value 2,value 3 \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression"
```

Windows

```
aws ssm create-association ^
--association-name association name ^
```

```
--targets Key=ParameterValues,Values=value,value 2,value 3 ^
--name runbook name ^
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression"
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ParameterValues"
$Targets.Values = "value","value 2","value 3"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

Targeting using AWS Resource Groups

Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ResourceGroup,Values=resource group name \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression"
```

Windows

```
aws ssm create-association ^
--association-name association name ^
--targets Key=ResourceGroup,Values=resource group name ^
--name runbook name ^
```

```
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression"
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "resource group name"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

Targeting multiple accounts and Regions

Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ResourceGroup,Values=resource group name \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression" \
--target-locations
 Accounts=111122223333,444455556666,444455556666,Regions=region,region
```

Windows

```
aws ssm create-association ^
--association-name association name ^
--targets Key=ResourceGroup,Values=resource group name ^
--name runbook name ^
```

```
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression" ^
--target-locations
 Accounts=111122223333,444455556666,444455556666,Regions=region,region
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "resource group name"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression" `
-TargetLocations @{
    "Accounts"=["111122223333,444455556666,444455556666"],
    "Regions"=["region,region"]
```

The command returns details for the new association similar to the following.

Linux & macOS

```
{
"AssociationDescription": {
    "ScheduleExpression": "cron(0 7 ? * MON *)",
    "Name": "AWS-StartEC2Instance",
    "Parameters": {
        "AutomationAssumeRole": [
            "arn:aws:iam::123456789012:role/RunbookAssumeRole"
        ]
    },
    "Overview": {
        "Status": "Pending",
        "DetailedStatus": "Creating"
    },
```

```
    "AssociationId": "1450b4b7-bea2-4e4b-b340-01234EXAMPLE",
    "DocumentVersion": "$DEFAULT",
    "AutomationTargetParameterName": "InstanceId",
    "LastUpdateAssociationDate": 1564686638.498,
    "Date": 1564686638.498,
    "AssociationVersion": "1",
    "AssociationName": "CLI",
    "Targets": [
        {
            "Values": [
                "DEV"
            ],
            "Key": "tag:ENV"
        }
    ]
}
}
```

Windows

```
{
"AssociationDescription": {
    "ScheduleExpression": "cron(0 7 ? * MON *)",
    "Name": "AWS-StartEC2Instance",
    "Parameters": {
        "AutomationAssumeRole": [
            "arn:aws:iam::123456789012:role/RunbookAssumeRole"
        ]
    },
    "Overview": {
        "Status": "Pending",
        "DetailedStatus": "Creating"
    },
    "AssociationId": "1450b4b7-bea2-4e4b-b340-01234EXAMPLE",
    "DocumentVersion": "$DEFAULT",
    "AutomationTargetParameterName": "InstanceId",
    "LastUpdateAssociationDate": 1564686638.498,
    "Date": 1564686638.498,
    "AssociationVersion": "1",
    "AssociationName": "CLI",
    "Targets": [
        {
            "Values": [
```

```
                "DEV"
            ],
            "Key": "tag:ENV"
        }
    ]
}
}
```

PowerShell

```
Name                 : AWS-StartEC2Instance
InstanceId           :
Date                 : 8/1/2019 7:31:38 PM
Status.Name          :
Status.Date          :
Status.Message       :
Status.AdditionalInfo :
```

Note

If you use tags to create an association on one or more target instances, and then you remove the tags from an instance, that instance no longer runs the association. The instance is disassociated from the State Manager document.

Troubleshooting automations run by State Manager associations

Systems Manager Automation enforces a limit of 100 concurrent automations, and 1,000 queued automations per account, per Region. If a State Manager association that uses a runbook shows a status of **Failed** and a detailed status of **AutomationExecutionLimitExceeded**, then your automation might have reached the limit. As a result, Systems Manager throttles the automations. To resolve this issue, do the following:

- Use a different rate or cron expression for your association. For example, if the association is scheduled to run every 30 minutes, then change the expression so that it runs every hour or two.
- Delete existing automations that have a status of **Pending**. By deleting these automations, you clear the current queue.

Schedule automations with maintenance windows

You can start an automation by configuring a runbook as a registered task for a maintenance window. By registering the runbook as a registered task, the maintenance window runs the automation during the scheduled maintenance period.

For example, let's say you create a runbook named `CreateAMI` that creates an Amazon Machine Image (AMI) of instances registered as targets to the maintenance window. To specify the `CreateAMI` runbook (and corresponding automation) as a registered task of a maintenance window, you first create a maintenance window and register targets. Then you use the following procedure to specify the `CreateAMI` document as a registered task within the maintenance window. When the maintenance window starts during the scheduled period, the system runs the automation and creates an AMI of the registered targets.

For information about creating Automation runbooks, see Creating your own runbooks. Automation is a tool in AWS Systems Manager.

Use the following procedures to configure an automation as a registered task for a maintenance window using the AWS Systems Manager console, AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell.

Registering an automation task to a maintenance window (console)

The following procedure describes how to use the Systems Manager console to configure an automation as a registered task for a maintenance window.

Before you begin

Before you complete the following procedure, you must create a maintenance window and register at least one target. For more information, see the following procedures:

- Create a maintenance window using the console.
- Assign targets to a maintenance window using the console

To configure an automation as a registered task for a maintenance window

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the left navigation pane, choose **Maintenance Windows**, and then choose the maintenance window you want to register an Automation task with.

3. Choose **Actions**. Then choose **Register Automation task** to run your choice of an automation on targets by using a runbook.
4. For **Name**, enter a name for the task.
5. For **Description**, enter a description.
6. For **Document**, choose the runbook that defines the tasks to run.
7. For **Document version**, choose the runbook version to use.
8. For **Task priority**, specify a priority for this task. 1 is the highest priority. Tasks in a maintenance window are scheduled in priority order; tasks that have the same priority are scheduled in parallel.
9. In the **Targets** section, if the runbook you chose is one that runs tasks on resources, identify the targets on which you want to run this automation by specifying tags or by selecting instances manually.

   > **Note**
   >
   > If you want to pass the resources through input parameters instead of targets, you don't need to specify a maintenance window target.
   > In many cases, you don't need to explicitly specify a target for an automation task. For example, say that you're creating an Automation-type task to update an Amazon Machine Image (AMI) for Linux using the `AWS-UpdateLinuxAmi` runbook. When the task runs, the AMI is updated with the latest available Linux distribution packages and Amazon software. New instances created from the AMI already have these updates installed. Because the ID of the AMI to be updated is specified in the input parameters for the runbook, there is no need to specify a target again in the maintenance window task.

   For information about maintenance window tasks that don't require targets, see the section called “Registering maintenance window tasks without targets”.
10. (Optional) For **Rate control**:

    > **Note**
    >
    > If the task you're running doesn't specify targets, you don;t need to specify rate controls.

- For **Concurrency**, specify either a number or a percentage of targets on which to run the automation at the same time.

  If you selected targets by choosing tag key-value pairs, and you aren't certain how many targets use the selected tags, then limit the number of automations that can run at the same time by specifying a percentage.

  When the maintenance window runs, a new automation is initiated per target. There is a limit of 100 concurrent automations per AWS account. If you specify a concurrency rate greater than 100, concurrent automations greater than 100 are automatically added to the automation queue. For information, see Systems Manager service quotas in the *Amazon Web Services General Reference*.

- For **Error threshold**, specify when to stop running the automation on other targets after it fails on either a number or a percentage of targets. For example, if you specify three errors, then Systems Manager stops running automations when the fourth error is received. Targets still processing the automation might also send errors.

11. In the **Input Parameters** section, specify parameters for the runbook. For runbooks, the system auto-populates some of the values. You can keep or replace these values.

    > **Important**
    >
    > For runbooks, you can optionally specify an Automation Assume Role. If you don't specify a role for this parameter, then the automation assumes the maintenance window service role you choose in step 11. As such, you must ensure that the maintenance window service role you choose has the appropriate AWS Identity and Access Management (IAM) permissions to perform the actions defined within the runbook.
    > For example, the service-linked role for Systems Manager doesn't have the IAM permission `ec2:CreateSnapshot`, which is required to use the runbook `AWS-CopySnapshot`. In this scenario, you must either use a custom maintenance window service role or specify an Automation assume role that has `ec2:CreateSnapshot` permissions. For information, see Setting up Automation.

12. In the **IAM service role** area, choose a role to provide permissions for Systems Manager to start the automation.

To create a service role for maintenance window tasks, see Setting up Maintenance Windows.

13. Choose **Register Automation task**.

Registering an Automation task to a maintenance window (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows Server) or AWS Tools for PowerShell to configure an automation as a registered task for a maintenance window.

Before you begin

Before you complete the following procedure, you must create a maintenance window and register at least one target. For more information, see the following procedures:

- Step 1: Create the maintenance window using the AWS CLI.
- Step 2: Register a target node with the maintenance window using the AWS CLI

To configure an automation as a registered task for a maintenance window

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Create a command to configure an automation as a registered task for a maintenance window. Replace each *example resource placeholder* with your own information.

   Linux & macOS

```
aws ssm register-task-with-maintenance-window \
--window-id window ID \
--name task name \
--task-arn runbook name \
--targets Key=targets,Values=value \
--service-role-arn IAM role arn \
--task-type AUTOMATION \
--task-invocation-parameters task parameters \
--priority task priority \
--max-concurrency 10% \
--max-errors 5
```

> **Note**
>
> If you configure an automation as a registered task by using the AWS CLI, use the `--Task-Invocation-Parameters` parameter to specify parameters to pass to a task when it runs. Don't use the `--Task-Parameters` parameter. The `--Task-Parameters` parameter is a legacy parameter.
> For maintenance window tasks without a target specified, you can't supply values for `--max-errors` and `--max-concurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as describe-maintenance-window-tasks and get-maintenance-window-task. These values don't affect the running of your task and can be ignored.
> For information about maintenance window tasks that don't require targets, see Registering maintenance window tasks without targets.

Windows

```
aws ssm register-task-with-maintenance-window ^
--window-id window ID ^
--name task name ^
--task-arn runbook name ^
--targets Key=targets,Values=value ^
--service-role-arn IAM role arn ^
--task-type AUTOMATION ^
--task-invocation-parameters task parameters ^
--priority task priority ^
--max-concurrency 10% ^
--max-errors 5
```

> **Note**
>
> If you configure an automation as a registered task by using the AWS CLI, use the `--task-invocation-parameters` parameter to specify parameters to pass to a task when it runs. Don't use the `--task-parameters` parameter. The `--task-parameters` parameter is a legacy parameter.
> For maintenance window tasks without a target specified, you can't supply values for `--max-errors` and `--max-concurrency`. Instead, the system inserts a

placeholder value of 1, which might be reported in the response to commands such as describe-maintenance-window-tasks and get-maintenance-window-task. These values don't affect the running of your task and can be ignored.
For information about maintenance window tasks that don't require targets, see Registering maintenance window tasks without targets.

PowerShell

```
Register-SSMTaskWithMaintenanceWindow `
-WindowId window ID `
-Name "task name" `
-TaskArn "runbook name" `
-Target @{ Key="targets";Values="value" } `
-ServiceRoleArn "IAM role arn" `
-TaskType "AUTOMATION" `
-Automation_Parameter @{ "task parameter"="task parameter value"} `
-Priority task priority `
-MaxConcurrency 10% `
-MaxError 5
```

Note

If you configure an automation as a registered task by using the AWS Tools for PowerShell, use the `-Automation_Parameter` parameter to specify parameters to pass to a task when the task runs. Don't use the `-TaskParameters` parameter. The `-TaskParameters` parameter is a legacy parameter.
For maintenance window tasks without a target specified, you can't supply values for `-MaxError` and `-MaxConcurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as `Get-SSMMaintenanceWindowTaskList` and `Get-SSMMaintenanceWindowTask`. These values don't affect the running of your task and can be ignored.
For information about maintenance window tasks that don't require targets, see Registering maintenance window tasks without targets.

The following example configures an automation as a registered task to a maintenance window with priority 1. It also demonstrates omitting the `--targets`, `--max-errors`, and

`--max-concurrency` options for a targetless maintenance window task. The automation uses the `AWS-StartEC2Instance` runbook and the specified Automation assume role to start EC2 instances registered as targets to the maintenance window. The maintenance window runs the automation simultaneously on 5 instances maximum at any given time. Also, the registered task stops running on more instances for a particular interval if the error count exceeds 1.

Linux & macOS

```
aws ssm register-task-with-maintenance-window \
--window-id mw-0c50858d01EXAMPLE \
--name StartEC2Instances \
--task-arn AWS-StartEC2Instance \
--service-role-arn arn:aws:iam::123456789012:role/MaintenanceWindowRole \
--task-type AUTOMATION \
--task-invocation-parameters "{\"Automation\":{\"Parameters\":{\"InstanceId\":
[\"{{TARGET_ID}}\"],\"AutomationAssumeRole\":[\"arn:aws:iam::123456789012:role/
AutomationAssumeRole\"]}}}" \
--priority 1
```

Windows

```
aws ssm register-task-with-maintenance-window ^
--window-id mw-0c50858d01EXAMPLE ^
--name StartEC2Instances ^
--task-arn AWS-StartEC2Instance ^
--service-role-arn arn:aws:iam::123456789012:role/MaintenanceWindowRole ^
--task-type AUTOMATION ^
--task-invocation-parameters "{\"Automation\":{\"Parameters\":{\"InstanceId\":
[\"{{TARGET_ID}}\"],\"AutomationAssumeRole\":[\"arn:aws:iam::123456789012:role/
AutomationAssumeRole\"]}}}" ^
--priority 1
```

PowerShell

```
Register-SSMTaskWithMaintenanceWindow `
-WindowId mw-0c50858d01EXAMPLE `
-Name "StartEC2" `
-TaskArn "AWS-StartEC2Instance" `
-ServiceRoleArn "arn:aws:iam::123456789012:role/MaintenanceWindowRole" `
-TaskType "AUTOMATION" `
```

```
-Automation_Parameter
 @{ "InstanceId"="{{TARGET_ID}}";"AutomationAssumeRole"="arn:aws:iam::123456789012:role/
AutomationAssumeRole" } `
-Priority 1
```

The command returns details for the new registered task similar to the following.

Linux & macOS

```
{
"WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

Windows

```
{
"WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

PowerShell

```
4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

3. To view the registered task, run the following command. Replace *maintenance windows ID* with your own information.

Linux & macOS

```
aws ssm describe-maintenance-window-tasks \
--window-id maintenance window ID
```

Windows

```
aws ssm describe-maintenance-window-tasks ^
--window-id maintenance window ID
```

PowerShell

```
Get-SSMMaintenanceWindowTaskList `
```

```
-WindowId maintenance window ID
```

The system returns information like the following.

Linux & macOS

```
{
"Tasks": [
    {
        "ServiceRoleArn": "arn:aws:iam::123456789012:role/
MaintenanceWindowRole",

Systems Manager Automation actions reference

This reference describes the Automation actions that you can specify in an Automation runbook. Automation is a tool in AWS Systems Manager. These actions can't be used in other types of Systems Manager (SSM) documents. For information about plugins for other types of SSM documents, see Command document plugin reference.

Systems Manager Automation runs steps defined in Automation runbooks. Each step is associated with a particular action. The action determines the inputs, behavior, and outputs of the step. Steps are defined in the `mainSteps` section of your runbook.

You don't need to specify the outputs of an action or step. The outputs are predetermined by the action associated with the step. When you specify step inputs in your runbooks, you can reference one or more outputs from an earlier step. For example, you can make the output of `aws:runInstances` available for a subsequent `aws:runCommand` action. You can also reference outputs from earlier steps in the `Output` section of the runbook.

Important

If you run an automation workflow that invokes other services by using an AWS Identity and Access Management (IAM) service role, be aware that the service role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (`AWS-*` runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom Automation runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:createStack`, or `aws:copyImage` actions, configure the service role with permission to invoke those services. You can give permissions to other AWS services by adding an IAM inline policy to the role. For more information, see (Optional) Add an Automation inline policy or customer managed policy to invoke other AWS services.

Topics

- aws:invokeLambdaFunction – Invoke an AWS Lambda function
- aws:loop – Iterate over steps in an automation
- aws:pause – Pause an automation
- aws:runCommand – Run a command on a managed instance
- aws:runInstances – Launch an Amazon EC2 instance
- aws:sleep – Delay an automation
- aws:updateVariable – Updates a value for a runbook variable
- aws:waitForAwsResourceProperty – Wait on an AWS resource property
- Automation system variables

Properties shared by all actions

Common properties are parameters or options that are found in all actions. Some options define behavior for a step, such as how long to wait for a step to complete and what to do if the step fails. The following properties are common to all actions.

description

Information you provide to describe the purpose of a runbook or a step.

Type: String

Required: No

name

An identifier that must be unique across all step names in the runbook.

Type: String

Allowed pattern: [a-zA-Z0-9_]+$

Required: Yes

action

The name of the action the step is to run. `aws:runCommand – Run a command on a managed instance` is an example of an action you can specify here. This document provides detailed information about all available actions.

Type: String

Required: Yes

maxAttempts

The number of times the step should be retried in case of failure. If the value is greater than 1, the step isn't considered to have failed until all retry attempts have failed. The default value is 1.

Type: Integer

Required: No

timeoutSeconds

The timeout value for the step. If the timeout is reached and the value of `maxAttempts` is greater than 1, then the step isn't considered to have timed out until all retries have been attempted.

Type: Integer

Required: No

onFailure

Indicates whether the automation should stop, continue, or go to a different step on failure. The default value for this option is abort.

Type: String

Valid values: Abort | Continue | step:*step_name*

Required: No

onCancel

Indicates which step the automation should go to in the event that a user cancels the automation. Automation runs the cancellation workflow for a maximum of two minutes.

Type: String

Valid values: Abort | step:*step_name*

Required: No

The `onCancel` property doesn't support moving to the following actions:

- `aws:approve`
- `aws:copyImage`
- `aws:createImage`
- `aws:createStack`
- `aws:createTags`
- `aws:loop`
- `aws:pause`
- `aws:runInstances`
- `aws:sleep`

isEnd

This option stops an automation at the end of a specific step. The automation stops if the step failed or succeeded. The default value is false.

Type: Boolean

Valid values: true | false

Required: No

nextStep

Specifies which step in an automation to process next after successfully completing a step.

Type: String

Required: No

isCritical

Designates a step as critical for the successful completion of the Automation. If a step with this designation fails, then Automation reports the final status of the Automation as Failed. This property is only evaluated if you explicitly define it in your step. If the `onFailure` property is set to `Continue` in a step, the value defaults to false. Otherwise, the default value for this option is true.

Type: Boolean

Valid values: true | false

Required: No

inputs

The properties specific to the action.

Type: Map

Required: Yes

Example

```

  inputs:
    Service: ec2
    Api: StartInstances
    InstanceIds:
    - "{{ InstanceId }}"
```

`aws:approve` – Pause an automation for manual approval

Temporarily pauses an automation until designated principals either approve or reject the action. After the required number of approvals is reached, the automation resumes. You can insert the approval step any place in the `mainSteps` section of your runbook.

Note

This action doesn't support multi-account and Region automations. The default timeout for this action is 7 days (604800 seconds) and the maximum value is 30 days (2592000 seconds). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:approve` step.

In the following example, the `aws:approve` action temporarily pauses the automation until one approver either accepts or rejects the automation. Upon approval, the automation runs a simple PowerShell command.

YAML

```
---
description: RunInstancesDemo1
schemaVersion: '0.3'
assumeRole: "{{ assumeRole }}"
parameters:
  assumeRole:
    type: String
  message:

```

```
                ]
            }
        }
    }
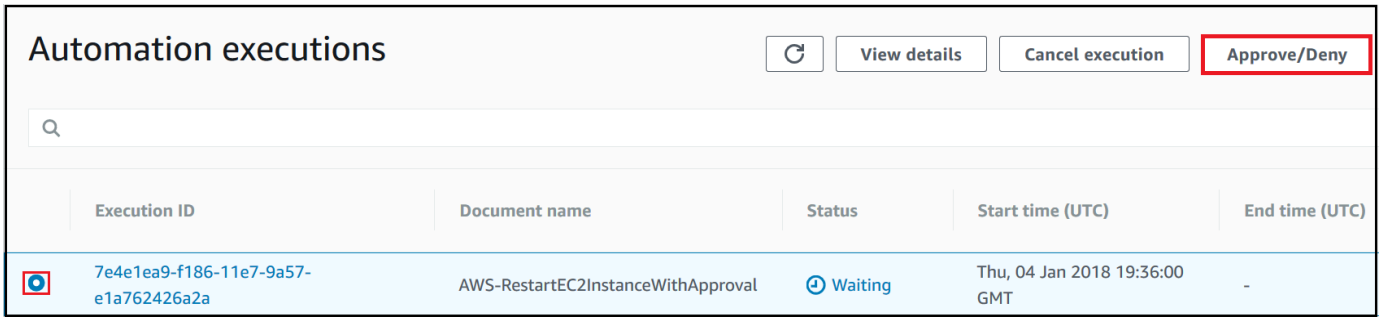
]
}
```

You can approve or deny Automations that are waiting for approval in the console.

To approve or deny waiting Automations

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose the option next to an Automation with a status of **Waiting**.



4. Choose **Approve/Deny**.
5. Review the details of the Automation.
6. Choose either **Approve** or **Deny**, type an optional comment, and then choose **Submit**.

Input example

YAML

```
NotificationArn: arn:aws:sns:us-west-1:12345678901:Automation-ApprovalRequest
Message: Please approve this step of the Automation.
MinRequiredApprovals: 3
Approvers:
- IamUser1
- IamUser2
- arn:aws:iam::12345678901:user/IamUser3
```

```
- arn:aws:iam::12345678901:role/IamRole
```

JSON

```
{
   "NotificationArn":"arn:aws:sns:us-west-1:12345678901:Automation-ApprovalRequest",
   "Message":"Please approve this step of the Automation.",
   "MinRequiredApprovals":3,
   "Approvers":[
      "IamUser1",
      "IamUser2",
      "arn:aws:iam::12345678901:user/IamUser3",
      "arn:aws:iam::12345678901:role/IamRole"
   ]
}
```

NotificationArn

The Amazon Resource Name (ARN of an Amazon Simple Notification Service (Amazon SNS) topic for Automation approvals. When you specify an `aws:approve` step in a runbook, Automation sends a message to this topic letting principals know that they must either approve or reject an Automation step. The title of the Amazon SNS topic must be prefixed with "Automation".

Type: String

Required: No

Message

The information you want to include in the Amazon SNS topic when the approval request is sent. The maximum message length is 4096 characters.

Type: String

Required: No

MinRequiredApprovals

The minimum number of approvals required to resume the automation. If you don't specify a value, the system defaults to one. The value for this parameter must be a positive number.

The value for this parameter can't exceed the number of approvers defined by the `Approvers` parameter.

Type: Integer

Required: No

Approvers

A list of AWS authenticated principals who are able to either approve or reject the action. The maximum number of approvers is 10. You can specify principals by using any of the following formats:

- A user name
- A user ARN
- An IAM role ARN
- An IAM assume role ARN

Type: StringList

Required: Yes

EnhancedApprovals

This input is only used for Change Manager templates. A list of AWS authenticated principals who are able to either approve or reject the action, the type of IAM principal, and the minimum number of approvers. The following is an example:

```
schemaVersion: "0.3"
emergencyChange: false
autoApprovable: false
mainSteps:
    - name: ApproveAction1
    action: aws:approve
    timeoutSeconds: 604800
    inputs:
        Message: Please approve this change request
        MinRequiredApprovals: 3
        EnhancedApprovals:
        Approvers:
            - approver: John Stiles
            type: IamUser
```

```
            minRequiredApprovals: 0
            - approver: Ana Carolina Silva
            type: IamUser
            minRequiredApprovals: 0
            - approver: GroupOfThree
            type: IamGroup
            minRequiredApprovals: 0
            - approver: RoleOfTen
            type: IamRole
            minRequiredApprovals: 0
```

Type: StringList

Required: Yes

Output

ApprovalStatus

The approval status of the step. The status can be one of the following: Approved, Rejected, or Waiting. Waiting means that Automation is waiting for input from approvers.

Type: String

ApproverDecisions

A JSON map that includes the approval decision of each approver.

Type: MapList

`aws:assertAwsResourceProperty` – Assert an AWS resource state or event state

The `aws:assertAwsResourceProperty` action allows you to assert a specific resource state or event state for a specific Automation step.

> **Note**
>
> The `aws:assertAwsResourceProperty` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

For more examples of how to use this action, see Additional runbook examples.

Input

Inputs are defined by the API operation that you choose.

YAML

```
action: aws:assertAwsResourceProperty
inputs:
  Service: The official namespace of the service
  Api: The API operation or method name
  API operation inputs or parameters: A value
  PropertySelector: Response object
  DesiredValues:
  - Desired property values
```

JSON

```
{
  "action": "aws:assertAwsResourceProperty",
  "inputs": {
    "Service":"The official namespace of the service",
    "Api":"The API operation or method name",
    "API operation inputs or parameters":"A value",
    "PropertySelector": "Response object",
    "DesiredValues": [
      "Desired property values"
    ]
  }
}
```

Service

The AWS service namespace that contains the API operation that you want to run. For example, the namespace for Systems Manager is `ssm`. The namespace for Amazon EC2 is `ec2`. You can view a list of supported AWS service namespaces in the Available Services section of the *AWS CLI Command Reference*.

Type: String

Required: Yes

Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: Amazon RDS methods.

Type: String

Required: Yes

API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**. Use the following format to specify more than one input.

YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

JSON

```
"inputs":{
      "Service":"The official namespace of the service",
      "Api":"The API operation name",
      "API input 1":"A value",
      "API Input 2":"A value",
      "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

PropertySelector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: String

Required: Yes

DesiredValues

The expected status or state on which to continue the automation. If you specify a Boolean value, you must use a capital letter such as True or False.

Type: StringList

Required: Yes

`aws:branch` – Run conditional automation steps

The `aws:branch` action allows you to create a dynamic automation that evaluates different choices in a single step and then jumps to a different step in the runbook based on the results of that evaluation.

When you specify the `aws:branch` action for a step, you specify `Choices` that the automation must evaluate. The `Choices` can be based on either a value that you specified in the `Parameters` section of the runbook, or a dynamic value generated as the output from the previous step. The automation evaluates each choice by using a Boolean expression. If the first choice is true, then the automation jumps to the step designated for that choice. If the first choice is false, the automation evaluates the next choice. The automation continues evaluating each choice until it process a true choice. The automation then jumps to the designated step for the true choice.

If none of the choices are true, the automation checks to see if the step contains a `default` value. A default value defines a step that the automation should jump to if none of the choices are true. If no `default` value is specified for the step, then the automation processes the next step in the runbook.

The `aws:branch` action supports complex choice evaluations by using a combination of `And`, `Not`, and `Or` operators. For more information about how to use `aws:branch`, including example runbooks and examples that use different operators, see Using conditional statements in runbooks.

Input

Specify one or more `Choices` in a step. The `Choices` can be based on either a value that you specified in the `Parameters` section of the runbook, or a dynamic value generated as the output from the previous step. Here is a YAML sample that evaluates a parameter.

```
mainSteps:
- name: chooseOS
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runWindowsCommand
      Variable: "{{Name of a parameter defined in the Parameters section. For example:
 OS_name}}"
      StringEquals: windows
    - NextStep: runLinuxCommand
      Variable: "{{Name of a parameter defined in the Parameters section. For example:
 OS_name}}"
      StringEquals: linux
    Default:
      sleep3
```

Here is a YAML sample that evaluates output from a previous step.

```
mainSteps:
- name: chooseOS
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runPowerShellCommand
      Variable: "{{Name of a response object. For example: GetInstance.platform}}"
      StringEquals: Windows
    - NextStep: runShellCommand
      Variable: "{{Name of a response object. For example: GetInstance.platform}}"
      StringEquals: Linux
    Default:
      sleep3
```

Choices

One or more expressions that the Automation should evaluate when determining the next step to process. Choices are evaluated by using a Boolean expression. Each choice must define the following options:

- **NextStep**: The next step in the runbook to process if the designated choice is true.
- **Variable**: Specify either the name of a parameter that is defined in the `Parameters` section of the runbook. Or specify an output object from a previous step in the runbook. For more information about creating variables for `aws:branch`, see About creating the output variable.
- **Operation**: The criteria used to evaluate the choice. The `aws:branch` action supports the following operations:

  String operations

  - StringEquals
  - EqualsIgnoreCase
  - StartsWith
  - EndsWith
  - Contains

  Numeric operations

  - NumericEquals
  - NumericGreater
  - NumericLesser
  - NumericGreaterOrEquals
  - NumericLesser
  - NumericLesserOrEquals

  Boolean operation

  - BooleanEquals

> **Important**
>
> When you create a runbook, the system validates each operation in the runbook. If an operation isn't supported, the system returns an error when you try to create the runbook.

Default

The name of a step the automation should jump to if none of the `Choices` are true.

Type: String

Required: No

> **Note**
>
> The `aws:branch` action supports `And`, `Or`, and `Not` operators. For examples of `aws:branch` that use operators, see Using conditional statements in runbooks.

`aws:changeInstanceState` – Change or assert instance state

Changes or asserts the state of the instance.

This action can be used in assert mode (doesn't run the API to change the state but verifies the instance is in the desired state.) To use assert mode, set the `CheckStateOnly` parameter to true. This mode is useful when running the Sysprep command on Windows Server, which is an asynchronous command that can run in the background for a long time. You can ensure that the instance is stopped before you create an Amazon Machine Image (AMI).

> **Note**
>
> The default timeout value for this action is 3600 seconds (one hour). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:changeInstanceState` step.

> **Note**
>
> The `aws:changeInstanceState` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

YAML

```
name: stopMyInstance
action: aws:changeInstanceState
maxAttempts: 3
timeoutSeconds: 3600
onFailure: Abort
inputs:
  InstanceIds:
  - i-1234567890abcdef0
  CheckStateOnly: true
  DesiredState: stopped
```

JSON

```
{
    "name":"stopMyInstance",
    "action": "aws:changeInstanceState",
    "maxAttempts": 3,
    "timeoutSeconds": 3600,
    "onFailure": "Abort",
    "inputs": {
        "InstanceIds": ["i-1234567890abcdef0"],
        "CheckStateOnly": true,
        "DesiredState": "stopped"
    }
}
```

InstanceIds

The IDs of the instances.

Type: StringList

Required: Yes

CheckStateOnly

If false, sets the instance state to the desired state. If true, asserts the desired state using polling.

Default: `false`

Type: Boolean

Required: No

DesiredState

The desired state. When set to `running`, this action waits for the Amazon EC2 state to be `Running`, the Instance Status to be `OK`, and the System Status to be `OK` before completing.

Type: String

Valid values: `running` | `stopped` | `terminated`

Required: Yes

Force

If set, forces the instances to stop. The instances don't have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures. This option isn't recommended for EC2 instances for Windows Server.

Type: Boolean

Required: No

AdditionalInfo

Reserved.

Type: String

Required: No

Output

None

`aws:copyImage` – Copy or encrypt an Amazon Machine Image

Copies an Amazon Machine Image (AMI) from any AWS Region into the current Region. This action can also encrypt the new AMI.

> **Note**
>
> The `aws:copyImage` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports most `CopyImage` parameters. For more information, see CopyImage.

The following example creates a copy of an AMI in the Seoul region (`SourceImageID`: ami-0fe10819. `SourceRegion`: ap-northeast-2). The new AMI is copied to the region where you initiated the Automation action. The copied AMI will be encrypted because the optional `Encrypted` flag is set to `true`.

YAML

```
name: createEncryptedCopy
action: aws:copyImage
maxAttempts: 3
onFailure: Abort
inputs:
  SourceImageId: ami-0fe10819
  SourceRegion: ap-northeast-2
  ImageName: Encrypted Copy of LAMP base AMI in ap-northeast-2
  Encrypted: true
```

JSON

```
{
    "name": "createEncryptedCopy",
    "action": "aws:copyImage",
    "maxAttempts": 3,
    "onFailure": "Abort",
```

```
    "inputs": {
        "SourceImageId": "ami-0fe10819",
        "SourceRegion": "ap-northeast-2",
        "ImageName": "Encrypted Copy of LAMP base AMI in ap-northeast-2",
        "Encrypted": true
    }
}
```

SourceRegion

The region where the source AMI exists.

Type: String

Required: Yes

SourceImageId

The AMI ID to copy from the source Region.

Type: String

Required: Yes

ImageName

The name for the new image.

Type: String

Required: Yes

ImageDescription

A description for the target image.

Type: String

Required: No

Encrypted

Encrypt the target AMI.

Type: Boolean

Required: No

KmsKeyId

The full Amazon Resource Name (ARN) of the AWS KMS key to use when encrypting the snapshots of an image during a copy operation. For more information, see CopyImage.

Type: String

Required: No

ClientToken

A unique, case-sensitive identifier that you provide to ensure request idempotency. For more information, see CopyImage.

Type: String

Required: No

Output

ImageId

The ID of the copied image.

ImageState

The state of the copied image.

Valid values: `available` | `pending` | `failed`

`aws:createImage` – Create an Amazon Machine Image

Creates an Amazon Machine Image (AMI) from an instance that is either running, stopping, or stopped, and polls for the `ImageState` to be `available`.

> **Note**
>
> The `aws:createImage` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports the following `CreateImage` parameters. For more information, see CreateImage.

YAML

```
name: createMyImage
action: aws:createImage
maxAttempts: 3
onFailure: Abort
inputs:
  InstanceId: i-1234567890abcdef0
  ImageName: AMI Created on{{global:DATE_TIME}}
  NoReboot: true
  ImageDescription: My newly created AMI
```

JSON

```
{
    "name": "createMyImage",
    "action": "aws:createImage",
    "maxAttempts": 3,
    "onFailure": "Abort",
    "inputs": {
        "InstanceId": "i-1234567890abcdef0",
        "ImageName": "AMI Created on{{global:DATE_TIME}}",
        "NoReboot": true,
        "ImageDescription": "My newly created AMI"
    }
}
```

InstanceId

The ID of the instance.

Type: String

Required: Yes

ImageName

The name for the image.

Type: String

Required: Yes

ImageDescription

A description of the image.

Type: String

Required: No

NoReboot

A Boolean literal.

By default, Amazon Elastic Compute Cloud (Amazon EC2) attempts to shut down and reboot the instance before creating the image. If the **No Reboot** option is set to `true`, Amazon EC2 doesn't shut down the instance before creating the image. When this option is used, file system integrity on the created image can't be guaranteed.

If you don't want the instance to run after you create an AMI from it, first use the `aws:changeInstanceState` – Change or assert instance state action to stop the instance, and then use this `aws:createImage` action with the **NoReboot** option set to `true`.

Type: Boolean

Required: No

BlockDeviceMappings

The block devices for the instance.

Type: Map

Required: No

Output

ImageId

The ID of the newly created image.

Type: String

ImageState

The current state of the image. If the state is available, the image is successfully registered and can be used to launch an instance.

Type: String

`aws:createStack` – Create an AWS CloudFormation stack

Creates an AWS CloudFormation stack from a template.

> **Note**
>
> The `aws:createStack` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

For supplemental information about creating CloudFormation stacks, see CreateStack in the *AWS CloudFormation API Reference*.

Input

YAML

```
name: makeStack
action: aws:createStack
maxAttempts: 1
onFailure: Abort
inputs:
  Capabilities:
  - CAPABILITY_IAM
  StackName: myStack
  TemplateURL: http://s3.amazonaws.com/amzn-s3-demo-bucket/myStackTemplate
  TimeoutInMinutes: 5
  Parameters:
    - ParameterKey: LambdaRoleArn
      ParameterValue: "{{LambdaAssumeRole}}"
    - ParameterKey: createdResource
      ParameterValue: createdResource-{{automation:EXECUTION_ID}}
```

JSON

```
{
    "name": "makeStack",
    "action": "aws:createStack",
    "maxAttempts": 1,
    "onFailure": "Abort",
    "inputs": {
        "Capabilities": [
            "CAPABILITY_IAM"
        ],
        "StackName": "myStack",
        "TemplateURL": "http://s3.amazonaws.com/amzn-s3-demo-bucket/
myStackTemplate",
        "TimeoutInMinutes": 5,
        "Parameters": [
          {
            "ParameterKey": "LambdaRoleArn",
            "ParameterValue": "{{LambdaAssumeRole}}"
          },
          {
            "ParameterKey": "createdResource",
            "ParameterValue": "createdResource-{{automation:EXECUTION_ID}}"
          }
    }
}
```

Capabilities

A list of values that you specify before CloudFormation can create certain stacks. Some stack templates include resources that can affect permissions in your AWS account. For those stacks, you must explicitly acknowledge their capabilities by specifying this parameter.

Valid values include `CAPABILITY_IAM`, `CAPABILITY_NAMED_IAM`, and `CAPABILITY_AUTO_EXPAND`.

CAPABILITY_IAM and CAPABILITY_NAMED_IAM

If you have IAM resources, you can specify either capability. If you have IAM resources with custom names, you must specify `CAPABILITY_NAMED_IAM`. If you don't specify this parameter, this action returns an `InsufficientCapabilities` error. The following resources require you to specify either `CAPABILITY_IAM` or `CAPABILITY_NAMED_IAM`.

- AWS::IAM::AccessKey
- AWS::IAM::Group
- AWS::IAM::InstanceProfile
- AWS::IAM::Policy
- AWS::IAM::Role
- AWS::IAM::User
- AWS::IAM::UserToGroupAddition

If your stack template contains these resources, we recommend that you review all permissions associated with them and edit their permissions, if necessary.

For more information, see Acknowledging IAM Resources in AWS CloudFormation Templates.

CAPABILITY_AUTO_EXPAND

Some template contain macros. Macros perform custom processing on templates; this can include simple actions like find-and-replace operations, all the way to extensive transformations of entire templates. Because of this, users typically create a change set from the processed template, so that they can review the changes resulting from the macros before actually creating the stack. If your stack template contains one or more macros, and you choose to create a stack directly from the processed template, without first reviewing the resulting changes in a change set, you must acknowledge this capability.

For more information, see Using AWS CloudFormation Macros to Perform Custom Processing on Templates in the *AWS CloudFormation User Guide*.

Type: array of Strings

Valid Values: `CAPABILITY_IAM | CAPABILITY_NAMED_IAM | CAPABILITY_AUTO_EXPAND`

Required: No

ClientRequestToken

A unique identifier for this CreateStack request. Specify this token if you set maxAttempts in this step to a value greater than 1. By specifying this token, CloudFormation knows that you aren't attempting to create a new stack with the same name.

Type: String

Required: No

Length Constraints: Minimum length of 1. Maximum length of 128.

Pattern: [a-zA-Z0-9][-a-zA-Z0-9]*

DisableRollback

Set to `true` to turn off rollback of the stack if stack creation failed.

Conditional: You can specify either the `DisableRollback` parameter or the `OnFailure` parameter, but not both.

Default: `false`

Type: Boolean

Required: No

NotificationARNs

The Amazon Simple Notification Service (Amazon SNS) topic ARNs for publishing stack-related events. You can find SNS topic ARNs using the Amazon SNS console, https://console.aws.amazon.com/sns/v3/home.

Type: array of Strings

Array Members: Maximum number of 5 items.

Required: No

OnFailure

Determines the action to take if stack creation failed. You must specify `DO_NOTHING`, `ROLLBACK`, or `DELETE`.

Conditional: You can specify either the `OnFailure` parameter or the `DisableRollback` parameter, but not both.

Default: `ROLLBACK`

Type: String

Valid Values: `DO_NOTHING | ROLLBACK | DELETE`

Required: No

Parameters

A list of `Parameter` structures that specify input parameters for the stack. For more information, see the Parameter data type.

Type: array of Parameter objects

Required: No

ResourceTypes

The template resource types that you have permissions to work with for this create stack action. For example: `AWS::EC2::Instance`, `AWS::EC2::*`, or `Custom::MyCustomInstance`. Use the following syntax to describe template resource types.

- For all AWS resources:

```
AWS::*
```

- For all custom resources:

```
Custom::*
```

- For a specific custom resource:

```
Custom::logical_ID
```

- For all resources of a particular AWS service:

```
AWS::service_name::*
```

- For a specific AWS resource:

```
AWS::service_name::resource_logical_ID
```

If the list of resource types doesn't include a resource that you're creating, the stack creation fails. By default, CloudFormation grants permissions to all resource types. IAM uses this parameter for CloudFormation-specific condition keys in IAM policies. For more information, see Controlling Access with AWS Identity and Access Management.

Type: array of Strings

Length Constraints: Minimum length of 1. Maximum length of 256.

Required: No

RoleARN

The Amazon Resource Name (ARN) of an IAM role that CloudFormation assumes to create the stack. CloudFormation uses the role's credentials to make calls on your behalf. CloudFormation always uses this role for all future operations on the stack. As long as users have permission to operate on the stack, CloudFormation uses this role even if the users don't have permission to pass it. Ensure that the role grants the least amount of privileges.

If you don't specify a value, CloudFormation uses the role that was previously associated with the stack. If no role is available, CloudFormation uses a temporary session that is generated from your user credentials.

Type: String

Length Constraints: Minimum length of 20. Maximum length of 2048.

Required: No

StackName

The name that is associated with the stack. The name must be unique in the Region in which you're creating the stack.

> **Note**
>
> A stack name can contain only alphanumeric characters (case sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters.

Type: String

Required: Yes

StackPolicyBody

Structure containing the stack policy body. For more information, see Prevent Updates to Stack Resources.

Conditional: You can specify either the `StackPolicyBody` parameter or the `StackPolicyURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 16384.

Required: No

StackPolicyURL

Location of a file containing the stack policy. The URL must point to a policy located in an S3 bucket in the same region as the stack. The maximum file size allowed for the stack policy is 16 KB.

Conditional: You can specify either the `StackPolicyBody` parameter or the `StackPolicyURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 1350.

Required: No

Tags

Key-value pairs to associate with this stack. CloudFormation also propagates these tags to the resources created in the stack. You can specify a maximum number of 10 tags.

Type: array of Tag objects

Required: No

TemplateBody

Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. For more information, see Template Anatomy.

Conditional: You can specify either the `TemplateBody` parameter or the `TemplateURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1.

Required: No

TemplateURL

Location of a file containing the template body. The URL must point to a template that is located in an S3 bucket. The maximum size allowed for the template is 460,800 bytes. For more information, see Template Anatomy.

Conditional: You can specify either the `TemplateBody` parameter or the `TemplateURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 1024.

Required: No

TimeoutInMinutes

The amount of time that can pass before the stack status becomes `CREATE_FAILED`. If `DisableRollback` isn't set or is set to `false`, the stack will be rolled back.

Type: Integer

Valid Range: Minimum value of 1.

Required: No

Outputs

StackId

Unique identifier of the stack.

Type: String

StackStatus

Current status of the stack.

Type: String

Valid Values: `CREATE_IN_PROGRESS | CREATE_FAILED | CREATE_COMPLETE | ROLLBACK_IN_PROGRESS | ROLLBACK_FAILED | ROLLBACK_COMPLETE`

```
| DELETE_IN_PROGRESS | DELETE_FAILED | DELETE_COMPLETE |
UPDATE_IN_PROGRESS | UPDATE_COMPLETE_CLEANUP_IN_PROGRESS |
UPDATE_COMPLETE | UPDATE_ROLLBACK_IN_PROGRESS | UPDATE_ROLLBACK_FAILED |
UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS | UPDATE_ROLLBACK_COMPLETE
| REVIEW_IN_PROGRESS
```

Required: Yes

StackStatusReason

Success or failure message associated with the stack status.

Type: String

Required: No

For more information, see CreateStack.

Security considerations

Before you can use the `aws:createStack` action, you must assign the following policy to the IAM Automation assume role. For more information about the assume role, see Task 1: Create a service role for Automation.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "sqs:*",
            "cloudformation:CreateStack",
            "cloudformation:DescribeStacks"
         ],
         "Resource":"*"
      }
   ]
}
```

`aws:createTags` – Create tags for AWS resources

Creates new tags for Amazon Elastic Compute Cloud (Amazon EC2) instances or AWS Systems Manager managed instances.

> **Note**
>
> The `aws:createTags` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports most Amazon EC2 `CreateTags` and Systems Manager `AddTagsToResource` parameters. For more information, see CreateTags and AddTagsToResource.

The following example shows how to tag an Amazon Machine Image (AMI) and an instance as production resources for a particular department.

YAML

```
name: createTags
action: aws:createTags
maxAttempts: 3
onFailure: Abort
inputs:
  ResourceType: EC2
  ResourceIds:
  - ami-9a3768fa
  - i-02951acd5111a8169
  Tags:
  - Key: production
    Value: ''
  - Key: department
    Value: devops
```

JSON

```
{
    "name": "createTags",
    "action": "aws:createTags",
```

```
    "maxAttempts": 3,
    "onFailure": "Abort",
    "inputs": {
        "ResourceType": "EC2",
        "ResourceIds": [
            "ami-9a3768fa",
            "i-02951acd5111a8169"
        ],
        "Tags": [
            {
                "Key": "production",
                "Value": ""
            },
            {
                "Key": "department",
                "Value": "devops"
            }
        ]
    }
}
```

ResourceIds

The IDs of the resource(s) to be tagged. If resource type isn't “EC2”, this field can contain only a single item.

Type: String List

Required: Yes

Tags

The tags to associate with the resource(s).

Type: List of Maps

Required: Yes

ResourceType

The type of resource(s) to be tagged. If not supplied, the default value of “EC2” is used.

Type: String

Required: No

Valid Values: EC2 | ManagedInstance | MaintenanceWindow | Parameter

Output

None

aws:deleteImage – Delete an Amazon Machine Image

Deletes the specified Amazon Machine Image (AMI) and all related snapshots.

> **Note**
>
> The aws:deleteImage action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports only one parameter. For more information, see the documentation for DeregisterImage and DeleteSnapshot.

YAML

```
name: deleteMyImage
action: aws:deleteImage
maxAttempts: 3
timeoutSeconds: 180
onFailure: Abort
inputs:
  ImageId: ami-12345678
```

JSON

```
{
    "name": "deleteMyImage",
    "action": "aws:deleteImage",
    "maxAttempts": 3,
    "timeoutSeconds": 180,
    "onFailure": "Abort",
```

```
    "inputs": {
        "ImageId": "ami-12345678"
    }
}
```

ImageId

The ID of the image to be deleted.

Type: String

Required: Yes

Output

None

`aws:deleteStack` – Delete an AWS CloudFormation stack

Deletes an AWS CloudFormation stack.

> **Note**
>
> The `aws:deleteStack` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

YAML

```
name: deleteStack
action: aws:deleteStack
maxAttempts: 1
onFailure: Abort
inputs:
  StackName: "{{stackName}}"
```

JSON

```
{
```

```
   "name":"deleteStack",
   "action":"aws:deleteStack",
   "maxAttempts":1,
   "onFailure":"Abort",
   "inputs":{
      "StackName":"{{stackName}}"
   }
}
```

ClientRequestToken

A unique identifier for this `DeleteStack` request. Specify this token if you plan to retry requests so that CloudFormation knows that you aren't attempting to delete a stack with the same name. You can retry `DeleteStack` requests to verify that CloudFormation received them.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 128.

Pattern: [a-zA-Z][-a-zA-Z0-9]*

Required: No

RetainResources.member.N

This input applies only to stacks that are in a `DELETE_FAILED` state. A list of logical resource IDs for the resources you want to retain. During deletion, CloudFormation deletes the stack, but doesn't delete the retained resources.

Retaining resources is useful when you can't delete a resource, such as a non-empty S3 bucket, but you want to delete the stack.

Type: array of strings

Required: No

RoleARN

The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that CloudFormation assumes to create the stack. CloudFormation uses the role's credentials to make calls on your behalf. CloudFormation always uses this role for all future operations on the stack. As long as users have permission to operate on the stack, CloudFormation uses this role

even if the users don't have permission to pass it. Ensure that the role grants the least amount of privileges.

If you don't specify a value, CloudFormation uses the role that was previously associated with the stack. If no role is available, CloudFormation uses a temporary session that is generated from your user credentials.

Type: String

Length Constraints: Minimum length of 20. Maximum length of 2048.

Required: No

StackName

The name or the unique stack ID that is associated with the stack.

Type: String

Required: Yes

Security considerations

Before you can use the `aws:deleteStack` action, you must assign the following policy to the IAM Automation assume role. For more information about the assume role, see Task 1: Create a service role for Automation.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "sqs:*",
            "cloudformation:DeleteStack",
            "cloudformation:DescribeStacks"
         ],
         "Resource":"*"
      }
   ]
```

```
}
```

`aws:executeAutomation` – Run another automation

Runs a secondary automation by calling a secondary runbook. With this action, you can create runbooks for your most common operations, and reference those runbooks during an automation. This action can simplify your runbooks by removing the need to duplicate steps across similar runbooks.

The secondary automation runs in the context of the user who initiated the primary automation. This means that the secondary automation uses the same AWS Identity and Access Management (IAM) role or user as the user who started the first automation.

> **Important**
>
> If you specify parameters in a secondary automation that use an assume role (a role that uses the iam:passRole policy), then the user or role that initiated the primary automation must have permission to pass the assume role specified in the secondary automation. For more information about setting up an assume role for Automation, see Create the service roles for Automation using the console.

Input

YAML

```
name: Secondary_Automation
action: aws:executeAutomation
maxAttempts: 3
timeoutSeconds: 3600
onFailure: Abort
inputs:
  DocumentName: secondaryAutomation
  RuntimeParameters:
    instanceIds:
    - i-1234567890abcdef0
```

JSON

```
{
```

```
   "name":"Secondary_Automation",
   "action":"aws:executeAutomation",
   "maxAttempts":3,
   "timeoutSeconds":3600,
   "onFailure":"Abort",
   "inputs":{
      "DocumentName":"secondaryAutomation",
      "RuntimeParameters":{
         "instanceIds":[
            "i-1234567890abcdef0"
         ]
      }
   }
}
```

DocumentName

The name of the secondary runbook to run during the step. For runbooks in the same AWS account, specify the runbook name. For runbooks shared from a different AWS account, specify the Amazon Resource Name (ARN) of the runbook. For information about using shared runbooks, see Using shared SSM documents.

Type: String

Required: Yes

DocumentVersion

The version of the secondary runbook to run. If not specified, Automation runs the default runbook version.

Type: String

Required: No

MaxConcurrency

The maximum number of targets allowed to run this task in parallel. You can specify a number, such as 10, or a percentage, such as 10%.

Type: String

Required: No

MaxErrors

The number of errors that are allowed before the system stops running the automation on additional targets. You can specify either an absolute number of errors, for example 10, or a percentage of the target set, for example 10%. If you specify 3, for example, the system stops running the automation when the fourth error is received. If you specify 0, then the system stops running the automation on additional targets after the first error result is returned. If you run an automation on 50 resources and set `MaxErrors` to 10%, then the system stops running the automation on additional targets when the sixth error is received.

Automations that are already running when the `MaxErrors` threshold is reached are allowed to complete, but some of these automations may fail as well. If you need to ensure that there won't be more failed automations than the specified `MaxErrors`, set `MaxConcurrency` to 1 so the automations proceed one at a time.

Type: String

Required: No

RuntimeParameters

Required parameters for the secondary runbook. The mapping uses the following format: {"parameter1" : "value1", "parameter2" : "value2" }

Type: Map

Required: No

Tags

Optional metadata that you assign to a resource. You can specify a maximum of five tags for an automation.

Type: MapList

Required: No

TargetLocations

A location is a combination of AWS Regions and/or AWS accounts where you want to run the automation. A minimum number of 1 item must be specified and a maximum number of 100 items can be specified. When specifying a value for this parameter, outputs aren't returned to the parent automation. If needed, you must make subsequent calls to API operations to retrieve the output from child automations.

Type: MapList

Required: No

TargetMaps

A list of key-value mappings of document parameters to target resources. Both `Targets` and `TargetMaps` can't be specified together.

Type: MapList

Required: No

TargetParameterName

The name of the parameter used as the target resource for the rate-controlled automation. Required if you specify `Targets`.

Type: String

Required: No

Targets

A list of key-value mappings to target resources. Required if you specify `TargetParameterName`.

Type: MapList

Required: No

Output

Output

The output generated by the secondary automation. You can reference the output by using the following format: *`Secondary_Automation_Step_Name`*.Output

Type: StringList

Here is an example:

```
- name: launchNewWindowsInstance
  action: 'aws:executeAutomation'
```

```
  onFailure: Abort
  inputs:
    DocumentName: launchWindowsInstance
  nextStep: getNewInstanceRootVolume
- name: getNewInstanceRootVolume
  action: 'aws:executeAwsApi'
  onFailure: Abort
  inputs:
    Service: ec2
    Api: DescribeVolumes
    Filters:
    - Name: attachment.device
      Values:
      - /dev/sda1
    - Name: attachment.instance-id
      Values:
      - '{{launchNewWindowsInstance.Output}}'
  outputs:
  - Name: rootVolumeId
    Selector: '$.Volumes[0].VolumeId'
    Type: String
  nextStep: snapshotRootVolume
- name: snapshotRootVolume
  action: 'aws:executeAutomation'
  onFailure: Abort
  inputs:
    DocumentName: AWS-CreateSnapshot
    RuntimeParameters:
    VolumeId:
    - '{{getNewInstanceRootVolume.rootVolumeId}}'
    Description:
    - 'Initial root snapshot for {{launchNewWindowsInstance.Output}}'
```

ExecutionId

The ID of the secondary automation.

Type: String

Status

The status of the secondary automation.

Type: String

`aws:executeAwsApi` – Call and run AWS API operations

Calls and runs AWS API operations. Most API operations are supported, although not all API operations have been tested. Streaming API operations, such as the GetObject operation, aren't supported. If you're not sure if an API operation you want to use is a streaming operation, review the Boto3 documentation for the service to determine if an API requires streaming inputs or outputs. We regularly update the Boto3 version used by this action. However, following the release of a new Boto3 version it can take up to a few weeks for changes to be reflected in this action. Each `aws:executeAwsApi` action can run up to a maximum duration of 25 seconds. For more examples of how to use this action, see Additional runbook examples.

> **Note**
>
> The `aws:executeAwsApi` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Inputs

Inputs are defined by the API operation that you choose.

YAML

```
action: aws:executeAwsApi
inputs:
  Service: The official namespace of the service
  Api: The API operation or method name
  API operation inputs or parameters: A value
outputs: # These are user-specified outputs
- Name: The name for a user-specified output key
  Selector: A response object specified by using jsonpath format
  Type: The data type
```

JSON

```
{
   "action":"aws:executeAwsApi",
   "inputs":{
      "Service":"The official namespace of the service",
      "Api":"The API operation or method name",
      "API operation inputs or parameters":"A value"
```

```
    },
    "outputs":[ These are user-specified outputs
       {
          "Name":"The name for a user-specified output key",
          "Selector":"A response object specified by using JSONPath format",
          "Type":"The data type"
       }
    ]
}
```

Service

The AWS service namespace that contains the API operation that you want to run. You can view a list of supported AWS service namespaces in Available services of the AWS SDK for Python (Boto3). The namespace can be found in the **Client** section. For example, the namespace for Systems Manager is `ssm`. The namespace for Amazon Elastic Compute Cloud (Amazon EC2) is `ec2`.

Type: String

Required: Yes

Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: Amazon RDS methods.

Type: String

Required: Yes

API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**.

YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

JSON

```
"inputs":{
      "Service":"The official namespace of the service",
      "Api":"The API operation name",
      "API input 1":"A value",
      "API Input 2":"A value",
      "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

Outputs

Outputs are specified by the user based on the response from the chosen API operation.

Name

A name for the output.

Type: String

Required: Yes

Selector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: Integer, Boolean, String, StringList, StringMap, or MapList

Required: Yes

Type

The data type for the response element.

Type: Varies

Required: Yes

`aws:executeScript` – Run a script

Runs the Python or PowerShell script provided using the specified runtime and handler. Each `aws:executeScript` action can run up to a maximum duration of 600 seconds (10 minutes). You can limit the timeout by specifying the `timeoutSeconds` parameter for an `aws:executeScript` step.

Use return statements in your function to add outputs to your output payload. For examples of defining outputs for your `aws:executeScript` action, see Example 2: Scripted runbook. You can also send the output from `aws:executeScript` actions in your runbooks to the Amazon CloudWatch Logs log group you specify. For more information, see Logging Automation action output with CloudWatch Logs.

If you want to send output from `aws:executeScript` actions to CloudWatch Logs, or if the scripts you specify for `aws:executeScript` actions call AWS API operations, an AWS Identity and Access Management (IAM) service role (or assume role) is always required to run the runbook.

> **Note**
>
> The `aws:executeScript` action does not support automatic throttling retry. If your script makes AWS API calls that might be throttled, you must implement your own retry logic in your script code.

The `aws:executeScript` action contains the following preinstalled PowerShell Core modules:

- Microsoft.PowerShell.Host
- Microsoft.PowerShell.Management

- Microsoft.PowerShell.Security
- Microsoft.PowerShell.Utility
- PackageManagement
- PowerShellGet

To use PowerShell Core modules that aren't preinstalled, your script must install the module with the `-Force` flag, as shown in the following command. The `AWSPowerShell.NetCore` module isn't supported. Replace *`ModuleName`* with the module you want to install.

```
Install-Module ModuleName -Force
```

To use PowerShell Core cmdlets in your script, we recommend using the `AWS.Tools` modules, as shown in the following commands. Replace each *`example resource placeholder`* with your own information.

- Amazon S3 cmdlets.

  ```
  Install-Module AWS.Tools.S3 -Force
  Get-S3Bucket -BucketName amzn-s3-demo-bucket
  ```

- Amazon EC2 cmdlets.

  ```
  Install-Module AWS.Tools.EC2 -Force
  Get-EC2InstanceStatus -InstanceId instance-id
  ```

- Common, or service independent AWS Tools for Windows PowerShell cmdlets.

  ```
  Install-Module AWS.Tools.Common -Force
  Get-AWSRegion
  ```

If your script initializes new objects in addition to using PowerShell Core cmdlets, you must also import the module as shown in the following command.

```
Install-Module AWS.Tools.EC2 -Force
Import-Module AWS.Tools.EC2

$tag = New-Object Amazon.EC2.Model.Tag
$tag.Key = "Tag"
```

```
$tag.Value = "TagValue"

New-EC2Tag -Resource i-02573cafcfEXAMPLE -Tag $tag
```

For examples of installing and importing `AWS.Tools` modules, and using PowerShell Core cmdlets in runbooks, see Visual design experience for Automation runbooks.

Input

Provide the information required to run your script. Replace each *example resource placeholder* with your own information.

> **Note**
>
> The attachment for a Python script can be a .py file or a .zip file that contains the script. PowerShell scripts must be stored in .zip files.

YAML

```
action: "aws:executeScript"
inputs:
 Runtime: runtime
 Handler: "functionName"
 InputPayload:
  scriptInput: '{{parameterValue}}'
 Script: |-
   def functionName(events, context):
   ...
 Attachment: "scriptAttachment.zip"
```

JSON

```
{
    "action": "aws:executeScript",
    "inputs": {
        "Runtime": "runtime",
        "Handler": "functionName",
        "InputPayload": {
            "scriptInput": "{{parameterValue}}"
        },
        "Attachment": "scriptAttachment.zip"
```

```
    }
}
```

Runtime

The runtime language to be used for running the provided script. `aws:executeScript` supports Python 3.7 (`python3.7`), Python 3.8 (`python3.8`), Python 3.9 (`python3.9`)Python 3.10 (`python3.10`), Python 3.11 (`python3.11`) PowerShell Core 6.0 (`dotnetcore2.1`), PowerShell 7.0 (`dotnetcore3.1`) scripts, and PowerShell 7.4 (`dotnet8`) scripts.

Supported values: **`python3.7`** | **`python3.8`** | **`python3.9`** | **`python3.10`** | **`python3.11`** | **`PowerShell Core 6.0`** | **`PowerShell 7.0`** | **`PowerShell 7.4`**

Type: String

Required: Yes

> **Note**
>
> For python runtimes, the environment provides 512MB of memory and 512MB of disk space. For PowerShell runtimes, the environment provides 1024MB of memory and 512MB of disk space.

Handler

The name of your function. You must ensure the function defined in the handler has two parameters, `events` and `context`. The PowerShell runtime does not support this parameter.

Type: String

Required: Yes (Python) | Not supported (PowerShell)

InputPayload

A JSON or YAML object that will be passed to the first parameter of the handler. This can be used to pass input data to the script.

Type: String

Required: No

Python

```
description: Tag an instance
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
    AutomationAssumeRole:
        type: String
        description: '(Required) The Amazon Resource Name (ARN) of the IAM role
 that allows Automation to perform the actions on your behalf. If no role is
 specified, Systems Manager Automation uses your IAM permissions to operate this
 runbook.'
    InstanceId:
        type: String
        description: (Required) The ID of the EC2 instance you want to tag.
mainSteps:
  - name: tagInstance
    action: 'aws:executeScript'
    inputs:
        Runtime: "python3.11"
        Handler: tagInstance
        InputPayload:
            instanceId: '{{InstanceId}}'
        Script: |-
          def tagInstance(events,context):
            import boto3

            #Initialize client
            ec2 = boto3.client('ec2')
            instanceId = events['instanceId']
            tag = {
                "Key": "Env",
                "Value": "ExamplePython"
            }
            print(f"Adding tag {tag} to instance id {instanceId}")
            ec2.create_tags(
                Resources=[instanceId],
                Tags=[tag]
            )
            return tag
    outputs:
      - Type: String
        Name: TagKey
        Selector: $.Payload.Key
```

```
outputs:
  - tagInstance.TagKey
```

PowerShell

```
description: Tag an instance
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: (Required) The Amazon Resource Name (ARN) of the IAM role
 that allows Automation to perform the actions on your behalf. If no role is
 specified, Systems Manager Automation uses your IAM permissions to operate this
 runbook.
  InstanceId:
    type: String
    description: (Required) The ID of the EC2 instance you want to tag.
mainSteps:
  - name: tagInstance
    action: aws:executeScript
    isEnd: true
    inputs:
      Runtime: PowerShell 7.0
      InputPayload:
        instanceId: '{{InstanceId}}'
      Script: |-
        Install-Module AWS.Tools.EC2 -Force
        Import-Module AWS.Tools.EC2

        $input = $env:InputPayload | ConvertFrom-Json

        $tag = New-Object Amazon.EC2.Model.Tag
        $tag.Key = "Env"
        $tag.Value = "ExamplePowerShell"

        Write-Information "Adding tag key: $($tag.Key) and value: $($tag.Value)
 to instance id $($input.instanceId)"
        New-EC2Tag -Resource $input.instanceId -Tag $tag

        return $tag
    outputs:
      - Type: String
```

```
        Name: TagKey
        Selector: $.Payload.Key
outputs:
  - tagInstance.TagKey
```

Script

An embedded script that you want to run during the automation.

Type: String

Required: No (Python) | Yes (PowerShell)

Attachment

The name of a standalone script file or .zip file that can be invoked by the action. Specify the same value as the `Name` of the document attachment file you specify in the `Attachments` request parameter. For more information, see Attachments in the *AWS Systems Manager API Reference*. If you're providing a script using an attachment, you must also define a `files` section in the top-level elements of your runbook. For more information, see Schema version 0.3.

To invoke a file for Python, use the `filename.method_name` format in `Handler`.

> **Note**
>
> The attachment for a Python script can be a .py file or a .zip file that contains the script. PowerShell scripts must be stored in .zip files.

When including Python libraries in your attachment, we recommend adding an empty `__init__.py` file in each module directory. This allows you to import the modules from the library in your attachment within your script content. For example: `from library import module`

Type: String

Required: No

Output

Payload

The JSON representation of the object returned by your function. Up to 100KB is returned. If you output a list, a maximum of 100 items is returned.

Using attachments with aws:executeScript

Attachments provide a powerful way to package and reuse complex scripts, multiple modules, and external dependencies with your `aws:executeScript` actions. Use attachments when you need to:

- Package multiple Python modules or PowerShell scripts together.
- Reuse the same script logic across multiple runbooks.
- Include external libraries or dependencies with your scripts.
- Keep your runbook definition clean by separating complex script logic.
- Share script packages across teams or automation workflows.

Attachment structure and packaging

You can attach either single files or zip packages containing multiple files. The structure depends on your use case:

Single file attachments

For simple scripts, you can attach a single `.py` file (Python) or a `.zip` file containing a single PowerShell script.

Multi-module packages

For complex automation that requires multiple modules, create a zip package with the following recommended structure:

```
my-automation-package.zip
### main.py                    # Entry point script
### utils/
#   ### __init__.py           # Required for Python module imports
#   ### helper_functions.py   # Utility functions
```

```
#   ### aws_operations.py     # AWS-specific operations
### config/
#   ### __init__.py
#   ### settings.py           # Configuration settings
### requirements.txt          # Optional: document dependencies
```

> **Important**
>
> For Python packages, you must include an empty `__init__.py` file in each directory that contains Python modules. This allows you to import modules using standard Python import syntax like `from utils import helper_functions`.

PowerShell package structure

PowerShell attachments must be packaged in zip files with the following structure:

```
my-powershell-package.zip
### Main.ps1                  # Entry point script
### Modules/
#   ### HelperFunctions.ps1   # Utility functions
#   ### AWSOperations.ps1     # AWS-specific operations
### Config/
    ### Settings.ps1          # Configuration settings
```

Creating runbooks with attachments

Follow these steps to create runbooks that use attachments:

1. **Upload your attachment to Amazon S3**

   Upload your script file or zip package to an S3 bucket that your automation role can access. Note the S3 URI for use in the next step.

   ```
   aws s3 cp my-automation-package.zip s3://my-automation-bucket/scripts/
   ```

2. **Calculate the attachment checksum**

   Calculate the SHA-256 checksum of your attachment file for security verification:

   ```
   # Linux/macOS
   ```

```
shasum -a 256 my-automation-package.zip

# Windows PowerShell
Get-FileHash -Algorithm SHA256 my-automation-package.zip
```

3. **Define the files section in your runbook**

   Add a `files` section at the top level of your runbook to reference your attachment:

```
files:
  my-automation-package.zip:
    sourceType: "S3"
    sourceInfo:
      path: "s3://my-automation-bucket/scripts/my-automation-package.zip"
      checksums:
        sha256: "your-calculated-checksum-here"
```

4. **Reference the attachment in your executeScript step**

   Use the `Attachment` parameter to reference your uploaded file:

```
- name: runMyScript
  action: aws:executeScript
  inputs:
    Runtime: python3.11
    Handler: main.process_data
    Attachment: my-automation-package.zip
    InputPayload:
      inputData: "{{InputParameter}}"
```

aws:executeScript attachment examples

The following examples demonstrate different ways to use attachments with the `aws:executeScript` action.

Example 1: Single file attachment

This example shows how to use a single Python file as an attachment to process EC2 instance data.

Attachment file: process_instance.py

Create a Python file with the following content:

```
import boto3
import json

def process_instance_data(events, context):
    """Process EC2 instance data and return formatted results."""
    try:
        instance_id = events.get('instanceId')
        if not instance_id:
            raise ValueError("instanceId is required")

        ec2 = boto3.client('ec2')

        # Get instance details
        response = ec2.describe_instances(InstanceIds=[instance_id])
        instance = response['Reservations'][0]['Instances'][0]

        # Format the response
        result = {
            'instanceId': instance_id,
            'instanceType': instance['InstanceType'],
            'state': instance['State']['Name'],
            'availabilityZone': instance['Placement']['AvailabilityZone'],
            'tags': {tag['Key']: tag['Value'] for tag in instance.get('Tags', [])}
        }

        print(f"Successfully processed instance {instance_id}")
        return result

    except Exception as e:
        print(f"Error processing instance: {str(e)}")
        raise
```

Complete runbook

Here's the complete runbook that uses the single file attachment:

```
description: Process EC2 instance data using single file attachment
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: (Required) IAM role for automation execution
```

```
  InstanceId:
    type: String
    description: (Required) EC2 instance ID to process

files:
  process_instance.py:
    sourceType: "S3"
    sourceInfo:
      path: "s3://my-automation-bucket/scripts/process_instance.py"
      checksums:
        sha256: "abc123def456..."

mainSteps:
  - name: processInstance
    action: aws:executeScript
    inputs:
      Runtime: python3.11
      Handler: process_instance.process_instance_data
      Attachment: process_instance.py
      InputPayload:
        instanceId: '{{InstanceId}}'
    outputs:
      - Type: StringMap
        Name: InstanceData
        Selector: $.Payload

outputs:
  - processInstance.InstanceData
```

Example 2: Multi-module package

This example demonstrates using a zip package containing multiple Python modules for complex S3 bucket operations.

Package structure

Create a zip package with the following structure:

```
s3-operations.zip
### main.py
### utils/
#   ### __init__.py
#   ### s3_helper.py
```

```
#   ### validation.py
### config/
    ### __init__.py
    ### settings.py
```

main.py (entry point)

The main script that orchestrates the operations:

```
from utils.s3_helper import S3Operations
from utils.validation import validate_bucket_name
from config.settings import get_default_settings

def cleanup_s3_bucket(events, context):
    """Clean up S3 bucket based on specified criteria."""
    try:
        bucket_name = events.get('bucketName')
        max_age_days = events.get('maxAgeDays', 30)

        # Validate inputs
        if not validate_bucket_name(bucket_name):
            raise ValueError(f"Invalid bucket name: {bucket_name}")

        # Initialize S3 operations
        s3_ops = S3Operations()
        settings = get_default_settings()

        # Perform cleanup
        deleted_objects = s3_ops.delete_old_objects(
            bucket_name,
            max_age_days,
            settings['dry_run']
        )

        result = {
            'bucketName': bucket_name,
            'deletedCount': len(deleted_objects),
            'deletedObjects': deleted_objects[:10],  # Return first 10 for brevity
            'dryRun': settings['dry_run']
        }

        print(f"Cleanup completed for bucket {bucket_name}")
        return result
```

```
    except Exception as e:
        print(f"Error during S3 cleanup: {str(e)}")
        raise
```

Troubleshooting aws:executeScript attachments

Use the following guidance to resolve common issues with `aws:executeScript` attachments:

Module import errors

If you receive import errors when using multi-module packages:

- Ensure you have included an empty `__init__.py` file in each directory containing Python modules.
- Verify that your import statements match the actual file and directory structure in your zip package.
- Use relative imports (e.g., `from .utils import helper`) or absolute imports (e.g., `from utils import helper`) consistently.

Attachment not found errors

If your automation fails to find the attachment:

- Verify that the `Attachment` parameter value exactly matches the key in your `files` section.
- Check that your S3 bucket path and file name are correct in the `files` section.
- Ensure your automation role has `s3:GetObject` permission for the attachment S3 location.
- Verify that the checksum in your runbook matches the actual file checksum.

Handler function errors

If you receive handler-related errors:

- For Python: Use the format `filename.function_name` in the `Handler` parameter (e.g., `main.process_data`).
- Ensure your handler function accepts exactly two parameters: `events` and `context`.
- For PowerShell: Do not specify a `Handler` parameter; the script runs directly.

Script execution failures

If your script fails during execution:

- Check the automation execution history for detailed error messages and stack traces.
- Use `print()` statements (Python) or `Write-Information` (PowerShell) to add debugging output.
- Verify that all required AWS permissions are granted to your automation role.
- Test your script logic locally before packaging it as an attachment.

Exit codes and error handling

To properly handle errors and return exit codes:

- In Python: Use `raise Exception("error message")` to indicate script failure.
- In PowerShell: Use `throw "error message"` or `Write-Error` to indicate failure.
- Return structured data from your functions to provide detailed success/failure information.
- Use try-catch blocks to handle exceptions gracefully and provide meaningful error messages.

`aws:executeStateMachine` – Run an AWS Step Functions state machine

Runs an AWS Step Functions state machine.

> **Note**
>
> The `aws:executeStateMachine` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports most parameters for the Step Functions StartExecution API operation.

Required AWS Identity and Access Management (IAM) permissions

- `states:DescribeExecution`
- `states:StartExecution`
- `states:StopExecution`

YAML

```
name: executeTheStateMachine
action: aws:executeStateMachine
inputs:
  stateMachineArn: StateMachine_ARN
  input: '{"parameters":"values"}'
  name: name
```

JSON

```
{
    "name": "executeTheStateMachine",
    "action": "aws:executeStateMachine",
    "inputs": {
        "stateMachineArn": "StateMachine_ARN",
        "input": "{\"parameters\":\"values\"}",
        "name": "name"
    }
}
```

stateMachineArn

The Amazon Resource Name (ARN) of the Step Functions state machine.

Type: String

Required: Yes

name

The name of the execution.

Type: String

Required: No

input

A string that contains the JSON input data for the execution.

Type: String

Required: No

Outputs

The following outputs are predefined for this action.

executionArn

The ARN of the execution.

Type: String

input

The string that contains the JSON input data of the execution. Length constraints apply to the payload size, and are expressed as bytes in UTF-8 encoding..

Type: String

name

The name of the execution.

Type: String

output

The JSON output data of the execution. Length constraints apply to the payload size, and are expressed as bytes in UTF-8 encoding.

Type: String

startDate

The date the execution is started.

Type: String

stateMachineArn

The ARN of the executed stated machine.

Type: String

status

The current status of the execution.

Type: String

stopDate

If the execution has already ended, the date the execution stopped.

Type: String

`aws:invokeWebhook` – Invoke an Automation webhook integration

Invokes the specified Automation webhook integration. For information about creating Automation integrations, see Creating webhook integrations for Automation.

> **Note**
>
> The `aws:invokeWebhook` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

> **Note**
>
> To use the `aws:invokeWebhook` action, your user or service role must allow the following actions:
>
> - ssm:GetParameter
> - kms:Decrypt
>
> Permission for the AWS Key Management Service (AWS KMS) `Decrypt` operation is only required if you use a customer managed key to encrypt the parameter for your integration.

Input

Provide the information for the Automation integration you want to invoke.

YAML

```
action: "aws:invokeWebhook"
inputs:
 IntegrationName: "exampleIntegration"
```

```
 Body: "Request body"
```

JSON

```
{
    "action": "aws:invokeWebhook",
    "inputs": {
        "IntegrationName": "exampleIntegration",
        "Body": "Request body"
    }
}
```

IntegrationName

The name of the Automation integration. For example, `exampleIntegration`. The integration you specify must already exist.

Type: String

Required: Yes

Body

The payload you want to send when your webhook integration is invoked.

Type: String

Required: No

Output

Response

The text received from the webhook provider response.

ResponseCode

The HTTP status code received from the webhook provider response.

`aws:invokeLambdaFunction` – Invoke an AWS Lambda function

Invokes the specified AWS Lambda function.

Note

Each `aws:invokeLambdaFunction` action can run up to a maximum duration of 300 seconds (5 minutes). You can limit the timeout by specifying the `timeoutSeconds` parameter for an `aws:invokeLambdaFunction` step.

Note

The `aws:invokeLambdaFunction` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports most invoked parameters for the Lambda service. For more information, see Invoke.

YAML

```
name: invokeMyLambdaFunction
action: aws:invokeLambdaFunction
maxAttempts: 3
timeoutSeconds: 120
onFailure: Abort
inputs:
  FunctionName: MyLambdaFunction
```

JSON

```
{
    "name": "invokeMyLambdaFunction",
    "action": "aws:invokeLambdaFunction",
    "maxAttempts": 3,
    "timeoutSeconds": 120,
    "onFailure": "Abort",
    "inputs": {
        "FunctionName": "MyLambdaFunction"
    }
}
```

FunctionName

The name of the Lambda function. This function must exist.

Type: String

Required: Yes

Qualifier

The function version or alias name.

Type: String

Required: No

InvocationType

The invocation type. The default value is `RequestResponse`.

Type: String

Valid values: `Event` | `RequestResponse` | `DryRun`

Required: No

LogType

If the default value is `Tail`, the invocation type must be `RequestResponse`. Lambda returns the last 4 KB of log data produced by your Lambda function, base64-encoded.

Type: String

Valid values: `None` | `Tail`

Required: No

ClientContext

The client-specific information.

Required: No

InputPayload

A YAML or JSON object that is passed to the first parameter of the handler. You can use this input to pass data to the function. This input provides more flexibility and support than

the legacy `Payload` input. If you define both `InputPayload` and `Payload` for the action, `InputPayload` takes precedence and the `Payload` value is not used.

Type: StringMap

Required: No

Payload

A JSON string that's passed to the first parameter of the handler. This can be used to pass input data to the function. We recommend using `InputPayload` input for added functionality.

Type: String

Required: No

Output

StatusCode

The HTTP status code.

FunctionError

If present, it indicates that an error occurred while executing the function. Error details are included in the response payload.

LogResult

The base64-encoded logs for the Lambda function invocation. Logs are present only if the invocation type is `RequestResponse`, and the logs were requested.

Payload

The JSON representation of the object returned by the Lambda function. Payload is present only if the invocation type is `RequestResponse`.

The following is a portion from the `AWS-PatchInstanceWithRollback` runbook demonstrating how to reference outputs from the `aws:invokeLambdaFunction` action.

YAML

```
- name: IdentifyRootVolume
```

```
  action: aws:invokeLambdaFunction
  inputs:
    FunctionName: "IdentifyRootVolumeLambda-{{automation:EXECUTION_ID}}"
    Payload: '{"InstanceId": "{{InstanceId}}"}'
- name: PrePatchSnapshot
  action: aws:executeAutomation
  inputs:
    DocumentName: "AWS-CreateSnapshot"
    RuntimeParameters:
      VolumeId: "{{IdentifyRootVolume.Payload}}"
      Description: "ApplyPatchBaseline restoration case contingency"
```

JSON

```
{
    "name": "IdentifyRootVolume",
    "action": "aws:invokeLambdaFunction",
    "inputs": {
      "FunctionName": "IdentifyRootVolumeLambda-{{automation:EXECUTION_ID}}",
      "Payload": "{\"InstanceId\": \"{{InstanceId}}\"}"
    }
  },
  {
    "name": "PrePatchSnapshot",
    "action": "aws:executeAutomation",
    "inputs": {
      "DocumentName": "AWS-CreateSnapshot",
      "RuntimeParameters": {
        "VolumeId": "{{IdentifyRootVolume.Payload}}",
        "Description": "ApplyPatchBaseline restoration case contingency"
      }
    }
  }
```

aws:loop – Iterate over steps in an automation

This action iterates over a subset of steps in an automation runbook. You can choose a do `while` or `for each` style loop. To construct a do `while` loop, use the `LoopCondition` input parameter. To construct a `for each` loop, use the `Iterators` and `IteratorDataType` input parameters. When using an `aws:loop` action, only specify either the `Iterators` or `LoopCondition` input parameter. The maximum number of iterations is 100.

The onCancel property can only be used for steps defined within a loop. The onCancel property isn't supported for the aws:loop action. The onFailure property can be used for an aws:loop action, however it will only be used if an unexpected error occurs causing the step to fail. If you define onFailure properties for the steps within a loop, the aws:loop action inherits those properties and reacts accordingly when a failure occurs.

Examples

The following are examples of how to construct the different types of loop actions.

do while

```
name: RepeatMyLambdaFunctionUntilOutputIsReturned
action: aws:loop
inputs:
    Steps:
    - name: invokeMyLambda
        action: aws:invokeLambdaFunction
        inputs:
        FunctionName: LambdaFunctionName
        outputs:
        - Name: ShouldRetry
            Selector: $.Retry
            Type: Boolean
    LoopCondition:
        Variable: "{{ invokeMyLambda.ShouldRetry }}"
        BooleanEquals: true
    MaxIterations: 3
```

for each

```
name: stopAllInstancesWithWaitTime
action: aws:loop
inputs:
    Iterators: "{{ DescribeInstancesStep.InstanceIds }}"
    IteratorDataType: "String"
    Steps:
    - name: stopOneInstance
        action: aws:changeInstanceState
        inputs:
        InstanceIds:
            - "{{stopAllInstancesWithWaitTime.CurrentIteratorValue}}"
        CheckStateOnly: false
```

```
        DesiredState: stopped
    - name: wait10Seconds
        action: aws:sleep
        inputs:
        Duration: PT10S
```

Input

The input is as follows.

Iterators

The list of items for the steps to iterate over. The maximum number of iterators is 100.

Type: StringList

Required: No

IteratorDataType

An optional parameter to specify the data type of the `Iterators`. A value for this parameter can be provided along with the `Iterators` input parameter. If you don't specify a value for this parameter and `Iterators`, then you must specify a value for the `LoopCondition` parameter.

Type: String

Valid values: Boolean | Integer | String | StringMap

Default: String

Required: No

LoopCondition

Consists of a `Variable` and an operator condition to evaluate. If you don't specify a value for this parameter, then you must specify values for the `Iterators` and `IteratorDataType` parameters. You can use complex operator evaluations by using a combination of `And`, `Not`, and `Or` operators. The condition is evaluated after the steps in the loop complete. If the condition is `true` and the `MaxIterations` value has not been reached, the steps in the loop run again. The operator conditions are as follows:

String operations

- StringEquals

- EqualsIgnoreCase
- StartsWith
- EndsWith
- Contains

Numeric operations

- NumericEquals
- NumericGreater
- NumericLesser
- NumericGreaterOrEquals
- NumericLesser
- NumericLesserOrEquals

Boolean operation

- BooleanEquals

Type: StringMap

Required: No

MaxIterations

The maximum number of times the steps in the loop run. Once the value specified for this input is reached, the loop stops running even if the `LoopCondition` is still `true` or if there are objects remaining in the `Iterators` parameter.

Type: Integer

Valid values: 1 - 100

Required: No

Steps

The list of steps to run in the loop. These function like a nested runbook. Within these steps you can access the current iterator value for a `for each` loop using the syntax `{{loopStepName.CurrentIteratorValue}}`. You can also access an integer value of the current iteration for both loop types using the syntax `{{loopStepName.CurrentIteration}}`.

Type: List of steps

Required: Yes

Output

CurrentIteration

The current loop iteration as an integer. Iteration values start at 1.

Type: Integer

CurrentIteratorValue

The value of the current iterator as a string. This output is only present in `for each` loops.

Type: String

aws:pause – Pause an automation

This action pauses the automation. Once paused, the automation status is *Waiting*. To continue the automation, use the SendAutomationSignal API operation with the `Resume` signal type. We recommend using the `aws:sleep` or `aws:approve` action for more granular control of your workflows.

> **Note**
>
> The default timeout for this action is 7 days (604800 seconds) and the maximum value is 30 days (2592000 seconds). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:pause` step.

Input

The input is as follows.

YAML

```
name: pauseThis
action: aws:pause
timeoutSeconds: 1209600
```

```
inputs: {}
```

JSON

```
{
    "name": "pauseThis",
    "action": "aws:pause",
    "timeoutSeconds": "1209600",
    "inputs": {}
}
```

Output

None

`aws:runCommand` – Run a command on a managed instance

Runs the specified commands.

> **Note**
>
> Automation only supports *output* of one AWS Systems Manager Run Command action. A runbook can include multiple Run Command actions, but output is supported for only one action at a time.

Input

This action supports most send command parameters. For more information, see SendCommand.

YAML

```
- name: checkMembership
  action: 'aws:runCommand'
  inputs:
    DocumentName: AWS-RunPowerShellScript
    InstanceIds:
      - '{{InstanceIds}}'
    Parameters:
      commands:
```

```
        - (Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain
```

JSON

```
{
    "name": "checkMembership",
    "action": "aws:runCommand",
    "inputs": {
        "DocumentName": "AWS-RunPowerShellScript",
        "InstanceIds": [
            "{{InstanceIds}}"
        ],
        "Parameters": {
            "commands": [
                "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
            ]
        }
    }
}
```

DocumentName

If the Command type document is owned by you or AWS, specify the name of the document. If you're using a document shared with you by a different AWS account, specify the Amazon Resource Name (ARN) of the document. For more information about using shared documents, see Using shared SSM documents.

Type: String

Required: Yes

InstanceIds

The instance IDs where you want the command to run. You can specify a maximum of 50 IDs.

You can also use the pseudo parameter `{{RESOURCE_ID}}` in place of instance IDs to run the command on all instances in the target group. For more information about pseudo parameters, see Using pseudo parameters when registering maintenance window tasks.

Another alternative is to send commands to a fleet of instances by using the `Targets` parameter. The `Targets` parameter accepts Amazon Elastic Compute Cloud (Amazon EC2) tags. For more information about how to use the `Targets` parameter, see Run commands at scale.

Type: StringList

Required: No (If you don't specify InstanceIds or use the `{{RESOURCE_ID}}` pseudo parameter, then you must specify the `Targets` parameter.)

Targets

An array of search criteria that targets instances by using a Key,Value combination that you specify. `Targets` is required if you don't provide one or more instance IDs in the call. For more information about how to use the `Targets` parameter, see Run commands at scale.

Type: MapList (The schema of the map in the list must match the object.) For information, see Target in the *AWS Systems Manager API Reference*.

Required: No (If you don't specify `Targets`, then you must specify InstanceIds or use the `{{RESOURCE_ID}}` pseudo parameter.)

Following is an example.

YAML

```
- name: checkMembership
  action: aws:runCommand
  inputs:
    DocumentName: AWS-RunPowerShellScript
    Targets:
      - Key: tag:Stage
        Values:
          - Gamma
          - Beta
      - Key: tag-key
        Values:
          - Suite
    Parameters:
      commands:
        - (Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain
```

JSON

```
{
    "name": "checkMembership",
    "action": "aws:runCommand",
    "inputs": {
```

```
        "DocumentName": "AWS-RunPowerShellScript",
        "Targets": [
            {
                "Key": "tag:Stage",
                "Values": [
                    "Gamma", "Beta"
                ]
            },
            {
                "Key": "tag:Application",
                "Values": [
                    "Suite"
                ]
            }
        ],
        "Parameters": {
            "commands": [
                "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
            ]
        }
    }
}
```

Parameters

The required and optional parameters specified in the document.

Type: Map

Required: No

CloudWatchOutputConfig

Configuration options for sending command output to Amazon CloudWatch Logs. For more information about sending command output to CloudWatch Logs, see Configuring Amazon CloudWatch Logs for Run Command.

Type: StringMap (The schema of the map must match the object. For more information, see CloudWatchOutputConfig in the *AWS Systems Manager API Reference*).

Required: No

Following is an example.

YAML

```
- name: checkMembership
  action: aws:runCommand
  inputs:
    DocumentName: AWS-RunPowerShellScript
    InstanceIds:
      - "{{InstanceIds}}"
    Parameters:
      commands:
        - "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
    CloudWatchOutputConfig:
      CloudWatchLogGroupName: CloudWatchGroupForSSMAutomationService
      CloudWatchOutputEnabled: true
```

JSON

```
{
    "name": "checkMembership",
    "action": "aws:runCommand",
    "inputs": {
        "DocumentName": "AWS-RunPowerShellScript",
        "InstanceIds": [
            "{{InstanceIds}}"
        ],
        "Parameters": {
            "commands": [
                "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
            ]
        },
        "CloudWatchOutputConfig" : {
                "CloudWatchLogGroupName":
 "CloudWatchGroupForSSMAutomationService",
                "CloudWatchOutputEnabled": true
        }
    }
}
```

Comment

User-defined information about the command.

Type: String

Required: No

DocumentHash

The hash for the document.

Type: String

Required: No

DocumentHashType

The type of the hash.

Type: String

Valid values: Sha256 | Sha1

Required: No

NotificationConfig

The configurations for sending notifications.

Required: No

OutputS3BucketName

The name of the S3 bucket for command output responses. Your managed node must have permissions for the S3 bucket to successfully log output.

Type: String

Required: No

OutputS3KeyPrefix

The prefix.

Type: String

Required: No

ServiceRoleArn

The ARN of the AWS Identity and Access Management (IAM) role.

Type: String

Required: No

TimeoutSeconds

The amount of time in seconds to wait for a command to deliver to the AWS Systems Manager SSM Agent on an instance. If the command isn't received by the SSM Agent on the instance before the value specified is reached, then the status of the command changes to `Delivery Timed Out`.

Type: Integer

Required: No

Valid values: 30-2592000

Output

CommandId

The ID of the command.

Status

The status of the command.

ResponseCode

The response code of the command. If the document you run has more than 1 step, a value isn't returned for this output.

Output

The output of the command. If you target a tag or multiple instances with your command, no output value is returned. You can use the `GetCommandInvocation` and `ListCommandInvocations` API operations to retrieve output for individual instances.

`aws:runInstances` – Launch an Amazon EC2 instance

Launches a new Amazon Elastic Compute Cloud (Amazon EC2) instance.

> **Note**
>
> The `aws:runInstances` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

The action supports most API parameters. For more information, see the RunInstances API documentation.

YAML

```
name: launchInstance
action: aws:runInstances
maxAttempts: 3
timeoutSeconds: 1200
onFailure: Abort
inputs:
  ImageId: ami-12345678
  InstanceType: t2.micro
  MinInstanceCount: 1
  MaxInstanceCount: 1
  IamInstanceProfileName: myRunCmdRole
  TagSpecifications:
  - ResourceType: instance
    Tags:
    - Key: LaunchedBy
      Value: SSMAutomation
    - Key: Category
      Value: HighAvailabilityFleetHost
```

JSON

```
{
   "name":"launchInstance",
   "action":"aws:runInstances",
   "maxAttempts":3,
   "timeoutSeconds":1200,
   "onFailure":"Abort",
   "inputs":{
      "ImageId":"ami-12345678",
      "InstanceType":"t2.micro",
      "MinInstanceCount":1,
      "MaxInstanceCount":1,
      "IamInstanceProfileName":"myRunCmdRole",
      "TagSpecifications":[
         {
            "ResourceType":"instance",
```

```
            "Tags":[
               {
                  "Key":"LaunchedBy",
                  "Value":"SSMAutomation"
               },
               {
                  "Key":"Category",
                  "Value":"HighAvailabilityFleetHost"
               }
            ]
         }
      ]
   }
}
```

AdditionalInfo

Reserved.

Type: String

Required: No

BlockDeviceMappings

The block devices for the instance.

Type: MapList

Required: No

ClientToken

The identifier to ensure idempotency of the request.

Type: String

Required: No

DisableApiTermination

Turns on or turns off instance API termination.

Type: Boolean

Required: No

EbsOptimized

Turns on or turns off Amazon Elastic Block Store (Amazon EBS) optimization.

Type: Boolean

Required: No

IamInstanceProfileArn

The Amazon Resource Name (ARN) of the AWS Identity and Access Management (IAM) instance profile for the instance.

Type: String

Required: No

IamInstanceProfileName

The name of the IAM instance profile for the instance.

Type: String

Required: No

ImageId

The ID of the Amazon Machine Image (AMI).

Type: String

Required: Yes

InstanceInitiatedShutdownBehavior

Indicates whether the instance stops or terminates on system shutdown.

Type: String

Required: No

InstanceType

The instance type.

> **Note**
>
> If an instance type value isn't provided, the m1.small instance type is used.

Type: String

Required: No

KernelId

The ID of the kernel.

Type: String

Required: No

KeyName

The name of the key pair.

Type: String

Required: No

MaxInstanceCount

The maximum number of instances to be launched.

Type: String

Required: No

MetadataOptions

The metadata options for the instance. For more information, see InstanceMetadataOptionsRequest.

Type: StringMap

Required: No

MinInstanceCount

The minimum number of instances to be launched.

Type: String

Required: No

Monitoring

Turns on or turns off detailed monitoring.

Type: Boolean

Required: No

NetworkInterfaces

The network interfaces.

Type: MapList

Required: No

Placement

The placement for the instance.

Type: StringMap

Required: No

PrivateIpAddress

The primary IPv4 address.

Type: String

Required: No

RamdiskId

The ID of the RAM disk.

Type: String

Required: No

SecurityGroupIds

The IDs of the security groups for the instance.

Type: StringList

Required: No

SecurityGroups

The names of the security groups for the instance.

Type: StringList

Required: No

SubnetId

The subnet ID.

Type: String

Required: No

TagSpecifications

The tags to apply to the resources during launch. You can only tag instances and volumes at launch. The specified tags are applied to all instances or volumes that are created during launch. To tag an instance after it has been launched, use the `aws:createTags` – Create tags for AWS resources action.

Type: MapList (For more information, see TagSpecification.)

Required: No

UserData

A script provided as a string literal value. If a literal value is entered, then it must be Base64-encoded.

Type: String

Required: No

Output

InstanceIds

The IDs of the instances.

InstanceStates

The current state of the instance.

`aws:sleep` – Delay an automation

Delays an automation for a specified amount of time. This action uses the International Organization for Standardization (ISO) 8601 date and time format. For more information about this date and time format, see ISO 8601.

Input

You can delay an automation for a specified duration.

YAML

```
name: sleep
action: aws:sleep
inputs:
  Duration: PT10M
```

JSON

```
{
   "name":"sleep",
   "action":"aws:sleep",
   "inputs":{
      "Duration":"PT10M"
   }
}
```

You can also delay an automation until a specified date and time. If the specified date and time has passed, the action proceeds immediately.

YAML

```
name: sleep
action: aws:sleep
inputs:
  Timestamp: '2020-01-01T01:00:00Z'
```

JSON

```
{
    "name": "sleep",
    "action": "aws:sleep",
    "inputs": {
        "Timestamp": "2020-01-01T01:00:00Z"
    }
}
```

> **Note**
>
> Automation supports a maximum delay of 604799 seconds (7 days).

Duration

An ISO 8601 duration. You can't specify a negative duration.

Type: String

Required: No

Timestamp

An ISO 8601 timestamp. If you don't specify a value for this parameter, then you must specify a value for the `Duration` parameter.

Type: String

Required: No

Output

None

`aws:updateVariable` – Updates a value for a runbook variable

This action updates a value for a runbook variable. The data type of the value must match the data type of the variable you want to update. Data type conversions aren't supported. The on`Cancel` property isn't supported for the `aws:updateVariable` action.

Input

The input is as follows.

YAML

```
name: updateStringList
action: aws:updateVariable
```

```
inputs:
    Name: variable:variable name
    Value:
    - "1"
    - "2"
```

JSON

```
{
    "name": "updateStringList",
    "action": "aws:updateVariable",
    "inputs": {
        "Name": "variable:variable name",
        "Value": ["1","2"]
    }
}
```

Name

The name of the variable whose value you want to update. You must use the format `variable:variable name`

Type: String

Required: Yes

Value

The new value to assign to the variable. The value must match the data type of the variable. Data type conversions aren't supported.

Type: Boolean | Integer | MapList | String | StringList | StringMap

Required: Yes

Constraints:

- MapList can contain a maximum number of 200 items.
- Key lengths can be a minimum length of 1 and a maximum length of 50.
- StringList can be a minimum number of 0 items and a maximum number of 50 items.
- String lengths can be a minimum length of 1 and a maximum length of 512.

Output

None

`aws:waitForAwsResourceProperty` – Wait on an AWS resource property

The `aws:waitForAwsResourceProperty` action allows your automation to wait for a specific resource state or event state before continuing the automation. For more examples of how to use this action, see Additional runbook examples.

> **Note**
>
> The default timeout value for this action is 3600 seconds (one hour). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:waitForAwsResourceProperty` step. For more information and examples of how to use this action, see Handling timeouts in runbooks.

> **Note**
>
> The `aws:waitForAwsResourceProperty` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

Inputs are defined by the API operation that you choose.

YAML

```
action: aws:waitForAwsResourceProperty
inputs:
  Service: The official namespace of the service
  Api: The API operation or method name
  API operation inputs or parameters: A value
  PropertySelector: Response object
  DesiredValues:
  - Desired property value
```

JSON

```
{
  "action": "aws:waitForAwsResourceProperty",
  "inputs": {
    "Service":"The official namespace of the service",
    "Api":"The API operation or method name",
    "API operation inputs or parameters":"A value",
    "PropertySelector": "Response object",
    "DesiredValues": [
      "Desired property value"
    ]
  }
}
```

Service

The AWS service namespace that contains the API operation that you want to run. For example, the namespace for AWS Systems Manager is `ssm`. The namespace for Amazon Elastic Compute Cloud (Amazon EC2) is `ec2`. You can view a list of supported AWS service namespaces in the Available Services section of the *AWS CLI Command Reference*.

Type: String

Required: Yes

Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: Amazon RDS methods.

Type: String

Required: Yes

API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following Services Reference page. Choose

a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**.

YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

JSON

```
"inputs":{
      "Service":"The official namespace of the service",
      "Api":"The API operation name",
      "API input 1":"A value",
      "API Input 2":"A value",
      "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

PropertySelector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: String

Required: Yes

DesiredValues

The expected status or state on which to continue the automation.

Type: MapList, StringList

Required: Yes

Automation system variables

AWS Systems Manager Automation runbooks use the following variables. For an example of how these variables are used, view the JSON source of the `AWS-UpdateWindowsAmi` runbook.

To view the JSON source of the `AWS-UpdateWindowsAmi` runbook

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the document list, use either the Search bar or the numbers to the right of the Search bar to choose the runbook **`AWS-UpdateWindowsAmi`**.
4. Choose the **Content** tab.

System variables

Automation runbooks support the following system variables.

Variable	Details
`global:ACCOUNT_ID`	The AWS account ID of the user or role in which Automation runs.
`global:DATE`	The date (at run time) in the format yyyy-MM-dd.
`global:DATE_TIME`	The date and time (at run time) in the format yyyy-MM-dd_HH.mm.ss.
`global:AWS_PARTITION`	The partition that the resource is in. For standard AWS Regions, the partition is `aws`. For resources in other partitions, the partition is `aws-`*`partitionname`* . For example, the

Variable	Details
	partition for resources in the AWS GovCloud (US-West) Region is `aws-us-gov` .
`global:REGION`	The Region that the runbook is run in. For example, us-east-2.

Automation variables

Automation runbooks support the following automation variables.

Variable	Details
`automation:EXECUTION_ID`	The unique identifier assigned to the current automation. For example, `1a2b3c-1a2b3c-1a2b3c-1a2b3c1a2b3c1a2b3c` .

Topics

- Terminology
- Supported scenarios
- Unsupported scenarios

Terminology

The following terms describe how variables and parameters are resolved.

Term	Definition	Example
Constant ARN	A valid Amazon Resource Name (ARN) without variables .	`arn:aws:iam::123456789012:role/roleName`
Runbook parameter	A parameter defined at the runbook level (for example, `instanceId`).	`{ "description": "Create Image Demo",`

Term	Definition	Example
	The parameter is used in a basic string replace. Its value is supplied at Start Execution time.	"version": "0.3", "assumeRole": "*Your_Automation_Assume_Role_ARN* ", "parameters":{ **"instanceId": { "type": "String", "description": "Instance to create image from"** } }

Term	Definition	Example
System variable	A general variable substituted into the runbook when any part of the runbook is evaluated.	`"activities": [{ "id": "copyImage", "activityType": "AWS-CopyImage", "maxAttempts": 1, "onFailure": "Continue", "inputs": { "ImageName": "{{imageName}}", "SourceImageId": "{{sourceImageId}}", "SourceRegion": "{{sourceRegion}}", "Encrypted": true, "ImageDescription": "Test CopyImage Description created on **{{global:DATE}}** " } }]`

Term	Definition	Example

Automation variable	A variable relating to the automation substituted into the runbook when any part of the runbook is evaluated.	{
		"name": "runFixedCmds",
		"action": "aws:runCommand",
		"maxAttempts": 1,
		"onFailure": "Continue",
		"inputs": {
		"DocumentName": "AWS-RunPowerShellScript",
		"InstanceIds": [
		"{{LaunchInstance.InstanceIds}}"
		],
		"Parameters": {
		"commands": [
		"dir",
		"date",
		"“{{outputFormat}}” -f “left”,”right”,”{{global:DATE}}”,” **{{automation:EXECUTION_ID}}** ”
		]
		}
		}
		}

Term	Definition	Example

Systems Manager Parameter	A variable defined within AWS Systems Manager Parameter Store. It can't be directly referenced in step input. Permissions might be required to access the parameter.	description: Launch new Windows test instance
		schemaVersion: '0.3'
		assumeRole: '{{AutomationAssumeRole}}'
		parameters:
		  AutomationAssumeRole:
		    type: String
		    default: ''
		    description: >-
		      (Required) The ARN of the role that allows Automation to perform the
		      actions on your behalf. If no role is specified, Systems Manager
		      Automation uses your IAM permissions to run this runbook.
		  LatestAmi:
		    type: String
		    default: >-
		      {{ssm:/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-Base}}
		    description: The latest Windows Server 2016 AMI queried from the public parameter.
		mainSteps:
		  - name: launchInstance
		    action: 'aws:runInstances'
		    maxAttempts: 3

Term	Definition	Example
		timeoutSeconds: 1200 onFailure: Abort inputs: ImageId: '{{LatestAmi}}' ...

Supported scenarios

Scenario	Comments	Example
Constant ARN `assumeRole` at creation.	An authorization check is performed to verify that the calling user is permitted to pass the given `assumeRole` .	{ "description": "Test all Automation resolvable parameters", "schemaVersion": "0.3", "assumeRole": ***"arn:aws:iam::123456789012:role/roleName"*** , "parameters": { ...
Runbook parameter supplied for `AssumeRole` when the automation is started.	Must be defined in the parameter list of the runbook.	{ "description": "Test all Automation resolvable parameters", "schemaVersion": "0.3", "assumeRole": **"{{dynamicARN}}"** , "parameters": { ...

Scenario	Comments	Example

Value supplied for runbook parameter at start.	Customer supplies the value to use for a parameter. Any inputs supplied at start time need to be defined in the parameter list of the runbook.	<pre>...
		"parameters": {
		    "amiId": {
		      "type": "String",
		      "default":
		"ami-12345678 ",
		      "description":
		"list of commands to
		run as part of first
		step"
		    },
		...</pre>
		Inputs to Start Automation Execution include : {"amiId" : ["ami-12345678 "] }

Scenario	Comments	Example

Systems Manager Parameter referenced within runbook content.	The variable exists within the customer's account, or is a publicly accessibly parameter , and the `AssumeRole` for the runbook has access to the variable. A check is performed at create time to confirm the `AssumeRole` has access. The parameter can't be directly referenced in step input.	```
		...
		parameters:
		    LatestAmi:
		    type: String
		    default: >-
		      {{ssm:/aws/
		service/ami-wind
		ows-latest/Windows
		_Server-2016-English-
		Full-Base}}
		    description: The
		 latest Windows Server
		 2016 AMI queried from
		 the public parameter.
		mainSteps:
		  - name: launchIns
		tance
		    action: 'aws:runI
		nstances'
		    maxAttempts: 3
		    timeoutSeconds:
		 1200
		    onFailure: Abort
		    inputs:
		      ImageId: '{{Latest
		Ami}}'
		...
		``

Scenario	Comments	Example
System variable referenced within step definition	A system variable is substituted into the runbook when the automation is started. The value injected into the runbook is relative to when the substitution occurs. That is, the value of a time variable injected at step 1 is different from the value injected at step 3 because of the time it takes to run the steps between. System variables don't need to be set in the parameter list of the runbook.	... "mainSteps": [{ "name": "RunSomeCommands", "action": "aws:runCommand", "maxAttempts": 1, "onFailure": "Continue", "inputs": { "DocumentName": "AWS:RunPowerShell", "InstanceIds": ["{{LaunchInstance.InstanceIds}}"], "Parameters": { "commands" : ["echo {The time is now {{global:DATE_TIME}}}"] } } }, ...

Scenario	Comments	Example
Automation variable referenced within step definition.	Automation variables don't need to be set in the parameter list of the runbook. The only supported Automation variable is **automation:EXECUTION_ID**.	... "mainSteps": [{ "name": "invokeLambdaFunction", "action": "aws:invokeLambdaFunction", "maxAttempts": 1, "onFailure": "Continue", "inputs": { "FunctionName": "Hello-World-LambdaFunction", "Payload" : "{ "executionId" : "{{automation:EXECUTION_ID}}" }" } } ...

Scenario	Comments	Example

Refer to output from previous step within next step definitio n.	This is parameter redirection. The output of a previous step is referenced using the syntax `{{stepName.OutputN ame}}` . This syntax can't be used by the customer for runbook parameters. This is resolved when the referring step runs. The parameter isn't listed in the parameters of the runbook.	```
		...
		"mainSteps": [
		    {
		      "name": "LaunchIn
		stance",
		      "action":
		 "aws:runInstances",
		      "maxAttempts": 1,
		      "onFailure":
		 "Continue",
		      "inputs": {
		        "ImageId":
		 "{{amiId}}",
		        "MinInsta
		nceCount": 1,
		        "MaxInsta
		nceCount": 2
		      }
		    },
		    {
		      "name":"c
		hangeState",
		      "action":
		 "aws:changeInstanc
		eState",
		      "maxAttempts": 1,
		      "onFailure":
		 "Continue",
		      "inputs": {
		        "InstanceIds":
		 ["{{LaunchInstance
		.InstanceIds}}"],
		        "DesiredState":
		 "terminated"
		      }
		    }
		
		...
		``

Unsupported scenarios

Scenario	Comment	Example

Systems Manager Parameter supplied for `assumeRole` at create	Not supported.	`...`
		
		`{`
		`  "description":`
		` "Test all Automation`
		` resolvable parameter`
		`s",`
		`  "schemaVersion":`
		` "0.3",`
		`  "assumeRole":`
		` "{{ssm:administrato`
		`rRoleARN}}  ",`
		`  "parameters": {`
		
		`...`

Systems Manager Parameter directly referenced in step input.	Returns `InvalidDocumentContent` exception at create time.	`...`
		`mainSteps:`
		`  - name: launchIns`
		`tance`
		`    action: 'aws:runI`
		`nstances'`
		`    maxAttempts: 3`
		`    timeoutSeconds:`
		` 1200`
		`    onFailure: Abort`
		`    inputs:`
		`      ImageId: '{{ssm:/`
		`aws/service/ami-win`
		`dows-latest/Window`
		`s_Server-2016-Engl`
		`ish-Full-Base}}'`
		`...`

Scenario	Comment	Example
Variable step definition	The definition of a step in the runbook is constructed by variables.	... "mainSteps": [{ "name": "LaunchInstance", "action": "aws:runInstances", "**{{attemptModel}}** ": 1, "onFailure": "Continue", "inputs": { "ImageId": "*ami-12345678* ", "MinInstanceCount": 1, "MaxInstanceCount": 2 } ... User supplies input : { "attemptModel" : "**minAttempts** " }

Scenario	Comment	Example
Cross referencing runbook parameters	The user supplies an input parameter at start time, which is a reference to another parameter in the runbook.	... "parameters": { "amiId": { "type": "String", "default": "ami-7f2e6015 ", "description": "list of commands to run as part of first step" }, "alternateAmiId": { "type": "String", "description": "The alternate AMI to try if this first fails". "default" : "{{amiId} }" }, ...

Scenario	Comment	Example
Multi-level expansion	The runbook defines a variable that evaluates to the name of a variable. This sits within the variable delimiters (that is *{{ }}*) and is expanded to the value of that variable/parameter.	... "parameters": { "*firstParameter* ": { "type": "String", "default": "param2", "description": "The parameter to reference" }, "*secondParameter* ": { "type": "String", "default" : "echo {Hello world}", "description": "What to run" } }, "mainSteps": [{ "name": "runFixedCmds", "action": "aws:runCommand", "maxAttempts": 1, "onFailure": "Continue", "inputs": { "DocumentName": "AWS-RunPowerShellScript", "InstanceIds" : "{{LaunchInstance.InstanceIds}}", "Parameters": { "commands": ["{{ ***{{firstParameter}}*** }}"] }

Scenario	Comment	Example
		... Note: The customer intention here would be to run a command of "echo {Hello world}"

Scenario	Comment	Example
Referencing output from a runbook step that is a different variable type	The user references the output from a preceding runbook step within a subsequent step. The output is a variable type that doesn't meet the requirements of the action in the subsequent step.	... mainSteps: - name: getImageId action: aws:executeAwsApi inputs: Service: ec2 Api: DescribeImages Filters: - Name: "name" Values: - "{{ImageName}}" outputs: - Name: ImageIdList Selector: "$.Images" Type: "StringList" - name: copyMyImages action: aws:copyImage maxAttempts: 3 onFailure: Abort inputs: SourceImageId: {{getImageId.ImageIdList}} SourceRegion: ap-northeast-2 ImageName: Encrypted Copies of LAMP base AMI in ap-northeast-2 Encrypted: true ... Note: You must provide the type required by the Automation action. In this case, aws:copyImage requires a "String" type variable but the preceding step

Scenario	Comment	Example
		`outputs a "StringList" type variable.`

Creating your own runbooks

An Automation runbook defines the *actions* that Systems Manager performs on your managed instances and other AWS resources when an automation runs. Automation is a tool in AWS Systems Manager. A runbook contains one or more steps that run in sequential order. Each step is built around a single action. Output from one step can be used as input in a later step.

The process of running these actions and their steps is called the *automation*.

Action types supported for runbooks let you automate a wide variety of operations in your AWS environment. For example, using the `executeScript` action type, you can embed a python or PowerShell script directly in your runbook. (When you create a custom runbook, you can add your script inline, or attach it from an S3 bucket or from your local machine.) You can automate management of your AWS CloudFormation resources by using the `createStack` and `deleteStack` action types. In addition, using the `executeAwsApi` action type, a step can run *any* API operation in any AWS service, including creating or deleting AWS resources, starting other processes, initiating notifications, and many more.

For a list of all 20 supported action types for Automation, see Systems Manager Automation actions reference.

AWS Systems Manager Automation provides several runbooks with pre-defined steps that you can use to perform common tasks like restarting one or more Amazon Elastic Compute Cloud (Amazon EC2) instances or creating an Amazon Machine Image (AMI). You can also create your own runbooks and share them with other AWS accounts, or make them public for all Automation users.

Runbooks are written using YAML or JSON. Using the **Document Builder** in the Systems Manager Automation console, however, you can create a runbook without having to author in native JSON or YAML.

Important

If you run an automation workflow that invokes other services by using an AWS Identity and Access Management (IAM) service role, be aware that the service role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (`AWS-*` runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom Automation runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:createStack`, or `aws:copyImage` actions, configure the service role with permission to invoke those services. You can give permissions to other AWS services by adding an IAM inline policy to the role. For more information, see (Optional) Add an Automation inline policy or customer managed policy to invoke other AWS services.

For information about the actions that you can specify in a runbook, see Systems Manager Automation actions reference.

For information about using the AWS Toolkit for Visual Studio Code to create runbooks, see Working with Systems Manager Automation documents in the *AWS Toolkit for Visual Studio Code User Guide*.

For information about using the visual designer to create a custom runbook, see Visual design experience for Automation runbooks.

Contents

Visual design experience for Automation runbooks

AWS Systems Manager Automation provides a low-code visual design experience that helps you create automation runbooks. The visual design experience provides a drag-and-drop interface with the option to add your own code so you can create and edit runbooks more easily. With the visual design experience, you can do the following:

- Control conditional statements.

- Control how input and output is filtered or transformed for each action.
- Configure error handling.
- Prototype new runbooks.
- Use your prototype runbooks as the starting point for local development with the AWS Toolkit for Visual Studio Code.

When you create or edit a runbook, you can access the visual design experience from the Automation console. As you create a runbook, the visual design experience validates your work and auto-generates code. You can review the generated code, or export it for local development. When you're finished, you can save your runbook, run it, and examine the results in the Systems Manager Automation console.

Before you begin

To use the visual design experience, you need an AWS account, and credentials that provide the correct permissions for any resources that you want to use.

In the visual design experience, Automation integrates with Amazon CodeGuru Security to help you detect security policy violations and vulnerabilities in your Python scripts. To use this feature for `aws:executeScript` actions, your AWS Identity and Access Management (IAM) policy must include the following permissions:

JSON

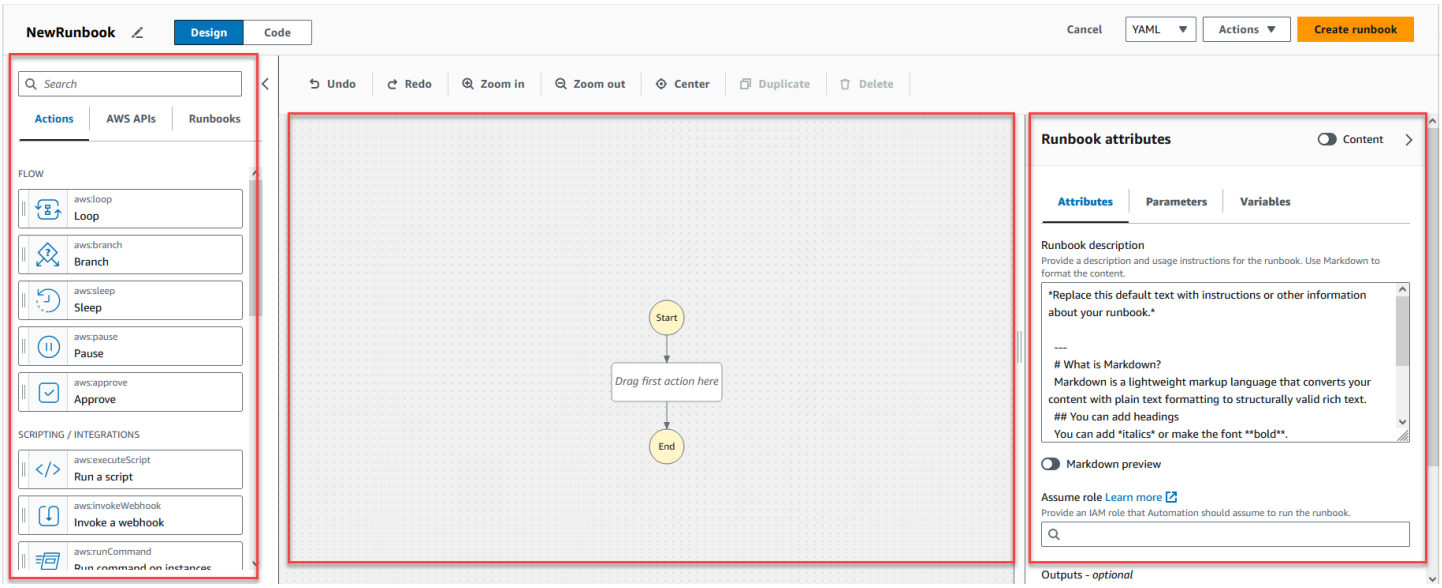
```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "codeguru-security:CreateUploadUrl",
                "codeguru-security:CreateScan",
                "codeguru-security:GetScan",
                "codeguru-security:GetFindings"
            ],
            "Resource": "*"
        }
    ]
}
```

Topics

Overview of the visual design experience interface

The visual design experience for Systems Manager Automation is a low-code visual workflow designer that helps you create automation runbooks.

Get to know the visual design experience with an overview of the interface components:



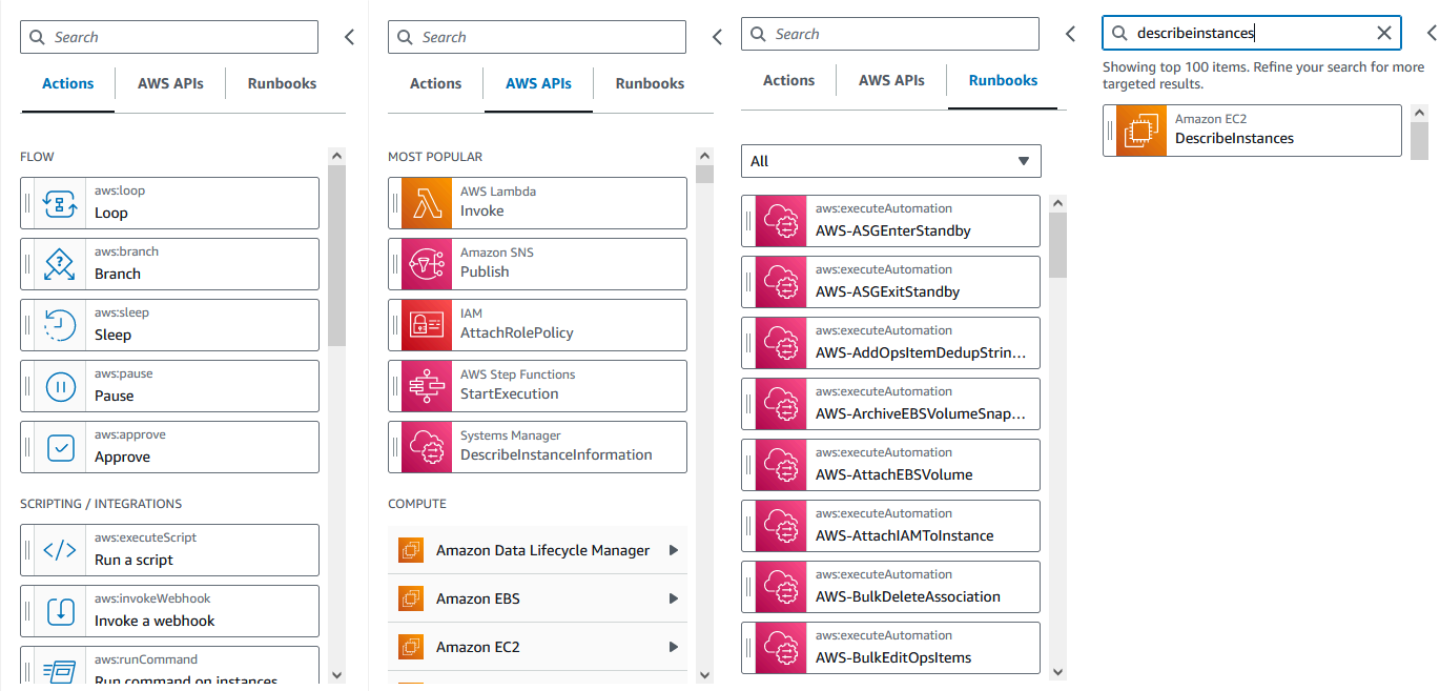
- The **Actions** browser contains the **Actions**, **AWS APIs**, and **Runbooks** tabs.
- The *canvas* is where you drag and drop actions into your workflow graph, change the order of actions, and select actions to configure or view.
- The **Form** panel is where you can view and edit the properties of any action that you selected on the canvas. Select the **Content** toggle to view the YAML or JSON for your runbook, with the currently selected action highlighted.

Info links open a panel with contextual information when you need help. These panels also include links to related topics in the Systems Manager Automation documentation.

Actions browser

From the **Actions** browser, you can select actions to drag and drop into your workflow graph. You can search all actions using the search field at the top of the **Actions** browser. The **Actions** browser contains the following tabs:

- The **Actions** tab provides a list of automation actions that you can drag and drop into your runbook's workflow graph in the canvas.
- The **AWS APIs** tab provides a list of AWS APIs that you can drag and drop into your runbook's workflow graph in the canvas.
- The **Runbooks** tab provides several ready-to-use, reusable runbooks as building blocks that you can use for a variety of use cases. For example, you can use runbooks to perform common remediation tasks on Amazon EC2 instances in your workflow without having to re-create the same actions.

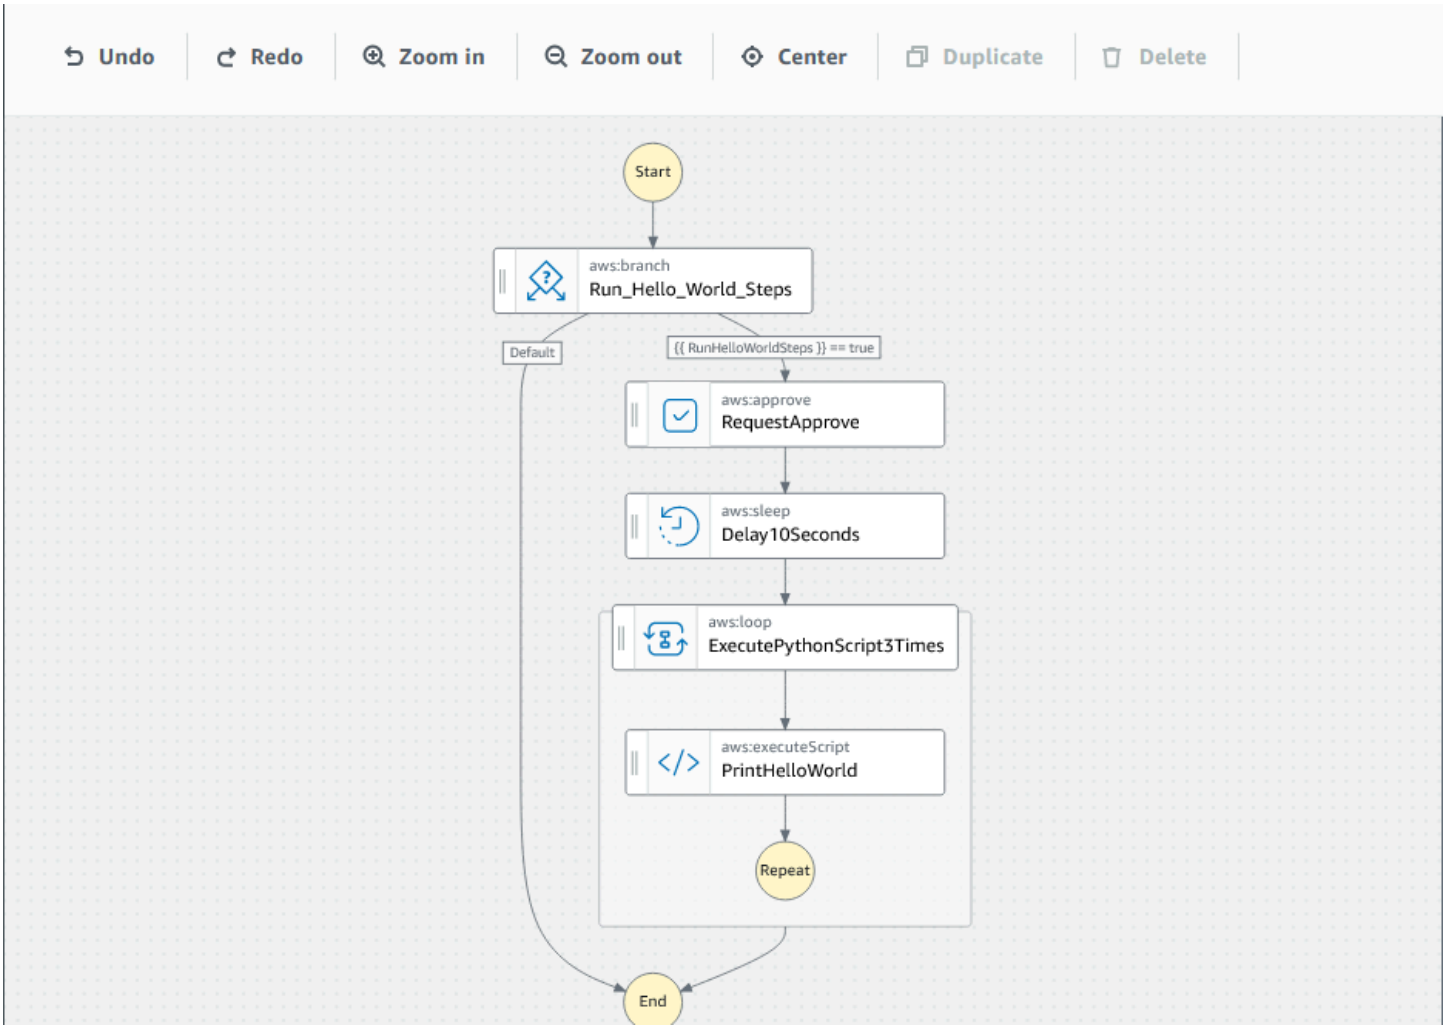


Canvas

After you choose an action to add to your automation, drag it to the canvas and drop it into your workflow graph. You can also drag and drop actions to move them to different places in your runbook's workflow. If your workflow is complex, you might not be able to view all of it in the

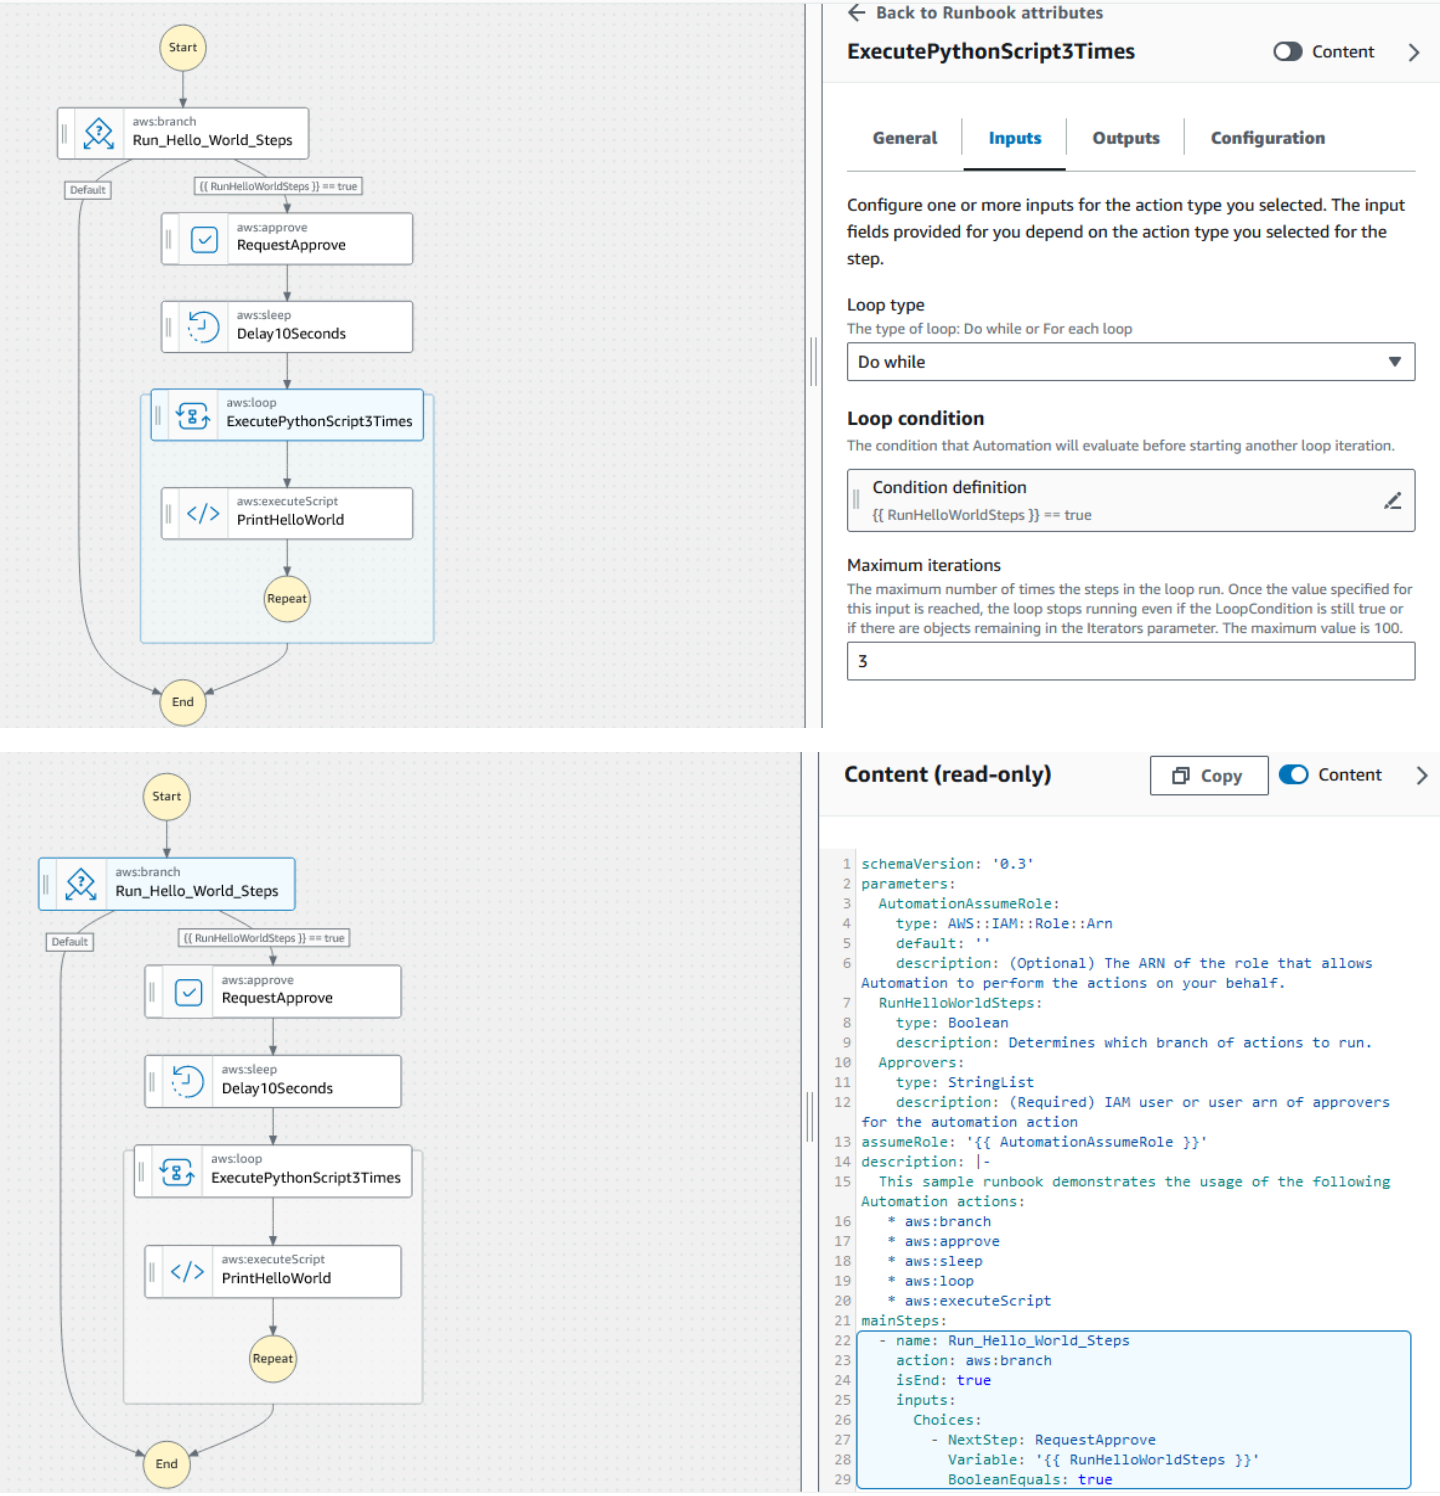
canvas panel. Use the controls at the top of the canvas to zoom in or out. To view different parts of a workflow, you can drag the workflow graph in the canvas.

Drag an action from the **Actions** browser, and drop it into your runbook's workflow graph. A line shows where it will be placed in your workflow. To change the order of an action, you can drag it to a different place in your workflow. The new action has been added to your workflow, and its code is auto-generated.



Form

After you add an action to your runbook workflow, you can configure it to meet your use case. Choose the action that you want to configure, and you will see its parameters and options in the **Form** panel. You can also see the YAML or JSON code by choosing the **Content** toggle. The code associated with the action you have selected is highlighted.



Keyboard shortcuts

The visual design experience supports the keyboard shortcuts shown in the following table.

Keyboard shortcut	
Ctrl+Z	Undo the last operation.
Ctrl+Shift+Z	Redo the last operation.
Ctrl+C	Center the workflow in the canvas.
Backspace	Remove all selected states.
Delete	Remove all selected states.
Ctrl+D	Duplicate the selected state.

Using the visual design experience

Learn to create, edit and run runbook workflows using the visual design experience. After your workflow is ready, you can save it or export it. You can also use the visual design experience for rapid prototyping.

Create a runbook workflow

1. Sign in to the Systems Manager Automation console.
2. Choose **Create runbook**.
3. In the **Name** box, enter a name for your runbook, for example, *MyNewRunbook*.
4. Next to the **Design** and **Code** toggle, select the pencil icon and enter a name for your runbook.

You can now design a workflow for your new runbook.

Design a runbook

To design a runbook workflow using the visual design experience, you drag an automation action from the **Actions** browser into the canvas, placing it where you want it in your runbook's workflow. You can also re-order actions in your workflow by dragging them to a different location. As you drag an action onto the canvas, a line appears wherever you can drop the action in your workflow. After an action is dropped onto the canvas, its code is auto-generated and added inside your runbook's content.

If you know the name of the action you want to add, use the search box at the top of the **Actions** browser to find the action.

After you drop an action onto the canvas, configure it using the **Form** panel on the right. This panel contains the **General**, **Inputs**, **Outputs**, and **Configuration** tabs for each automation action or API action that you place on the canvas. For example, the **General** tab consists of the following sections:

- The **Step name** identifies the step. Specify a unique value for the step name.
- The **Description** helps you describe what the action is doing in your runbook's workflow.

The **Inputs** tab contains fields that vary based on the action. For example, the `aws:executeScript` automation action consists of the following sections:

- The **Runtime** is the language to use for running the provided script.
- The **Handler** is the name of your function. You must ensure that the function defined in the handler has two parameters: `events` and `context`. The PowerShell runtime doesn't support this parameter.
- The **Script** is an embedded script that you want to run during the workflow.
- (Optional) The **Attachment** is for standalone scripts or .zip files that can be invoked by the action. This parameter is required for JSON runbooks.

The **Outputs** tab helps you specify the values that you want to output from an action. You can reference output values in later actions of your workflow, or generate output from actions for logging purposes. Not all actions will have an **Outputs** tab because not all actions support outputs. For example, the `aws:pause` action doesn't support outputs. For actions that do support outputs, the **Outputs** tab consists of the following sections:

- The **Name** is the name to be used for the output value. You can reference outputs in later actions of your workflow.
- The **Selector** is a JSONPath expression string beginning with `"$."` that is used to select one or more components within a JSON element.
- The **Type** is the data type for the output value. For example, a `String` or `Integer` data type.

The **Configuration** tab contains properties and options that all automation actions can use. The action consists of the following sections:

- The **Max attempts** property is the number of times an action retries if it fails.
- The **Timeout seconds** property specifies the timeout value for an action.
- The **Is critical** property determines if the action failure stops the entire automation.
- The **Next step** property determines which action the automation goes to next in the runbook.
- The **On failure** property determines which action the automation goes to next in the runbook if the action fails.
- The **On cancel** property determines which action the automation goes to next in the runbook if the action is canceled by a user.

To delete an action, you can use backspace, the toolbar above the canvas, or right-click and choose **Delete action**.

As your workflow grows, it might not fit in the canvas. To help make the workflow fit in the canvas, try one of the following options:

- Use the controls on the side panels to resize or close the panels.
- Use the toolbar at the top of the canvas to zoom the workflow graph in or out.

Update your runbook

You can update an existing runbook workflow by creating a new version of your runbook. Updates to your runbooks can be made by using the visual design experience, or by editing the code directly. To update an existing runbook, use the following procedure:

1. Sign in to the Systems Manager Automation console.
2. Choose the runbook that you want to update.
3. Choose **Create new version**.
4. The visual design experience has two panes: A code pane and a visual workflow pane. Choose **Design** in the visual workflow pane to edit your workflow with the visual design experience. When you're done, choose **Create new version** to save your changes and exit.
5. (Optional) Use the code pane to edit the runbook content in YAML or JSON.

Export your runbook

To export your runbook's workflow YAML or JSON code, and also a graph of your workflow, use the following procedure:

1. Choose your runbook in the **Documents** console.
2. Choose **Create new version**.
3. In the **Actions** dropdown, choose whether you want to export the graph or runbook, and which format you prefer.

Configuring inputs and outputs for your actions

Each automation action responds based on input that it receives. In most cases, you then pass output to the subsequent actions. In the visual design experience, you can configure an action's input and output data in the **Inputs** and **Outputs** tabs of the **Form** panel.

For detailed information about how to define and use output for automation actions, see Using action outputs as inputs.

Provide input data for an action

Each automation action has one or more inputs that you must provide a value for. The value you provide for an action's input is determined by the data type and format that's accepted by the action. For example, the `aws:sleep` actions requires an ISO 8601 formatted string value for the `Duration` input.

Generally, you use actions in your runbook's workflow that return output that you want to use in subsequent actions. It's important to make sure your input values are correct to avoid errors in your runbook's workflow. Input values are also important because they determine whether the action returns the expected output. For example, when using the `aws:executeAwsApi` action, you want to make sure that you're providing the right value for the API operation.

Define output data for an action

Some automation actions return output after performing their defined operations. Actions that return output either have predefined outputs, or allow you to define the outputs yourself. For example, the `aws:createImage` action has predefined outputs that return an `ImageId` and `ImageState`. Comparatively, with the `aws:executeAwsApi` action, you can define the outputs you that want from the specified API operation. As a result, you can return one or more values from a single API operation to use in subsequent actions.

Defining your own outputs for an automation action requires that you specify a name of the output, the data type, and the output value. To continue using the `aws:executeAwsApi` action as an example, let's say you're calling the `DescribeInstances` API operation from Amazon EC2. In this example, you want to return, or output, the `State` of an Amazon EC2 instance and branch your runbook's workflow based on the output. You choose to name the output **`InstanceState`**, and use the **`String`** data type.

The process to define the actual value of the output differs, depending on the action. For example, if you're using the `aws:executeScript` action, you must use `return` statements in your functions to provide data to your outputs. With other actions like `aws:executeAwsApi`, `aws:waitForAwsResourceProperty`, and `aws:assertAwsResourceProperty`, a `Selector` is required. The `Selector`, or `PropertySelector` as some actions refer to it, is a JSONPath string that is used to process the JSON response from an API operation. It's important to understand how the JSON response object from an API operation is structured so you can select the correct

value for your output. Using the `DescribeInstances` API operation mentioned earlier, see the following example JSON response:

```

        }
      }
    }
  }
```

```
}
```

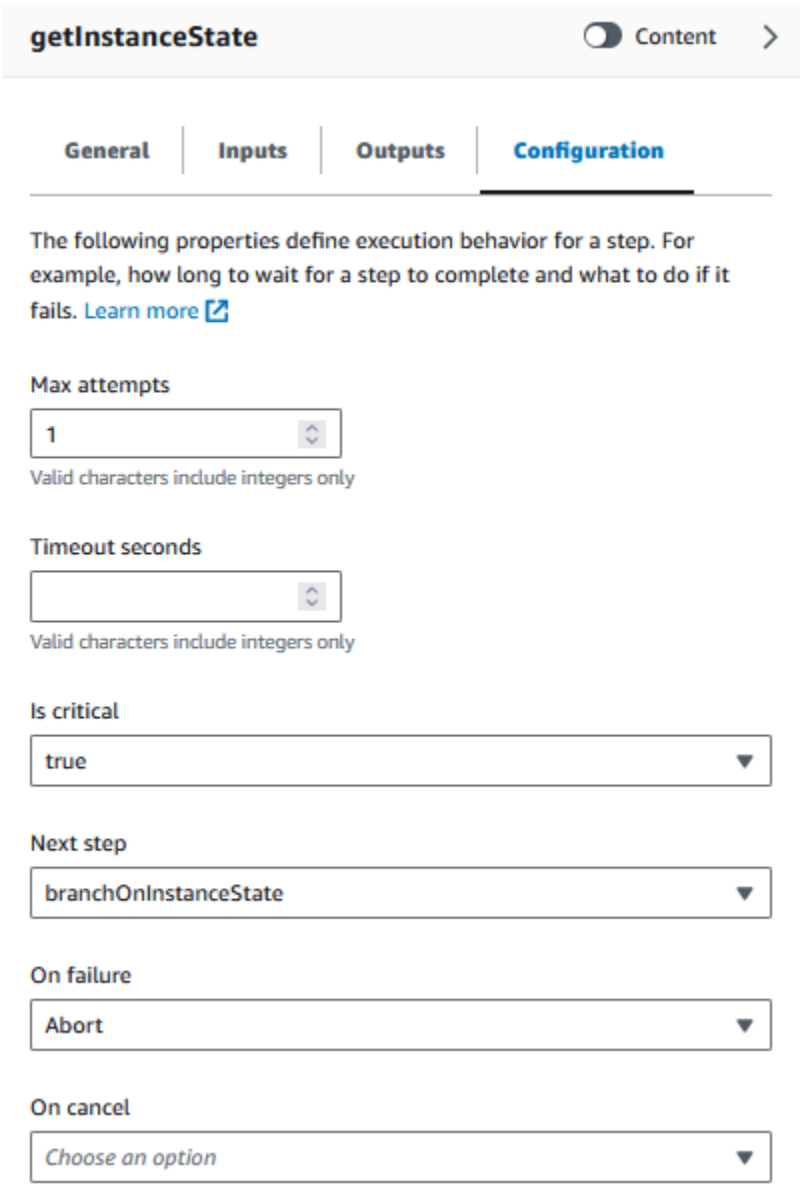
In the JSON response object, the instance `State` is nested in an `Instances` object, which is nested in the `Reservations` object. To return the value of the instance `State`, use the following string for the `Selector` so the value can be used in our output: **`$.Reservations[0].Instances[0].State.Name`**.

To reference an output value in subsequent actions of your runbook's workflow, the following format is used: `{{ StepName.NameOfOutput }}`. For example, **`{{ GetInstanceState.InstanceState }}`**. In the visual design experience, you can choose output values to use in subsequent actions using the dropdown for the input. When using outputs in subsequent actions, the data type of the output must match the data type for the input. In this example, the `InstanceState` output is a `String`. Therefore, to use the value in a subsequent action's input, the input must accept a `String`.

Error handling with the visual design experience

By default, when an action reports an error, Automation stops the runbook's workflow entirely. This is because the default value for the `onFailure` property on all actions is `Abort`. You can configure how Automation handles errors in your runbook's workflow. Even if you have configured error handling, some errors might still cause an automation to fail. For more information, see Troubleshooting Systems Manager Automation. In the visual design experience, you configure error handling in the **Configuration** panel.



Retry action on error

To retry an action in case of an error, specify a value for the **Max attempts** property. The default value is 1. If you specify a value greater than 1, the action isn't considered to have failed until all of the retry attempts have failed.

Timeouts

You can configure a timeout for actions to set the maximum number of seconds your action can run before it fails. To configure a timeout, enter the number of seconds that your action should wait before the action fails in the **Timeout seconds** property. If the timeout is reached and the

action has a value of `Max attempts` that is greater than 1, the step isn't considered to have timed out until the retries complete.

Failed actions

By default, when an action fails, Automation stops the runbook's workflow entirely. You can modify this behavior by specifying an alternative value for the **On failure** property of the actions in your runbook. If you want the workflow to continue to the next step in the runbook, choose **Continue**. If you want the workflow to jump to a different subsequent step in the runbook, choose **Step** and then enter the name of the step.

Canceled actions

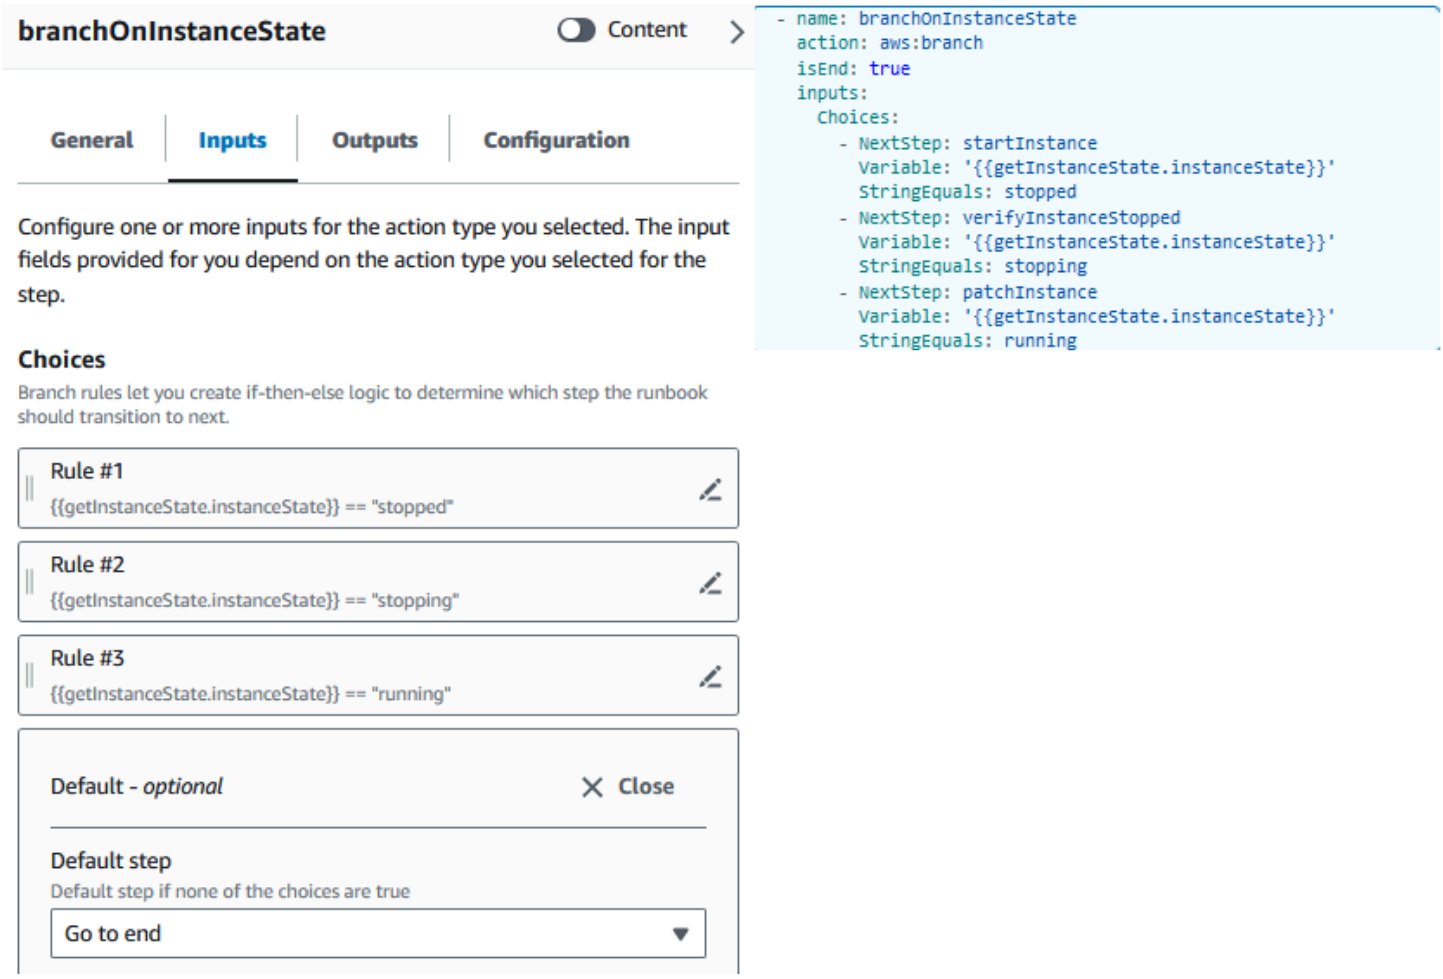
By default, when an action is canceled by a user, Automation stops the runbook's workflow entirely. You can modify this behavior by specifying an alternative value for the **On cancel** property of the actions in your runbook. If you want the workflow to jump to a different subsequent step in the runbook, choose **Step** and then enter the name of the step.

Critical actions

You can designate an action as *critical*, meaning it determines the overall reporting status of your automation. If a step with this designation fails, Automation reports the final status as `Failed` regardless of the success of other actions. To configure an action as critical, leave the default value as **True** for the **Is critical** property.

Ending actions

The **Is end** property stops an automation at the end of the specified action. The default value for this property is `false`. If you configure this property for an action, the automation stops whether the action succeeds or fails. This property is most often used with `aws:branch` actions to handle unexpected or undefined input values. The following example shows a runbook that is expecting an instance state of either `running`, `stopping`, or `stopped`. If an instance is in a different state, the automation ends.



Tutorial: Create a runbook using the visual design experience

In this tutorial, you will learn the basics of working with the visual design experience provided by Systems Manager Automation. In the visual design experience, you can create a runbook that uses multiple actions. You use the drag and drop feature to arrange actions on the canvas. You also search for, select, and configure these actions. Then, you can view the auto-generated YAML code for your runbook's workflow, exit the visual design experience, run the runbook, and review the execution details.

This tutorial also shows you how to update the runbook and view the new version. At the end of the tutorial, you perform a clean-up step and delete your runbook.

After you complete this tutorial, you'll know how to use the visual design experience to create a runbook. You'll also know how to update, run, and delete your runbook.

> **Note**
>
> Before you start this tutorial, make sure to complete Setting up Automation.

Topics

Step 1: Navigate to the visual design experience

1. Sign in to the Systems Manager Automation console.
2. Choose **Create automation runbook**.

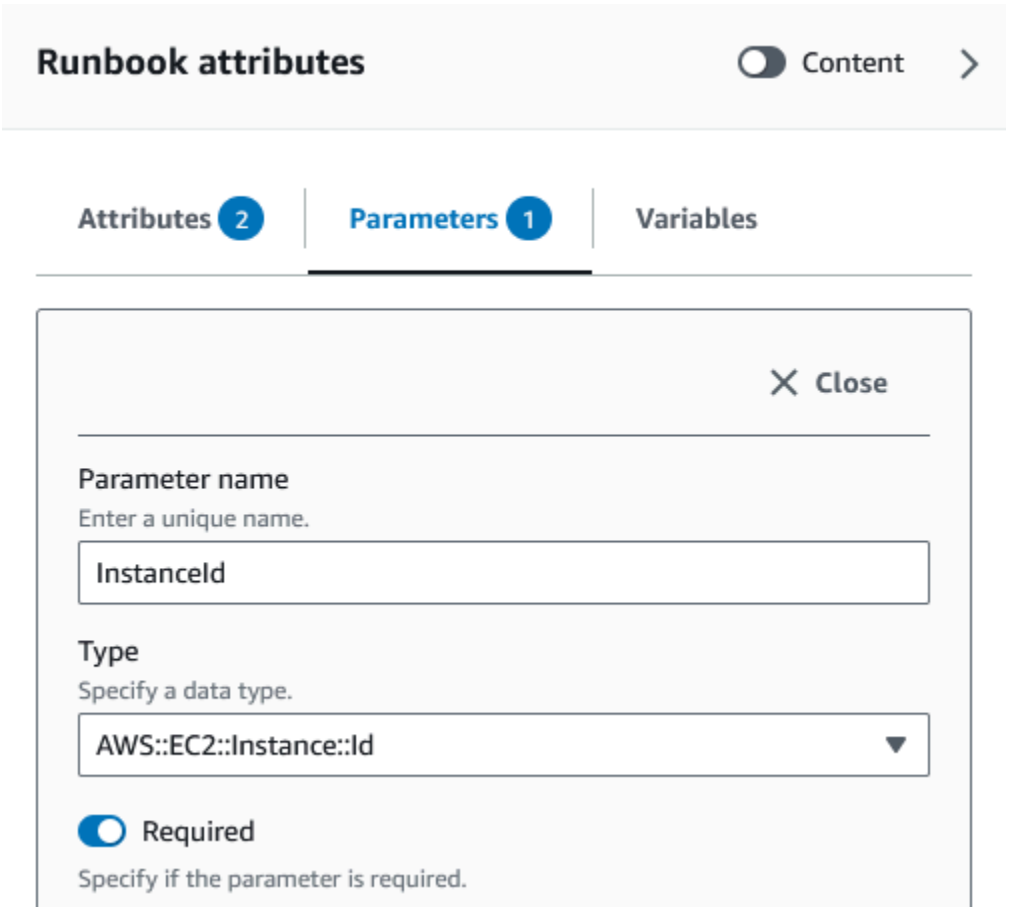
Step 2: Create a workflow

In the visual design experience, a workflow is a graphical representation of your runbook on the canvas. You can use the visual design experience to define, configure, and examine the individual actions of your runbook.

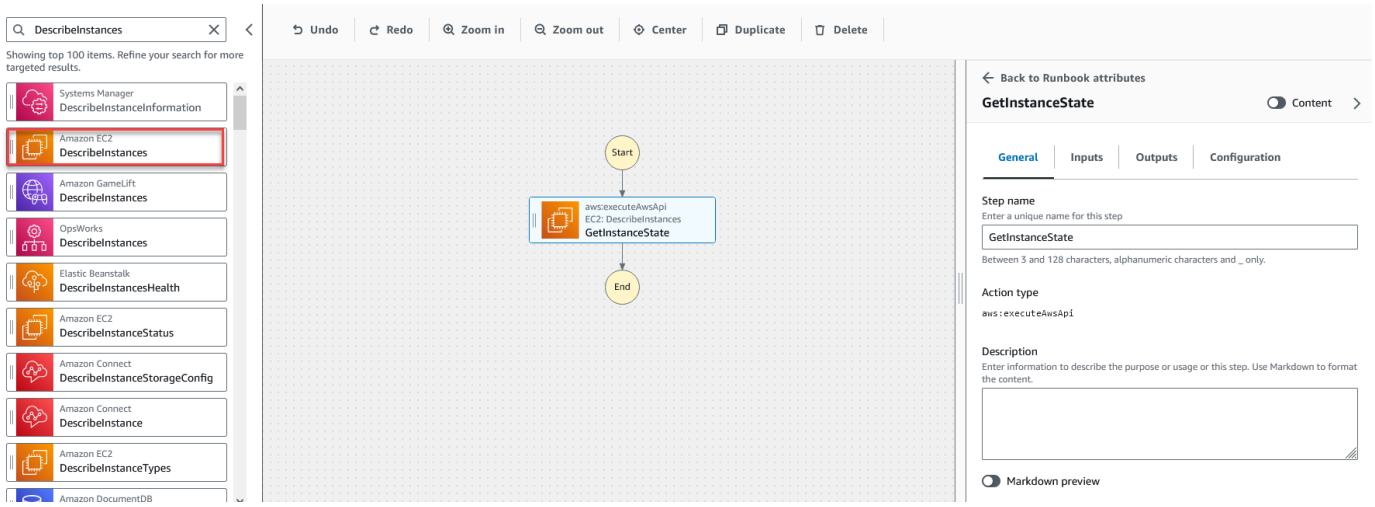
To create a workflow

1. Next to the **Design** and **Code** toggle, select the pencil icon and enter a name for your runbook. For this tutorial, enter **`VisualDesignExperienceTutorial`**.

2. In the **Document attributes** section of the **Form** panel, expand the **Input parameters** dropdown, and select **Add a parameter**.
   a. In the **Parameter name** field, enter **`InstanceId`**.
   b. In the **Type** dropdown, choose **AWS::EC2::Instance**.
   c. Select the **Required** toggle.



3. In the **AWS APIs** browser, enter **`DescribeInstances`** in the search bar.
4. Drag an **Amazon EC2 – DescribeInstances** action to the empty canvas.
5. For **Step name**, enter a value. For this tutorial, you can use the name **`GetInstanceState`**.



a. Expand the **Additional inputs** dropdown, and in the **Input name** field, enter **`InstanceIds`**.

b. Choose the **Inputs** tab.

c. In the **Input value** field, choose the **`InstanceId`** document input. This references the value of the input parameter that you created at the beginning of the procedure. Since the **InstanceIds** input for the `DescribeInstances` action accepts `StringList` values, you must wrap the **InstanceId** input in square brackets. The YAML for the **Input value** should match the following: **`['{{ InstanceId }}']`**.

d. In the **Outputs** tab, select **Add an output** and enter **`InstanceState`** in the **Name** field.

e. In the **Selector** field, enter **`$.Reservations[0].Instances[0].State.Name`**.

f. In the **Type** dropdown, choose **String**.

6. Drag a **Branch** action from the **Actions** browser, and drop it below the **`GetInstanceState`** step.

7. For **Step name**, enter a value. For this tutorial, use the name **`BranchOnInstanceState`**.

   To define the branching logic, do the following:

   a. Choose the **`Branch`** state on the canvas. Then, under **Inputs** and **Choices**, select the pencil icon to edit **Rule #1**.

   b. Choose **Add conditions**.

   c. In the **Conditions for rule #1** dialog box, choose the **`GetInstanceState.InstanceState`** step output from the **Variable** dropdown.

   d. For **Operator**, choose **is equal to**.

   e. For **Value**, choose **String** from the dropdown list. Enter **`stopped`**.

   f. Select **Save conditions**.

   g. Choose **Add new choice rule**.

   h. Choose **Add conditions** for **Rule #2**.

i. In the **Conditions for rule #2** dialog box, choose the **`GetInstanceState.InstanceState`** step output from the **Variable** dropdown.

j. For **Operator**, choose **is equal to**.

k. For **Value**, choose **String** from the dropdown list. Enter **`stopping`**.

l. Select **Save conditions**.

m. Choose **Add new choice rule**.

n. For **Rule #3**, choose **Add conditions**.

o. In the **Conditions for rule #3** dialog box, choose the **`GetInstanceState.InstanceState`** step output from the **Variable** dropdown.

p. For **Operator**, choose **is equal to**.

q. For **Value**, choose **String** from the dropdown list. Enter **`running`**.

r. Select **Save conditions**.

s. In the **Default rule**, choose **Go to end** for the **Default step**.

8. Drag a **Change an instance state** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "stopped"** condition.

   a. For the **Step name**, enter **`StartInstance`**.

   b. In the **Inputs** tab, under **Instance IDs**, choose the **InstanceId** document input value from the dropdown.

   c. For the **Desired state**, specify **`running`**.

9. Drag a **Wait on AWS resource** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "stopping"** condition.

10. For **Step name**, enter a value. For this tutorial, use the name **`WaitForInstanceStop`**.

    a. For the **Service** field, choose **Amazon EC2**.

    b. For the **API** field, choose **DescribeInstances**.

    c. For the **Property selector** field, enter **`$.Reservations[0].Instances[0].State.Name`**.

    d. For the **Desired values** parameter, enter **`["stopped"]`**.

    e. In the **Configuration** tab of the **WaitForInstanceStop** action, choose **StartInstance** from the **Next step** dropdown.

11. Drag a **Run command on instances** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "running"** condition.

12. For the **Step name**, enter **`SayHello`**.

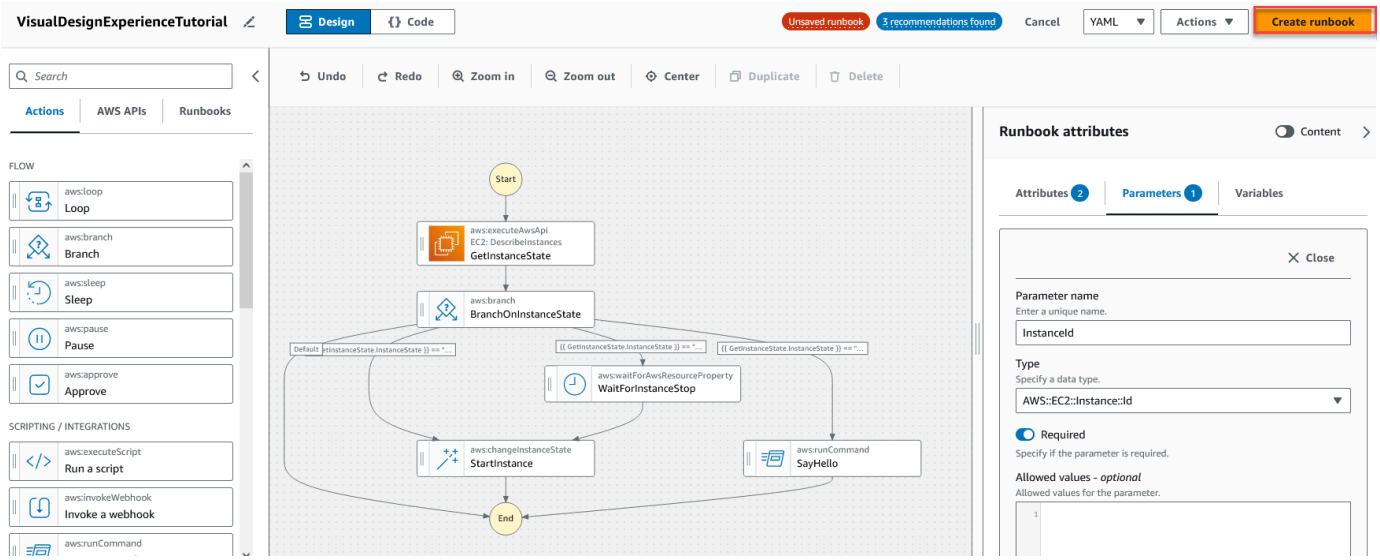
    a. In the **Inputs** tab, enter **`AWS-RunShellScript`** for the **Document name** parameter.

    b. For **InstanceIds**, choose the **InstanceId** document input value from the dropdown.

    c. Expand the **Additional inputs** dropdown, and in the **Input name** dropdown, choose **Parameters**.

    d. In the **Input value** field, enter **`{"commands": "echo 'Hello World'"}`**.

13. Review the completed runbook in the canvas and select **Create runbook** to save the tutorial runbook.



Step 3: Review the auto-generated code

As you drag and drop actions from the **Actions** browser onto the canvas, the visual design experience automatically composes the YAML or JSON content of your runbook in real-time. You can view and edit this code. To view the auto-generated code, select **Code** for the **Design** and **Code** toggle.

Step 4: Run your new runbook

After creating your runbook, you can run the automation.

To run your new automation runbook

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.

2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

   > **Note**
   >
   > You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:

   - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
   - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
   - **1 (Default)** – Choose this option to run the first version of the document, which is the default.

5. Choose **Next**.
6. In the **Execute automation runbook** section, choose **Simple execution**.
7. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.
8. (Optional) Choose an Amazon CloudWatch alarm to apply to your automation for monitoring. To attach a CloudWatch alarm to your automation, the IAM principal that starts the automation must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms. If your alarm activates, the automation is stopped. If you use AWS CloudTrail, you will see the API call in your trail.
9. Choose **Execute**.

Step 5: Clean up

To delete your runbook

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Select the **Owned by me** tab.
4. Locate the **VisualDesignExperienceTutorial** runbook.
5. Select the button on the document card page, and then choose **Delete document** from the **Actions** dropdown.

Authoring Automation runbooks

Each runbook in Automation, a tool in AWS Systems Manager, defines an automation. Automation runbooks define the actions that are performed during an automation. In the runbook content, you define the input parameters, outputs, and actions that Systems Manager performs on your managed instances and AWS resources.

Automation includes several pre-defined runbooks that you can use to perform common tasks like restarting one or more Amazon Elastic Compute Cloud (Amazon EC2) instances or creating an Amazon Machine Image (AMI). However, your use cases might extend beyond the capabilities of the pre-defined runbooks. If this is the case, you can create your own runbooks and modify them to your needs.

A runbook consists of automation actions, parameters for those actions, and input parameters that you specify. A runbook's content is written in either YAML or JSON. If you're not familiar with either YAML or JSON, we recommend using the visual designer, or learning more about either markup language before attempting to author your own runbook. For more information about the visual designer, see Visual design experience for Automation runbooks.

The following sections will help you author your first runbook.

Identify your use case

The first step in authoring a runbook is identifying your use case. For example, you scheduled the `AWS-CreateImage` runbook to run daily on all of your production Amazon EC2 instances. At the end of the month, you decide you have more images than are necessary for recovery points. Going

forward, you want to automatically delete the oldest AMI of an Amazon EC2 instance when a new AMI is created. To accomplish this, you create a new runbook that does the following:

1. Runs the `aws:createImage` action and specifies the instance ID in the image description.
2. Runs the `aws:waitForAwsResourceProperty` action to poll the state of the image until it's `available`.
3. After the image state is `available`, the `aws:executeScript` action runs a custom Python script that gathers the IDs of all images associated with your Amazon EC2 instance. The script does this by filtering, using the instance ID in the image description you specified at creation. Then, the script sorts the list of image IDs based on the `creationDate` of the image and outputs the ID of the oldest AMI.
4. Lastly, the `aws:deleteImage` action runs to delete the oldest AMI using the ID from the output of the previous step.

In this scenario, you were already using the `AWS-CreateImage` runbook but found that your use case required greater flexibility. This is a common situation because there can be overlap between runbooks and automation actions. As a result, you might have to adjust which runbooks or actions you use to address your use case.

For example, the `aws:executeScript` and `aws:invokeLambdaFunction` actions both allow you to run custom scripts as part of your automation. To choose between them, you might prefer `aws:invokeLambdaFunction` because of the additional supported runtime languages. However, you might prefer `aws:executeScript` because it allows you to author your script content directly in YAML runbooks and provide script content as attachments for JSON runbooks. You might also consider `aws:executeScript` to be simpler in terms of AWS Identity and Access Management (IAM) setup. Because it uses the permissions provided in the `AutomationAssumeRole`, `aws:executeScript` doesn't require an additional AWS Lambda function execution role.

In any given scenario, one action might provide more flexibility, or added functionality, over another. Therefore, we recommend that you review the available input parameters for the runbook or action you want to use to determine which best fits your use case and preferences.

Set up your development environment

After you've identified your use case and the pre-defined runbooks or automation actions you want to use in your runbook, it's time to set up your development environment for the content of your

runbook. To develop your runbook content, we recommend using the AWS Toolkit for Visual Studio Code instead of the Systems Manager Documents console.

The Toolkit for VS Code is an open-source extension for Visual Studio Code (VS Code) that offers more features than the Systems Manager Documents console. Helpful features include schema validation for both YAML and JSON, snippets for automation action types, and auto-complete support for various options in both YAML and JSON.

For more information about installing the Toolkit for VS Code, see Installing the AWS Toolkit for Visual Studio Code. For more information about using the Toolkit for VS Code to develop runbooks, see Working with Systems Manager Automation documents in the *AWS Toolkit for Visual Studio Code User Guide*.
