The Content section includes attributes and data. These items aren't case-sensitive. However, if you define an attribute (for example: "Vendor": "DELL"), then you must consistently reference this attribute in your custom inventory files. If you specify "Vendor": "DELL" (using a capital “V” in vendor) in one file, and then you specify "vendor": "DELL" (using a lowercase “v” in vendor) in another file, the system returns an error.

Tip
You must save the file with a .json extension and the inventory you define must consist only of string values.

After you create the file, you must save it on the node. The following table shows the location where custom inventory JSON files must be stored on the node.

<table>
<thead>
<tr>
<th>Operating system</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>/var/lib/amazon/ssm/node-id/inventory/custom</td>
</tr>
<tr>
<td>macOS</td>
<td>/opt/aws/ssm/data/node-id/inventory/custom</td>
</tr>
<tr>
<td>Windows</td>
<td>%SystemDrive%\ProgramData\Amazon\SSM\InstanceData\node-id\inventory\custom</td>
</tr>
</tbody>
</table>

For an example of how to use custom inventory, see Get Disk Utilization of Your Fleet Using EC2 Systems Manager Custom Inventory Types.

Deleting custom inventory

You can use the DeleteInventory API operation to delete a custom inventory type and the data associated with that type. You call the delete-inventory command by using the AWS Command Line Interface (AWS CLI) to delete all data for an inventory type. You call the delete-inventory command with the SchemaDeleteOption to delete a custom inventory type.

An inventory type is also called an inventory schema.

The SchemaDeleteOption parameter includes the following options:

- **DeleteSchema**: This option deletes the specified custom type and all data associated with it. You can recreate the schema later, if you want.

- **DisableSchema**: If you choose this option, the system turns off the current version, deletes all data for it, and ignores all new data if the version is less than or equal to the turned off version. You can allow this inventory type again by calling the **PutInventory** action for a version greater than the turned off version.

To delete or turn off custom inventory by using the AWS CLI

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to use the **dry-run** option to see which data will be deleted from the system. This command doesn't delete any data.

   ```bash
   aws ssm delete-inventory --type-name "Custom:custom_type_name" --dry-run
   ```

   The system returns information like the following.

   ```json
   {
     "DeletionSummary": {
       "RemainingCount": 3,
       "SummaryItems": [
         {
           "Count": 2,
           "RemainingCount": 2,
           "Version": "1.0"
         },
         {
           "Count": 1,
           "RemainingCount": 1,
           "Version": "2.0"
         }
       ]
     }
   }
   ```
For information about how to understand the delete inventory summary, see Understanding the delete inventory summary.

3. Run the following command to delete all data for a custom inventory type.

   ```bash
   aws ssm delete-inventory --type-name "Custom:custom_type_name"
   ```

   **Note**
   The output of this command doesn't show the deletion progress. For this reason, TotalCount and Remaining Count are always the same because the system hasn't deleted anything yet. You can use the describe-inventory-deletions command to show the deletion progress, as described later in this topic.

   The system returns information like the following.

   ```json
   {
     "DeletionId":"system_generated_deletion_ID",
     "DeletionSummary":{
       "RemainingCount":3,
       "SummaryItems":[
         {
           "Count":2,
           "RemainingCount":2,
           "Version":"1.0"
         },
         {
           "Count":1,
           "RemainingCount":1,
           "Version":"2.0"
         }
       ],
       "TotalCount":3
   }
   ```
The system deletes all data for the specified custom inventory type from the Systems Manager Inventory service.

4. Run the following command. The command performs the following actions for the current version of the inventory type: turns off the current version, deletes all data for it, and ignores all new data if the version is less than or equal to the turned off version.

```bash
aws ssm delete-inventory --type-name "Custom:custom_type_name" --schema-delete-option "DisableSchema"
```

The system returns information like the following.

```json
{
   "DeletionId": "system_generated_deletion_ID",
   "DeletionSummary":{
      "RemainingCount":3,
      "SummaryItems":[
         { "Count":2, "RemainingCount":2, "Version":"1.0" },
         { "Count":1, "RemainingCount":1, "Version":"2.0" }
      ],
      "TotalCount":3
   },
   "TypeName":"Custom:custom_type_name"
}
```

You can view a turned off inventory type by using the following command.

```bash
aws ssm get-inventory-schema --type-name Custom:custom_type_name
```

5. Run the following command to delete an inventory type.
aws ssm delete-inventory --type-name "Custom:custom_type_name" --schema-delete-option "DeleteSchema"

The system deletes the schema and all inventory data for the specified custom type.

The system returns information like the following.

```
{
    "DeletionId":"system_generated_deletion_ID",
    "DeletionSummary":{
        "RemainingCount":3,
        "SummaryItems":[
            {
                "Count":2,
                "RemainingCount":2,
                "Version":"1.0"
            },
            {
                "Count":1,
                "RemainingCount":1,
                "Version":"2.0"
            }
        ],
        "TotalCount":3
    },
    "TypeName":"Custom:custom_type_name"
}
```

### Viewing the deletion status

You can check the status of a delete operation by using the `describe-inventory-deletions` AWS CLI command. You can specify a deletion ID to view the status of a specific delete operation. Or, you can omit the deletion ID to view a list of all deletions run in the last 30 days.

1. Run the following command to view the status of a deletion operation. The system returned the deletion ID in the `delete-inventory` summary.

   ```bash
   aws ssm describe-inventory-deletions --deletion-id system_generated_deletion_ID
   ```
AWS Systems Manager

User Guide

The system returns the latest status. The delete operation might not be ﬁnished yet. The
system returns information like the following.
{"InventoryDeletions":
[
{"DeletionId": "system_generated_deletion_ID",
"DeletionStartTime": 1521744844,
"DeletionSummary":
{"RemainingCount": 1,
"SummaryItems":
[
{"Count": 1,
"RemainingCount": 1,
"Version": "1.0"}
],
"TotalCount": 1},
"LastStatus": "InProgress",
"LastStatusMessage": "The Delete is in progress",
"LastStatusUpdateTime": 1521744844,
"TypeName": "Custom:custom_type_name"}
]
}

If the delete operation is successful, the LastStatusMessage states: Deletion is successful.
{"InventoryDeletions":
[
{"DeletionId": "system_generated_deletion_ID",
"DeletionStartTime": 1521744844,
"DeletionSummary":
{"RemainingCount": 0,
"SummaryItems":
[
{"Count": 1,
"RemainingCount": 0,
"Version": "1.0"}
],
"TotalCount": 1},
"LastStatus": "Complete",
"LastStatusMessage": "Deletion is successful",
"LastStatusUpdateTime": 1521745253,
"TypeName": "Custom:custom_type_name"}

Working with custom inventory

1421


2. Run the following command to view a list of all deletions run in the last 30 days.

```
aws ssm describe-inventory-deletions --max-results a number
```
Understanding the delete inventory summary

To help you understand the contents of the delete inventory summary, consider the following example. A user assigned Custom:RackSpace inventory to three nodes. Inventory items 1 and 2 use custom type version 1.0 ("SchemaVersion":"1.0"). Inventory item 3 uses custom type version 2.0 ("SchemaVersion":"2.0").

RackSpace custom inventory 1

```json
{
    "TypeName":"CustomType:RackSpace",
    "InstanceId":"i-1234567890",
    "SchemaVersion":"1.0"
    "Content": [
        {
            "content of custom type omitted"
        }
    ]
}
```

RackSpace custom inventory 2

```json
{
    "TypeName":"CustomType:RackSpace",
    "InstanceId":"i-1234567891",
    "SchemaVersion":"2.0"
    "Content": [
        {
            "content of custom type omitted"
        }
    ]
}
```
The user runs the following command to preview which data will be deleted.

```
aws ssm delete-inventory --type-name "Custom:RackSpace" --dry-run
```

The system returns information like the following.

```
{
    "DeletionId":"1111-2222-333-444-66666",
    "DeletionSummary":{
        "RemainingCount":3,
        "TotalCount":3,
    }
}
```

TotalCount and RemainingCount are the number of items that would be deleted if this was not a dry run. These numbers are the same because the system didn’t delete anything.

```
    "SummaryItems":[
        {
            "Count":2,
            "Version":"1.0"
        },
        {
```

The system found two items that use SchemaVersion 1.0. Neither item was deleted.

```
    "RemainingCount":2,
    "Version":"1.0"
    
},
```
The user runs the following command to delete the Custom:RackSpace inventory.

```bash
aws ssm delete-inventory --type-name "Custom:RackSpace"
```

The system returns information like the following.

```
{
    "DeletionId":"1111-2222-333-444-7777777",
    "DeletionSummary":{
        "RemainingCount":3,
        "SummaryItems":[
            {
                "Count":2,
                "Version":"1.0"
            },
            {
                "Count":1,
                "Version":"2.0"
            }
        ]
    }
}
```

There are three items to delete

The system found two items that use SchemaVersion 1.0.

The system found one item that uses SchemaVersion 2.0.
Viewing inventory delete actions in EventBridge

You can configure Amazon EventBridge to create an event anytime a user deletes custom inventory. EventBridge offers three types of events for custom inventory delete operations:

- **Delete action for an instance**: If the custom inventory for a specific managed node was successfully deleted or not.
- **Delete action summary**: A summary of the delete action.
- **Warning for turned off custom inventory type**: A warning event if a user called the PutInventory API operation for a custom inventory type version that was previously turned off.

Here are examples of each event.

**Delete action for an instance**

```json
{
    "version": "0",
    "id": "998c9cde-56c0-b38b-707f-0411b3ff9d11",
    "detail-type": "Inventory Resource State Change",
    "source": "aws.ssm",
    "account": "47867815555",
    "time": "2018-05-24T22:24:34Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ssm:us-east-1:47867815555:managed-instance/i-0a5feb270fc3f0b97"
    ],
    "detail": {
        "action-status": "succeeded",
        "action": "delete",
        "resource-type": "managed-instance",
        "resource-id": "i-0a5feb270fc3f0b97",
        "action-reason": "",
        "type-name": "Custom:MyInfo"
    }
}
```
Delete action summary

```
{
    "version": "0",
    "id": "83898300-f576-5181-7a67-fb3e45e4fad4",
    "detail-type": "Inventory Resource State Change",
    "source": "aws.ssm",
    "account": "478678815555",
    "region": "us-east-1",
    "resources": [],
    "detail": {
        "action-status": "succeeded",
        "action": "delete-summary",
        "resource-type": "managed-instance",
        "resource-id": "",
        "action-reason": "The delete for type name Custom:MyInfo was completed. The
deletion summary is: {"totalCount":2,"remainingCount":0,"summaryItems":
[
{"version":"1.0","count":2,"remainingCount":0}]
}
    }
}
```

Warning for turned off custom inventory type

```
{
    "version": "0",
    "id": "49c1855c-9c57-b5d7-8518-b64aeeef5e4a",
    "detail-type": "Inventory Resource State Change",
    "source": "aws.ssm",
    "account": "478678815555",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ssm:us-east-1:478678815555:managed-instance/i-0ee2d86a2cfc371f6"
    ],
    "detail": {
        "action-status": "failed",
        "action": "put",
    }
}
```
Use the following procedure to create an EventBridge rule for custom inventory delete operations. This procedure shows you how to create a rule that sends notifications for custom inventory delete operations to an Amazon SNS topic. Before you begin, verify that you have an Amazon SNS topic, or create a new one. For more information, see [Getting Started](https://docs.aws.amazon.com/AWS.SimpleNotificationService/latest/devguide/GS-Getting-Started.html) in the *Amazon Simple Notification Service Developer Guide*.

**To configure EventBridge for delete inventory operations**

1. Open the Amazon EventBridge console at [https://console.aws.amazon.com/events/](https://console.aws.amazon.com/events/).
2. In the navigation pane, choose Rules.
3. Choose Create rule.
4. Enter a name and description for the rule.

   A rule can't have the same name as another rule in the same Region and on the same event bus.

5. For Event bus, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own AWS account, select default. When an AWS service in your account emits an event, it always goes to your account’s default event bus.

6. For Rule type, choose Rule with an event pattern.
7. Choose Next.
8. For Event source, choose AWS events or EventBridge partner events.
9. In the Event pattern section, choose Event pattern form.
10. For Event source, choose AWS services.
11. For AWS service, choose Systems Manager.
12. For Event type, choose Inventory.
13. For Specific detail type(s), choose Inventory Resource State Change.
15. For **Target types**, choose **AWS service**.

16. For **Select a target**, choose **SNS topic**, and then for **Topic**, choose your topic.

17. In the **Additional settings** section, for **Configure target input**, verify that **Matched event** is selected.

18. Choose **Next**.

19. (Optional) Enter one or more tags for the rule. For more information, see [Tagging Your Amazon EventBridge Resources](#) in the *Amazon EventBridge User Guide*.

20. Choose **Next**.

21. Review the details of the rule and choose **Create rule**.

### Viewing inventory history and change tracking

You can view AWS Systems Manager Inventory history and change tracking for all of your managed nodes by using [AWS Config](#). AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time. To view inventory history and change tracking, you must turn on the following resources in AWS Config:

- SSM:ManagedInstanceInventory
- SSM:PatchCompliance
- SSM:AssociationCompliance
- SSM:FileData

---

**Note**

Note the following important details about Inventory history and change tracking:

- If you use AWS Config to track changes in your system, you must configure Systems Manager Inventory to collect AWS:File metadata so that you can view file changes in AWS Config (SSM:FileData). If you don't, then AWS Config doesn't track file changes on your system.
- By turning on SSM:PatchCompliance and SSM:AssociationCompliance, you can view Systems Manager Patch Manager patching and Systems Manager State Manager...
The following procedure describes how to turn on inventory history and change-track recording in AWS Config by using the AWS Command Line Interface (AWS CLI). For more information about how to choose and configure these resources in AWS Config, see Selecting Which Resources AWS Config Records in the AWS Config Developer Guide. For information about AWS Config pricing, see Pricing.

Before you begin

AWS Config requires AWS Identity and Access Management (IAM) permissions to get configuration details about Systems Manager resources. In the following procedure, you must specify an Amazon Resource Name (ARN) for an IAM role that gives AWS Config permission to Systems Manager resources. You can attach the AWS_ConfigRole managed policy to the IAM role that you assign to AWS Config. For more information about this role, see AWS managed policy: AWS_ConfigRole in the AWS Config Developer Guide. For information about how to create an IAM role and assign the AWS_ConfigRole managed policy to that role, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

To turn on inventory history and change-track recording in AWS Config

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven’t already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Copy and paste the following JSON sample into a simple text file and save it as recordingGroup.json.

```json
{
   "allSupported":false,
   "includeGlobalResourceTypes":false,
   "resourceTypes":[
   "AWS::SSM::AssociationCompliance",
   "AWS::SSM::PatchCompliance",
   "AWS::SSM::ManagedInstanceInventory",
   "AWS::SSM::FileData"
   ]
}
```

3. Run the following command to load the recordingGroup.json file into AWS Config.
aws configservice put-configuration-recorder --configuration-recorder-name=myRecorder,roleARN=arn:aws:iam::123456789012:role/myConfigRole --recording-group file://recordingGroup.json

4. Run the following command to start recording inventory history and change tracking.

aws configservice start-configuration-recorder --configuration-recorder-name myRecorder

After you configure history and change tracking, you can drill down into the history for a specific managed node by choosing the AWS Config button in the Systems Manager console. You can access the AWS Config button from either the Managed Instances page or the Inventory page. Depending on your monitor size, you might need to scroll to the right side of the page to see the button.

**Stopping data collection and deleting inventory data**

If you no longer want to use AWS Systems Manager Inventory to view metadata about your AWS resources, you can stop data collection and delete data that has already been collected. This section includes the following information.

**Topics**

- [Stopping data collection](#)
- [Deleting an Inventory resource data sync](#)

**Stopping data collection**

When you initially configure Systems Manager to collect inventory data, the system creates a State Manager association that defines the schedule and the resources from which to collect metadata. You can stop data collection by deleting any State Manager associations that use the AWS-GatherSoftwareInventory document.

**To delete an Inventory association**

2. In the navigation pane, choose State Manager.
3. Choose an association that uses the AWS-GatherSoftwareInventory document and then choose Delete.

4. Repeat step three for any remaining associations that use the AWS-GatherSoftwareInventory document.

Deleting an Inventory resource data sync

If you no longer want to use AWS Systems Manager Inventory to view metadata about your AWS resources, then we also recommend deleting resource data syncs used for inventory data collection.

To delete an Inventory resource data sync

2. In the navigation pane, choose Inventory.
3. Choose Resource Data Syncs.
4. Choose a sync in the list.

**Important**

Make sure you choose the sync used for Inventory. Systems Manager supports resource data sync for multiple capabilities. If you choose the wrong sync, you could disrupt data aggregation for Systems Manager Explorer or Systems Manager Compliance.

5. Choose Delete
6. Repeat these steps for any remaining resource data syncs you want to delete.
7. Delete the Amazon Simple Storage Service (Amazon S3) bucket where the data was stored. For information about deleting an Amazon S3 bucket, see Deleting a bucket.

**Systems Manager Inventory walkthroughs**

Use the following walkthroughs to collect and manage inventory data by using AWS Systems Manager Inventory. We recommend that you initially perform these walkthroughs with managed nodes in a test environment.

**Before you begin**
Before you start these walkthroughs, complete the following tasks:

- Update AWS Systems Manager SSM Agent on the nodes you want to inventory. By running the latest version of SSM Agent, you ensure that you can collect metadata for all supported inventory types. For information about how to update SSM Agent by using State Manager, see Walkthrough: Automatically update SSM Agent (CLI).

- Verify that you have completed the setup requirements for your Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 machines in a hybrid and multicloud environment. For information, see Setting up AWS Systems Manager.

- (Optional) Create a JSON file to collect custom inventory. For more information, see Working with custom inventory.

Contents

- Walkthrough: Assign custom inventory metadata to a managed node
- Walkthrough: Configure your managed nodes for Inventory by using the CLI
- Walkthrough: Use resource data sync to aggregate inventory data

Walkthrough: Assign custom inventory metadata to a managed node

The following procedure walks you through the process of using the AWS Systems Manager PutInventory API operation to assign custom inventory metadata to a managed node. This example assigns rack location information to a node. For more information about custom inventory, see Working with custom inventory.

To assign custom inventory metadata to a node

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.
   
   For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command to assign rack location information to a node.

   Linux

   ```
   aws ssm put-inventory --instance-id "ID" --items '[["CaptureTime": "2016-08-22T10:01:01Z", "TypeName": "Custom:RackInfo", "Content":[{"RackLocation": "Bay B/Row C/Rack D/Shelf E"}], "SchemaVersion": "1.0"]]
   ```
3. Run the following command to view custom inventory entries for this node.

```bash
aws ssm list-inventory-entries --instance-id ID --type-name "Custom:RackInfo"
```

The system responds with information like the following.

```json
{
   "InstanceId": "ID",
   "TypeName": "Custom:RackInfo",
   "Entries": [
      {
         "RackLocation": "Bay B/Row C/Rack D/Shelf E"
      }
   ],
   "SchemaVersion": "1.0",
   "CaptureTime": "2016-08-22T10:01:01Z"
}
```

4. Run the following command to view the custom inventory schema.

```bash
aws ssm get-inventory-schema --type-name Custom:RackInfo
```

The system responds with information like the following.

```json
{
   "Schemas": [
      {
         "TypeName": "Custom:RackInfo",
         "Version": "1.0",
         "Attributes": [
            {
               "DataType": "STRING",
               "Name": "RackLocation"
            }
         ]
      }
   ]
}
```
Walkthrough: Configure your managed nodes for Inventory by using the CLI

The following procedures walk you through the process of configuring AWS Systems Manager Inventory to collect metadata from your managed nodes. When you configure inventory collection, you start by creating a Systems Manager State Manager association. Systems Manager collects the inventory data when the association is run. If you don't create the association first, and attempt to invoke the aws:softwareInventory plugin by using, for example, Systems Manager Run Command, the system returns the following error:

The aws:softwareInventory plugin can only be invoked via ssm-associate.

**Note**

A node can have only one inventory association configured at a time. If you configure a node with two or more inventory associations, the association doesn't run and no inventory data is collected.

Quickly configure all of your managed nodes for Inventory (CLI)

You can quickly configure all managed nodes in your AWS account and in the current Region to collect inventory data. This is called creating a global inventory association. To create a global inventory association by using the AWS CLI, use the wildcard option for the instanceIds value, as shown in the following procedure.

To configure inventory for all managed nodes in your AWS account and in the current Region (CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.
   - For information, see [Installing or updating the latest version of the AWS CLI](#).
2. Run the following command.
Amazon Web Services Systems Manager
User Guide

Linux & macOS

aws ssm create-association \
--name AWS-GatherSoftwareInventory \
--targets Key=InstanceIds,Values=* \
--schedule-expression "rate(1 day)" \
--parameters 
  applications=Enabled,awsComponents=Enabled,customInventory=Enabled,instanceDetailedInformation=Enabled

Windows

aws ssm create-association ^
--name AWS-GatherSoftwareInventory ^
--targets Key=InstanceIds,Values=* ^
--schedule-expression "rate(1 day)" ^
--parameters 
  applications=Enabled,awsComponents=Enabled,customInventory=Enabled,instanceDetailedInformation=Enabled

Note
This command doesn't allow Inventory to collect metadata for the Windows Registry or files. To inventory these datatypes, use the next procedure.

Manually configuring Inventory on your managed nodes (CLI)

Use the following procedure to manually configure AWS Systems Manager Inventory on your managed nodes by using node IDs or tags.

To manually configure your managed nodes for inventory (CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command to create a State Manager association that runs Systems Manager Inventory on the node. Replace each example resource placeholder with your own information. This command configures the service to run every six hours and to collect network configuration, Windows Update, and application metadata from a node.
Linux & macOS

```
aws ssm create-association \
--name "AWS-GatherSoftwareInventory" \ 
--targets "Key=instanceids,Values=an_instance_ID" \ 
--schedule-expression "rate(240 minutes)" \
--output-location "{ "S3Location": { "OutputS3Region": "region_ID, 
    for example us-east-2", "OutputS3BucketName": "DOC-EXAMPLE-BUCKET", 
    "OutputS3KeyPrefix": "Test\" } }" \
--parameters "networkConfig=Enabled,windowsUpdates=Enabled,applications=Enabled"
```

Windows

```
aws ssm create-association ^ 
--name "AWS-GatherSoftwareInventory" ^ 
--targets "Key=instanceids,Values=an_instance_ID" ^ 
--schedule-expression "rate(240 minutes)" ^ 
--output-location "{ "S3Location": { "OutputS3Region": "region_ID, 
    for example us-east-2", "OutputS3BucketName": "DOC-EXAMPLE-BUCKET", 
    "OutputS3KeyPrefix": "Test\" } }" ^ 
--parameters "networkConfig=Enabled,windowsUpdates=Enabled,applications=Enabled"
```

The system responds with information like the following.

```
{
    "AssociationDescription": {
        "ScheduleExpression": "rate(240 minutes)",
        "OutputLocation": {
            "S3Location": {
                "OutputS3KeyPrefix": "Test",
                "OutputS3BucketName": "Test bucket",
                "OutputS3Region": "us-east-2"
            }
        },
        "Name": "The name you specified",
        "Parameters": {
            "applications": [
                "Enabled"
            ],
            "networkConfig": [
```
You can target large groups of nodes by using the Targets parameter with EC2 tags. See the following example.

**Linux & macOS**

```bash
aws ssm create-association \
  --name "AWS-GatherSoftwareInventory" \
  --targets "Key=tag:Environment,Values=Production" \
  --schedule-expression "rate(240 minutes)" \
  --output-location "{ "S3Location": { "OutputS3Region": "us-east-2", "OutputS3BucketName": "DOC-EXAMPLE-BUCKET", "OutputS3KeyPrefix": "Test" } }" \
  --parameters "networkConfig=Enabled,windowsUpdates=Enabled,applications=Enabled"
```

**Windows**

```bash
aws ssm create-association ^
```
You can also inventory files and Windows Registry keys on a Windows Server node by using the `files` and `windowsRegistry` inventory types with expressions. For more information about these inventory types, see [Working with file and Windows registry inventory](#).

**Linux & macOS**

```bash/aws ssm create-association
--name "AWS-GatherSoftwareInventory"
--targets "Key=instanceids,Values=i-0704358e3a3da9eb1"
--schedule-expression "rate(240 minutes)"
--parameters '{"files":[{"Path": "C:\Program Files", "Pattern": "*.exe"}, "Recursive": true}], "windowsRegistry": [{"Path": "HKEY_LOCAL_MACHINE\Software\Amazon", "Recursive":true}]}'
--profile dev-pdx
```

**Windows**

```bash
/aws ssm create-association
--name "AWS-GatherSoftwareInventory"
--targets "Key=instanceids,Values=i-0704358e3a3da9eb1"
--schedule-expression "rate(240 minutes)"
--parameters '{"files":[{"Path": "C:\Program Files", "Pattern": "*.exe"}, "Recursive": true}], "windowsRegistry": [{"Path": "HKEY_LOCAL_MACHINE\Software\Amazon", "Recursive":true}]}'
--profile dev-pdx
```

3. Run the following command to view the association status.

```bash
/aws ssm describe-instance-associations-status --instance-id an_instance_ID
```

The system responds with information like the following.
Walkthrough: Use resource data sync to aggregate inventory data

The following walkthrough describes how to create a resource data sync configuration for AWS Systems Manager Inventory by using the AWS Command Line Interface (AWS CLI). A resource data sync automatically ports inventory data from all of your managed nodes to a central Amazon Simple Storage Service (Amazon S3) bucket. The sync automatically updates the data in the central Amazon S3 bucket whenever new inventory data is discovered.

This walkthrough also describes how to use Amazon Athena and Amazon QuickSight to query and analyze the aggregated data. For information about creating a resource data sync by using Systems Manager in the AWS Management Console, see Configuring resource data sync for Inventory. For information about querying inventory from multiple AWS Regions and accounts by using Systems Manager in the AWS Management Console, see Querying inventory data from multiple Regions and accounts.

Note

This walkthrough includes information about how to encrypt the sync by using AWS Key Management Service (AWS KMS). Inventory doesn't collect any user-specific, proprietary, or sensitive data so encryption is optional. For more information about AWS KMS, see AWS Key Management Service Developer Guide.

Before you begin

```json
{
  "InstanceAssociationStatusInfos": [
    {
      "Status": "Pending",
      "DetailedStatus": "Associated",
      "Name": "reInvent2016PolicyDocumentTest",
      "InstanceId": "i-1a2b3c4d5e6f7g",
      "AssociationId": "1a2b3c4d5e6f7g-1a2b3c-1a2b3c-1a2b3c-1a2b3c4d5e6f7g",
      "DocumentVersion": "1"
    }
  ]
}
```
Review or complete the following tasks before you begin the walkthrough in this section:

- Collect inventory data from your managed nodes. For the purpose of the Amazon Athena and Amazon QuickSight sections in this walkthrough, we recommend that you collect Application data. For more information about how to collect inventory data, see Configuring inventory collection or Walkthrough: Configure your managed nodes for Inventory by using the CLI.
- (Optional) If the inventory data is stored in an Amazon Simple Storage Service (Amazon S3) bucket that uses AWS Key Management Service (AWS KMS) encryption, you must also configure your IAM account and the Amazon-GlueServiceRoleForSSM service role for AWS KMS encryption. If you don’t configure your IAM account and this role, Systems Manager displays Cannot load Glue tables when you choose the Detailed View tab in the console. For more information, see (Optional) Configure permissions for viewing AWS KMS encrypted data.
- (Optional) If you want to encrypt the resource data sync by using AWS KMS, then you must either create a new key that includes the following policy, or you must update an existing key and add this policy to it.

```json
{
    "Version": "2012-10-17",
    "Id": "ssm-access-policy",
    "Statement": [
        {
            "Sid": "ssm-access-policy-statement",
            "Action": [
                "kms:GenerateDataKey"
            ],
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Condition": {
                "StringLike": {
                    "aws:SourceAccount": "123456789012"
                },
                "ArnLike": {
                }
            }
        }
    ]
}
```
To create a resource data sync for Inventory

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Create a bucket to store your aggregated inventory data. For more information, see Create a Bucket in the Amazon Simple Storage Service User Guide. Make a note of the bucket name and the AWS Region where you created it.

3. After you create the bucket, choose the Permissions tab, and then choose Bucket Policy.

4. Copy and paste the following bucket policy into the policy editor. Replace DOC-EXAMPLE-BUCKET and account-id with the name of the Amazon S3 bucket you created and a valid AWS account ID. When adding multiple accounts, add an additional condition string and ARN for each account. Remove the additional placeholders from the example when adding one account. Optionally, replace bucket-prefix with the name of an Amazon S3 prefix (subdirectory). If you didn't created a prefix, remove bucket-prefix/ from the ARN in the policy.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "SSMBucketDelivery",
         "Effect": "Allow",
         "Principal": {
            "Service": "ssm.amazonaws.com"
         },
         "Action": "s3:PutObject",
         "Resource": [
            "arn:aws:s3:::DOC-EXAMPLE-BUCKET/bucket-prefix/*/accountid=account-id/*"
         ],
         "Condition": {
            "StringEquals": {
               "s3:x-amz-acl": "bucket-owner-full-control",
               "aws:SourceAccount": [
                  "account-id1",
                  "account-id2",
                  "account-id3",
                  "account-id4"
               ]
            }
         }
      }
   ]
}
```
5. (Optional) If you want to encrypt the sync, then you must add the following conditions to the policy listed in the previous step. Add these in the StringEquals section.

```
"ArnLike": {
  "aws:SourceArn": [
    "arn:aws:ssm:*:account-id1:resource-data-sync/*",
    "arn:aws:ssm:*:account-id3:resource-data-sync/*",
    "arn:aws:ssm:*:account-id4:resource-data-sync/*"
  ]
}
```

Here is an example:

```
"StringEquals": {
  "s3:x-amz-server-side-encryption": "aws:kms",
  "s3:x-amz-server-side-encryption-aws-kms-key-id": "arn:aws:kms:region:account_ID:key/KMS_key_ID"
}
```

6. Install and configure the AWS Command Line Interface (AWS CLI), if you haven’t already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

7. (Optional) If you want to encrypt the sync, run the following command to verify that the bucket policy is enforcing the AWS KMS key requirement. Replace each example resource placeholder with your own information.

**Linux & macOS**

```
aws s3 cp ./A_file_in_the_bucket s3://DOC-EXAMPLE-BUCKET/prefix/ \
```
8. Run the following command to create a resource data sync configuration with the Amazon S3 bucket you created at the start of this procedure. This command creates a sync from the AWS Region you're logged into.

Note
If the sync and the target Amazon S3 bucket are located in different regions, you might be subject to data transfer pricing. For more information, see Amazon S3 Pricing.

Windows

```bash
aws s3 cp ./A_file_in_the_bucket s3://DOC-EXAMPLE-BUCKET/prefix/ ^
--sse aws:kms ^
--sse-kms-key-id "arn:aws:kms:region:account_ID:key/KMS_key_id" ^
--region region, for example, us-east-2
```

Linux & macOS

```bash
aws ssm create-resource-data-sync \\
--sync-name a_name \\
--s3-destination "BucketName=DOC-EXAMPLE-BUCKET,Prefix=prefix_name, if_specified,SyncFormat=JsonSerDe,Region=bucket_region"
```

Windows

```bash
aws ssm create-resource-data-sync ^
--sync-name a_name ^
--s3-destination "BucketName=DOC-EXAMPLE-BUCKET,Prefix=prefix_name, if_specified,SyncFormat=JsonSerDe,Region=bucket_region"
```

You can use the `region` parameter to specify where the sync configuration should be created. In the following example, inventory data from the us-west-1 Region, will be synchronized in the Amazon S3 bucket in the us-west-2 Region.
Linux & macOS

```bash
aws ssm create-resource-data-sync \
  --sync-name InventoryDataWest \
  --s3-destination "BucketName=DOC-EXAMPLE-BUCKET,Prefix=HybridEnv,SyncFormat=JsonSerDe,Region=us-west-2" \
  --region us-west-1
```

Windows

```bash
aws ssm create-resource-data-sync ^
  --sync-name InventoryDataWest ^
  --s3-destination "BucketName=DOC-EXAMPLE-BUCKET,Prefix=HybridEnv,SyncFormat=JsonSerDe,Region=us-west-2" ^ --region us-west-1
```

(Optional) If you want to encrypt the sync by using AWS KMS, run the following command to create the sync. If you encrypt the sync, then the AWS KMS key and the Amazon S3 bucket must be in the same Region.

Linux & macOS

```bash
aws ssm create-resource-data-sync \
  --sync-name sync_name \
  --s3-destination "BucketName=DOC-EXAMPLE-BUCKET,Prefix=prefix_name,if_specified,SyncFormat=JsonSerDe,AWSKMSKeyARN=arn:aws:kms:region:account_ID:key/KMS_key_ID,Region=bucket_region" \
  --region region
```

Windows

```bash
aws ssm create-resource-data-sync ^
  --sync-name sync_name ^
  --s3-destination "BucketName=DOC-EXAMPLE-BUCKET,Prefix=prefix_name,if_specified,SyncFormat=JsonSerDe,AWSKMSKeyARN=arn:aws:kms:region:account_ID:key/KMS_key_ID,Region=bucket_region" ^
  --region region
```

9. Run the following command to view the status of sync configuration.
aws ssm list-resource-data-sync

If you created the sync configuration in a different Region, then you must specify the `region` parameter, as shown in the following example.

aws ssm list-resource-data-sync --region us-west-1

10. After the sync configuration is created successfully, examine the target bucket in Amazon S3. Inventory data should be displayed within a few minutes.

**Working with the Data in Amazon Athena**

The following section describes how to view and query the data in Amazon Athena. Before you begin, we recommend that you learn about Athena. For more information, see [What is Amazon Athena?](https://aws.amazon.com/athena/) and [Working with Data](https://docs.aws.amazon.com/athena/latest/userguide/working-with-data.html) in the *Amazon Athena User Guide*.

**To view and query the data in Amazon Athena**

2. Copy and paste the following statement into the query editor and then choose Run Query.

   ```sql
   CREATE DATABASE ssminventory
   ```

   The system creates a database called ssminventory.

3. Copy and paste the following statement into the query editor and then choose Run Query. Replace DOC-EXAMPLE-BUCKET and `bucket_prefix` with the name and prefix of the Amazon S3 target.

   ```sql
   CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_Application (Name string,
   ResourceId string,
   ApplicationType string,
   Publisher string,
   Version string,
   InstalledTime string,
   Architecture string,
   URL string,
   Summary string,
   );
   ```
4. Copy and paste the following statement into the query editor and then choose Run Query.

```
MSCK REPAIR TABLE ssminventory.AWS_Application
```

The system partitions the table.

**Note**

If you create resource data syncs from additional AWS Regions or AWS accounts, then you must run this command again to update the partitions. You might also need to update your Amazon S3 bucket policy.

5. To preview your data, choose the view icon next to the AWS_Application table.

```
SELECT a.name, a.version, count(a.version) frequency
from aws_application a where a.name = 'aws-cfn-bootstrap'
group by a.name, a.version
order by frequency desc
```

The query returns a count of different versions of aws-cfn-bootstrap, which is an AWS application present on Amazon Elastic Compute Cloud (Amazon EC2) instances for Linux, macOS, and Windows Server.

6. Copy and paste the following statement into the query editor and then choose Run Query.

```
SELECT a.name, a.version, count(a.version) frequency
from aws_application a where a.name = 'aws-cfn-bootstrap'
group by a.name, a.version
order by frequency desc
```

7. Individually copy and paste the following statements into the query editor, replace DOC-EXAMPLE-BUCKET and `bucket-prefix` with information for Amazon S3, and then choose Run Query. These statements set up additional inventory tables in Athena.
CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_AWSComponent (  `ResourceId` string,  `Name` string,  `ApplicationType` string,  `Publisher` string,  `Version` string,  `InstalledTime` string,  `Architecture` string,  `URL` string  )  PARTITIONED BY (AccountId string, Region string, ResourceType string)  ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'  WITH SERDEPROPERTIES (  'serialization.format' = '1'  )  LOCATION 's3://DOC-EXAMPLE-BUCKET/bucket-prefix/AWS:AWSComponent/'

MSCK REPAIR TABLE ssminventory.AWS_AWSComponent

CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_WindowsUpdate (  `ResourceId` string,  `HotFixId` string,  `Description` string,  `InstalledTime` string,  `InstalledBy` string  )  PARTITIONED BY (AccountId string, Region string, ResourceType string)  ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'  WITH SERDEPROPERTIES (  'serialization.format' = '1'  )  LOCATION 's3://DOC-EXAMPLE-BUCKET/bucket-prefix/AWS:WindowsUpdate/'

MSCK REPAIR TABLE ssminventory.AWS_WindowsUpdate

CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_InstanceInformation (  `AgentType` string,  `AgentVersion` string,  `ComputerName` string,  `IamRole` string,  `InstanceId` string,  `IpAddress` string  )
`PlatformName` string,
`PlatformType` string,
`PlatformVersion` string
)
PARTITIONED BY (AccountId string, Region string, ResourceType string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES ( 'serialization.format' = '1'
) LOCATION 's3://DOC-EXAMPLE-BUCKET/bucket-prefix/AWS:InstanceInformation/

MSCK REPAIR TABLE ssminventory.AWS_InstanceInformation

CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_Network ( `ResourceId` string,
`Name` string,
`SubnetMask` string,
`Gateway` string,
`DHCPServer` string,
`DNSServer` string,
`MacAddress` string,
`IPV4` string,
`IPV6` string
)
PARTITIONED BY (AccountId string, Region string, ResourceType string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES ( 'serialization.format' = '1'
) LOCATION 's3://DOC-EXAMPLE-BUCKET/bucket-prefix/AWS:Network/

MSCK REPAIR TABLE ssminventory.AWS_Network

CREATE EXTERNAL TABLE IF NOT EXISTS ssminventory.AWS_PatchSummary ( `ResourceId` string,
`PatchGroup` string,
`BaselineId` string,
`SnapshotId` string,
`OwnerInformation` string,
`InstalledCount` int,
`InstalledOtherCount` int,
`NotApplicableCount` int,
`MissingCount` int,
Working with the Data in Amazon QuickSight

The following section provides an overview with links for building a visualization in Amazon QuickSight.

To build a visualization in Amazon QuickSight

1. Sign up for [Amazon QuickSight](https://aws.amazon.com/quicksite/) and then log in to the QuickSight console.
2. Create a data set from the `AWS_Application` table and any other tables you created. For more information, see [Creating a Data Set Using Amazon Athena Data](https://docs.aws.amazon.com/athena/latest/ug/creating-data-set.html).
3. Join tables. For example, you could join the `instanceid` column from `AWS_InstanceInformation` because it matches the `resourceid` column in other inventory tables. For more information about joining tables, see [Joining Tables](https://docs.aws.amazon.com/quicksite/latest/userguide/working-with-tables.html).
4. Build a visualization. For more information, see [Working with Amazon QuickSight Visuals](https://docs.aws.amazon.com/quicksite/latest/userguide/working-with-visuals.html).

Troubleshooting problems with Systems Manager Inventory

This topic includes information about how to troubleshoot common errors or problems with AWS Systems Manager Inventory. If you're having trouble viewing your nodes in Systems Manager, see [Troubleshooting managed node availability](https://docs.aws.amazon.com/systemsmanager/latest/APIReference/API_FilterNodes.html).

Topics

- [Multiple apply all associations with document 'AWS-GatherSoftwareInventory' are not supported](https://docs.aws.amazon.com/systemsmanager/latest/APIReference/API_FilterNodes.html)
- [Inventory execution status never exits pending](https://docs.aws.amazon.com/systemsmanager/latest/APIReference/API_FilterNodes.html)
- The AWS-ListWindowsInventory document fails to run
- Console doesn't display Inventory Dashboard | Detailed View | Settings tabs
- UnsupportedAgent
- Skipped
- Failed
- Inventory compliance failed for an Amazon EC2 instance
- S3 bucket object contains old data

Multiple apply all associations with document 'AWS-GatherSoftwareInventory' are not supported

An error that Multiple apply all associations with document 'AWS-GatherSoftwareInventory' are not supported means that one or more AWS Regions where you're trying to configure an Inventory association for all nodes are already configured with an inventory association for all nodes. If necessary, you can delete the existing inventory association for all nodes and then create a new one. To view existing inventory associations, choose State Manager in the Systems Manager console and then locate associations that use the AWS-GatherSoftwareInventory SSM document. If the existing inventory association for all nodes was created across multiple Regions, and you want to create a new one, you must delete the existing association from each Region where it exists.

Inventory execution status never exits pending

There are two reasons why inventory collection never exits the Pending status:

- No nodes in the selected AWS Region:

  If you create a global inventory association by using Systems Manager Quick Setup, the status of the inventory association (AWS-GatherSoftwareInventory document) shows Pending if there are no nodes available in the selected Region.

- Insufficient permissions:

  An inventory association shows Pending if one or more nodes don't have permission to run Systems Manager Inventory. Verify that the AWS Identity and Access Management (IAM) instance profile includes the AmazonSSMManagedInstanceCore managed policy. For information about how to add this policy to an instance profile, see Alternative configuration for EC2 instance permissions.
At a minimum, the instance profile must have the following IAM permissions.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ssm:DescribeAssociation",
            "ssm:ListAssociations",
            "ssm:ListInstanceAssociations",
            "ssm:PutInventory",
            "ssm:PutComplianceItems",
            "ssm:UpdateAssociationStatus",
            "ssm:UpdateInstanceAssociationStatus",
            "ssm:UpdateInstanceInformation",
            "ssm:GetDocument",
            "ssm:DescribeDocument"
         ],
         "Resource": "*
      }
   ]
}
```

**The AWS-ListWindowsInventory document fails to run**

The AWS-ListWindowsInventory document is deprecated. Don't use this document to collect inventory. Instead, use one of the processes described in [Configuring inventory collection](#).

**Console doesn't display Inventory Dashboard | Detailed View | Settings tabs**

The Inventory **Detailed View** page is only available in AWS Regions that offer Amazon Athena. If the following tabs aren't displayed on the Inventory page, it means Athena isn't available in the Region and you can't use the **Detailed View** to query data.
UnsupportedAgent

If the detailed status of an inventory association shows **UnsupportedAgent**, and the **Association status** shows **Failed**, then the version of AWS Systems Manager SSM Agent on the managed node isn't correct. To create a global inventory association (to inventory all nodes in your AWS account) for example, you must use SSM Agent version 2.0.790.0 or later. You can view the agent version running on each of your nodes on the **Managed Instances** page in the **Agent version** column. For information about how to update SSM Agent on your nodes, see [Updating the SSM Agent using Run Command](#).

Skipped

If the status of the inventory association for a node shows **Skipped**, this means that you created a **global inventory association** (to collect inventory from all nodes), but the skipped node already had an inventory association assigned to it. The global inventory association wasn't assigned to this node, and no inventory was collected by the global inventory association. However, the node will still report inventory data when the existing inventory association runs.

If you don't want the node to be skipped by the global inventory association, you must delete the existing inventory association. To view existing inventory associations, choose **State Manager** in the Systems Manager console and then locate associations that use the **AWS-GatherSoftwareInventory** SSM document.
Failed

If the status of the inventory association for a node shows **Failed**, this could mean that the node has multiple inventory associations assigned to it. A node can only have one inventory association assigned at a time. An inventory association uses the **AWS-GatherSoftwareInventory** AWS Systems Manager document (SSM document). You can run the following command by using the AWS Command Line Interface (AWS CLI) to view a list of associations for a node.

```
aws ssm describe-instance-associations-status
     --instance-id instance ID
```

**Inventory compliance failed for an Amazon EC2 instance**

Inventory compliance for an Amazon Elastic Compute Cloud (Amazon EC2) instance can fail if you assign multiple inventory associations to the instance.

To resolve this issue, delete one or more inventory associations assigned to the instance. For more information, see [Deleting an association](#).

**Note**

Be aware of the following behavior if you create multiple inventory associations for a managed node:

- Each node can be assigned an inventory association that targets all nodes (--targets "Key=Instancelds,Values=*").
- Each node can also be assigned a specific association that uses either tag key-value pairs or an AWS resource group.
- If a node is assigned multiple inventory associations, the status shows **Skipped** for the association that hasn't run. The association that ran most recently displays the actual status of the inventory association.
- If a node is assigned multiple inventory associations and each uses a tag key-value pair, then those inventory associations fail to run on the node because of the tag conflict. The association still runs on nodes that don't have the tag key-value conflict.
S3 bucket object contains old data

Data inside the Amazon S3 bucket object is updated when the inventory association is successful and new data is discovered. The Amazon S3 bucket object is updated for each node when the association runs and fails, but the data inside the object is not updated in this case. Data inside the Amazon S3 bucket object will update only when the association runs successfully. When the inventory association fails, you will see old data in the Amazon S3 bucket object.

AWS Systems Manager Hybrid Activations

To configure non-EC2 machines for use with AWS Systems Manager in a hybrid and multicloud environment, you create a hybrid activation. Non-EC2 machine types supported as managed nodes include the following:

- Servers on your own premises (on-premises servers)
- AWS IoT Greengrass core devices
- AWS IoT and non-AWS edge devices
- Virtual machines (VMs), including VMs in other cloud environments

When you run the create-activation command to start a hybrid activation process, you receive an activation code and ID in the command response. You then include the activation code and ID with the command to install SSM Agent on the machine, as described in step 3 of Using Systems Manager in hybrid and multicloud environments. This activation process applies to all non-EC2 machine types except AWS IoT Greengrass core devices. For information about configuring AWS IoT Greengrass core devices for Systems Manager, see Managing edge devices with Systems Manager.

Note

Support isn't currently provided for non-EC2 macOS machines.

About Systems Manager instances tiers

AWS Systems Manager offers a standard-instances tier and an advanced-instances tier. Both support managed nodes in your hybrid and multicloud environment. The standard-instances tier allows you to register a maximum of 1,000 machines per AWS account per AWS Region. If you
need to register more than 1,000 machines in a single account and Region, then use the advanced-instances tier. You can create as many managed nodes as you like in the advanced-instances tier. All managed nodes configured for Systems Manager are priced on a pay-per-use basis. For more information about enabling the advanced instances tier, see Turning on the advanced-instances tier. For more information about pricing, see AWS Systems Manager Pricing.

Note

• Advanced instances also allow you to connect to your non-EC2 nodes in a hybrid and multicloud environment by using AWS Systems Manager Session Manager. Session Manager provides interactive shell access to your instances. For more information, see AWS Systems Manager Session Manager.
• The standard-instances quota also applies to EC2 instances that use a Systems Manager on-premises activation (which isn't a common scenario).
• To patch applications released by Microsoft on virtual machines (VMs) on-premises instances, activate the advanced-instances tier. There is a charge to use the advanced-instances tier. There is no additional charge to patch applications released by Microsoft on Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information, see About patching applications released by Microsoft on Windows Server.

AWS Systems Manager Session Manager

Session Manager is a fully managed AWS Systems Manager capability. With Session Manager, you can manage your Amazon Elastic Compute Cloud (Amazon EC2) instances, edge devices, on-premises servers, and virtual machines (VMs). You can use either an interactive one-click browser-based shell or the AWS Command Line Interface (AWS CLI). Session Manager provides secure and auditable node management without the need to open inbound ports, maintain bastion hosts, or manage SSH keys. Session Manager also allows you to comply with corporate policies that require controlled access to managed nodes, strict security practices, and fully auditable logs with node access details, while providing end users with simple one-click cross-platform access to your managed nodes. To get started with Session Manager, open the Systems Manager console. In the navigation pane, choose Session Manager.

How can Session Manager benefit my organization?

Session Manager offers these benefits:
• **Centralized access control to managed nodes using IAM policies**

  Administrators have a single place to grant and revoke access to managed nodes. Using only AWS Identity and Access Management (IAM) policies, you can control which individual users or groups in your organization can use Session Manager and which managed nodes they can access.

• **No open inbound ports and no need to manage bastion hosts or SSH keys**

  Leaving inbound SSH ports and remote PowerShell ports open on your managed nodes greatly increases the risk of entities running unauthorized or malicious commands on the managed nodes. Session Manager helps you improve your security posture by letting you close these inbound ports, freeing you from managing SSH keys and certificates, bastion hosts, and jump boxes.

• **One-click access to managed nodes from the console and CLI**

  Using the AWS Systems Manager console or Amazon EC2 console, you can start a session with a single click. Using the AWS CLI, you can also start a session that runs a single command or a sequence of commands. Because permissions to managed nodes are provided through IAM policies instead of SSH keys or other mechanisms, the connection time is greatly reduced.

• **Connect to both Amazon EC2 instances and non-EC2 managed nodes in hybrid and multicloud environments**

  You can connect to both Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 nodes in your hybrid and multicloud environment.

  To connect to non-EC2 nodes using Session Manager, you must first activate the advanced-instances tier. **There is a charge to use the advanced-instances tier.** However, there is no additional charge to connect to EC2 instances using Session Manager. For information, see Configuring instance tiers.

• **Port forwarding**

  Redirect any port inside your managed node to a local port on a client. After that, connect to the local port and access the server application that is running inside the node.

• **Cross-platform support for Windows, Linux, and macOS**

  Session Manager provides support for Windows, Linux, and macOS from a single tool. For example, you don't need to use an SSH client for Linux and macOS managed nodes or an RDP connection for Windows Server managed nodes.

• **Logging and auditing session activity**

How can Session Manager benefit my organization?
To meet operational or security requirements in your organization, you might need to provide a record of the connections made to your managed nodes and the commands that were run on them. You can also receive notifications when a user in your organization starts or ends session activity.

Logging and auditing capabilities are provided through integration with the following AWS services:

- **AWS CloudTrail** – AWS CloudTrail captures information about Session Manager API calls made in your AWS account and writes it to log files that are stored in an Amazon Simple Storage Service (Amazon S3) bucket you specify. One bucket is used for all CloudTrail logs for your account. For more information, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#).

- **Amazon Simple Storage Service** – You can choose to store session log data in an Amazon S3 bucket of your choice for debugging and troubleshooting purposes. Log data can be sent to your Amazon S3 bucket with or without encryption using your AWS KMS key. For more information, see [Logging session data using Amazon S3 (console)](#).

- **Amazon CloudWatch Logs** – CloudWatch Logs allows you to monitor, store, and access log files from various AWS services. You can send session log data to a CloudWatch Logs log group for debugging and troubleshooting purposes. Log data can be sent to your log group with or without AWS KMS encryption using your KMS key. For more information, see [Logging session data using Amazon CloudWatch Logs (console)](#).

- **Amazon EventBridge and Amazon Simple Notification Service** – EventBridge allows you to set up rules to detect when changes happen to AWS resources that you specify. You can create a rule to detect when a user in your organization starts or stops a session, and then receive a notification through Amazon SNS (for example, a text or email message) about the event. You can also configure a CloudWatch event to initiate other responses. For more information, see [Monitoring session activity using Amazon EventBridge (console)](#).

---

**Note**

Logging isn’t available for Session Manager sessions that connect through port forwarding or SSH. This is because SSH encrypts all session data, and Session Manager only serves as a tunnel for SSH connections.
Who should use Session Manager?

- Any AWS customer who wants to improve their security and audit posture, reduce operational overhead by centralizing access control on managed nodes, and reduce inbound node access.

- Information Security experts who want to monitor and track managed node access and activity, close down inbound ports on managed nodes, or allow connections to managed nodes that don't have a public IP address.

- Administrators who want to grant and revoke access from a single location, and who want to provide one solution to users for Linux, macOS, and Windows Server managed nodes.

- Users who want to connect to a managed node with just one click from the browser or AWS CLI without having to provide SSH keys.

What are the main features of Session Manager?

- **Support for Windows Server, Linux and macOS managed nodes**

  Session Manager enables you to establish secure connections to your Amazon Elastic Compute Cloud (EC2) instances, edge devices, on-premises servers, and virtual machines (VMs). For a list of supported operating system types, see [Setting up Session Manager](#).

  **Note**

  Session Manager support for on-premises machines is provided for the advanced-instances tier only. For information, see [Turning on the advanced-instances tier](#).

- **Console, CLI, and SDK access to Session Manager capabilities**

  You can work with Session Manager in the following ways:

  The **AWS Systems Manager console** includes access to all the Session Manager capabilities for both administrators and end users. You can perform any task that is related to your sessions by using the Systems Manager console.

  The Amazon EC2 console provides the ability for end users to connect to EC2 instances for which they have been granted session permissions.

  The **AWS CLI** includes access to Session Manager capabilities for end users. You can start a session, view a list of sessions, and permanently end a session by using the AWS CLI.
To use the AWS CLI to run session commands, you must be using version 1.16.12 of the CLI (or later), and you must have installed the Session Manager plugin on your local machine. For information, see [Install the Session Manager plugin for the AWS CLI](#). To view the plugin on GitHub, see [session-manager-plugin](#).

**IAM access control**

Through the use of IAM policies, you can control which members of your organization can initiate sessions to managed nodes and which nodes they can access. You can also provide temporary access to your managed nodes. For example, you might want to give an on-call engineer (or a group of on-call engineers) access to production servers only for the duration of their rotation.

**Logging and auditing capability support**

Session Manager provide you with options for auditing and logging session histories in your AWS account through integration with a number of other AWS services. For more information, see [Auditing session activity](#) and [Enabling and disabling session activity logging](#).

**Configurable shell profiles**

Session Manager provides you with options to configure preferences within sessions. These customizable profiles allow you to define preferences such as shell preferences, environment variables, working directories, and running multiple commands when a session is started.

**Customer key data encryption support**

You can configure Session Manager to encrypt the session data logs that you send to an Amazon Simple Storage Service (Amazon S3) bucket or stream to a CloudWatch Logs log group. You can also configure Session Manager to further encrypt the data transmitted between client machines and your managed nodes during your sessions. For information, see [Enabling and disabling session activity logging](#) and [Configure session preferences](#).

**AWS PrivateLink support for managed nodes without public IP addresses**

You can also set up VPC Endpoints for Systems Manager using AWS PrivateLink to further secure your sessions. AWS PrivateLink limits all network traffic between your managed nodes, Systems Manager, and Amazon EC2 to the Amazon network. For more information, see [Improve the security of EC2 instances by using VPC endpoints for Systems Manager](#).

**Tunneling**

---

What are the main features of Session Manager?
In a session, use a Session-type AWS Systems Manager (SSM) document to tunnel traffic, such as http or a custom protocol, between a local port on a client machine and a remote port on a managed node.

**Interactive commands**

Create a Session-type SSM document that uses a session to interactively run a single command, giving you a way to manage what users can do on a managed node.

**What is a session?**

A session is a connection made to a managed node using Session Manager. Sessions are based on a secure bi-directional communication channel between the client (you) and the remote managed node that streams inputs and outputs for commands. Traffic between a client and a managed node is encrypted using TLS 1.2, and requests to create the connection are signed using Sigv4. This two-way communication allows interactive bash and PowerShell access to managed nodes. You can also use an AWS Key Management Service (AWS KMS) key to further encrypt data beyond the default TLS encryption.

For example, say that John is an on-call engineer in your IT department. He receives notification of an issue that requires him to remotely connect to a managed node, such as a failure that requires troubleshooting or a directive to change a simple configuration option on a node. Using the AWS Systems Manager console, the Amazon EC2 console, or the AWS CLI, John starts a session connecting him to the managed node, runs commands on the node needed to complete the task, and then ends the session.

When John sends that first command to start the session, the Session Manager service authenticates his ID, verifies the permissions granted to him by an IAM policy, checks configuration settings (such as verifying allowed limits for the sessions), and sends a message to SSM Agent to open the two-way connection. After the connection is established and John types the next command, the command output from SSM Agent is uploaded to this communication channel and sent back to his local machine.

Setting up Session Manager

Before you use AWS Systems Manager Session Manager to connect to the managed nodes in your account, complete the steps in the following topics.

Topics

- **Step 1: Complete Session Manager prerequisites**
- **Step 2: Verify or add instance permissions for Session Manager**
- **Step 3: Control session access to managed nodes**
- **Step 4: Configure session preferences**
- **Step 5: (Optional) Restrict access to commands in a session**
- **Step 6: (Optional) Use AWS PrivateLink to set up a VPC endpoint for Session Manager**
- **Step 7: (Optional) Turn on or turn off ssm-user account administrative permissions**
- **Step 8: (Optional) Allow and control permissions for SSH connections through Session Manager**

**Step 1: Complete Session Manager prerequisites**

Before using Session Manager, make sure your environment meets the following requirements.

**Session Manager prerequisites**

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supported operating systems</td>
<td>Session Manager supports connecting to Amazon Elastic Compute Cloud (Amazon EC2) instances, in addition to non-EC2 machines in your hybrid and multicloud environment that use the advanced-instances tier. Session Manager supports the following operating system versions:</td>
</tr>
<tr>
<td>Requirement</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Session Manager supports EC2 instances, edge devices, and on-premises servers and virtual machines (VMs) in your hybrid and multicloud environment that use the advanced-instances tier. For more information about advanced instances, see Configuring instance tiers.</td>
</tr>
</tbody>
</table>

### Linux and macOS

Session Manager supports all the versions of Linux and macOS that are supported by AWS Systems Manager. For information, see Supported operating systems and machine types.

### Windows

**Note**

Microsoft Windows Server 2016 Nano isn't supported.
<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSM Agent</td>
<td>At minimum, AWS Systems Manager SSM Agent version 2.3.68.0 or later must be installed on the managed nodes you want to connect to through sessions. To use the option to encrypt session data using a key created in AWS Key Management Service (AWS KMS), version 2.3.539.0 or later of SSM Agent must be installed on the managed node. To use shell profiles in a session, SSM Agent version 3.0.161.0 or later must be installed on the managed node. To start a Session Manager port forwarding or SSH session, SSM Agent version 3.0.222.0 or later must be installed on the managed node. To stream session data using Amazon CloudWatch Logs, SSM Agent version 3.0.284.0 or later must be installed on the managed node. For information about how to determine the version number running on an instance, see Checking the SSM Agent version number. For information about manually installing or automatically updating SSM Agent, see Working with SSM Agent.</td>
</tr>
</tbody>
</table>

**About the ssm-user account**

Starting with version 2.3.50.0 of SSM Agent, the agent creates a user account on the managed node, with root or administrator permissions, called ssm-user. (On versions
<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>before 2.3.612.0, the account is created when SSM Agent starts or restarts.</td>
<td>On version 2.3.612.0 and later, <code>ssm-user</code> is created the first time a session starts on the managed node.) Sessions are launched using the administrative credentials of this user account. For information about restricting administrative control for this account, see <a href="#">Turn off or turn on ssm-user account administrative permissions</a>.</td>
</tr>
</tbody>
</table>

**ssm-user on Windows Server domain controllers**

Beginning with SSM Agent version 2.3.612.0, the `ssm-user` account isn't created automatically on managed nodes that are used as Windows Server domain controllers. To use Session Manager on a Windows Server machine being used as a domain controller, you must create the `ssm-user` account manually if it isn't already present, and assign Domain Administrator permissions to the user. On Windows Server, SSM Agent sets a new password for the `ssm-user` account each time a session starts, so you don't need to specify a password when you create the account.

<tbody>
<tr>
<td>AWS CLI</td>
<td>(Optional) If you use the AWS Command Line Interface (AWS CLI) to start your sessions (instead of using the AWS Systems Manager console or Amazon EC2 console), version 1.16.12 or later of the CLI must be installed on your local machine. You can call <code>aws --version</code> to check the version. If you need to install or upgrade the CLI, see <a href="#">Installing the AWS Command Line Interface</a> in the AWS Command Line Interface User Guide.</td>
</tr>
</tbody>
</table>

⚠️ **Important**

An updated version of SSM Agent is released whenever new capabilities are added to Systems Manager or updates are made to existing capabilities. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager capabilities and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see [Automating updates to SSM Agent](#). Subscribe to the [SSM Agent Release Notes](#) page on GitHub to get notifications about SSM Agent updates.
<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Requirement</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Verify IAM service role permissions (<a href="#">hybrid and multicloud</a> environments)</td>
<td>Hybrid-activated nodes use the AWS Identity and Access Management (IAM) service role specified in the hybrid activation to communicate with Systems Manager API operations. This service role must contain the permissions required to connect to your hybrid and multicloud machines using Session Manager. If your service role contains the AWS managed policy <code>AmazonSSMManagedInstanceCore</code>, the required permissions for Session Manager are already provided. If you find that the service role does not contain the required permissions, you must deregister the managed instance and register it with a new hybrid activation that uses an IAM service role with the required permissions. For more information about deregistering managed instances, see <a href="#">Deregistering managed nodes in a hybrid and multicloud environment</a>. For more information about creating IAM policies with Session Manager permissions, see <a href="#">Step 2: Verify or add instance permissions for Session Manager</a>.</td>
</tr>
</tbody>
</table>

### Step 2: Verify or add instance permissions for Session Manager

By default, AWS Systems Manager doesn't have permission to perform actions on your instances. You can provide instance permissions at the account level using an AWS Identity and Access Management (IAM) role, or at the instance level using an instance profile. If your use case allows, we recommend granting access at the account level using the Default Host Management Configuration. If you've already set up the Default Host Management Configuration for your account using the `AmazonSSMManagedEC2InstanceDefaultPolicy` policy, you can proceed to...
the next step. For more information about the Default Host Management Configuration, see Using the Default Host Management Configuration setting.

Alternatively, you can use instance profiles to provide the required permissions to your instances. An instance profile passes an IAM role to an Amazon EC2 instance. You can attach an IAM instance profile to an Amazon EC2 instance as you launch it or to a previously launched instance. For more information, see Using instance profiles.

For on-premises servers or virtual machines (VMs), permissions are provided by the IAM service role associated with the hybrid activation used to register your on-premises servers and VMs with Systems Manager. On-premises servers and VMs do not use instance profiles.

If you already use other Systems Manager capabilities, such as Run Command or Parameter Store, an instance profile with the required basic permissions for Session Manager might already be attached to your Amazon EC2 instances. If an instance profile that contains the AWS managed policy AmazonSSMManagedInstanceCore is already attached to your instances, the required permissions for Session Manager are already provided. This is also true if the IAM service role used in your hybrid activation contains the AmazonSSMManagedInstanceCore managed policy.

⚠️ Important

You can't change the IAM service role associated with a hybrid activation. If you find that the service role does not contain the required permissions, you must deregister the managed instance and register it with a new hybrid activation that uses a service role with the required permissions. For more information about deregistering managed instances, see Deregistering managed nodes in a hybrid and multicloud environment. For more information about creating an IAM service role for on-premises machines, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.

However, in some cases, you might need to modify the permissions attached to your instance profile. For example, you want to provide a narrower set of instance permissions, you have created a custom policy for your instance profile, or you want to use Amazon Simple Storage Service (Amazon S3) encryption or AWS Key Management Service (AWS KMS) encryption options for securing session data. For these cases, do one of the following to allow Session Manager actions to be performed on your instances:

- Embed permissions for Session Manager actions in a custom IAM role
To add permissions for Session Manager actions to an existing IAM role that doesn't rely on the AWS-provided default policy AmazonSSMManagedInstanceCore, follow the steps in Adding Session Manager permissions to an existing IAM role.

- Create a custom IAM role with Session Manager permissions only

To create an IAM role that contains permissions only for Session Manager actions, follow the steps in Create a custom IAM role for Session Manager.

- Create and use a new IAM role with permissions for all Systems Manager actions

To create an IAM role for Systems Manager managed instances that uses a default policy supplied by AWS to grant all Systems Manager permissions, follow the steps in Configure instance permissions required for Systems Manager.

Topics

- Adding Session Manager permissions to an existing IAM role
- Create a custom IAM role for Session Manager

Adding Session Manager permissions to an existing IAM role

Use the following procedure to add Session Manager permissions to an existing AWS Identity and Access Management (IAM) role. By adding permissions to an existing role, you can enhance the security of your computing environment without having to use the AWS AmazonSSMManagedInstanceCore policy for instance permissions.

Note

Note the following information:

- This procedure assumes that your existing role already includes other Systems Manager ssm permissions for actions you want to allow access to. This policy alone isn't enough to use Session Manager.
- The following policy example includes an s3:GetEncryptionConfiguration action. This action is required if you chose the Enforce S3 log encryption option in Session Manager logging preferences.
To add Session Manager permissions to an existing role (console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

2. In the navigation pane, choose Roles.

3. Select the name of the role that you are adding the permissions to.

4. Choose the Permissions tab.

5. Choose Add permissions, and then select Create inline policy.

6. Choose the JSON tab.

7. Replace the default policy content with the following content. Replace key-name with the Amazon Resource Name (ARN) of the AWS Key Management Service key (AWS KMS key) that you want to use.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ssmmessages:CreateControlChannel",
            "ssmmessages:CreateDataChannel",
            "ssmmessages:OpenControlChannel",
            "ssmmessages:OpenDataChannel"
         ],
         "Resource": "*
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetEncryptionConfiguration"
         ],
         "Resource": "*
      },
      {
         "Effect": "Allow",
         "Action": [
            "kms:Decrypt"
         ],
         "Resource": "key-name"
      }
   ]
}
```
For information about using a KMS key to encrypt session data, see Turn on KMS key encryption of session data (console).

If you won't use AWS KMS encryption for your session data, you can remove the following content from the policy.

```json
{}

8. Choose Next: Tags.

9. (Optional) Add tags by choosing Add tag, and entering the preferred tags for the policy.

10. Choose Next: Review.

11. On the Review policy page, for Name, enter a name for the inline policy, such as SessionManagerPermissions.

12. (Optional) For Description, enter a description for the policy.

Choose Create policy.

For information about the ssmmessages actions, see Reference: ec2messages, ssmmessages, and other API operations.

Create a custom IAM role for Session Manager

You can create an AWS Identity and Access Management (IAM) role that grants Session Manager the permission to perform actions on your Amazon EC2 managed instances. You can also include a policy to grant the permissions needed for session logs to be sent to Amazon Simple Storage Service (Amazon S3) and Amazon CloudWatch Logs.

After you create the IAM role, for information about how to attach the role to an instance, see Attach or Replace an Instance Profile at the AWS re:Post website. For more information about
IAM instance profiles and roles, see Using instance profiles in the IAM User Guide and IAM roles for Amazon EC2 in the Amazon Elastic Compute Cloud User Guide for Linux Instances. For more information about creating an IAM service role for on-premises machines, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.

Topics

- Creating an IAM role with minimal Session Manager permissions (console)
- Creating an IAM role with permissions for Session Manager and Amazon S3 and CloudWatch Logs (console)

Creating an IAM role with minimal Session Manager permissions (console)

Use the following procedure to create a custom IAM role with a policy that provides permissions for only Session Manager actions on your instances.

To create an instance profile with minimal Session Manager permissions (console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies, and then choose Create policy. (If a Get Started button is displayed, choose it, and then choose Create Policy.)
3. Choose the JSON tab.
4. Replace the default content with the following policy. To encrypt session data using AWS Key Management Service (AWS KMS), replace key-name with the Amazon Resource Name (ARN) of the AWS KMS key that you want to use.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ssm:UpdateInstanceInformation",
            "ssmmessages:CreateControlChannel",
            "ssmmessages:CreateDataChannel",
            "ssmmessages:OpenControlChannel",
            "ssmmessages:OpenDataChannel"
         ],
         "Resource": "*"
      }
   ]
}
```
For information about using a KMS key to encrypt session data, see Turn on KMS key encryption of session data (console).

If you won’t use AWS KMS encryption for your session data, you can remove the following content from the policy.

```
},
{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ],
  "Resource": "key-name"
}
```

5. Choose **Next: Tags**.
6. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the policy.
7. Choose **Next: Review**.
8. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as `SessionManagerPermissions`.
9. (Optional) For **Description**, enter a description for the policy.
10. Choose **Create policy**.
11. In the navigation pane, choose **Roles**, and then choose **Create role**.
12. On the **Create role** page, choose **AWS service**, and for **Use case**, choose **EC2**.
13. Choose **Next**.
14. On the **Add permissions** page, select the check box to the left of name of the policy you just created, such as `SessionManagerPermissions`. 
15. Choose Next.

16. On the Name, review, and create page, for Role name, enter a name for the IAM role, such as MySessionManagerRole.

17. (Optional) For Role description, enter a description for the instance profile.

18. (Optional) Add tags by choosing Add tag, and entering the preferred tags for the role.

Choose Create role.

For information about ssmmessages actions, see Reference: ec2messages, ssmmessages, and other API operations.

Creating an IAM role with permissions for Session Manager and Amazon S3 and CloudWatch Logs (console)

Use the following procedure to create a custom IAM role with a policy that provides permissions for Session Manager actions on your instances. The policy also provides the permissions needed for session logs to be stored in Amazon Simple Storage Service (Amazon S3) buckets and Amazon CloudWatch Logs log groups.

**Important**

To output session logs to an Amazon S3 bucket owned by a different AWS account, you must add the s3:PutObjectAcl permission to the IAM role policy. Additionally, you must ensure that the bucket policy grants cross-account access to the IAM role used by the owning account to grant Systems Manager permissions for managed instances. If the bucket uses Key Management Service (KMS) encryption, then the bucket’s KMS policy must also grant this cross-account access. For more information about configuring cross-account bucket permissions in Amazon S3, see Granting cross-account bucket permissions in the Amazon Simple Storage Service User Guide. If the cross-account permissions aren’t added, the account that owns the Amazon S3 bucket can’t access the session output logs.

For information about specifying preferences for storing session logs, see Enabling and disabling session activity logging.
To create an IAM role with permissions for Session Manager and Amazon S3 and CloudWatch Logs (console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

2. In the navigation pane, choose Policies, and then choose Create policy. (If a Get Started button is displayed, choose it, and then choose Create Policy.)

3. Choose the JSON tab.

4. Replace the default content with the following policy. Replace each example resource placeholder with your own information.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ssmmessages:CreateControlChannel",
            "ssmmessages:CreateDataChannel",
            "ssmmessages:OpenControlChannel",
            "ssmmessages:OpenDataChannel",
            "ssm:UpdateInstanceInformation"
         ],
         "Resource": "*"
      },
      {
         "Effect": "Allow",
         "Action": [
            "logs:CreateLogStream",
            "logs:PutLogEvents",
            "logs:DescribeLogGroups",
            "logs:DescribeLogStreams"
         ],
         "Resource": "*"
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:PutObject"
         ],
         "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/s3-prefix/*"
      }
   ]
}
```
5. Choose **Next: Tags**.

6. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the policy.

7. Choose **Next: Review**.

8. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **SessionManagerPermissions**.

9. (Optional) For **Description**, enter a description for the policy.

10. Choose **Create policy**.

11. In the navigation pane, choose **Roles**, and then choose **Create role**.

12. On the **Create role** page, choose **AWS service**, and for **Use case**, choose **EC2**.

13. Choose **Next**.

14. On the **Add permissions** page, select the check box to the left of name of the policy you just created, such as **SessionManagerPermissions**.

15. Choose **Next**.

16. On the **Name, review, and create** page, for **Role name**, enter a name for the IAM role, such as **MySessionManagerRole**.
17. (Optional) For **Role description**, enter a description for the role.
18. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the role.
19. Choose **Create role**.

**Step 3: Control session access to managed nodes**

You grant or revoke Session Manager access to managed nodes by using AWS Identity and Access Management (IAM) policies. You can create a policy and attach it to an IAM user or group that specifies which managed nodes the user or group can connect to. You can also specify the Session Manager API operations the user or groups can perform on those managed nodes.

To help you get started with IAM permission policies for Session Manager, we've created sample policies for an end user and an administrator user. You can use these policies with only minor changes. Or, use them as a guide to create custom IAM policies. For more information, see [Sample IAM policies for Session Manager](#). For information about how to create IAM policies and attach them to users or groups, see [Creating IAM Policies](#) and [Adding and Removing IAM Policies](#) in the [IAM User Guide](#).

**About session ID ARN formats**

When you create an IAM policy for Session Manager access, you specify a session ID as part of the Amazon Resource Name (ARN). The session ID includes the user name as a variable. To help illustrate this, here's the format of a Session Manager ARN and an example:

\[
\text{arn:aws:ssm:region-id:account-id:session/session-id}
\]

For example:

\[
\text{arn:aws:ssm:us-east-2:123456789012:session/JohnDoe-1a2b3c4d5eEXAMPLE}
\]

For more information about using variables in IAM policies, see [IAM Policy Elements: Variables](#).

**Topics**

Start a default shell session by specifying the default session document in IAM policies

When you configure Session Manager for your AWS account or when you change session preferences in the Systems Manager console, the system creates an SSM session document called SSM-SessionManagerRunShell. This is the default session document. Session Manager uses this document to store your session preferences, which include information like the following:

- A location where you want to save session data, such as an Amazon Simple Storage Service (Amazon S3) bucket or a Amazon CloudWatch Logs log group.
- An AWS Key Management Service (AWS KMS) key ID for encrypting session data.
- Whether Run As support is allowed for your sessions.

Here is an example of the information contained in the SSM-SessionManagerRunShell session preferences document.

```
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": "DOC-EXAMPLE-BUCKET",
        "s3KeyPrefix": "MyS3Prefix",
        "s3EncryptionEnabled": true,
        "cloudWatchLogGroupName": "MyCWLogGroup",
        "cloudWatchEncryptionEnabled": false,
        "kmsKeyId": "1a2b3c4d",
        "runAsEnabled": true,
        "runAsDefaultUser": "RunAsUser"
    }
}
```

By default, Session Manager uses the default session document when a user starts a session from the AWS Management Console. This applies to either Fleet Manager or Session Manager in the Systems Manager console, or EC2 Connect in the Amazon EC2 console. Session Manager also uses the default session document when a user starts a session by using an AWS CLI command like the following example:

```
aws ssm start-session \
   --target i-02573cafcfEXAMPLE
```
To start a default shell session, you must specify the default session document in the IAM policy, as shown in the following example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnableSSMSession",
      "Effect": "Allow",
      "Action": ["ssm:StartSession"],
      "Resource": [
      ]
    }
  ]
}
```

### Start a session with a document by specifying the session documents in IAM policies

If you use the `start-session` AWS CLI command using the default session document, you can omit the document name. The system automatically calls the `SSM-SessionManagerRunShell` session document.

In all other cases, you must specify a value for the `document-name` parameter. When a user specifies the name of a session document in a command, the system checks their IAM policy to verify they have permission to access the document. If they don't have permission, the connection request fails. The following examples includes the `document-name` parameter with the `AWS-StartPortForwardingSession` session document.

```
aws ssm start-session
  --target i-02573cafcfEXAMPLE
  --document-name AWS-StartPortForwardingSession
  --parameters '{"portNumber":["80"], "localPortNumber":["56789"]}'
```

### Enforce a session document permission check when starting a session

To restrict access to the `AWS-StartPortForwardingSession` session document, you can add a condition element to the user's IAM policy that validates whether the user has explicit access to a
session document. When this condition is applied, the user must specify a value for the document-name option of the `start-session` command. The following condition element, when added to the `ssm:StartSession` action in the IAM policy, performs a session document access check.

```
"Condition": {
  "BoolIfExists": {
    "ssm:SessionDocumentAccessCheck": "true"
  }
}
```

With this condition element set to `true`, explicit access to a session document must be granted in the IAM policy for the user to start a session. To ensure the condition element is enforced, it must be included in all policy statements which allow the `ssm:StartSession` action. Here is an example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnableSSMSession",
      "Effect": "Allow",
      "Action": [
        "ssm:StartSession"
      ],
      "Resource": [
        "arn:aws:ssm:us-west-2::document/AWS-StartPortForwardingSession"
      ],
      "Condition": {
        "BoolIfExists": {
          "ssm:SessionDocumentAccessCheck": "true"
        }
      }
    }
  ]
}
```

With this IAM policy in place, if the `SessionDocumentAccessCheck` condition element is set to `true`, users must enter the document-name parameter in their command when starting a session using the AWS CLI. The value of document-name must be the document specified in the
Resource section of the IAM policy. If the user enters a different document name or they don't specify the document-name parameter, the request fails.

If the SessionDocumentAccessCheck condition element is set to false, it doesn't affect the evaluation of the IAM policy.

For an example of specifying a Session Manager session document in an IAM policy, see Quickstart end user policies for Session Manager.

Other scenarios

To start a session using SSH, configuration steps must be completed on both the target managed node and the user's local machine. For information, see (Optional) Allow and control permissions for SSH connections through Session Manager.

Sample IAM policies for Session Manager

Use the samples in this section to help you create AWS Identity and Access Management (IAM) policies that provide the most commonly needed permissions for Session Manager access.

Note

You can also use an AWS KMS key policy to control which IAM entities (users or roles) and AWS accounts are given access to your KMS key. For information, see Overview of Managing Access to Your AWS KMS Resources and Using Key Policies in AWS KMS in the AWS Key Management Service Developer Guide.

Topics

- Quickstart end user policies for Session Manager
- Quickstart administrator policy for Session Manager

Quickstart end user policies for Session Manager

Use the following examples to create IAM end user policies for Session Manager.

You can create a policy that allows users to start sessions from only the Session Manager console and AWS Command Line Interface (AWS CLI), from only the Amazon Elastic Compute Cloud (Amazon EC2) console, or from all three.
These policies provide end users the ability to start a session to a particular managed node and the ability to end only their own sessions. Refer to [Additional sample IAM policies for Session Manager](#) for examples of customizations you might want to make to the policy.

In the following sample policies, replace each *example resource placeholder* with your own information.

Refer to the following sections to view sample policies for the range of session access you want to provide.

**Session Manager and Fleet Manager**

Use this sample policy to give users the ability to start and resume sessions from only the Session Manager and Fleet Manager consoles.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ssm:StartSession"
         ],
         "Resource": [
            "arn:aws:ssm:region:account-id:document/SSM-SessionManagerRunShell"
         ],
         "Condition": {
            "BoolIfExists": {
               "ssm:SessionDocumentAccessCheck":
               "true"
            }
         }
      },
      {
         "Effect": "Allow",
         "Action": [
            "ssm:DescribeSessions",
            "ssm:GetConnectionStatus",
            "ssm:DescribeInstanceProperties",
            "ec2:DescribeInstances"
         ],
         "Resource": [
            "arn:aws:ec2:region:account-id:instance/instance-id"
         ],
         "Condition": {
            "BoolIfExists": {
               "ssm:SessionDocumentAccessCheck":
               "true"
            }
         }
      }
   ]
}
```
Amazon EC2

Use this sample policy to give users the ability to start and resume sessions from only the Amazon EC2 console. This policy doesn't provide all the permissions needed to start sessions from the Session Manager console and the AWS CLI.
AWS CLI

Use this sample policy to give users the ability to start and resume sessions from the AWS CLI.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:SendCommand"
            ],
            "Resource": [
                "arn:aws:ssm:region:account-id:document/SSM-SessionManagerRunShell"
            ],
            "Condition": {

```
SSM-SessionManagerRunShell is the default name of the SSM document that Session Manager creates to store your session configuration preferences. You can create a custom Session document and specify it in this policy instead. You can also specify the AWS-provided document AWS-StartSSHSession for users who are starting sessions using SSH. For information about configuration steps needed to support sessions using SSH, see (Optional) Allow and control permissions for SSH connections through Session Manager.

If you specify the condition element, ssm:SessionDocumentAccessCheck, as true, the system checks that a user has explicit access to the defined Session document, in this example SSM-SessionManagerRunShell, before a session is established. For more information, see Enforce a session document permission check when starting a session.
3 The `kms:GenerateDataKey` permission enables the creation of a data encryption key that will be used to encrypt session data. If you will use AWS Key Management Service (AWS KMS) encryption for your session data, replace `key-name` with the Amazon Resource Name (ARN) of the KMS key you want to use, in the format `arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-12345EXAMPLE`. If you won't use KMS key encryption for your session data, remove the following content from the policy.

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": "key-name"
}
```

For information about using AWS KMS for encrypting session data, see [Turn on KMS key encryption of session data (console)](https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-turn:kms-key-encryption.html).

4 The permission for `SendCommand` is needed for cases where a user attempts to start a session from the Amazon EC2 console, but the SSM Agent must be updated to the minimum required version for Session Manager first. Run Command is used to send a command to the instance to update the agent.

**Quickstart administrator policy for Session Manager**

Use the following examples to create IAM administrator policies for Session Manager.

These policies provide administrators the ability to start a session to managed nodes that are tagged with `Key=Finance,Value=WebServers`, permission to create, update, and delete preferences, and permission to end only their own sessions. Refer to [Additional sample IAM policies for Session Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-admin-policies.html) for examples of customizations you might want to make to the policy.

You can create a policy that allows administrators to perform these tasks from only the Session Manager console and AWS CLI, from only the Amazon EC2 console, or from all three.

In the following sample policies, replace each `example resource placeholder` with your own information.

Refer to the following sections to view sample policies for the three permissions scenarios.
Session Manager and CLI

Use this sample policy to give administrators the ability to perform session-related tasks from only the Session Manager console and the AWS CLI. This policy doesn't provide all the permissions needed to perform session-related tasks from the Amazon EC2 console.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ssm:StartSession"],
    },
    {"Condition": {
        "StringLike": {
          "ssm:resourceTag/Finance": ["WebServers"]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:DescribeSessions",
        "ssm:GetConnectionStatus",
        "ssm:DescribeInstanceProperties",
        "ssm:DescribeInstances",
        "ec2:DescribeInstances"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:CreateDocument",
        "ssm:UpdateDocument",
        "ssm:GetDocument",
        "ssm:StartSession"
      ]
    }
  ]
}
```
Amazon EC2

Use this sample policy to give administrators the ability to perform session-related tasks from only the Amazon EC2 console. This policy doesn't provide all the permissions needed to perform session-related tasks from the Session Manager console and the AWS CLI.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:SendCommand"
            ],
            "Resource": [
                "arn:aws:ec2:*:*:instance/*"
            ],
            "Condition": {
                "StringLike": {
                    "ssm:resourceTag/tag-key": [
                        "tag-value"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:TerminateSession",
                "ssm:ResumeSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}-*"
            ]
        }
    ]
}
```
Session Manager, CLI, and Amazon EC2

Use this sample policy to give administrators the ability to perform session-related tasks from the Session Manager console, the AWS CLI, and the Amazon EC2 console.
"ssm:SendCommand",

"Resource": [
  "arn:aws:ec2:region:account-id:instance/**"
],

"Condition": {
  "StringLike": {
    "ssm:resourceTag/tag-key": [
      "tag-value"
    ]
  }
},

{
  "Effect": "Allow",
  "Action": [
    "ssm:DescribeSessions",
    "ssm:GetConnectionStatus",
    "ssm:DescribeInstanceInformation",
    "ssm:DescribeInstanceProperties",
    "ec2:DescribeInstances"
  ],
  "Resource": "*"
},

{
  "Effect": "Allow",
  "Action": [
    "ssm:CreateDocument",
    "ssm:UpdateDocument",
    "ssm:GetDocument",
    "ssm:StartSession"
  ],
},

{
  "Effect": "Allow",
  "Action": [
    "ssm:TerminateSession",
    "ssm:ResumeSession"
  ],
  "Resource": [
    "arn:aws:ssm:*::*:session/${aws:userid}-*"
  ]
}
The permission for SendCommand is needed for cases where a user attempts to start a session from the Amazon EC2 console, but a command must be sent to update SSM Agent first.

Additional sample IAM policies for Session Manager

Refer to the following example policies to help you create a custom AWS Identity and Access Management (IAM) policy for any Session Manager user access scenarios you want to support.

Topics

- Example 1: Grant access to documents in the console
- Example 2: Restrict access to specific managed nodes
- Example 3: Restrict access based on tags
- Example 4: Allow a user to end only sessions they started
- Example 5: Allow full (administrative) access to all sessions

Example 1: Grant access to documents in the console

You can allow users to specify a custom document when they launch a session using the Session Manager console. The following example IAM policy grants permission to access documents with names that begin with SessionDocument- in the specified AWS Region and AWS account.

To use this policy, replace each example resource placeholder with your own information.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetDocument",
                "ssm:ListDocuments"
            ],
            "Resource": [
            ]
        }
    ]
}
```
Note

The Session Manager console only supports Session documents that have a sessionType of Standard_Stream which are used to define session preferences. For more information, see Session document schema.

Example 2: Restrict access to specific managed nodes

You can create an IAM policy that defines which managed nodes that a user is allowed to connect to using Session Manager. For example, the following policy grants a user the permission to start, end, and resume their sessions on three specific nodes. The policy restricts the user from connecting to nodes other than those specified.

Note

For federated users, see Example 4: Allow a user to end only sessions they started.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ssm:StartSession"],
      "Resource": [
        "arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890EXAMPLE"
      ]
    }
  ]
}
```
Example 3: Restrict access based on tags

You can restrict access to managed nodes based on specific tags. In the following example, the user is allowed to start and resume sessions (Effect: Allow, Action: ssm:StartSession, ssm:ResumeSession) on any managed node (Resource: arn:aws:ec2:region:987654321098:instance/*) with the condition that the node is a Finance WebServer (ssm:resourceTag/Finance: WebServer). If the user sends a command to a managed node that isn't tagged or that has any tag other than Finance: WebServer, the command result will include AccessDenied.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession"
            ],
            "Resource": [
                "arn:aws:ssm:*:*:session/${aws:userid}**"
            ],
            "Condition": {
                "StringLike": {
                    "Setting up Session Manager"
                }
            }
        }
    ]
}
```
You can create IAM policies that allow a user to start sessions to managed nodes that are tagged with multiple tags. The following policy allows the user to start sessions to managed nodes that have both the specified tags applied to them. If a user sends a command to a managed node that isn't tagged with both of these tags, the command result will include AccessDenied.
"Condition":{
  "StringLike":{
    "ssm:resourceTag/tag-key1": [
      "tag-value1"
    ],
    "ssm:resourceTag/tag-key2": [
      "tag-value2"
    ]
  }
},
{
  "Effect": "Allow",
  "Action": [
    "ssm:StartSession"
  ],
  "Resource": [
  ]
}
}

For more information about creating IAM policies, see Managed Policies and Inline Policies in the IAM User Guide. For more information about tagging managed nodes, see Tagging managed nodes and Tagging your Amazon EC2 resources in the Amazon EC2 User Guide (content applies to Windows and Linux managed nodes). For more information about increasing your security posture against unauthorized root-level commands on your managed nodes, see Restricting access to root-level commands through SSM Agent

Example 4: Allow a user to end only sessions they started

Session Manager provides two methods to control which sessions a federated user in your AWS account is allowed to end.

- Use the variable {aws:userid} in an AWS Identity and Access Management (IAM) permissions policy. Federated users can end only sessions they started. For unfederated users, use the variable {aws:username} instead of {aws:userid}.
- Use tags supplied by AWS tags in an IAM permissions policy. In the policy, you include a condition that allows users to end only sessions that are tagged with specific tags that have been provided
by AWS. This method works for all accounts, including those that use federated IDs to grant access to AWS.

**Method 1: Grant TerminateSession privileges using the variable `{aws:username}`**

The following IAM policy allows a user to view the IDs of all sessions in your account. However, users can interact with managed nodes only through sessions they started. A user who is assigned the following policy can't connect to or end other users' sessions. The policy uses the variable `{aws:username}` to achieve this.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "ssm:DescribeSessions"
         ],
         "Effect": "Allow",
         "Resource": [
            "*
         ]
      },
      {
         "Action": [
            "ssm:TerminateSession"
         ],
         "Effect": "Allow",
         "Resource": [
            "arn:aws:ssm:*:*:session/${aws:username}-*
         ]
      }
   ]
}
```

---

**Note**

This method doesn't work for accounts that grant access to AWS using federated IDs.
Method 2: Grant TerminateSession privileges using tags supplied by AWS

You can control which sessions that a user can end by including conditional tag key variables in an IAM policy. The condition specifies that the user can only end sessions that are tagged with one or both of these specific tag key variables and a specified value.

When a user in your AWS account starts a session, Session Manager applies two resource tags to the session. The first resource tag is `aws:ssmmessages:target-id`, with which you specify the ID of the target the user is allowed to end. The other resource tag is `aws:ssmmessages:session-id`, with a value in the format of `role-id:caller-specified-role-name`.

**Note**

Session Manager doesn’t support custom tags for this IAM access control policy. You must use the resource tags supplied by AWS, described below.

### aws:ssmmessages:target-id

With this tag key, you include the managed node ID as the value in policy. In the following policy block, the condition statement allows a user to end only the node i-02573cafEXAMPLE.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:TerminateSession"
      ],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "ssm:resourceTag/aws:ssmmessages:target-id": [
            "i-02573cafEXAMPLE"
          ]
        }
      }
    }
  ]
}
```
If the user tries to end a session for which they haven’t been granted this TerminateSession permission, they receive an AccessDeniedException error.

**aws:ssmmessages:session-id**

This tag key includes a variable for the session ID as the value in the request to start a session.

The following example demonstrates a policy for cases where the caller type is User. The value you supply for aws:ssmmessages:session-id is the ID of the user. In this example, AIDIODR4TAW7CSEXAMPLE represents the ID of a user in your AWS account. To retrieve the ID for a user in your AWS account, use the IAM command, get-user. For information, see [get-user](#) in the AWS Identity and Access Management section of the [IAM User Guide](#).

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ssm:TerminateSession"
         ],
         "Resource": "*",
         "Condition": {
            "StringLike": {
               "ssm:resourceTag/aws:ssmmessages:session-id": [
                  "AIDIODR4TAW7CSEXAMPLE"
               ]
            }
         }
      }
   ]
}
```

The following example demonstrates a policy for cases where the caller type is AssumedRole. You can use the \{aws:userid\} variable for the value you supply for aws:ssmmessages:session-id. Alternatively, you can hardcode a role ID for the value you supply for aws:ssmmessages:session-id. If you hardcode a role ID, you must provide the value in the format `role-id:caller-specified-role-name`. For example, AIDIODR4TAW7CSEXAMPLE:MyRole.
Important

In order for system tags to be applied, the role ID you supply can contain the following characters only: Unicode letters, 0-9, space, _, ., :, /, =, +, -, @, and \.

To retrieve the role ID for a role in your AWS account, use the `get-caller-identity` command. For information, see `get-caller-identity` in the AWS CLI Command Reference.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ssm:TerminateSession"],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "ssm:resourceTag/aws:ssmmessages:session-id": ["${aws:userid}"],
        }
      }
    }
  ]
}
```

If a user tries to end a session for which they haven’t been granted this `TerminateSession` permission, they receive an `AccessDeniedException` error.

**aws:ssmmessages:target-id** and **aws:ssmmessages:session-id**

You can also create IAM policies that allow a user to end sessions that are tagged with both system tags, as shown in this example.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ssm:StopSession"],
      "Resource": ["*"],
      "Condition": {
        "StringLike": {
          "ssm:resourceTag/aws:ssmmessages:session-id": ["${aws:userid}"],
          "ssm:resourceTag/aws:ssmmessages:target-id": ["${aws:userid}"],
        }
      }
    }
  ]
}
```
Example 5: Allow full (administrative) access to all sessions

The following IAM policy allows a user to fully interact with all managed nodes and all sessions created by all users for all nodes. It should be granted only to an Administrator who needs full control over your organization’s Session Manager activities.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ssm:StartSession",
                "ssm:TerminateSession",
                "ssm:ResumeSession",
                "ssm:DescribeSessions",
                "ssm:GetConnectionStatus"
            ],
            "Effect": "Allow",
            "Resource": [
                "*"
            ]
        }
    ]
}
```
Step 4: Configure session preferences

Users that have been granted administrative permissions in their AWS Identity and Access Management (IAM) policy can configure session preferences, including the following:

• Turn on Run As support for Linux managed nodes. This makes it possible to start sessions using the credentials of a specified operating system user instead of the credentials of a system-generated `ssm-user` account that AWS Systems Manager Session Manager can create on a managed node.

• Configure Session Manager to use AWS KMS key encryption to provide additional protection to the data transmitted between client machines and managed nodes.

• Configure Session Manager to create and send session history logs to an Amazon Simple Storage Service (Amazon S3) bucket or an Amazon CloudWatch Logs log group. The stored log data can then be used to audit or report on the session connections made to your managed nodes and the commands run on them during the sessions.

• Configure session timeouts. You can use this setting to specify when to end a session after a period of inactivity.

• Configure Session Manager to use configurable shell profiles. These customizable profiles allow you to define preferences within sessions such as shell preferences, environment variables, working directories, and running multiple commands when a session is started.

For more information about the permissions needed to configure Session Manager preferences, see the section called “Grant or deny a user permissions to update Session Manager preferences”.

Topics

• Grant or deny a user permissions to update Session Manager preferences

• Specify an idle session timeout value

• Specify maximum session duration

• Allow configurable shell profiles

• Turn on Run As support for Linux and macOS managed nodes

• Turn on KMS key encryption of session data (console)

• Create a Session Manager preferences document (command line)

• Update Session Manager preferences (command line)
For information about using the Systems Manager console to configure options for logging session data, see the following topics:

- Logging session data using Amazon S3 (console)
- Streaming session data using Amazon CloudWatch Logs (console)
- Logging session data using Amazon CloudWatch Logs (console)

**Grant or deny a user permissions to update Session Manager preferences**

Account preferences are stored as AWS Systems Manager (SSM) documents for each AWS Region. Before a user can update account preferences for sessions in your account, they must be granted the necessary permissions to access the type of SSM document where these preferences are stored. These permissions are granted through an AWS Identity and Access Management (IAM) policy.

**Administrator policy to allow preferences to be created and updated**

An administrator can have the following policy to create and update preferences at any time. The following policy allows permission to access and update the SSM-SessionManagerRunShell document in the us-east-2 account 123456789012.

```json
{
  "Version": "2012-10-17",
  "Statement": [ 
    { 
      "Action": [ 
        "ssm:CreateDocument",
        "ssm:GetDocument",
        "ssm:UpdateDocument",
        "ssm:DeleteDocument"
      ],
      "Effect": "Allow",
      "Resource": [ 
      ]
    } 
  ]
}
```

**User policy to prevent preferences from being updated**
Use the following policy to prevent end users in your account from updating or overriding any Session Manager preferences.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ssm:CreateDocument",
        "ssm:GetDocument",
        "ssm:UpdateDocument",
        "ssm:DeleteDocument"
      ],
      "Effect": "Deny",
      "Resource": [
      ]
    }
  ]
}
```

Specify an idle session timeout value

Session Manager, a capability of AWS Systems Manager, allows you to specify the amount of time to allow a user to be inactive before the system ends a session. By default, sessions time out after 20 minutes of inactivity. You can modify this setting to specify that a session times out between 1 and 60 minutes of inactivity. Some professional computing security agencies recommend setting idle session timeouts to a maximum of 15 minutes.

**To allow idle session timeout (console)**

2. In the navigation pane, choose Session Manager.
3. Choose the Preferences tab, and then choose Edit.
4. Specify the amount of time to allow a user to be inactive before a session ends in the minutes field under Idle session timeout.
5. Choose Save.
Specify maximum session duration

Session Manager, a capability of AWS Systems Manager, allows you to specify the maximum duration of a session before it ends. By default, sessions do not have a maximum duration. The value you specify for maximum session duration must be between 1 and 1,440 minutes.

To specify maximum session duration (console)

2. In the navigation pane, choose Session Manager.
3. Choose the Preferences tab, and then choose Edit.
4. Select the check box next to Enable maximum session duration.
5. Specify the maximum duration of session before it ends in the minutes field under Maximum session duration.
6. Choose Save.

Allow configurable shell profiles

By default, sessions on EC2 instances for Linux start using the Bourne shell (sh). However, you might prefer to use another shell like bash. By allowing configurable shell profiles, you can customize preferences within sessions such as shell preferences, environment variables, working directories, and running multiple commands when a session is started.

⚠️ Important

Systems Manager doesn't check the commands or scripts in your shell profile to see what changes they would make to an instance before they're run. To restrict a user's ability to modify commands or scripts entered in their shell profile, we recommend the following:

- Create a customized Session-type document for your AWS Identity and Access Management (IAM) users and roles. Then modify the IAM policy for these users and roles so the StartSession API operation can only use the Session-type document you have created for them. For information see, Create a Session Manager preferences document (command line) and Quickstart end user policies for Session Manager.
- Modify the IAM policy for your IAM users and roles to deny access to the UpdateDocument API operation for the Session-type document resource you create.
To turn on configurable shell profiles

2. In the navigation pane, choose Session Manager.
3. Choose the Preferences tab, and then choose Edit.
4. Specify the environment variables, shell preferences, or commands you want to run when your session starts in the fields for the applicable operating systems.
5. Choose Save.

The following are some example commands that can be added to your shell profile.

Change to the bash shell and change to the /usr directory on Linux instances.

```
exec /bin/bash
cd /usr
```

Output a timestamp and welcome message at the start of a session.

Linux & macOS

```
timestamp=$(date '+%Y-%m-%dT%H:%M:%SZ')
user=$(whoami)
echo $timestamp && echo "Welcome $user"!
```

```
echo "You have logged in to a production instance. Note that all session activity is being logged."
```

Windows

```
$timestamp = (Get-Date).ToString("yyyy-MM-ddTH:mm:ssZ")
$splitName = (whoami).Split("\")
$user = $splitName[1]
Write-Host $timestamp
Write-Host "Welcome $user!"
```
View dynamic system activity at the start of a session.

**Linux & macOS**

```bash
Write-Host "Handles  NPM(K)    PM(K)      WS(K) VM(M)   CPU(s)     Id ProcessName"
Write-Host "-------  ------    -----      ----- -----   ------     -- -----------"
```

**Windows**

```bash
while ($true) { Get-Process | Sort-Object -Descending CPU | Select-Object -First 30;
    Start-Sleep -Seconds 2; cls
    Write-Host "Handles  NPM(K)    PM(K)      WS(K) VM(M)   CPU(s)     Id ProcessName"
    Write-Host "-------  ------    -----      ----- -----   ------     -- -----------"}
```

**Turn on Run As support for Linux and macOS managed nodes**

By default, Session Manager authenticates connections using the credentials of the system-generated `ssm-user` account that is created on a managed node. (On Linux and macOS machines, this account is added to `/etc/sudoers/`.) If you choose, you can instead authenticate sessions using the credentials of an operating system (OS) user account. In this case, Session Manager verifies that the OS account that you specified exists on the node before starting the session. If you attempt to start a session using an OS account that doesn't exist on the node, the connection fails.

### Note

Session Manager does not support using an operating system's root user account to authenticate connections. For sessions that are authenticated using an OS user account, the node's OS-level and directory policies, like login restrictions or system resource usage restrictions, might not apply.

**How it works**

If you turn on Run As support for sessions, the system checks for access permissions as follows:
1. For the user who is starting the session, has their IAM entity (user or role) been tagged with SSMSessionRunAs = *os user account name*?

   If Yes, does the OS user name exist on the managed node? If it does, start the session. If it doesn't, don't allow a session to start.

   If the IAM entity has not been tagged with SSMSessionRunAs = *os user account name*, continue to step 2.

2. If the IAM entity hasn't been tagged with SSMSessionRunAs = *os user account name*, has an OS user name been specified in the AWS account's Session Manager preferences?

   If Yes, does the OS user name exist on the managed node? If it does, start the session. If it doesn't, don't allow a session to start.

---

**Note**

When you activate Run As support, it prevents Session Manager from starting sessions using the `ssm-user` account on a managed node. This means that if Session Manager fails to connect using the specified OS user account, it doesn't fall back to connecting using the default method.

If you activate Run As without specifying an OS account or tagging an IAM entity, and you have not specified an OS account in Session Manager preferences, session connection attempts will fail.

---

**To turn on Run As support for Linux and macOS managed nodes**

2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Enable Run As support for Linux instances**.
5. Do one of the following:
   - **Option 1**: In the **Operating system user name** field, enter the name of the OS user account that you want to use to start sessions. Using this option, all sessions are run by the same OS user for all users in your AWS account who connect using Session Manager.
• **Option 2** (Recommended): Choose the IAM console link. In the navigation pane, choose either Users or Roles. Choose the entity (user or role) to add tags to, and then choose the Tags tab. Enter SSMSessionRunAs for the key name. Enter the name of an OS user account for the key value. Choose **Save changes**.

Using this option, you can specify unique OS users for different IAM entities if you choose. For more information about tagging IAM entities (users or roles), see [Tagging IAM resources](#) in the IAM User Guide

The following is an example.

```
<table>
<thead>
<tr>
<th>Key</th>
<th>Value (optional)</th>
<th>Remove</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSMSessionRunAs</td>
<td>My-OS-User-Name</td>
<td></td>
</tr>
</tbody>
</table>

You can add 49 more tags.
```

6. Choose **Save**.

**Turn on KMS key encryption of session data (console)**

Use AWS Key Management Service (AWS KMS) to create and manage encryption keys. With AWS KMS, you can control the use of encryption across a wide range of AWS services and in your applications. You can specify that session data transmitted between your managed nodes and the local machines of users in your AWS account is encrypted using KMS key encryption. (This is in addition to the TLS 1.2 encryption that AWS already provides by default.) To encrypt Session Manager session data, create a symmetric KMS key using AWS KMS.

AWS KMS encryption is available for Standard_Stream, InteractiveCommands, and NonInteractiveCommands session types. To use the option to encrypt session data using a key created in AWS KMS, version 2.3.539.0 or later of AWS Systems Manager SSM Agent must be installed on the managed node.
You must allow AWS KMS encryption in order to reset passwords on your managed nodes from the AWS Systems Manager console. For more information, see [Reset a password on a managed node](#).

You can use a key that you created in your AWS account. You can also use a key that was created in a different AWS account. The creator of the key in a different AWS account must provide you with the permissions needed to use the key.

After you turn on KMS key encryption for your session data, both the users who start sessions and the managed nodes that they connect to must have permission to use the key. You provide permission to use the KMS key with Session Manager through AWS Identity and Access Management (IAM) policies. For information, see the following topics:

- Add AWS KMS permissions for users in your account: [Sample IAM policies for Session Manager](#).
- Add AWS KMS permissions for managed nodes in your account: [Step 2: Verify or add instance permissions for Session Manager](#).

For more information about creating and managing KMS keys, see the [AWS Key Management Service Developer Guide](#).

For information about using the AWS CLI to turn on KMS key encryption of session data in your account, see [Create a Session Manager preferences document (command line)](#) or [Update Session Manager preferences (command line)](#).

There is a charge to use KMS keys. For information, see [AWS Key Management Service pricing](#).

### To turn on KMS key encryption of session data (console)

2. In the navigation pane, choose **Session Manager**.
3. Choose the **Preferences** tab, and then choose **Edit**.

4. Select the check box next to **Enable KMS encryption**.

5. Do one of the following:

   - Choose the button next to **Select a KMS key in my current account**, then select a key from the list.

   -or-

   Choose the button next to **Enter a KMS key alias or KMS key ARN**. Manually enter a KMS key alias for a key created in your current account, or enter the key Amazon Resource Name (ARN) for a key in another account. The following are examples:

     - Key alias: `alias/my-kms-key-alias`
     - Key ARN: `arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-12345EXAMPLE`

   -or-

   Choose **Create new key** to create a new KMS key in your account. After you create the new key, return to the **Preferences** tab and select the key for encrypting session data in your account.

   For more information about sharing keys, see [Allowing External AWS accounts to Access a key](#) in the *AWS Key Management Service Developer Guide*.

6. Choose **Save**.

**Create a Session Manager preferences document (command line)**

Use the following procedure to create SSM documents that define your preferences for AWS Systems Manager Session Manager sessions. You can use the document to configure session options including data encryption, session duration, and logging. For example, you can specify whether to store session log data in an Amazon Simple Storage Service (Amazon S3) bucket or Amazon CloudWatch Logs log group. You can create documents that define general preferences for all sessions for an AWS account and AWS Region, or that define preferences for individual sessions.
You can also configure general session preferences by using the Session Manager console.

Documents used to set Session Manager preferences must have a sessionType of Standard_Stream. For more information about Session documents, see the section called “Session document schema”.

For information about using the command line to update existing Session Manager preferences, see Update Session Manager preferences (command line).

For an example of how to create session preferences using AWS CloudFormation, see Create a Systems Manager document for Session Manager preferences in the AWS CloudFormation User Guide.

This procedure describes how to create documents for setting Session Manager preferences at the AWS account level. To create documents that will be used for setting session-level preferences, specify a value other than SSM-SessionManagerRunShell for the file name related command inputs.

To use your document to set preferences for sessions started from the AWS Command Line Interface (AWS CLI), provide the document name as the --document-name parameter value. To set preferences for sessions started from the Session Manager console, you can type or select the name of your document from a list.

To create Session Manager preferences (command line)

1. Create a JSON file on your local machine with a name such as SessionManagerRunShell.json, and then paste the following content into it.

```json
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": "",
        "s3KeyPrefix": ""
    }
}
```
You can also pass values to your session preferences using parameters instead of hardcoding the values as shown in the following example.

```json
{
    "schemaVersion":"1.0",
    "description":"Session Document Parameter Example JSON Template",
    "sessionType":"Standard_Stream",
    "parameters":{
        "s3BucketName":{
            "type":"String",
            "default":""
        },
        "s3KeyPrefix":{
            "type":"String",
            "default":""
        },
        "s3EncryptionEnabled":{
            "type":"Boolean",
            "default":"false"
        },
        "cloudWatchLogGroupName":{
            "type":"String",
            "default":""
        },
        "cloudWatchEncryptionEnabled":{
            "type":"Boolean",
            "default":"false"
        }
    }
}
```
2. Specify where you want to send session data. You can specify an S3 bucket name (with an optional prefix) or a CloudWatch Logs log group name. If you want to further encrypt data between local client and managed nodes, provide the KMS key to use for encryption. The following is an example.

```json
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": "DOC-EXAMPLE-BUCKET",
        "s3KeyPrefix": "MyS3Prefix",
        "s3EncryptionEnabled": true,
        "cloudWatchLogGroupName": "MyLogGroupName",
        "cloudWatchEncryptionEnabled": true,
        "cloudWatchStreamingEnabled": false,
        "kmsKeyId": "MyKMSKeyID",
        "runAsEnabled": true,
        "runAsDefaultUser": "MyDefaultRunAsUser",
        "idleSessionTimeout": "20",
        "maxSessionDuration": "60",
        "shellProfile": {
            "windows": "MyCommands",
            "linux": "MyCommands"
        }
    }
}
```
Note

If you don't want to encrypt the session log data, change `true` to `false` for `s3EncryptionEnabled`. If you aren't sending logs to either an Amazon S3 bucket or a CloudWatch Logs log group, don't want to encrypt active session data, or don't want to turn on Run As support for the sessions in your account, you can delete the lines for those options. Make sure the last line in the `inputs` section doesn't end with a comma. If you add a KMS key ID to encrypt your session data, both the users who start sessions and the managed nodes that they connect to must have permission to use the key. You provide permission to use the KMS key with Session Manager through IAM policies. For information, see the following topics:

- Add AWS KMS permissions for users in your account: [Sample IAM policies for Session Manager](#)
- Add AWS KMS permissions for managed nodes in your account: [Step 2: Verify or add instance permissions for Session Manager](#)

3. Save the file.

4. In the directory where you created the JSON file, run the following command.

**Linux & macOS**

```
aws ssm create-document \
--name SSM-SessionManagerRunShell \
--content "file://SessionManagerRunShell.json" \
--document-type "Session" \
--document-format JSON
```

**Windows**

```
aws ssm create-document ^
   --name SSM-SessionManagerRunShell ^
   --content "file://SessionManagerRunShell.json" ^
   --document-type "Session" ^
   --document-format JSON
```
PowerShell

```
New-SSMDocument 
-Name "SSM-SessionManagerRunShell" 
-Content (Get-Content -Raw SessionManagerRunShell.json) 
-DocumentType "Session" 
-DocumentFormat JSON
```

If successful, the command returns output similar to the following.

```
{
   "DocumentDescription": {
      "Status": "Creating",
      "Hash": "ce4fd0a2ab9b0fae759004ba603174c3ec2231f21a81db8690a33eb66EXAMPLE",
      "Name": "SSM-SessionManagerRunShell",
      "Tags": [],
      "DocumentType": "Session",
      "PlatformTypes": [
         "Windows",
         "Linux"
      ],
      "DocumentVersion": "1",
      "HashType": "Sha256",
      "CreatedDate": 1547750660.918,
      "Owner": "111122223333",
      "SchemaVersion": "1.0",
      "DefaultVersion": "1",
      "DocumentFormat": "JSON",
      "LatestVersion": "1"
   }
}
```

**Update Session Manager preferences (command line)**

The following procedure describes how to use your preferred command line tool to make changes to the AWS Systems Manager Session Manager preferences for your AWS account in the selected AWS Region. Use Session Manager preferences to specify options for logging session data in an Amazon Simple Storage Service (Amazon S3) bucket or Amazon CloudWatch Logs log group. You can also use Session Manager preferences to encrypt your session data.
To update Session Manager preferences (command line)

1. Create a JSON file on your local machine with a name such as SessionManagerRunShell.json, and then paste the following content into it.

```json
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": ",",
        "s3KeyPrefix": ",",
        "s3EncryptionEnabled": true,
        "cloudWatchLogGroupName": ",",
        "cloudWatchEncryptionEnabled": true,
        "cloudWatchStreamingEnabled": false,
        "kmsKeyId": ",",
        "runAsEnabled": true,
        "runAsDefaultUser": ",",
        "idleSessionTimeout": ",",
        "maxSessionDuration": ",",
        "shellProfile": {
            "windows": "date",
            "linux": "pwd;ls"
        }
    }
}
```

2. Specify where you want to send session data. You can specify an S3 bucket name (with an optional prefix) or a CloudWatch Logs log group name. If you want to further encrypt data between local client and managed nodes, provide the AWS KMS key to use for encryption. The following is an example.

```json
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": "DOC-EXAMPLE-BUCKET",
        "s3KeyPrefix": "MyS3Prefix",
        "s3EncryptionEnabled": true,
        "cloudWatchLogGroupName": "MyLogGroupName",
```

"cloudWatchEncryptionEnabled": true,
"cloudWatchStreamingEnabled": false,
"kmsKeyId": "MyKMSKeyID",
"runAsEnabled": true,
"runAsDefaultUser": "MyDefaultRunAsUser",
"idleSessionTimeout": "20",
"maxSessionDuration": "60",
"shellProfile": {
    "windows": "MyCommands",
    "linux": "MyCommands"
}
}
}

° Note

If you don't want to encrypt the session log data, change true to false for s3EncryptionEnabled.
If you aren't sending logs to either an Amazon S3 bucket or a CloudWatch Logs log group, don't want to encrypt active session data, or don't want to turn on Run As support for the sessions in your account, you can delete the lines for those options.
Make sure the last line in the inputs section doesn't end with a comma.
If you add a KMS key ID to encrypt your session data, both the users who start sessions and the managed nodes that they connect to must have permission to use the key. You provide permission to use the KMS key with Session Manager through AWS Identity and Access Management (IAM) policies. For information, see the following topics:

- Add AWS KMS permissions for users in your account: Sample IAM policies for Session Manager.
- Add AWS KMS permissions for managed nodes in your account: Step 2: Verify or add instance permissions for Session Manager.

3. Save the file.
4. In the directory where you created the JSON file, run the following command.

    Linux & macOS

    aws ssm update-document \  
        --name "SSM-SessionManagerRunShell"

Setting up Session Manager
Windows

```bash
aws ssm update-document ^
--name "SSM-SessionManagerRunShell" ^
--content "file://SessionManagerRunShell.json" ^
--document-version "$LATEST"
```

PowerShell

```powershell
Update-SSMDocument `
-Name "SSM-SessionManagerRunShell" `
-Content (Get-Content -Raw SessionManagerRunShell.json) `
-DocumentVersion '$LATEST'
```

If successful, the command returns output similar to the following.

```json
{
    "DocumentDescription": {
        "Status": "Updating",
        "Hash": "ce4fd0a2ab9b0fae759004ba603174c3ec2231f21a81db8690a33eb66EXAMPLE",
        "Name": "SSM-SessionManagerRunShell",
        "Tags": [],
        "DocumentType": "Session",
        "PlatformTypes": [
            "Windows",
            "Linux"
        ],
        "DocumentVersion": "2",
        "HashType": "Sha256",
        "CreatedDate": 1537206341.565,
        "Owner": "111122223333",
        "SchemaVersion": "1.0",
        "DefaultVersion": "1",
        "DocumentFormat": "JSON",
        "LatestVersion": "2"
    }
}
```
Step 5: (Optional) Restrict access to commands in a session

You can restrict the commands that a user can run in an AWS Systems Manager Session Manager session by using a custom Session type AWS Systems Manager (SSM) document. In the document, you define the command that is run when the user starts a session and the parameters that the user can provide to the command. The Session document schemaVersion must be 1.0, and the sessionType of the document must be InteractiveCommands. You can then create AWS Identity and Access Management (IAM) policies that allow users to access only the Session documents that you define. For more information about using IAM policies to restrict access to commands in a session, see IAM policy examples for interactive commands.

Documents with the sessionType of InteractiveCommands are only supported for sessions started from the AWS Command Line Interface (AWS CLI). The user provides the custom document name as the --document-name parameter value and provides any command parameter values using the --parameters option. For more information about running interactive commands, see Starting a session (interactive and noninteractive commands).

Use following procedure to create a custom Session type SSM document that defines the command a user is allowed to run.

Restrict access to commands in a session (console)

To restrict the commands a user can run in a Session Manager session (console)

2. In the navigation pane, choose Documents.
3. Choose Create command or session.
4. For Name, enter a descriptive name for the document.
5. For Document type, choose Session document.
6. Enter your document content that defines the command a user can run in a Session Manager session using JSON or YAML, as shown in the following example.

YAML

```yaml
---
schemaVersion: '1.0'
description: Document to view a log file on a Linux instance
sessionType: InteractiveCommands
```
parameters:
  logpath:
    type: String
    description: The log file path to read.
    default: "/var/log/amazon/ssm/amazon-ssm-agent.log"
    allowedPattern: "^[a-zA-Z0-9-_/]+(.log)$"

properties:
  linux:
    commands: "tail -f {{ logpath }}"
    runAsElevated: true

JSON

{
  "schemaVersion": "1.0",
  "description": "Document to view a log file on a Linux instance",
  "sessionType": "InteractiveCommands",
  "parameters": {
    "logpath": {
      "type": "String",
      "description": "The log file path to read.",
      "default": "/var/log/amazon/ssm/amazon-ssm-agent.log",
      "allowedPattern": "^[a-zA-Z0-9-_/]+(.log)$"
    }
  },
  "properties": {
    "linux": {
      "commands": "tail -f {{ logpath }}",
      "runAsElevated": true
    }
  }
}

7. Choose **Create document**.

**Restrict access to commands in a session (command line)**

**Before you begin**

If you haven’t already, install and configure the AWS Command Line Interface (AWS CLI) or the AWS Tools for PowerShell. For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).
To restrict the commands a user can run in a Session Manager session (command line)

1. Create a JSON or YAML file for your document content that defines the command a user can run in a Session Manager session, as shown in the following example.

YAML

```yaml
---
schemaVersion: '1.0'
description: Document to view a log file on a Linux instance
sessionType: InteractiveCommands
parameters:
  logpath:
    type: String
description: The log file path to read.
default: "/var/log/amazon/ssm/amazon-ssm-agent.log"
allowedPattern: "^[a-zA-Z0-9-/_]+(.log)$"
properties:
linux:
  commands: "tail -f {{ logpath }}"
runAsElevated: true
```

JSON

```json
{
    "schemaVersion": "1.0",
    "description": "Document to view a log file on a Linux instance",
    "sessionType": "InteractiveCommands",
    "parameters": {
        "logpath": {
            "type": "String",
            "description": "The log file path to read.",
            "default": "/var/log/amazon/ssm/amazon-ssm-agent.log",
            "allowedPattern": "^[a-zA-Z0-9-/_]+(.log)$"
        }
    },
    "properties": {
        "linux": {
            "commands": "tail -f {{ logpath }}",
            "runAsElevated": true
        }
    }
}
```
2. Run the following commands to create an SSM document using your content that defines the command a user can run in a Session Manager session.

**Linux & macOS**

```bash
aws ssm create-document \
--content file://path/to/file/documentContent.json \n--name "exampleAllowedSessionDocument" \n--document-type "Session"
```

**Windows**

```bash
aws ssm create-document ^
--content file://C:\path\to\file\documentContent.json ^
--name "exampleAllowedSessionDocument" ^
--document-type "Session"
```

**PowerShell**

```powershell
$json = Get-Content -Path "C:\path\to\file\documentContent.json" | Out-String
New-SSMDocument `
-Content $json `
-Name "exampleAllowedSessionDocument" `
-DocumentType "Session"
```

**Interactive command parameters and the AWS CLI**

There are a variety of ways you can provide interactive command parameters when using the AWS CLI. Depending on the operating system (OS) of your client machine that you use to connect to managed nodes with the AWS CLI, the syntax you provide for commands that contain special or escape characters might differ. The following examples show some of the different ways you can provide command parameters when using the AWS CLI, and how to handle special or escape characters.

Parameters stored in Parameter Store can be referenced in the AWS CLI for your command parameters as shown in the following example.
Linux & macOS

aws ssm start-session \
    --target instance-id \
    --document-name MyInteractiveCommandDocument \
    --parameters '"command":['{{ssm:mycommand}}']"

Windows

aws ssm start-session ^
    --target instance-id ^
    --document-name MyInteractiveCommandDocument ^
    --parameters '"command":['{{ssm:mycommand}}']"

The following example shows how you can use a shorthand syntax with the AWS CLI to pass parameters.

Linux & macOS

aws ssm start-session \
    --target instance-id \
    --document-name MyInteractiveCommandDocument \
    --parameters command="ifconfig"

Windows

aws ssm start-session ^
    --target instance-id ^
    --document-name MyInteractiveCommandDocument ^
    --parameters command="ipconfig"

You can also provide parameters in JSON as shown in the following example.

Linux & macOS

aws ssm start-session \
    --target instance-id \
    --document-name MyInteractiveCommandDocument \
    --parameters '"command":['ifconfig']"
Parameters can also be stored in a JSON file and provided to the AWS CLI as shown in the following example. For more information about using AWS CLI parameters from a file, see Loading AWS CLI parameters from a file in the AWS Command Line Interface User Guide.

```json
{
    "command": [
        "my command"
    ]
}
```

You can also generate an AWS CLI skeleton from a JSON input file as shown in the following example. For more information about generating AWS CLI skeletons from JSON input files, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the AWS Command Line Interface User Guide.

```json
{
    "Target": "instance-id",
}
"DocumentName": "MyInteractiveCommandDocument",
"Parameters": {
    "command": [
        "my command"
    ]
}
}

Linux & macOS

aws ssm start-session \
--cli-input-json file://complete/path/to/file/parameters.json

Windows

aws ssm start-session ^
--cli-input-json file://complete/path/to/file/parameters.json

To escape characters inside quotation marks, you must add additional backslashes to the escape characters as shown in the following example.

Linux & macOS

aws ssm start-session \
--target instance-id \
--document-name MyInteractiveCommandDocument \
--parameters '{"command": ["printf "abc\\tdef"" ]}'

Windows

aws ssm start-session ^
--target instance-id ^
--document-name MyInteractiveCommandDocument ^
--parameters '{"command": ["printf "abc\\tdef"" ]}'

For information about using quotation marks with command parameters in the AWS CLI, see Using quotation marks with strings in the AWS CLI in the AWS Command Line Interface User Guide.
IAM policy examples for interactive commands

You can create IAM policies that allow users to access only the Session documents you define. This restricts the commands a user can run in a Session Manager session to only the commands defined in your custom Session type SSM documents.

Allow a user to run an interactive command on a single managed node

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action":"ssm:StartSession",
            "Resource": [  
            ],
            "Condition":{
                "BoolIfExists":{
                    "ssm:SessionDocumentAccessCheck":"true"
                }
            }
        }
    ]
}
```

Allow a user to run an interactive command on all managed nodes

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action":"ssm:StartSession",
            "Resource": [  
            ],
            "Condition":{
                "BoolIfExists":{
                    "ssm:SessionDocumentAccessCheck":"true"
                }
            }
        }
    ]
}
```
Allow a user to run multiple interactive commands on all managed nodes

```json
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect":"Allow",
      "Action":"ssm:StartSession",
      "Resource": [
      ],
      "Condition": {
        "BoolIfExists": {
          "ssm:SessionDocumentAccessCheck": "true"
        }
      }
    }
  ]
}
```

Step 6: (Optional) Use AWS PrivateLink to set up a VPC endpoint for Session Manager

You can further improve the security posture of your managed nodes by configuring AWS Systems Manager to use an interface virtual private cloud (VPC) endpoint. Interface endpoints are powered by AWS PrivateLink, a technology that allows you to privately access Amazon Elastic Compute Cloud (Amazon EC2) and Systems Manager APIs by using private IP addresses.

AWS PrivateLink restricts all network traffic between your managed nodes, Systems Manager, and Amazon EC2 to the Amazon network. (Managed nodes don't have access to the internet.) Also, you don't need an internet gateway, a NAT device, or a virtual private gateway.
For information about creating a VPC endpoint, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

The alternative to using a VPC endpoint is to allow outbound internet access on your managed nodes. In this case, the managed nodes must also allow HTTPS (port 443) outbound traffic to the following endpoints:

- ec2messages.region.amazonaws.com
- ssm.region.amazonaws.com
- ssmmessages.region.amazonaws.com

Systems Manager uses the last of these endpoints, ssmmessages.region.amazonaws.com, to make calls from SSM Agent to the Session Manager service in the cloud.

To use optional features like AWS Key Management Service (AWS KMS) encryption, streaming logs to Amazon CloudWatch Logs (CloudWatch Logs), and sending logs to Amazon Simple Storage Service (Amazon S3) you must allow HTTPS (port 443) outbound traffic to the following endpoints:

- kms.region.amazonaws.com
- logs.region.amazonaws.com
- s3.region.amazonaws.com

For more information about required endpoints for Systems Manager, see Reference: ec2messages, ssmmessages, and other API operations.

Step 7: (Optional) Turn on or turn off ssm-user account administrative permissions

Starting with version 2.3.50.0 of AWS Systems Manager SSM Agent, the agent creates a local user account called ssm-user and adds it to /etc/sudoers (Linux and macOS) or to the Administrators group (Windows). On agent versions earlier than 2.3.612.0, the account is created the first time SSM Agent starts or restarts after installation. On version 2.3.612.0 and later, the ssm-user account is created the first time a session is started on a node. This ssm-user is the default operating system (OS) user when a AWS Systems Manager Session Manager session is started. SSM Agent version 2.3.612.0 was released on May 8th, 2019.
If you want to prevent Session Manager users from running administrative commands on a node, you can update the `ssm-user` account permissions. You can also restore these permissions after they have been removed.

**Topics**

- Managing ssm-user sudo account permissions on Linux and macOS
- Managing ssm-user Administrator account permissions on Windows Server

**Managing ssm-user sudo account permissions on Linux and macOS**

Use one of the following procedures to turn on or turn off the ssm-user account sudo permissions on Linux and macOS managed nodes.

**Use Run Command to modify ssm-user sudo permissions (console)**

- Use the procedure in Running commands from the console with the following values:
  
  - For **Command document**, choose AWS-RunShellScript.
  - To remove sudo access, in the **Command parameters** area, paste the following in the **Commands** box.

    ```
    cd /etc/sudoers.d
    echo "#User rules for ssm-user" > ssm-agent-users
    ```

    -or-

    To restore sudo access, in the **Command parameters** area, paste the following in the **Commands** box.

    ```
    cd /etc/sudoers.d
    echo "ssm-user ALL=(ALL) NOPASSWD:ALL" > ssm-agent-users
    ```

**Use the command line to modify ssm-user sudo permissions (AWS CLI)**

1. Connect to the managed node and run the following command.

    ```
    sudo -s
    ```
2. Change the working directory using the following command.

   \texttt{cd /etc/sudoers.d}

3. Open the file named \texttt{ssm-agent-users} for editing.

4. To remove sudo access, delete the following line.

   \texttt{ssm-user ALL=(ALL) NOPASSWD:ALL}

   \texttt{-or-}

   To restore sudo access, add the following line.

   \texttt{ssm-user ALL=(ALL) NOPASSWD:ALL}

5. Save the file.

\textbf{Managing ssm-user Administrator account permissions on Windows Server}

Use one of the following procedures to turn on or turn off the ssm-user account Administrator permissions on Windows Server managed nodes.

\textbf{Use Run Command to modify Administrator permissions (console)}

- Use the procedure in \texttt{Running commands from the console} with the following values:

  \texttt{For Command document, choose AWS-RunPowerShellScript.}

  To remove administrative access, in the \texttt{Command parameters} area, paste the following in the \texttt{Commands} box.

  \texttt{net localgroup "Administrators" "ssm-user" /delete}

  \texttt{-or-}

  To restore administrative access, in the \texttt{Command parameters} area, paste the following in the \texttt{Commands} box.

  \texttt{net localgroup "Administrators" "ssm-user" /add}
Use the PowerShell or command prompt window to modify Administrator permissions

1. Connect to the managed node and open the PowerShell or Command Prompt window.
2. To remove administrative access, run the following command.

   ```bash
   net localgroup "Administrators" "ssm-user" /delete
   
   -or-
   
   To restore administrative access, run the following command.
   ```

   ```bash
   net localgroup "Administrators" "ssm-user" /add
   ```

Use the Windows console to modify Administrator permissions

1. Connect to the managed node and open the PowerShell or Command Prompt window.
2. From the command line, run `lusrmgr.msc` to open the Local Users and Groups console.
3. Open the Users directory, and then open `ssm-user`.
4. On the Member Of tab, do one of the following:
   - To remove administrative access, select Administrators, and then choose Remove.
     -or-
   - To restore administrative access, enter Administrators in the text box, and then choose Add.
5. Choose OK.

Step 8: (Optional) Allow and control permissions for SSH connections through Session Manager

You can allow users in your AWS account to use the AWS Command Line Interface (AWS CLI) to establish Secure Shell (SSH) connections to managed nodes using AWS Systems Manager Session Manager. Users who connect using SSH can also copy files between their local machines and managed nodes using Secure Copy Protocol (SCP). You can use this functionality to connect to managed nodes without opening inbound ports or maintaining bastion hosts.
After allowing SSH connections, you can use AWS Identity and Access Management (IAM) policies to explicitly allow or deny users, groups, or roles to make SSH connections using Session Manager.

**Note**

Logging isn't available for Session Manager sessions that connect through port forwarding or SSH. This is because SSH encrypts all session data, and Session Manager only serves as a tunnel for SSH connections.

**Topics**

- [Allowing SSH connections for Session Manager](#)
- [Controlling user permissions for SSH connections through Session Manager](#)

**Allowing SSH connections for Session Manager**

Use the following steps to allow SSH connections through Session Manager on a managed node.

**To allow SSH connections for Session Manager**

1. On the managed node to which you want to allow SSH connections, do the following:

   - Ensure that SSH is running on the managed node. (You can close inbound ports on the node.)
   - Ensure that SSM Agent version 2.3.672.0 or later is installed on the managed node.

   For information about installing or updating SSM Agent on a managed node, see the following topics:

   - [Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server](#)
   - [Manually installing and uninstalling SSM Agent on EC2 instances for Linux](#)
   - [Manually installing and uninstalling SSM Agent on EC2 instances for macOS](#)
   - [How to install the SSM Agent on hybrid Windows nodes](#)
   - [How to install the SSM Agent on hybrid Linux nodes](#)
Note

To use Session Manager with on-premises servers, edge devices, and virtual machines (VMs) that you activated as managed nodes, you must use the advanced-instances tier. For more information about advanced instances, see Configuring instance tiers.

2. On the local machine from which you want to connect to a managed node using SSH, do the following:

   • Ensure that version 1.1.23.0 or later of the Session Manager plugin is installed.

     For information about installing the Session Manager plugin, see Install the Session Manager plugin for the AWS CLI.

   • Update the SSH configuration file to allow running a proxy command that starts a Session Manager session and transfer all data through the connection.

     **Linux and macOS**

     Tip

     The SSH configuration file is typically located at ~/.ssh/config.

     Add the following to the configuration file on the local machine.

     ```
     # SSH over Session Manager
     host i-* mi-*
     ProxyCommand sh -c "aws ssm start-session --target %h --document-name AWS-StartSSHSes..."
     ```

     **Windows**

     Tip

     The SSH configuration file is typically located at C:Users<username>.ssh\config.
Add the following to the configuration file on the local machine.

```bash
# SSH over Session Manager
host i-* mi-*
    ProxyCommand C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe "aws
    ssm start-session --target %h --document-name AWS-StartSSHSession --parameters
    portNumber=%p"
```

- Create or verify that you have a Privacy Enhanced Mail certificate (a PEM file), or at minimum a public key, to use when establishing connections to managed nodes. This must be a key that is already associated with the managed node. The permissions of your private key file must be set so that only you can read it. You can use the following command to set the permissions of your private key file so that only you can read it.

  ```bash
  chmod 400 <my-key-pair>.pem
  ```

  For example, for an Amazon Elastic Compute Cloud (Amazon EC2) instance, the key pair file you created or selected when you created the instance. (You specify the path to the certificate or key as part of the command to start a session. For information about starting a session using SSH, see [Starting a session (SSH)](#).

**Controlling user permissions for SSH connections through Session Manager**

After you enable SSH connections through Session Manager on a managed node, you can use IAM policies to allow or deny users, groups, or roles the ability to make SSH connections through Session Manager.

**To use an IAM policy to allow SSH connections through Session Manager**

- Use one of the following options:
  
  - **Option 1**: Open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).

    In the navigation pane, choose **Policies**, and then update the permissions policy for the user or role you want to allow to start SSH connections through Session Manager.
For example, add the following element to the Quickstart policy you created in Quickstart end user policies for Session Manager. Replace each example resource placeholder with your own information.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "ssm:StartSession",
         "Resource": [
            "arn:aws:ssm:*:*:document/AWS-StartSSHSession"
         ],
         "Condition": {
            "BoolIfExists": {
               "ssm:SessionDocumentAccessCheck": "true"
            }
         }
      }
   ]
}
```

- **Option 2**: Attach an inline policy to a user policy by using the AWS Management Console, the AWS CLI, or the AWS API.

Using the method of your choice, attach the policy statement in **Option 1** to the policy for an AWS user, group, or role.

### To use an IAM policy to deny SSH connections through Session Manager

- Use one of the following options:

  - **Option 1**: Open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/). In the navigation pane, choose **Policies**, and then update the permissions policy for the user or role to block from starting Session Manager sessions.
For example, add the following element to the Quickstart policy you created in Quickstart
end user policies for Session Manager.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor1",
      "Effect": "Deny",
      "Action": "ssm:StartSession",
      "Resource": "arn:aws:ssm::*:document/AWS-StartSSHSession"
    }
  ],
  "Condition": {
    "BoolIfExists": {
      "ssm:SessionDocumentAccessCheck": "true"
    }
  }
}
```

- **Option 2**: Attach an inline policy to a user policy by using the AWS Management Console, the AWS CLI, or the AWS API.

Using the method of your choice, attach the policy statement in **Option 1** to the policy for an AWS user, group, or role.

For information, see [Adding and Removing IAM Identity Permissions](https://docs.aws.amazon.com/IAM/latest/UserGuide/) in the IAM User Guide.

**Working with Session Manager**

You can use the AWS Systems Manager console, the Amazon Elastic Compute Cloud (Amazon EC2) console, or the AWS Command Line Interface (AWS CLI) to start sessions that connect you to the managed nodes your system administrator has granted you access to using AWS Identity and Access Management (IAM) policies. Depending on your permissions, you can also view information about sessions, resume inactive sessions that haven't timed out, and end sessions. After a session is established, it is not affected by IAM role session duration. For information about limiting session duration with Session Manager, see [Specify an idle session timeout value](https://docs.aws.amazon.com/AWSSystemsManager/latest/SessionManagerUserGuide/session-manager-limiting-session-duration.html) and [Specify maximum session duration](https://docs.aws.amazon.com/AWSSystemsManager/latest/SessionManagerUserGuide/session-manager-limiting-session-duration.html).

For more information about sessions, see [What is a session?](https://docs.aws.amazon.com/AWSSystemsManager/latest/SessionManagerUserGuide/session-manager-limiting-session-duration.html)
Install the Session Manager plugin for the AWS CLI

To initiate Session Manager sessions with your managed nodes by using the AWS Command Line Interface (AWS CLI), you must install the Session Manager plugin on your local machine. You can install the plugin on supported versions of Microsoft Windows Server, macOS, Linux, and Ubuntu Server.

Tip
To use the Session Manager plugin, you must have AWS CLI version 1.16.12 or later installed on your local machine. For more information, see Installing or updating the latest version of the AWS Command Line Interface.

Topics
- Session Manager plugin latest version and release history
- Install the Session Manager plugin on Windows
- Install the Session Manager plugin on macOS
- Install the Session Manager plugin on Amazon Linux 2 and Red Hat Enterprise Linux distributions
- Install the Session Manager plugin on Debian Server and Ubuntu Server
- Verify the Session Manager plugin installation

- (Optional) Turn on Session Manager plugin logging

Session Manager plugin latest version and release history

Your local machine must be running a supported version of the Session Manager plugin. The current minimum supported version is 1.17.0. If you're running an earlier version, your Session Manager operations might not succeed.
To see if you have the latest version, run the following command in the AWS CLI.

```
session-manager-plugin --version
```

The following table lists all releases of the Session Manager plugin and the features and enhancements included with each version.

## Important

We recommend you always run the latest version. The latest version includes enhancements that improve the experience of using the plugin.

<table>
<thead>
<tr>
<th>Version</th>
<th>Release date</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.2.633.0</td>
<td>May 30, 2024</td>
<td><strong>Enhancement</strong>: Updated the Dockerfile to use an Amazon Elastic Container Registry (Amazon ECR) image.</td>
</tr>
<tr>
<td>1.2.553.0</td>
<td>January 10, 2024</td>
<td><strong>Enhancement</strong>: Upgraded aws-sdk-go and dependent Golang packages.</td>
</tr>
<tr>
<td>1.2.536.0</td>
<td>December 4, 2023</td>
<td><strong>Enhancement</strong>: Added support for passing a <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-session-manager.html">StartSession</a> API response as an environment variable to session-manager-plugin.</td>
</tr>
<tr>
<td>1.2.497.0</td>
<td>August 1, 2023</td>
<td><strong>Enhancement</strong>: Upgraded Go SDK to v1.44.302.</td>
</tr>
<tr>
<td>1.2.463.0</td>
<td>March 15, 2023</td>
<td><strong>Enhancement</strong>: Added Mac with Apple silicon support for Apple Mac (M1) in macOS bundle installer and signed installer.</td>
</tr>
<tr>
<td>Version</td>
<td>Release date</td>
<td>Details</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>1.2.398.0</td>
<td>October 14, 2022</td>
<td><strong>Enhancement</strong>: Support golang version 1.17. Update default session-manager-plugin runner for macOS to use python3. Update import path from SSMCLI to session-manager-plugin.</td>
</tr>
<tr>
<td>1.2.339.0</td>
<td>June 16, 2022</td>
<td><strong>Bug fix</strong>: Fix idle session timeout for port sessions.</td>
</tr>
<tr>
<td>1.2.331.0</td>
<td>May 27, 2022</td>
<td><strong>Bug fix</strong>: Fix port sessions closing prematurely when the local server doesn't connect before timeout.</td>
</tr>
<tr>
<td>1.2.323.0</td>
<td>May 19, 2022</td>
<td><strong>Bug fix</strong>: Disable smux keep alive to use idle session timeout feature.</td>
</tr>
<tr>
<td>1.2.312.0</td>
<td>March 31, 2022</td>
<td><strong>Enhancement</strong>: Supports more output message payload types.</td>
</tr>
<tr>
<td>1.2.295.0</td>
<td>January 12, 2022</td>
<td><strong>Bug fix</strong>: Hung sessions caused by client resending stream data when agent becomes inactive, and incorrect logs for start_publication and pause_publication messages.</td>
</tr>
<tr>
<td>1.2.279.0</td>
<td>October 27, 2021</td>
<td><strong>Enhancement</strong>: Zip packaging for Windows platform.</td>
</tr>
<tr>
<td>1.2.245.0</td>
<td>August 19, 2021</td>
<td><strong>Enhancement</strong>: Upgrade aws-sdk-go to latest version (v1.40.17) to support AWS IAM Identity Center.</td>
</tr>
<tr>
<td>1.2.234.0</td>
<td>July 26, 2021</td>
<td><strong>Bug fix</strong>: Handle session abruptly terminated scenario in interactive session type.</td>
</tr>
<tr>
<td>1.2.205.0</td>
<td>June 10, 2021</td>
<td><strong>Enhancement</strong>: Added support for signed macOS installer.</td>
</tr>
<tr>
<td>1.2.54.0</td>
<td>January 29, 2021</td>
<td><strong>Enhancement</strong>: Added support for running sessions in NonInteractiveCommands execution mode.</td>
</tr>
<tr>
<td>1.2.30.0</td>
<td>November 24, 2020</td>
<td><strong>Enhancement</strong>: (Port forwarding sessions only) Improved overall performance.</td>
</tr>
<tr>
<td>Version</td>
<td>Release date</td>
<td>Details</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>1.2.7.0</td>
<td>October 15, 2020</td>
<td><strong>Enhancement</strong>: (Port forwarding sessions only) Reduced latency and improved overall performance.</td>
</tr>
<tr>
<td>1.1.61.0</td>
<td>April 17, 2020</td>
<td><strong>Enhancement</strong>: Added ARM support for Linux and Ubuntu.</td>
</tr>
<tr>
<td>1.1.54.0</td>
<td>January 6, 2020</td>
<td><strong>Bug fix</strong>: Handle race condition scenario of packets being dropped when the Session Manager plugin isn't ready.</td>
</tr>
<tr>
<td>1.1.50.0</td>
<td>November 19, 2019</td>
<td><strong>Enhancement</strong>: Added support for forwarding a port to a local unix socket.</td>
</tr>
<tr>
<td>1.1.35.0</td>
<td>November 7, 2019</td>
<td><strong>Enhancement</strong>: (Port forwarding sessions only) Send a TerminateSession command to SSM Agent when the local user presses Ctrl+C.</td>
</tr>
<tr>
<td>1.1.33.0</td>
<td>September 26, 2019</td>
<td><strong>Enhancement</strong>: (Port forwarding sessions only) Send a disconnect signal to the server when the client drops the TCP connection.</td>
</tr>
<tr>
<td>1.1.31.0</td>
<td>September 6, 2019</td>
<td><strong>Enhancement</strong>: Update to keep port forwarding session open until remote server closes the connection.</td>
</tr>
<tr>
<td>1.1.26.0</td>
<td>July 30, 2019</td>
<td><strong>Enhancement</strong>: Update to limit the rate of data transfer during a session.</td>
</tr>
<tr>
<td>1.1.23.0</td>
<td>July 9, 2019</td>
<td><strong>Enhancement</strong>: Added support for running SSH sessions using Session Manager.</td>
</tr>
<tr>
<td>1.1.17.0</td>
<td>April 4, 2019</td>
<td><strong>Enhancement</strong>: Added support for further encryption of session data using AWS Key Management Service (AWS KMS).</td>
</tr>
<tr>
<td>1.0.37.0</td>
<td>September 20, 2018</td>
<td><strong>Enhancement</strong>: Bug fix for Windows version.</td>
</tr>
<tr>
<td>1.0.0.0</td>
<td>September 11, 2018</td>
<td>Initial release of the Session Manager plugin.</td>
</tr>
</tbody>
</table>
Install the Session Manager plugin on Windows

You can install the Session Manager plugin on Windows Vista or later using the standalone installer.

When updates are released, you must repeat the installation process to get the latest version of the Session Manager plugin.

Note

For best results, we recommend that you start sessions on Windows clients using Windows PowerShell, version 5 or later. Alternatively, you can use the Command shell in Windows 10. The Session Manager plugin only supports PowerShell and the Command shell. Third-party command line tools might not be compatible with the plugin.

To install the Session Manager plugin using the EXE installer

1. Download the installer using the following URL.

   https://s3.amazonaws.com/session-manager-downloads/plugin/latest/windows/
   SessionManagerPluginSetup.exe

   Alternatively, you can download a zipped version of the installer using the following URL.

   https://s3.amazonaws.com/session-manager-downloads/plugin/latest/windows/
   SessionManagerPlugin.zip

2. Run the downloaded installer, and follow the on-screen instructions. If you downloaded the zipped version of the installer, you must unzip the installer first.

   Leave the install location box blank to install the plugin to the default directory.

   • %PROGRAMFILES%\Amazon\SessionManagerPlugin\bin\n
3. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.
**Note**

If Windows is unable to find the executable, you might need to re-open the command prompt or add the installation directory to your PATH environment variable manually. For information, see the troubleshooting topic [Session Manager plugin not automatically added to command line path (Windows)].

---

**Install the Session Manager plugin on macOS**

Choose one of the following topics to install the Session Manager plugin on macOS. The bundled installer uses a ZIP file. Once unzipped, you can install the plugin using the binary. The signed installer is a signed .pkg file.

**Topics**

- [Install the Session Manager plugin on macOS](#)
- [Install the Session Manager plugin on macOS with the signed installer](#)

**Install the Session Manager plugin on macOS**

This section describes how to install the Session Manager plugin on macOS using the bundled installer.

**Important**

The bundled installer doesn't support installing to paths that contain spaces.

**To install the Session Manager plugin using the bundled installer (macOS)**

1. Download the bundled installer.
   
   x86_64
   ```bash
   ```
Mac with Apple silicon

```shell
```

2. Unzip the package.

```shell
unzip sessionmanager-bundle.zip
```

3. Run the install command.

```shell
sudo ./sessionmanager-bundle/install -i /usr/local/sessionmanagerplugin -b /usr/local/bin/session-manager-plugin
```

**Note**

The plugin requires either Python 2.6.5 or later, or Python 3.3 or later. By default, the install script runs under the system default version of Python. If you have installed an alternative version of Python and want to use that to install the Session Manager plugin, run the install script with that version by absolute path to the Python executable. The following is an example.

```shell
sudo /usr/local/bin/python3.8 sessionmanager-bundle/install -i /usr/local/sessionmanagerplugin -b /usr/local/bin/session-manager-plugin
```

The installer installs the Session Manager plugin at `/usr/local/sessionmanagerplugin` and creates the symlink `session-manager-plugin` in the `/usr/local/bin` directory. This eliminates the need to specify the install directory in the user's `PATH` variable.

To see an explanation of the `-i` and `-b` options, use the `-h` option.

```shell
./sessionmanager-bundle/install -h
```

4. Verify that the installation was successful. For information, see [Verify the Session Manager plugin installation](#).
Install the Session Manager plugin on macOS with the signed installer

This section describes how to install the Session Manager plugin on macOS using the signed installer.

To install the Session Manager plugin using the signed installer (macOS)

1. Download the signed installer.
   - x86_64
     
   ```bash
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/mac/session-manager-plugin.pkg" -o "session-manager-plugin.pkg"
   ```
   - Mac with Apple silicon
     
   ```bash
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/mac_arm64/session-manager-plugin.pkg" -o "session-manager-plugin.pkg"
   ```

2. Run the install commands.

   ```bash
   sudo installer -pkg session-manager-plugin.pkg -target /
   sudo ln -s /usr/local/sessionmanagerplugin/bin/session-manager-plugin /usr/local/bin/session-manager-plugin
   ```

3. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.
Install the Session Manager plugin on Amazon Linux 2 and Red Hat Enterprise Linux distributions

Use the following procedure to install the Session Manager plugin on RHEL distributions.

**Note**

The Session Manager plugin is not supported on Amazon Linux 1. It is supported on Amazon Linux 2 and later distributions.

1. Download and install the Session Manager plugin RPM package.

   **x86_64**

   On RHEL 7, run the following command:

   ```
   sudo yum install -y https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_64bit/session-manager-plugin.rpm
   ```

   On RHEL 8 and 9, run the following command:

   ```
   sudo dnf install -y https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_64bit/session-manager-plugin.rpm
   ```

   **x86**

   On RHEL 7, run the following command:

   ```
   ```

   On RHEL 8 and 9, run the following command:

   ```
   ```

   **ARM64**

   On RHEL 7, run the following command:
sudo yum install -y https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_arm64/session-manager-plugin.rpm

On RHEL 8 and 9, run the following command:

sudo dnf install -y https://s3.amazonaws.com/session-manager-downloads/plugin/latest/linux_arm64/session-manager-plugin.rpm

2. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.

Note
If you ever want to uninstall the plugin, run sudo yum erase session-manager-plugin -y

Install the Session Manager plugin on Debian Server and Ubuntu Server

1. Download the Session Manager plugin deb package.
   
   x86_64
   
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/ubuntu_64bit/session-manager-plugin.deb" -o "session-manager-plugin.deb"

   x86
   

   ARM64
   
   curl "https://s3.amazonaws.com/session-manager-downloads/plugin/latest/ubuntu_arm64/session-manager-plugin.deb" -o "session-manager-plugin.deb"

2. Run the install command.
sudo dpkg -i session-manager-plugin.deb

3. Verify that the installation was successful. For information, see Verify the Session Manager plugin installation.

Note
If you ever want to uninstall the plugin, run sudo dpkg -r session-manager-plugin.

Verify the Session Manager plugin installation

Run the following commands to verify that the Session Manager plugin installed successfully.

```
session-manager-plugin
```

If the installation was successful, the following message is returned.

```
The Session Manager plugin is installed successfully. Use the AWS CLI to start a session.
```

You can also test the installation by running the start-session command in the AWS Command Line Interface (AWS CLI). In the following command, replace instance-id with your own information.

```
aws ssm start-session --target instance-id
```

This command will work only if you have installed and configured the AWS CLI, and if your Session Manager administrator has granted you the necessary IAM permissions to access the target managed node using Session Manager.

Session Manager plugin on GitHub

The source code for Session Manager plugin is available on GitHub so that you can adapt the plugin to meet your needs. We encourage you to submit pull requests for changes that you would like to have included. However, Amazon Web Services doesn't provide support for running modified copies of this software.
(Optional) Turn on Session Manager plugin logging

The Session Manager plugin includes an option to allow logging for sessions that you run. By default, logging is turned off.

If you allow logging, the Session Manager plugin creates log files for both application activity (session-manager-plugin.log) and errors (errors.log) on your local machine.

Topics

• Turn on logging for the Session Manager plugin (Windows)
• Enable logging for the Session Manager plugin (Linux and macOS)

Turn on logging for the Session Manager plugin (Windows)

1. Locate the seelog.xml.template file for the plugin.
   
   The default location is C:\Program Files\Amazon\SessionManagerPlugin\seelog.xml.template.

2. Change the name of the file to seelog.xml.

3. Open the file and change minlevel="off" to minlevel="info" or minlevel="debug".

   \[ Note \]
   
   By default, log entries about opening a data channel and reconnecting sessions are recorded at the INFO level. Data flow (packets and acknowledgement) entries are recorded at the DEBUG level.

4. Change other configuration options you want to modify. Options you can change include:

   • **Debug level**: You can change the debug level from formatid="fmtinfo" to formatid="fmtdebug".
   
   • **Log file options**: You can make changes to the log file options, including where the logs are stored, with the exception of the log file names.

   \[ Important \]
   
   Don't change the file names or logging won't work correctly.
5. Save the file.

**Enable logging for the Session Manager plugin (Linux and macOS)**

1. Locate the seelog.xml.template file for the plugin.
   
   The default location is `/usr/local/sessionmanagerplugin/seelog.xml.template`.
2. Change the name of the file to seelog.xml.
3. Open the file and change `minlevel="off"` to `minlevel="info"` or `minlevel="debug"`.

   **Note**

   By default, log entries about opening data channels and reconnecting sessions are recorded at the **INFO** level. Data flow (packets and acknowledgement) entries are recorded at the **DEBUG** level.

4. Change other configuration options you want to modify. Options you can change include:

   - **Debug level**: You can change the debug level from `formatid="fmtinfo"` to `outputs formatid="fmtdebug"`
   
   - **Log file options**: You can make changes to the log file options, including where the logs are stored, with the exception of the log file names.

   **Important**

   Don't change the file names or logging won't work correctly.
Important

If you use the specified default directory for storing logs, you must either run session commands using `sudo` or give the directory where the plugin is installed full read and write permissions. To bypass these restrictions, change the location where logs are stored.

5. Save the file.

Start a session

You can use the AWS Systems Manager console, the Amazon Elastic Compute Cloud (Amazon EC2) console, the AWS Command Line Interface (AWS CLI), or SSH to start a session.

Topics

- Starting a session (Systems Manager console)
- Starting a session (Amazon EC2 console)
- Starting a session (AWS CLI)
- Starting a session (SSH)
- Starting a session (port forwarding)
- Starting a session (port forwarding to remote host)
- Starting a session (interactive and noninteractive commands)

Starting a session (Systems Manager console)

You can use the AWS Systems Manager console to start a session with a managed node in your account.

Note

Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.
To start a session (Systems Manager console)

2. In the navigation pane, choose Session Manager.
3. Choose Start session.
4. (Optional) Enter a session description in the Reason for session field.
5. For Target instances, choose the option button to the left of the managed node that you want to connect to.

   If the node that you want isn't in the list, or if you select a node and receive a configuration error, see Managed node not available or not configured for Session Manager for troubleshooting steps.
6. Choose Start session to launch the session immediately.

   -or-

   Choose Next for session options.
7. (Optional) For Session document, select the document that you want to run when the session starts. If your document supports runtime parameters, you can enter one or more comma-separated values in each parameter field.
8. Choose Next.
9. Choose Start session.

After the connection is made, you can run bash commands (Linux and macOS) or PowerShell commands (Windows) as you would through any other connection type.

⚠️ Important

If you want to allow users to specify a document when starting sessions in the Session Manager console, note the following:

- You must grant users the ssm:GetDocument and ssm:ListDocuments permissions in their IAM policy. For more information, see Grant access to custom Session documents in the console.
The console only supports Session documents that have the `sessionType` defined as `Standard_Stream`. For more information, see Session document schema.

Starting a session (Amazon EC2 console)

You can use the Amazon Elastic Compute Cloud (Amazon EC2) console to start a session with an instance in your account.

**Note**

If you receive an error that you aren't authorized to perform one or more Systems Manager actions (ssm: *command-name*), then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to start sessions from the Amazon EC2 console. If you're an administrator, see Sample IAM policies for Session Manager for more information.

To start a session (Amazon EC2 console)

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. For **Connection method**, choose **Session Manager**.
5. Choose **Connect**.

After the connection is made, you can run bash commands (Linux and macOS) or PowerShell commands (Windows) as you would through any other connection type.

Starting a session (AWS CLI)

Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see Installing or updating the latest version of the AWS CLI.

Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.
To use the AWS CLI to run session commands, the Session Manager plugin must also be installed on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.

To start a session using the AWS CLI, run the following command replacing `instance-id` with your own information.

```
aws ssm start-session \
   --target instance-id
```

For information about other options you can use with the `start-session` command, see `start-session` in the AWS Systems Manager section of the AWS CLI Command Reference.

**Starting a session (SSH)**

To start a Session Manager SSH session, version 2.3.672.0 or later of SSM Agent must be installed on the managed node.

**SSH connection requirements**

Take note of the following requirements and limitations for session connections using SSH:

- Your target managed node must be configured to support SSH connections. For more information, see *(Optional) Allow and control permissions for SSH connections through Session Manager*.
- You must connect using the managed node account associated with the Privacy Enhanced Mail (PEM) certificate, not the `ssm-user` account that is used for other types of session connections. For example, on EC2 instances for Linux and macOS, the default user is `ec2-user`. For information about identifying the default user for each instance type, see Get Information About Your Instance in the Amazon EC2 User Guide.
- Logging isn't available for Session Manager sessions that connect through port forwarding or SSH. This is because SSH encrypts all session data, and Session Manager only serves as a tunnel for SSH connections.

**Note**

Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.
To start a session using SSH, run the following command. Replace each example resource placeholder with your own information.

```
ssh -i /path/my-key-pair.pem username@instance-id
```

Tip

When you start a session using SSH, you can copy local files to the target managed node using the following command format.

```
scp -i /path/my-key-pair.pem /path/ExampleFile.txt username@instance-id:~
```

For information about other options you can use with the start-session command, see start-session in the AWS Systems Manager section of the AWS CLI Command Reference.

Starting a session (port forwarding)

To start a Session Manager port forwarding session, version 2.3.672.0 or later of SSM Agent must be installed on the managed node.

Note

Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.

To use the AWS CLI to run session commands, you must install the Session Manager plugin on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.

Depending on your operating system and command line tool, the placement of quotation marks can differ and escape characters might be required.

To start a port forwarding session, run the following command from the CLI. Replace each example resource placeholder with your own information.

Linux & macOS

```
aws ssm start-session
```
Windows

```bash
aws ssm start-session ^
   --target instance-id ^
   --document-name AWS-StartPortForwardingSession ^
   --parameters portNumber="3389",localPortNumber="56789"
```

**portNumber** is the remote port on the managed node where you want the session traffic to be redirected. For example, you might specify port 3389 for connecting to a Windows node using the Remote Desktop Protocol (RDP). If you don't specify the **portNumber** parameter, Session Manager uses 80 as the default value.

**localPortNumber** is the port on your local computer where traffic starts, such as 56789. This value is what you enter when connecting to a managed node using a client. For example, `localhost:56789`.

For information about other options you can use with the **start-session** command, see [start-session](#) in the AWS Systems Manager section of the AWS CLI Command Reference.

For more information about port forwarding sessions, see [Port Forwarding Using AWS Systems Manager Session Manager](#) in the AWS News Blog.

### Starting a session (port forwarding to remote host)

To start a Session Manager port forwarding session to a remote host, version 3.1.1374.0 or later of SSM Agent must be installed on the managed node. The remote host isn't required to be managed by Systems Manager.

> **Note**
> Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see [Setting up Session Manager](#).
> To use the AWS CLI to run session commands, you must install the Session Manager plugin on your local machine. For information, see [Install the Session Manager plugin for the AWS CLI](#).
Depending on your operating system and command line tool, the placement of quotation marks can differ and escape characters might be required.

To start a port forwarding session, run the following command from the AWS CLI. Replace each example resource placeholder with your own information.

**Linux & macOS**

```bash
aws ssm start-session \
  --target instance-id \
  --document-name AWS-StartPortForwardingSessionToRemoteHost \
  --parameters "host":["mydb.example.us-east-2.rds.amazonaws.com"],"portNumber": ["3306"], "localPortNumber": ["3306"]'
```

**Windows**

```bash
aws ssm start-session ^
  --target instance-id ^
  --document-name AWS-StartPortForwardingSessionToRemoteHost ^
  --parameters host="mydb.example.us-east-2.rds.amazonaws.com",portNumber="3306",localPortNumber="3306"
```

The host value represents the hostname or IP address of the remote host that you want to connect to. General connectivity and name resolution requirements between the managed node and the remote host still apply.

`portNumber` is the remote port on the managed node where you want the session traffic to be redirected. For example, you might specify port 3389 for connecting to a Windows node using the Remote Desktop Protocol (RDP). If you don't specify the `portNumber` parameter, Session Manager uses 80 as the default value.

`localPortNumber` is the port on your local computer where traffic starts, such as 56789. This value is what you enter when connecting to a managed node using a client. For example, `localhost:56789`.

For information about other options you can use with the `start-session` command, see [start-session](#) in the AWS Systems Manager section of the AWS CLI Command Reference.
Starting a session with an Amazon ECS task

Session Manager supports starting a port forwarding session with a task inside an Amazon Elastic Container Service (Amazon ECS) cluster. To do so, you must update the task role in IAM to include the following permissions:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssmmessages:CreateControlChannel",
        "ssmmessages:CreateDataChannel",
        "ssmmessages:OpenControlChannel",
        "ssmmessages:OpenDataChannel"
      ],
      "Resource": "*"
    }
  ]
}
```

To start a port forwarding session with an Amazon ECS task, run the following command from the AWS CLI. Replace each example resource placeholder with your own information.

**Note**

Remove the < and > symbols from the target parameter. These symbols are provided for reader clarification only.

**Linux & macOS**

```bash
aws ssm start-session
  --target ecs:<ECS_cluster_name>_<ECS_container_ID>_<container_runtime_ID> \
  --document-name AWS-StartPortForwardingSessionToRemoteHost \
  --parameters '{"host": ["URL"], "portNumber": ["port_number"], "localPortNumber": ["port_number"]}'
```
Starting a session (interactive and noninteractive commands)

Before you start a session, make sure that you have completed the setup steps for Session Manager. For information, see Setting up Session Manager.

To use the AWS CLI to run session commands, the Session Manager plugin must also be installed on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.

To start an interactive command session, run the following command. Replace each example resource placeholder with your own information.

**Windows**

```bash
aws ssm start-session ^
  --target ecs:<ECS_cluster_name>_:<ECS_container_ID>_:<container_runtime_ID> ^
  --document-name AWS-StartPortForwardingSessionToRemoteHost ^
  --parameters host="URL",portNumber="port_number",localPortNumber="port_number"
```

For information about other options you can use with the `start-session` command, see start-session in the AWS Systems Manager section of the AWS CLI Command Reference.

**More info**

- Use port forwarding in AWS Systems Manager Session Manager to connect to remote hosts
- Amazon EC2 instance port forwarding with AWS Systems Manager
End a session

You can use the AWS Systems Manager console or the AWS Command Line Interface (AWS CLI) to end a session that you started in your account. If there is no user activity after 20 minutes, a session is ended. After a session is ended, it can't be resumed.

Topics
- Ending a session (console)
- Ending a session (AWS CLI)

Ending a session (console)

You can use the AWS Systems Manager console to end a session in your account.

To end a session (console)

2. In the navigation pane, choose Session Manager.
3. For Sessions, choose the option button to the left of the session you want to end.
4. Choose Terminate.

Ending a session (AWS CLI)

To end a session using the AWS CLI, run the following command. Replace session-id with your own information.

```
aws ssm terminate-session \
   --session-id session-id
```

For more information about the terminate-session command, see terminate-session in the AWS Systems Manager section of the AWS CLI Command Reference.
View session history

You can use the AWS Systems Manager console or the AWS Command Line Interface (AWS CLI) to view information about sessions in your account. In the console, you can view session details such as the following:

- The ID of the session
- Which user connected to a managed node through a session
- The ID of the managed node
- When the session began and ended
- The status of the session
- The location specified for storing session logs (if turned on)

Using the AWS CLI, you can view a list of sessions in your account, but not the additional details that are available in the console.

For information about logging session history information, see Enabling and disabling session activity logging.

Topics

- Viewing session history (console)
- Viewing session history (AWS CLI)

Viewing session history (console)

You can use the AWS Systems Manager console to view details about the sessions in your account.

To view session history (console)

2. In the navigation pane, choose Session Manager.
3. Choose the Session history tab.
   -or-

   ...
If the Session Manager home page opens first, choose **Configure Preferences** and then choose the **Session history** tab.

### Viewing session history (AWS CLI)

To view a list of sessions in your account using the AWS CLI, run the following command.

```bash
aws ssm describe-sessions --state History
```

**Note**

This command returns only results for connections to targets initiated using Session Manager. It doesn't list connections made through other means, such as Remote Desktop Protocol (RDP) or the Secure Shell Protocol (SSH).

For information about other options you can use with the `describe-sessions` command, see `describe-sessions` in the AWS Systems Manager section of the AWS CLI Command Reference.

### Auditing session activity

In addition to providing information about current and completed sessions in the Systems Manager console, Session Manager provides you with the ability to audit session activity in your AWS account using AWS CloudTrail.

CloudTrail captures session API calls through the Systems Manager console, the AWS Command Line Interface (AWS CLI), and the Systems Manager SDK. You can view the information on the CloudTrail console or store it in a specified Amazon Simple Storage Service (Amazon S3) bucket. One Amazon S3 bucket is used for all CloudTrail logs for your account. For more information, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#).

**Note**

For recurring, historical, analytical analysis of your log files, consider querying CloudTrail logs using [CloudTrail Lake](#) or a table you maintain. For more information, see [Querying AWS CloudTrail logs](#) in the *AWS CloudTrail User Guide*. 
Monitoring session activity using Amazon EventBridge (console)

With EventBridge, you can set up rules to detect when changes happen to AWS resources. You can create a rule to detect when a user in your organization starts or ends a session, and then, for example, receive a notification through Amazon SNS about the event.

EventBridge support for Session Manager relies on records of API operations that were recorded by CloudTrail. (You can use CloudTrail integration with EventBridge to respond to most AWS Systems Manager events.) Actions that take place within a session, such as an exit command, that don't make an API call aren't detected by EventBridge.

The following steps outline how to initiate notifications through Amazon Simple Notification Service (Amazon SNS) when a Session Manager API event occurs, such as StartSession.

To monitor session activity using Amazon EventBridge (console)

1. Create an Amazon SNS topic to use for sending notifications when the Session Manager event occurs that you want to track.

   For more information, see Create a Topic in the Amazon Simple Notification Service Developer Guide.

2. Create an EventBridge rule to invoke the Amazon SNS target for the type of Session Manager event you want to track.

   For information about how to create the rule, see Creating Amazon EventBridge rules that react to events in the Amazon EventBridge User Guide.

As you follow the steps to create the rule, make the following selections:

- For **AWS service**, choose Systems Manager.
- For **Event type**, choose AWS API Call through CloudTrail.
- Choose **Specific operation(s)**, and then enter the Session Manager command or commands (one at a time) you want to receive notifications for. You can choose StartSession, ResumeSession, and TerminateSession. (EventBridge doesn't support Get*, List*, and Describe* commands.)
- For **Select a target**, choose SNS topic. For **Topic**, choose the name of the Amazon SNS topic you created in Step 1.
For more information, see the Amazon EventBridge User Guide and the Amazon Simple Notification Service Getting Started Guide.

Enabling and disabling session activity logging

In addition to providing information about current and completed sessions in the Systems Manager console, Session Manager provides you with options for logging session activity in your AWS account. This allows you to do the following:

- Create and store session logs for archival purposes.
- Generate a report showing details of every connection made to your managed nodes using Session Manager over the past 30 days.
- Generate notifications of session activity in your AWS account, such as Amazon Simple Notification Service (Amazon SNS) notifications.
- Automatically initiate another action on an AWS resource as the result of session activity, such as running an AWS Lambda function, starting an AWS CodePipeline pipeline, or running an AWS Systems Manager Run Command document.

⚠️ Important

Take note of the following requirements and limitations for Session Manager:

- Session Manager logs the commands you enter and their output during a session depending on your session preferences. To prevent sensitive data, such as passwords, from being viewed in your session logs we recommend using the following commands when entering sensitive data during a session.

  **Linux & macOS**

  stty -echo; read passwd; stty echo;

  **Windows**

  $Passwd = Read-Host -AsSecureString

- If you're using Windows Server 2012 or earlier, the data in your logs might not be formatted optimally. We recommend using Windows Server 2012 R2 and later for optimal log formats.
• If you’re using Linux or macOS managed nodes, ensure that the screen utility is installed. If it isn’t, your log data might be truncated. On Amazon Linux 1, Amazon Linux 2, AL2023 and Ubuntu Server, the screen utility is installed by default. To install screen manually, depending on your version of Linux, run either `sudo yum install screen` or `sudo apt-get install screen`.

• Logging isn't available for Session Manager sessions that connect through port forwarding or SSH. This is because SSH encrypts all session data, and Session Manager only serves as a tunnel for SSH connections.

For more information about the permissions required to use Amazon S3 or Amazon CloudWatch Logs for logging session data, see Creating an IAM role with permissions for Session Manager and Amazon S3 and CloudWatch Logs (console).

Refer to the following topics for more information about logging options for Session Manager.

Topics

• Streaming session data using Amazon CloudWatch Logs (console)

• Logging session data using Amazon S3 (console)

• Logging session data using Amazon CloudWatch Logs (console)

• Disabling Session Manager activity logging in CloudWatch Logs and Amazon S3

Streaming session data using Amazon CloudWatch Logs (console)

You can send a continual stream of session data logs to Amazon CloudWatch Logs. Essential details, such as the commands a user has run in a session, the ID of the user who ran the commands, and timestamps for when the session data is streamed to CloudWatch Logs, are included when streaming session data. When streaming session data, the logs are JSON-formatted to help you integrate with your existing logging solutions. Streaming session data isn't supported for interactive commands.

Note

To stream session data from Windows Server managed nodes, you must have PowerShell 5.1 or later installed. By default, Windows Server 2016 and later have the required PowerShell version installed. However, Windows Server 2012 and 2012 R2 don’t have the...
required PowerShell version installed by default. If you haven't already updated PowerShell on your Windows Server 2012 or 2012 R2 managed nodes, you can do so using Run Command. For information about updating PowerShell using Run Command, see Updating PowerShell using Run Command.

⚠️ Important

If you have the PowerShell Transcription policy setting configured on your Windows Server managed nodes, you won't be able to stream session data.

To stream session data using Amazon CloudWatch Logs (console)

2. In the navigation pane, choose Session Manager.
3. Choose the Preferences tab, and then choose Edit.
4. Select the check box next to Enable under CloudWatch logging.
5. Choose the Stream session logs option.
6. (Recommended) Select the check box next to Allow only encrypted CloudWatch log groups. With this option turned on, log data is encrypted using the server-side encryption key specified for the log group. If you don't want to encrypt the log data that is sent to CloudWatch Logs, clear the check box. You must also clear the check box if encryption isn't allowed on the log group.
7. For CloudWatch logs, to specify the existing CloudWatch Logs log group in your AWS account to upload session logs to, select one of the following:
   - Enter the name of a log group in the text box that has already been created in your account to store session log data.
   - Browse log groups: Select a log group that has already been created in your account to store session log data.
8. Choose Save.
Logging session data using Amazon S3 (console)

You can choose to store session log data in a specified Amazon Simple Storage Service (Amazon S3) bucket for debugging and troubleshooting purposes. The default option is for logs to be sent to an encrypted Amazon S3 bucket. Encryption is performed using the key specified for the bucket, either an AWS KMS key or an Amazon S3 Server-Side Encryption (SSE) key (AES-256).

⚠️ Important
When you use virtual hosted–style buckets with Secure Sockets Layer (SSL), the SSL wildcard certificate only matches buckets that don't contain periods. To work around this, use HTTP or write your own certificate verification logic. We recommend that you don't use periods (".") in bucket names when using virtual hosted–style buckets.

Amazon S3 bucket encryption

In order to send logs to your Amazon S3 bucket with encryption, encryption must be allowed on the bucket. For more information about Amazon S3 bucket encryption, see Amazon S3 Default Encryption for S3 Buckets.

Customer managed key

If you're using a KMS key that you manage yourself to encrypt your bucket, then the IAM instance profile attached to your instances must have explicit permissions to read the key. If you use an AWS managed key, the instance doesn't require this explicit permission. For more information about providing the instance profile with access to use the key, see Allows Key Users to Use the key in the AWS Key Management Service Developer Guide.

Follow these steps to configure Session Manager to store session logs in an Amazon S3 bucket.

🔍 Note
You can also use the AWS CLI to specify or change the Amazon S3 bucket that session data is sent to. For information, see Update Session Manager preferences (command line).
To log session data using Amazon S3 (console)

2. In the navigation pane, choose Session Manager.
3. Choose the Preferences tab, and then choose Edit.
4. Select the check box next to Enable under S3 logging.
5. (Recommended) Select the check box next to Allow only encrypted S3 buckets. With this option turned on, log data is encrypted using the server-side encryption key specified for the bucket. If you don't want to encrypt the log data that is sent to Amazon S3, clear the check box. You must also clear the check box if encryption isn't allowed on the S3 bucket.
6. For S3 bucket name, select one of the following:
   - Choose a bucket name from the list: Select an Amazon S3 bucket that has already been created in your account to store session log data.
   - Enter a bucket name in the text box: Enter the name of an Amazon S3 bucket that has already been created in your account to store session log data.
7. (Optional) For S3 key prefix, enter the name of an existing or new folder to store logs in the selected bucket.
8. Choose Save.

For more information about working with Amazon S3 and Amazon S3 buckets, see the Amazon Simple Storage Service User Guide and the Amazon Simple Storage Service User Guide.

Logging session data using Amazon CloudWatch Logs (console)

With Amazon CloudWatch Logs, you can monitor, store, and access log files from various AWS services. You can send session log data to a CloudWatch Logs log group for debugging and
troubleshooting purposes. The default option is for log data to be sent with encryption using your KMS key, but you can send the data to your log group with or without encryption.

Follow these steps to configure AWS Systems Manager Session Manager to send session log data to a CloudWatch Logs log group at the end of your sessions.

**Note**

You can also use the AWS CLI to specify or change the CloudWatch Logs log group that session data is sent to. For information, see [Update Session Manager preferences (command line)](https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-update-preferences.html).

---

To log session data using Amazon CloudWatch Logs (console)

2. In the navigation pane, choose Session Manager.
3. Choose the Preferences tab, and then choose Edit.
4. Select the check box next to Enable under CloudWatch logging.
5. Choose the Upload session logs option.
6. (Recommended) Select the check box next to Allow only encrypted CloudWatch log groups. With this option turned on, log data is encrypted using the server-side encryption key specified for the log group. If you don't want to encrypt the log data that is sent to CloudWatch Logs, clear the check box. You must also clear the check box if encryption isn't allowed on the log group.
7. For CloudWatch logs, to specify the existing CloudWatch Logs log group in your AWS account to upload session logs to, select one of the following:
   - **Choose a log group from the list**: Select a log group that has already been created in your account to store session log data.
   - **Enter a log group name in the text box**: Enter the name of a log group that has already been created in your account to store session log data.
8. Choose Save.
For more information about working with CloudWatch Logs, see the Amazon CloudWatch Logs User Guide.

Disabling Session Manager activity logging in CloudWatch Logs and Amazon S3

You can use the Systems Manager console or AWS CLI to disable session activity logging in your account.

To disable session activity logging (console)

2. In the navigation pane, choose Session Manager.
3. Choose the Preferences tab, and then choose Edit.
4. To disable CloudWatch logging, in the CloudWatch logging section, clear the Enable checkbox.
5. To disable S3 logging, in the S3 logging section, clear the Enable checkbox.
6. Choose Save.

To disable session activity logging (AWS CLI)

To disable session activity logging using the AWS CLI, follow the instructions in Update Session Manager preferences (command line).

In your JSON file, ensure that the s3BucketName and cloudWatchLogGroupName inputs contain no values. For example:

```
"inputs": {
    "s3BucketName": "",
    ...
    "cloudWatchLogGroupName": "",
    ...
}
```

Alternatively, you can remove all the S3* and cloudWatch* inputs from your JSON file to disable logging.
Session document schema

The following information describes the schema elements of a Session document. AWS Systems Manager Session Manager uses Session documents to determine which type of session to start, such as a standard session, a port forwarding session, or a session to run an interactive command.

**schemaVersion**

The schema version of the Session document. Session documents only support version 1.0.

Type: String

Required: Yes

**description**

A description you specify for the Session document. For example, "Document to start port forwarding session with Session Manager".

Type: String

Required: No

**sessionType**

The type of session the Session document is used to establish.

Type: String

Required: Yes

Valid values: InteractiveCommands | NonInteractiveCommands | Port | Standard_Stream

**inputs**

The session preferences to use for sessions established using this Session document. This element is required for Session documents that are used to create Standard_Stream sessions.

Type: StringMap

Required: No

**s3BucketName**

The Amazon Simple Storage Service (Amazon S3) bucket you want to send session logs to at the end of your sessions.
**s3KeyPrefix**

The prefix to use when sending logs to the Amazon S3 bucket you specified in the s3BucketName input. For more information about using a shared prefix with objects stored in Amazon S3, see [How do I use folders in an S3 bucket?](https://docs.aws.amazon.com/AmazonS3/latest/userguide/how-do-i-use-folders-in-an-s3-bucket.html) in the *Amazon Simple Storage Service User Guide*.

Type: String  
Required: No

**s3EncryptionEnabled**

If set to `true`, the Amazon S3 bucket you specified in the s3BucketName input must be encrypted.

Type: Boolean  
Required: Yes

**cloudWatchLogGroupName**

The name of the Amazon CloudWatch Logs (CloudWatch Logs) group you want to send session logs to at the end of your sessions.

Type: String  
Required: No

**cloudWatchEncryptionEnabled**

If set to `true`, the log group you specified in the cloudWatchLogGroupName input must be encrypted.

Type: Boolean  
Required: Yes

**cloudWatchStreamingEnabled**

If set to `true`, a continual stream of session data logs are sent to the log group you specified in the cloudWatchLogGroupName input. If set to `false`, session logs are sent to the log group you specified in the cloudWatchLogGroupName input at the end of your sessions.
**kmsKeyId**

The ID of the AWS KMS key you want to use to further encrypt data between your local client machines and the Amazon Elastic Compute Cloud (Amazon EC2) managed nodes you connect to.

- Type: String
- Required: No

**runAsEnabled**

If set to `true`, you must specify a user account that exists on the managed nodes you will be connecting to in the `runAsDefaultUser` input. Otherwise, sessions will fail to start. By default, sessions are started using the `ssm-user` account created by the AWS Systems Manager SSM Agent. The Run As feature is only supported for connecting to Linux managed nodes.

- Type: Boolean
- Required: Yes

**runAsDefaultUser**

The name of the user account to start sessions with on Linux managed nodes when the `runAsEnabled` input is set to `true`. The user account you specify for this input must exist on the managed nodes you will be connecting to; otherwise, sessions will fail to start.

- Type: String
- Required: No

**idleSessionTimeout**

The amount of time of inactivity you want to allow before a session ends. This input is measured in minutes.

- Type: String
- Valid values: 1-60
- Required: No
**maxSessionDuration**

The maximum amount of time you want to allow before a session ends. This input is measured in minutes.

Type: String

Valid values: 1-1440

Required: No

**shellProfile**

The preferences you specify per operating system to apply within sessions such as shell preferences, environment variables, working directories, and running multiple commands when a session is started.

Type: StringMap

Required: No

**windows**

The shell preferences, environment variables, working directories, and commands you specify for sessions on Windows managed nodes.

Type: String

Required: No

**linux**

The shell preferences, environment variables, working directories, and commands you specify for sessions on Linux managed nodes.

Type: String

Required: No

**parameters**

An object that defines the parameters the document accepts. For more information about defining document parameters, see **parameters** in the Top-level data elements. For parameters that you reference often, we recommend that you store those parameters in Systems Manager Parameter Store and then reference them. You can reference String and StringList Parameter Store parameters in this section of a document. You can't reference SecureString
Parameter Store parameters in this section of a document. You can reference a Parameter Store parameter using the following format.

```yaml
{{ssm:parameter-name}}
```

For more information about Parameter Store, see [AWS Systems Manager Parameter Store](https://docs.aws.amazon.com/systemsmanager/latest/userguide/parameters-store.html).

**Type:** StringMap

**Required:** No

**properties**

An object whose values you specify that are used in the `StartSession` API operation.

For Session documents that are used for `InteractiveCommands` sessions, the `properties` object includes the commands to run on the operating systems you specify. You can also determine whether commands are run as root using the `runAsElevated` boolean property. For more information, see [Restrict access to commands in a session](https://docs.aws.amazon.com/systemsmanager/latest/userguide/interactive-commands.html).

For Session documents that are used for `Port` sessions, the `properties` object contains the port number where traffic should be redirected to. For an example, see the `Port` type Session document example later in this topic.

**Type:** StringMap

**Required:** No

**Standard_Stream** type Session document example

**YAML**

```yaml
---
schemaVersion: '1.0'
description: Document to hold regional settings for Session Manager
sessionType: Standard_Stream
inputs:
  s3BucketName: ''
  s3KeyPrefix: ''
  s3EncryptionEnabled: true
  cloudWatchLogGroupName: ''
  cloudWatchEncryptionEnabled: true
```

Session document schema
cloudWatchStreamingEnabled: true
kmsKeyId: ''
runAsEnabled: true
runAsDefaultUser: ''
idleSessionTimeout: '20'
maxSessionDuration: '60'
shellProfile:
    windows: ''
    linux: ''

JSON

```
{
    "schemaVersion": "1.0",
    "description": "Document to hold regional settings for Session Manager",
    "sessionType": "Standard_Stream",
    "inputs": {
        "s3BucketName": "",
        "s3KeyPrefix": "",
        "s3EncryptionEnabled": true,
        "cloudWatchLogGroupName": "",
        "cloudWatchEncryptionEnabled": true,
        "cloudWatchStreamingEnabled": true,
        "kmsKeyId": "",
        "runAsEnabled": true,
        "runAsDefaultUser": "",
        "idleSessionTimeout": "20",
        "maxSessionDuration": "60",
        "shellProfile": {
            "windows": "date",
            "linux": "pwd;ls"
        }
    }
}
```

InteractiveCommands type Session document example

YAML

```yaml
---
schemaVersion: '1.0'
description: Document to view a log file on a Linux instance
```
sessionType: InteractiveCommands
parameters:
  logpath:
    type: String
    description: The log file path to read.
    default: "/var/log/amazon/ssm/amazon-ssm-agent.log"
    allowedPattern: "^[a-zA-Z0-9-_/]+(.log)$"
properties:
  linux:
    commands: "tail -f {{ logpath }}"
    runAsElevated: true

JSON

```json
{
  "schemaVersion": "1.0",
  "description": "Document to view a log file on a Linux instance",
  "sessionType": "InteractiveCommands",
  "parameters": {
    "logpath": {
      "type": "String",
      "description": "The log file path to read.",
      "default": "/var/log/amazon/ssm/amazon-ssm-agent.log",
      "allowedPattern": "^[a-zA-Z0-9-_/]+(.log)$"
    }
  },
  "properties": {
    "linux": {
      "commands": "tail -f {{ logpath }}",
      "runAsElevated": true
    }
  }
}
```

Port type Session document example

YAML

```yaml
---
schemaVersion: '1.0'
description: Document to open given port connection over Session Manager
sessionType: Port
```
parameters:
  paramExample:
    type: string
    description: document parameter
properties:
  portNumber: *anyPortNumber*

**JSON**

```json
{
  "schemaVersion": "1.0",
  "description": "Document to open given port connection over Session Manager",
  "sessionType": "Port",
  "parameters": {
    "paramExample": {
      "type": "string",
      "description": "document parameter"
    }
  }
}
```

**YAML**

```yaml
---
schemaVersion: '1.0'
description: Example document with quotation marks
sessionType: InteractiveCommands
parameters:
  Test:
    type: String
    description: Test Input
    maxChars: 32
properties:
  windows:
    commands: |
      $Test = '{{ Test }}'
      $myVariable = "Computer name is $env:COMPUTERNAME"
```

Session document example with special characters
Write-Host "Test variable: $myVariable`.nInput parameter: $Test"
runAsElevated: false

JSON

```
{
    "schemaVersion":"1.0",
    "description":"Test document with quotation marks",
    "sessionType":"InteractiveCommands",
    "parameters":{
        "Test":{
            "type":"String",
            "description":"Test Input",
            "maxChars":32
        }
    },
    "properties":{
        "windows":{
            "commands":[
                "$Test = '{{ Test }}'",
                "$myVariable = ""Computer name is $env:COMPUTERNAME""",
                "Write-Host "Test variable: $myVariable`.nInput parameter: $Test"
            ],
            "runAsElevated":false
        }
    }
}
```

Troubleshooting Session Manager

Use the following information to help you troubleshoot problems with AWS Systems Manager Session Manager.

Topics

- [Session Manager can't connect from the Amazon EC2 console](#)
- [No permission to start a session](#)
- [No permission to change session preferences](#)
- [Managed node not available or not configured for Session Manager](#)
- [Session Manager plugin not found](#)
• **Session Manager plugin not automatically added to command line path (Windows)**
• **Session Manager plugin becomes unresponsive**
• **TargetNotConnected**
• **Blank screen displays after starting a session**
• **Managed node becomes unresponsive during long running sessions**
• **An error occurred (InvalidDocument) when calling the StartSession operation**

**Session Manager can't connect from the Amazon EC2 console**

**Problem:** After creating a new instance, the **Session Manager** tab in the Amazon Elastic Compute Cloud (Amazon EC2) console doesn't give you the option to connect.

**Solution A: Create an instance profile:** If you haven't already done so (as instructed by the information on the **Session Manager** tab in the EC2 console), create an AWS Identity and Access Management (IAM) instance profile by using Quick Setup. Quick Setup is a capability of AWS Systems Manager.

Session Manager requires an IAM instance profile to connect to your instance. You can create an instance profile and assign it to your instance by creating a [host management configuration](#) with Quick Setup. A *host management configuration* creates an instance profile with the required permissions and assigns it to your instance. A host management configuration also enables other Systems Manager capabilities and creates IAM roles for running those capabilities. There is no charge to use Quick Setup or the capabilities enabled by the host management configuration. **Open Quick Setup and create a host management configuration.**

⚠️ **Important**

After you create the host management configuration, Amazon EC2 can take several minutes to register the change and refresh the **Session Manager** tab. If the tab doesn't show you a **Connect** button after two minutes, reboot your instance. After it reboots, if you still don't see the option to connect, open [Quick Setup](#) and verify you have only one host management configuration. If there are two, delete the older configuration and wait a few minutes.

If you still can't connect after creating a host management configuration, or if you receive an error, including an error about SSM Agent, see one of the following solutions:
Solution B: No error, but still can't connect

If you created the host management configuration, waited several minutes before trying to connect, and still can't connect, then you might need to manually apply the host management configuration to your instance. Use the following procedure to update a Quick Setup host management configuration and apply changes to an instance.

To update a host management configuration using Quick Setup

2. In the navigation pane, choose Quick Setup.
3. In the Configurations list, choose the Host Management configuration you created.
4. Choose Actions, and then choose Edit configuration.
5. In the Targets section, choose Manual.
6. In the Instances section, choose the instance you created.
7. Choose Update.

Wait a few minutes for EC2 to refresh the Session Manager tab. If you still can't connect or if you receive an error, review the remaining solutions for this issue.

Solution C: Error about missing SSM Agent

If you weren't able to create a host management configuration by using Quick Setup, or if you received an error about SSM Agent not being installed, you may need to manually install SSM Agent on your instance. SSM Agent is Amazon software that enables Systems Manager to connect to your instance by using Session Manager. SSM Agent is installed by default on most Amazon Machine Images (AMIs). If your instance was created from a non-standard AMI or an older AMI, you might have to manually install the agent. For the procedure to install SSM Agent, see the following topic that corresponds to your instance operating system.

- [Windows Server](#)
- [macOS](#)
AWS Systems Manager

- AlmaLinux
- Amazon Linux 1
- Amazon Linux 2 and AL2023
- CentOS
- CentOS Stream
- Debian Server
- Oracle Linux
- Red Hat Enterprise Linux
- Rocky Linux
- SUSE Linux Enterprise Server
- Ubuntu Server

For issues with SSM Agent, see [Troubleshooting SSM Agent](#).

**No permission to start a session**

**Problem:** You try to start a session, but the system tells you that you don't have the necessary permissions.

**Solution:** A system administrator hasn't granted you AWS Identity and Access Management (IAM) policy permissions for starting Session Manager sessions. For information, see [Control user session access to instances](#).

**No permission to change session preferences**

**Problem:** You try to update global session preferences for your organization, but the system tells you that you don't have the necessary permissions.

**Solution:** A system administrator hasn't granted you IAM policy permissions for setting Session Manager preferences. For information, see [Grant or deny a user permissions to update Session Manager preferences](#).

**Managed node not available or not configured for Session Manager**

**Problem 1:** You want to start a session on the **Start a session** console page, but a managed node isn't in the list.
• **Solution A:** The managed node you want to connect to might not have been configured for AWS Systems Manager. For more information, see [Setting up AWS Systems Manager](#).

**Note**

If AWS Systems Manager SSM Agent is already running on a managed node when you attach the IAM instance profile, you might need to restart the agent before the instance is listed on the *Start a session* console page.

• **Solution B:** The proxy configuration you applied to the SSM Agent on your managed node might be incorrect. If the proxy configuration is incorrect, the managed node won't be able to reach the needed service endpoints, or the node might report as a different operating system to Systems Manager. For more information, see [Configuring SSM Agent to use a proxy on Linux nodes](#) and [Configure SSM Agent to use a proxy for Windows Server instances](#).

**Problem 2:** A managed node you want to connect is in the list on the *Start a session* console page, but the page reports that "The instance you selected isn't configured to use Session Manager."

• **Solution A:** The managed node has been configured for use with the Systems Manager service, but the IAM instance profile attached to the node might not include permissions for the Session Manager capability. For information, see [Verify or Create an IAM Instance Profile with Session Manager Permissions](#).

• **Solution B:** The managed node isn't running a version of SSM Agent that supports Session Manager. Update SSM Agent on the node to version 2.3.68.0 or later.

Update SSM Agent manually on a managed node by following the steps in [Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server](#), [Manually installing and uninstalling SSM Agent on EC2 instances for Linux](#), or [Manually installing and uninstalling SSM Agent on EC2 instances for macOS](#), depending on the operating system.

Alternatively, use the Run Command document *AWS-UpdateSSMAgent* to update the agent version on one or more managed nodes at a time. For information, see [Updating the SSM Agent using Run Command](#).

**Tip**

To always keep your agent up to date, we recommend updating SSM Agent to the latest version on an automated schedule that you define using either of the following methods:
• Run AWS-UpdateSSMAgent as part of a State Manager association. For information, see Walkthrough: Automatically update SSM Agent (CLI).

• Run AWS-UpdateSSMAgent as part of a maintenance window. For information about working with maintenance windows, see Working with maintenance windows (console) and Tutorial: Create and configure a maintenance window (AWS CLI).

• **Solution C**: The managed node can't reach the requisite service endpoints. You can improve the security posture of your managed nodes by using interface endpoints powered by AWS PrivateLink to connect to Systems Manager endpoints. The alternative to using interface endpoints is to allow outbound internet access on your managed nodes. For more information, see Use PrivateLink to set up a VPC endpoint for Session Manager.

• **Solution D**: The managed node has limited available CPU or memory resources. Although your managed node might otherwise be functional, if the node doesn't have enough available resources, you can't establish a session. For more information, see Troubleshooting an Unreachable Instance.

### Session Manager plugin not found

To use the AWS CLI to run session commands, the Session Manager plugin must also be installed on your local machine. For information, see Install the Session Manager plugin for the AWS CLI.

### Session Manager plugin not automatically added to command line path (Windows)

When you install the Session Manager plugin on Windows, the session-manager-plugin executable should be automatically added to your operating system's PATH environment variable. If the command failed after you ran it to check whether the Session Manager plugin installed correctly (aws ssm start-session --target instance-id), you might need to set it manually using the following procedure.

**To modify your PATH variable (Windows)**

1. Press the Windows key and enter environment variables.
2. Choose Edit environment variables for your account.
3. Choose PATH and then choose Edit.
4. Add paths to the Variable value field, separated by semicolons, as shown in this example: 

```
C:\existing\path;C:\new\path
```

*C:\existing\path* represents the value already in the field. *C:\new\path* represents the path you want to add, as shown in these examples.

- **64-bit machines:** `C:\Program Files\Amazon\SessionManagerPlugin\bin\`
- **32-bit machines:** `C:\Program Files (x86)\Amazon\SessionManagerPlugin\bin\`

5. Choose OK twice to apply the new settings.

6. Close any running command prompts and re-open.

**Session Manager plugin becomes unresponsive**

During a port forwarding session, traffic might stop forwarding if you have antivirus software installed on your local machine. In some cases, antivirus software interferes with the Session Manager plugin causing process deadlocks. To resolve this issue, allow or exclude the Session Manager plugin from the antivirus software. For information about the default installation path for the Session Manager plugin, see [Install the Session Manager plugin for the AWS CLI](#).

**TargetNotConnected**

**Problem:** You try to start a session, but the system returns the error message, "An error occurred (TargetNotConnected) when calling the StartSession operation: InstanceID isn't connected."

- **Solution A:** This error is returned when the specified target managed node for the session isn't fully configured for use with Session Manager. For information, see [Setting up Session Manager](#).
- **Solution B:** This error is also returned if you attempt to start a session on a managed node that is located in a different AWS account or AWS Region.

**Blank screen displays after starting a session**

**Problem:** You start a session and Session Manager displays a blank screen.

- **Solution A:** This issue can occur when the root volume on the managed node is full. Due to lack of disk space, SSM Agent on the node stops working. To resolve this issue, use Amazon CloudWatch to collect metrics and logs from the operating systems. For information, see [Collect metrics, logs, and traces with the CloudWatch agent](#) in the *Amazon CloudWatch User Guide*. 
Solution B: A blank screen might display if you accessed the console using a link that includes a mismatched endpoint and Region pair. For example, in the following console URL, us-west-2 is the specified endpoint, but us-west-1 is the specified AWS Region.

Solution C: The managed node is connecting to Systems Manager using VPC endpoints, and your Session Manager preferences write session output to an Amazon S3 bucket or Amazon CloudWatch Logs log group, but an s3 gateway endpoint or logs interface endpoint doesn’t exist in the VPC. An s3 endpoint in the format com.amazonaws.region.s3 is required if your managed nodes are connecting to Systems Manager using VPC endpoints, and your Session Manager preferences write session output to an Amazon S3 bucket. Alternatively, a logs endpoint in the format com.amazonaws.region.logs is required if your managed nodes are connecting to Systems Manager using VPC endpoints, and your Session Manager preferences write session output to a CloudWatch Logs log group. For more information, see Creating VPC endpoints for Systems Manager.

Solution D: The log group or Amazon S3 bucket you specified in your session preferences has been deleted. To resolve this issue, update your session preferences with a valid log group or S3 bucket.

Solution E: The log group or Amazon S3 bucket you specified in your session preferences isn't encrypted, but you have set the cloudWatchEncryptionEnabled or s3EncryptionEnabled input to true. To resolve this issue, update your session preferences with a log group or Amazon S3 bucket that is encrypted, or set the cloudWatchEncryptionEnabled or s3EncryptionEnabled input to false. This scenario is only applicable to customers who create session preferences using command line tools.

Managed node becomes unresponsive during long running sessions

Problem: Your managed node becomes unresponsive or crashes during a long running session.

Solution: Decrease the SSM Agent log retention duration for Session Manager.

To decrease the SSM Agent log retention duration for sessions

1. Locate the amazon-ssm-agent.json.template in the /etc/amazon/ssm/ directory for Linux, or C:\Program Files\Amazon\SSM for Windows.
2. Copy the contents of the `amazon-ssm-agent.json.template` to a new file in the same directory named `amazon-ssm-agent.json`.

3. Decrease the default value of the `SessionLogsRetentionDurationHours` value in the SSM property, and save the file.

4. Restart the SSM Agent.

**An error occurred (InvalidDocument) when calling the StartSession operation**

**Problem:** You receive the following error when starting a session by using the AWS CLI.

```
An error occurred (InvalidDocument) when calling the StartSession operation: Document type: 'Command' is not supported. Only type: 'Session' is supported for Session Manager.
```

**Solution:** The SSM document you specified for the `--document-name` parameter isn't a `Session` document. Use the following procedure to view a list of Session documents in the AWS Management Console.

**To view a list of Session documents**

2. In the navigation pane, choose **Documents**.
3. In the **Categories** list, choose **Session documents**.

**AWS Systems Manager Run Command**

Using Run Command, a capability of AWS Systems Manager, you can remotely and securely manage the configuration of your managed nodes. A **managed node** is any Amazon Elastic Compute Cloud (Amazon EC2) instance or non-EC2 machine in your [hybrid and multicloud](https://aws.amazon.com/hybrid) environment that has been configured for Systems Manager. Run Command allows you to automate common administrative tasks and perform one-time configuration changes at scale. You can use Run Command from the AWS Management Console, the AWS Command Line Interface (AWS CLI), AWS Tools for Windows PowerShell, or the AWS SDKs. Run Command is offered at no additional cost. To get started with Run Command, open the **Systems Manager console**. In the navigation pane, choose **Run Command**.
Administrators use Run Command to install or bootstrap applications, build a deployment pipeline, capture log files when an instance is removed from an Auto Scaling group, join instances to a Windows domain, and more.

The Run Command API follows an eventual consistency model, due to the distributed nature of the system supporting the API. This means that the result of an API command you run that affects your resources might not be immediately visible to all subsequent commands you run. You should keep this in mind when you carry out an API command that immediately follows a previous API command.

**Getting Started**

The following table includes information to help you get started with Run Command.

<table>
<thead>
<tr>
<th>Topic</th>
<th>Details</th>

**EventBridge support**
This Systems Manager capability is supported as both an *event* type and a *target* type in Amazon EventBridge rules. For information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

More info

- Remotely Run Command on an EC2 Instance (10 minute tutorial)
- Systems Manager service quotas in the Amazon Web Services General Reference
- AWS Systems Manager API Reference

Topics

- Setting up Run Command
- Running commands on managed nodes
- Using exit codes in commands
- Understanding command statuses
- Run Command walkthroughs
- Troubleshooting Systems Manager Run Command

**Setting up Run Command**

Before you can manage nodes by using Run Command, a capability of AWS Systems Manager, configure an AWS Identity and Access Management (IAM) policy for any user who will run commands.

You must also configure your nodes for Systems Manager. For more information, see Setting up AWS Systems Manager.

We recommend completing the following optional setup tasks to help minimize the security posture and day-to-day management of your managed nodes.

Monitor command executions using Amazon EventBridge

You can use EventBridge to log command execution status changes. You can create a rule that runs whenever there is a state transition, or when there is a transition to one or more states that are of interest. You can also specify Run Command as a target action when an EventBridge event occurs. For more information, see Configuring EventBridge for Systems Manager events.
Monitor command executions using Amazon CloudWatch Logs

You can configure Run Command to periodically send all command output and error logs to an Amazon CloudWatch log group. You can monitor these output logs in near real-time, search for specific phrases, values, or patterns, and create alarms based on the search. For more information, see Configuring Amazon CloudWatch Logs for Run Command.

Restrict Run Command access to specific managed nodes

You can restrict a user's ability to run commands on managed nodes by using AWS Identity and Access Management (IAM). Specifically, you can create an IAM policy with a condition that the user can only run commands on managed nodes that are tagged with specific tags. For more information, see Restricting Run Command access based on tags.

Restricting Run Command access based on tags

This section describes how to restrict a user's ability to run commands on managed nodes by specifying a tag condition in an IAM policy. Managed nodes include Amazon EC2 instances and non-EC2 nodes in a hybrid and multicloud environment that are configured for Systems Manager. Though the information is not explicitly presented, you can also restrict access to managed AWS IoT Greengrass core devices. To get started, you must tag your AWS IoT Greengrass devices. For more information, see Tag your AWS IoT Greengrass Version 2 resources in the AWS IoT Greengrass Version 2 Developer Guide.

You can restrict command execution to specific managed nodes by creating an IAM policy that includes a condition that the user can only run commands on nodes with specific tags. In the following example, the user is allowed to use Run Command (Effect: Allow, Action: ssm:SendCommand) by using any SSM document (Resource: arn:aws:ssm:*::*:document/*) on any node (Resource: arn:aws:ec2:*::*:instance/*) with the condition that the node is a Finance WebServer (ssm:resourceTag/Finance: WebServer). If the user sends a command to a node that isn't tagged or that has any tag other than Finance: WebServer, the execution results show AccessDenied.

```json
{
   "Version":"2012-10-17",
   "Statement": [ 
      { 
         "Effect":"Allow",
         "Action": [ 
            "ssm:SendCommand"
         ]
      }
   ]
}
```
You can create IAM policies that allow a user to run commands on managed nodes that are tagged with multiple tags. The following policy allows the user to run commands on managed nodes that have two tags. If a user sends a command to a node that isn't tagged with both of these tags, the execution results show **AccessDenied**.

```json
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Effect":"Allow",
            "Action":[
                "ssm:SendCommand"
            ],
            "Resource":[
                "arn:aws:ec2:*:*:instance/**
            ],
            "Condition":{
                "StringLike":{
                    "ssm:resourceTag/Finance":[
                        "WebServers"
                    ]
                }
            }
        }
    ]
}
```
You can also create IAM policies that allows a user to run commands on multiple groups of tagged managed nodes. The following example policy allows the user to run commands on either group of tagged nodes, or both groups.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:SendCommand"
            ],
            "Resource": [
                "arn:aws:ssm:us-west-1::document/AWS-*",
                "arn:aws:ssm:us-east-2::document/AWS-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:UpdateInstanceInformation",
                "ssm:ListCommands",
                "ssm:ListCommandInvocations",
                "ssm:GetDocument"
            ],
            "Resource": "*
        }
    ]
}
```
"StringLike": {
    "ssm:resourceTag/tag_key1": [
        "tag_value1"
    ]
},
"Effect": "Allow",
"Action": [
    "ssm:SendCommand"
],
"Resource": "*",
"Condition": {
    "StringLike": {
        "ssm:resourceTag/tag_key2": [
            "tag_value2"
        ]
    }
},
"Effect": "Allow",
"Action": [
    "ssm:SendCommand"
],
"Resource": [
    "arn:aws:ssm:us-west-1::document/AWS-*",
    "arn:aws:ssm:us-east-2::document/AWS-*"
]
},
"Effect": "Allow",
"Action": [
    "ssm:UpdateInstanceInformation",
    "ssm:ListCommands",
    "ssm:ListCommandInvocations",
    "ssm:GetDocument"
],
"Resource": "*"
For more information about creating IAM policies, see Managed policies and inline policies in the IAM User Guide. For more information about tagging managed nodes, see Tag Editor in the AWS Resource Groups User Guide.

Running commands on managed nodes

This section includes information about how to send commands from the AWS Systems Manager console to managed nodes. This section also includes information about how to cancel a command.

For information about how to send commands using Windows PowerShell, see Walkthrough: Use the AWS Tools for Windows PowerShell with Run Command or the examples in the AWS Systems Manager section of the AWS Tools for PowerShell Cmdlet Reference. For information about how to send commands using the AWS Command Line Interface (AWS CLI), see the Walkthrough: Use the AWS CLI with Run Command or the examples in the SSM CLI Reference.

⚠️ Important

When you send a command using Run Command, don't include sensitive information formatted as plaintext, such as passwords, configuration data, or other secrets. All Systems Manager API activity in your account is logged in an S3 bucket for AWS CloudTrail logs. This means that any user with access to S3 bucket can view the plaintext values of those secrets. For this reason, we recommend creating and using SecureString parameters to encrypt sensitive data you use in your Systems Manager operations.

For more information, see Restricting access to Systems Manager parameters using IAM policies.

Contents

- Running commands from the console
- Running commands using a specific document version
- Run commands at scale
- Canceling a command
Running commands from the console

You can use Run Command, a capability of AWS Systems Manager, from the AWS Management Console to configure managed nodes without having to log into them. This topic includes an example that shows how to update SSM Agent on a managed node by using Run Command.

Before you begin

Before you send a command using Run Command, verify that your managed nodes meet all Systems Manager setup requirements.

To send a command using Run Command

2. In the navigation pane, choose Run Command.
3. Choose Run command.
4. In the Command document list, choose a Systems Manager document.
5. In the Command parameters section, specify values for required parameters.
6. In the Targets section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

Tip
If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

7. For Other parameters:

   • For Comment, enter information about this command.
   • For Timeout (seconds), specify the number of seconds for the system to wait before failing the overall command execution.

8. For Rate control:

   • For Concurrency, specify either a number or a percentage of managed nodes on which to run the command at the same time.
If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren’t certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) Choose a CloudWatch alarm to apply to your command for monitoring. To attach a CloudWatch alarm to your command, the IAM principal that runs the command must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see [Using Amazon CloudWatch alarms](#). Note that if your alarm activates, any pending command invocations do not run.

10. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

- The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

11. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

For information about canceling a command, see the section called “Canceling a command”.

Rerunning commands

Systems Manager includes two options to help you rerun a command from the Run Command page in the Systems Manager console.

- **Rerun**: This button allows you to run the same command without making changes to it.
- **Copy to new**: This button copies the settings of one command to a new command and gives you the option to edit those settings before you run it.

To rerun a command

2. In the navigation pane, choose Run Command.
3. Choose a command to rerun. You can rerun a command immediately after executing it from the command details page. Or, you can choose a command that you previously ran from the Command history tab.
4. Choose either Rerun to run the same command without changes, or choose Copy to new to edit the command settings before you run it.

Running commands using a specific document version

You can use the document version parameter to specify which version of an AWS Systems Manager document to use when the command runs. You can specify one of the following options for this parameter:

- $DEFAULT
- $LATEST
- Version number

Run the following procedure to run a command using the document version parameter.
**Linux**

**To run commands using the AWS CLI on local Linux machines**

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.
   
   For information, see [Installing or updating the latest version of the AWS CLI](#).

2. List all available documents

   This command lists all of the documents available for your account based on AWS Identity and Access Management (IAM) permissions.

   ```
   aws ssm list-documents
   ```

3. Run the following command to view the different versions of a document. Replace `document name` with your own information.

   ```
   aws ssm list-document-versions \
   --name "document name"
   ```

4. Run the following command to run a command that uses an SSM document version. Replace each `example resource placeholder` with your own information.

   ```
   aws ssm send-command \
   --document-name "AWS-RunShellScript" \
   --parameters commands="echo Hello" \
   --instance-ids instance-ID \
   --document-version '$LATEST'
   ```

**Windows**

**To run commands using the AWS CLI on local Windows machines**

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see [Installing or updating the latest version of the AWS CLI](#).

2. List all available documents

   This command lists all of the documents available for your account based on AWS Identity and Access Management (IAM) permissions.
3. Run the following command to view the different versions of a document. Replace `document name` with your own information.

```bash
aws ssm list-document-versions
  --name "document name"
```

4. Run the following command to run a command that uses an SSM document version. Replace each `example resource placeholder` with your own information.

```bash
aws ssm send-command
  --document-name "AWS-RunShellScript"
  --parameters commands="echo Hello"
  --instance-ids instance-ID
  --document-version "$LATEST"
```

### PowerShell

#### To run commands using the Tools for PowerShell

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

   For information, see [Installing the AWS Tools for PowerShell](#).

2. List all available documents

   This command lists all of the documents available for your account based on AWS Identity and Access Management (IAM) permissions.

   ```powershell
   Get-SSMDocumentList
   ```

3. Run the following command to view the different versions of a document. Replace `document name` with your own information.

   ```powershell
   Get-SSMDocumentVersionList
     -Name "document name"
   ```
4. Run the following command to run a command that uses an SSM document version. Replace each example resource placeholder with your own information.

```
Send-SSMCommand 
-DocumentName "AWS-RunShellScript" 
-Parameter @{commands = "echo helloWorld"} 
-InstanceIds "instance-ID" 
-DocumentVersion $LATEST
```

**Run commands at scale**

You can use Run Command, a capability of AWS Systems Manager, to run commands on a fleet of managed nodes by using the targets. The targets parameter accepts a Key, Value combination based on tags that you specified for your managed nodes. When you run the command, the system locates and attempts to run the command on all managed nodes that match the specified tags. For more information about tagging managed instances, see [Tagging your AWS resources](#) in the **Tagging AWS Resources User Guide**. For information about tagging your managed IoT devices, see [Tag your AWS IoT Greengrass Version 2 resources](#) in the **AWS IoT Greengrass Version 2 Developer Guide**.

You can also use the targets parameter to target a list of specific managed node IDs, as described in the next section.

To control how commands run across hundreds or thousands of managed nodes, Run Command also includes parameters for restricting how many nodes can simultaneously process a request and how many errors can be thrown by a command before the command is canceled.

**Contents**

- [Targeting multiple managed nodes](#)
- [Using rate controls](#)

**Targeting multiple managed nodes**

You can run a command and target managed nodes by specifying tags, AWS resource group names, or managed node IDs.
The following examples show the command format when using Run Command from the AWS Command Line Interface (AWS CLI). Replace each example resource placeholder with your own information. Sample commands in this section are truncated using [...].

**Example 1: Targeting tags**

Linux & macOS

```
aws ssm send-command \
   --document-name document-name \
   --targets Key=tag:tag-name,Values=tag-value \
   [...] 
```

Windows

```
aws ssm send-command ^
   --document-name document-name ^
   --targets Key=tag:tag-name,Values=tag-value ^
   [...] 
```

**Example 2: Targeting an AWS resource group by name**

You can specify a maximum of one resource group name per command. When you create a resource group, we recommend including `AWS::SSM::ManagedInstance` and `AWS::EC2::Instance` as resource types in your grouping criteria.

**Note**

In order to send commands that target a resource group, you must have been granted AWS Identity and Access Management (IAM) permissions to list or view the resources that belong to that group. For more information, see [Set up permissions](#) in the AWS Resource Groups User Guide.

Linux & macOS

```
aws ssm send-command \
   --document-name document-name \
   --targets Key=resource-groups:Name,Values=resource-group-name 
```
Example 3: Targeting an AWS resource group by resource type

You can specify a maximum of five resource group types per command. When you create a resource group, we recommend including `AWS::SSM::ManagedInstance` and `AWS::EC2::Instance` as resource types in your grouping criteria.

ℹ️ Note

In order to send commands that target a resource group, you must have been granted IAM permissions to list, or view, the resources that belong to that group. For more information, see [Set up permissions](<http://aws.amazon.com>) in the *AWS Resource Groups User Guide*. 

Example 4: Targeting instance IDs
The following examples show how to target managed nodes by using the instanceids key with the targets parameter. You can use this key to target managed AWS IoT Greengrass core devices because each device is assigned an mi-ID_number. You can view device IDs in Fleet Manager, a capability of AWS Systems Manager.

**Linux & macOS**

```bash
aws ssm send-command \
  --document-name document-name \
  --targets Key=instanceids,Values=instance-ID-1,instance-ID-2,instance-ID-3 \\n[...]
```

**Windows**

```bash
aws ssm send-command ^
  --document-name document-name ^
  --targets Key=instanceids,Values=instance-ID-1,instance-ID-2,instance-ID-3 ^
[...]
```

If you tagged managed nodes for different environments using a Key named Environment and Values of Development, Test, Pre-production and Production, then you could send a command to all managed nodes in one of these environments by using the targets parameter with the following syntax.

**Linux & macOS**

```bash
aws ssm send-command \
  --document-name document-name \
  --targets Key=tag:Environment,Values=Development \\n[...]
```

**Windows**

```bash
aws ssm send-command ^
  --document-name document-name ^
  --targets Key=tag:Environment,Values=Development ^
[...]
```
You could target additional managed nodes in other environments by adding to the Values list. Separate items using commas.

**Linux & macOS**

```bash
aws ssm send-command \
  --document-name document-name \
  --targets Key=tag:Environment,Values=Development,Test,Pre-production \
  [...] 
```

**Windows**

```bash
aws ssm send-command ^
  --document-name document-name ^
  --targets Key=tag:Environment,Values=Development,Test,Pre-production ^
  [...] 
```

**Variation: Refining your targets using multiple Key criteria**

You can refine the number of targets for your command by including multiple Key criteria. If you include more than one Key criterion, the system targets managed nodes that meet *all* of the criteria. The following command targets all managed nodes tagged for the Finance Department *and* tagged for the database server role.

**Linux & macOS**

```bash
aws ssm send-command \
  --document-name document-name \
  --targets Key=tag:Department,Values=Finance Key=tag:ServerRole,Values=Database \
  [...] 
```

**Windows**

```bash
aws ssm send-command ^
  --document-name document-name ^
  --targets Key=tag:Department,Values=Finance Key=tag:ServerRole,Values=Database ^
  [...] 
```

**Variation: Using multiple Key and Value criteria**
Expanding on the previous example, you can target multiple departments and multiple server roles by including additional items in the Values criteria.

Linux & macOS

```bash
aws ssm send-command \
  --document-name document-name \
  --targets Key=tag:Department,Values=Finance,Marketing
Key=tag:ServerRole,Values=WebServer,Database \
[...]
```

Windows

```bash
aws ssm send-command ^
  --document-name document-name ^
  --targets Key=tag:Department,Values=Finance,Marketing
Key=tag:ServerRole,Values=WebServer,Database ^
[...]
```

**Variation: Targeting tagged managed nodes using multiple Values criteria**

If you tagged managed nodes for different environments using a Key named Department and Values of Sales and Finance, then you could send a command to all of the nodes in these environments by using the targets parameter with the following syntax.

Linux & macOS

```bash
aws ssm send-command \
  --document-name document-name \
  --targets Key=tag:Department,Values=Sales,Finance \
[...]
```

Windows

```bash
aws ssm send-command ^
  --document-name document-name ^
  --targets Key=tag:Department,Values=Sales,Finance ^
[...]
```

You can specify a maximum of five keys, and five values for each key.
If either a tag key (the tag name) or a tag value includes spaces, enclose the tag key or the value in quotation marks, as shown in the following examples.

**Example: Spaces in Value tag**

Linux & macOS

```bash
aws ssm send-command \
   --document-name document-name \
   --targets Key=tag:OS,Values="Windows Server 2016 Nano" \
   [...]
```

Windows

```bash
aws ssm send-command ^
   --document-name document-name ^
   --targets Key=tag:OS,Values="Windows Server 2016 Nano" ^
   [...]
```

**Example: Spaces in tag key and Value**

Linux & macOS

```bash
aws ssm send-command \
   --document-name document-name \
   --targets Key="tag:Operating System",Values="Windows Server 2016 Nano" \
   [...]
```

Windows

```bash
aws ssm send-command ^
   --document-name document-name ^
   --targets Key="tag:Operating System",Values="Windows Server 2016 Nano" ^
   [...]
```

**Example: Spaces in one item in a list of Values**

Linux & macOS

```bash
aws ssm send-command \
```
Using rate controls

You can control the rate at which commands are sent to managed nodes in a group by using concurrency controls and error controls.

Topics

- Using concurrency controls
- Using error controls

Using concurrency controls

You can control the number of managed nodes that run a command simultaneously by using the max-concurrency parameter (the Concurrency options in the Run a command page). You can specify either an absolute number of managed nodes, for example 10, or a percentage of the target set, for example 10%. The queueing system delivers the command to a single node and waits until the system acknowledges the initial invocation before sending the command to two more nodes. The system exponentially sends commands to more nodes until the system meets the value of max-concurrency. The default for value max-concurrency is 50. The following examples show you how to specify values for the max-concurrency parameter.

Linux & macOS

```
aws ssm send-command \
  --document-name document-name \
  --max-concurrency 10 \
  --targets Key=tag:Environment,Values=Development \
  [...]```
aws ssm send-command \ 
  --document-name *document-name* \ 
  --max-concurrency 10% \ 
  --targets Key=tag:Department,Values=Finance,Marketing \ 
  Key=tag:ServerRole,Values=WebServer,Database \ 
  [...] 

Windows

aws ssm send-command ^ 
  --document-name *document-name* ^ 
  --max-concurrency 10 ^ 
  --targets Key=tag:Environment,Values=Development ^ 
  [...] 

aws ssm send-command ^ 
  --document-name *document-name* ^ 
  --max-concurrency 10% ^ 
  --targets Key=tag:Department,Values=Finance,Marketing 
  Key=tag:ServerRole,Values=WebServer,Database ^ 
  [...] 

**Using error controls**

You can also control the execution of a command to hundreds or thousands of managed nodes by setting an error limit using the `max-errors` parameters (the *Error threshold* field in the Run a command page). The parameter specifies how many errors are allowed before the system stops sending the command to additional managed nodes. You can specify either an absolute number of errors, for example 10, or a percentage of the target set, for example 10%. If you specify 3, for example, the system stops sending the command when the fourth error is received. If you specify 0, then the system stops sending the command to additional managed nodes after the first error result is returned. If you send a command to 50 managed nodes and set `max-errors` to 10%, then the system stops sending the command to additional nodes when the sixth error is received.

Invocations that are already running a command when `max-errors` is reached are allowed to complete, but some of these invocations might fail as well. If you need to ensure that there won’t be more than `max-errors` failed invocations, set `max-concurrency` to 1 so the invocations proceed one at a time. The default for `max-errors` is 0. The following examples show you how to specify values for the `max-errors` parameter.
Linux & macOS

```bash
aws ssm send-command \
  --document-name document-name \
  --max-errors 10 \
  --targets Key=tag:Database,Values=Development \
  [...]
```

```bash
aws ssm send-command \
  --document-name document-name \
  --max-errors 10% \
  --targets Key=tag:Environment,Values=Development \
  [...]
```

```bash
aws ssm send-command \
  --document-name document-name \
  --max-concurrency 1 \
  --max-errors 1 \
  --targets Key=tag:Environment,Values=Production \
  [...]
```

Windows

```bash
aws ssm send-command ^ \
  --document-name document-name ^ \
  --max-errors 10 ^ \
  --targets Key=tag:Database,Values=Development ^ 
  [...]
```

```bash
aws ssm send-command ^ \
  --document-name document-name ^ \
  --max-errors 10% ^ \
  --targets Key=tag:Environment,Values=Development ^ 
  [...]
```

```bash
aws ssm send-command ^ \
  --document-name document-name ^ \
  --max-concurrency 1 ^ \
  --max-errors 1 ^ \
  --targets Key=tag:Environment,Values=Production ^
```
Canceling a command

You can attempt to cancel a command as long as the service shows that it's in either a Pending or Executing state. However, even if a command is still in one of these states, we can't guarantee that the command will be canceled and the underlying process stopped.

To cancel a command using the console

2. In the navigation pane, choose Run Command.
3. Select the command invocation that you want to cancel.
4. Choose Cancel command.

To cancel a command using the AWS CLI

Run the following command. Replace each example resource placeholder with your own information.

Linux & macOS

```bash
aws ssm cancel-command \
   --command-id "command-ID" \
   --instance-ids "instance-ID"
```

Windows

```bash
aws ssm cancel-command ^
   --command-id "command-ID" ^
   --instance-ids "instance-ID"
```

For information about the status of a canceled command, see Understanding command statuses.

Using exit codes in commands

In some cases, you might need to manage how your commands are handled by using exit codes.
Specify exit codes in commands

Using Run Command, a capability of AWS Systems Manager, you can specify exit codes to determine how commands are handled. By default, the exit code of the last command run in a script is reported as the exit code for the entire script. For example, you have a script that contains three commands. The first one fails but the following ones succeed. Because the final command succeeded, the status of the execution is reported as succeeded.

Shell scripts

To fail the entire script at the first command failure, you can include a shell conditional statement to exit the script if any command before the final one fails. Use the following approach.

```bash
<command 1>
    if [ $? != 0 ]
    then
        exit <N>
    fi
<command 2>
<command 3>
```

In the following example, the entire script fails if the first command fails.

```bash
cd /test
    if [ $? != 0 ]
    then
        echo "Failed"
        exit 1
    fi
date
```

PowerShell scripts

PowerShell requires that you call exit explicitly in your scripts for Run Command to successfully capture the exit code.

```powershell
<command 1>
    if ($?) {<do something>}
    else {exit <N>}
<command 2>
<command 3>
```
exit <N>

Here is an example:

cd C:\
    if ($?) {echo "Success"}
else {exit 1}
date

Handling reboots when running commands

If you use Run Command, a capability of AWS Systems Manager, to run scripts that reboot managed nodes, we recommend that you specify an exit code in your script. If you attempt to reboot a node from a script by using some other mechanism, the script execution status might not be updated correctly, even if the reboot is the last step in your script. For Windows managed nodes, you specify exit 3010 in your script. For Linux and macOS managed nodes, you specify exit 194. The exit code instructs AWS Systems Manager Agent (SSM Agent) to reboot the managed node, and then restart the script after the reboot completed. Before starting the reboot, SSM Agent informs the Systems Manager service in the cloud that communication will be disrupted during the server reboot.

Note

The reboot script can't be part of an aws:runDocument plugin. If a document contains the reboot script and another document tries to run that document through the aws:runDocument plugin, SSM Agent returns an error.

Create idempotent scripts

When developing scripts that reboot managed nodes, make the scripts idempotent so the script execution continues where it left off after the reboot. Idempotent scripts manage state and validate if the action was performed or not. This prevents a step from running multiple times when it's only intended to run once.

Here is an outline example of an idempotent script that reboots a managed node multiple times.

$name = Get current computer name
If ($name -ne $desiredName)
$domain = Get current domain name
If ($domain –ne $desiredDomain)
{
    Join domain
    exit 3010
}

If (desired package not installed)
{
    Install package
    exit 3010
}

Examples

The following script samples use exit codes to restart managed nodes. The Linux example installs package updates on Amazon Linux, and then restarts the node. The Windows Server example installs the Telnet-Client on the node, and then restarts it.

Amazon Linux

    #!/bin/bash
    yum -y update
    needs-restarting -r
    if [ $? -eq 1 ]
    then
        exit 194
    else
        exit 0
    fi

Windows

    $telnet = Get-WindowsFeature -Name Telnet-Client
    if (-not $telnet.Installed)
    {
        # Install Telnet and then send a reboot request to SSM Agent.
        Install-WindowsFeature -Name "Telnet-Client"
Understanding command statuses

Run Command, a capability of AWS Systems Manager, reports detailed status information about the different states a command experiences during processing and for each managed node that processed the command. You can monitor command statuses using the following methods:

- Choose the **Refresh** icon on the **Commands** tab in the Run Command console interface.
- Call `list-commands` or `list-command-invocations` using the AWS Command Line Interface (AWS CLI). Or call `Get-SSMCommand` or `Get-SSMCommandInvocation` using AWS Tools for Windows PowerShell.
- Configure Amazon EventBridge to respond to state or status changes.
- Configure Amazon Simple Notification Service (Amazon SNS) to send notifications for all status changes or specific statuses such as Failed or TimedOut.

Run Command status

Run Command reports status details for three areas: plugins, invocations, and an overall command status. A **plugin** is a code-execution block that is defined in your command's SSM document. For more information about plugins, see [Command document plugin reference](#).

When you send a command to multiple managed nodes at the same time, each copy of the command targeting each node is a **command invocation**. For example, if you use the AWS-RunShellScript document and send an `ifconfig` command to 20 Linux instances, that command has 20 invocations. Each command invocation individually reports status. The plugins for a given command invocation individually report status as well.

Lastly, Run Command includes an aggregated command status for all plugins and invocations. The aggregated command status can be different than the status reported by plugins or invocations, as noted in the following tables.

---

**Note**

If you run commands to large numbers of managed nodes using the `max-concurrency` or `max-errors` parameters, command status reflects the limits imposed by those...
parameters, as described in the following tables. For more information about these parameters, see [Run commands at scale](#).

### Detailed status for command plugins and invocations

<table>
<thead>
<tr>
<th>Status</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pending</td>
<td>The command hasn't yet been sent to the managed node or hasn't been received by SSM Agent. If the command isn't received by the agent before the length of time passes that is equal to the sum of the <strong>Timeout (seconds)</strong> parameter and the <strong>Execution timeout</strong> parameter, the status changes to Delivery Timed Out.</td>
</tr>
<tr>
<td>InProgress</td>
<td>Systems Manager is attempting to send the command to the managed node, or the command was received by SSM Agent and has started running on the instance. Depending on the result of all command plugins, the status changes to Success, Failed, Delivery Timed Out, or Execution Timed Out. <em>Exception:</em> If the agent isn't running or available on the node, the command status remains at In Progress until the agent is available again, or until the execution timeout limit is reached. The status then changes to a terminal state.</td>
</tr>
<tr>
<td>Delayed</td>
<td>The system attempted to send the command to the managed node but wasn't successful. The system retries again.</td>
</tr>
<tr>
<td>Success</td>
<td>This status is returned under a variety of conditions. This status <em>doesn't</em> mean the command was processed on the node. For</td>
</tr>
<tr>
<td>Status</td>
<td>Details</td>
</tr>
<tr>
<td>--------</td>
<td>---------</td>
</tr>
<tr>
<td></td>
<td>example, the command can be received by SSM Agent on the managed node and return an exit code of zero as a result of your PowerShell ExecutionPolicy preventing the command from running. This is a terminal state. Conditions that result in a command returning a Success status are:</td>
</tr>
<tr>
<td></td>
<td>• When targeting a single instance, the command was received by SSM Agent on the managed node and returned an exit code of zero.</td>
</tr>
<tr>
<td></td>
<td>• When targeting multiple instances, the number of failed invocations has not crossed the error threshold specified in the command.</td>
</tr>
<tr>
<td></td>
<td>• When targeting multiple instances, at least 1 invocation has succeeded while others have timed out. The specified error threshold still applies.</td>
</tr>
<tr>
<td></td>
<td>• When targeting a tag, no instances are found associated with the tag.</td>
</tr>
<tr>
<td></td>
<td>• When targeting a tag, the number of failed invocations has not crossed the error threshold specified in the command.</td>
</tr>
<tr>
<td></td>
<td>• When targeting a tag, at least 1 invocation has succeeded while others have timed out. The specified error threshold still applies.</td>
</tr>
<tr>
<td></td>
<td>• You have applications or policies enforced at the OS level that prevent or override the execution of a command resulting in an exit code of zero being returned.</td>
</tr>
<tr>
<td>Status</td>
<td>Details</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>The same conditions apply when targeting resource groups. To troubleshoot errors or get more information about the command execution, send a command that handles errors or exceptions by returning appropriate exit codes (non-zero exit codes for command failure).</td>
</tr>
<tr>
<td>DeliveryTimedOut</td>
<td>The command wasn't delivered to the managed node before the total timeout expired. Total timeouts don't count against the parent command's max-errors limit, but they do contribute to whether the parent command status is Success, Incomplete, or Delivery Timed Out. This is a terminal state.</td>
</tr>
<tr>
<td>ExecutionTimedOut</td>
<td>Command automation started on the managed node, but the command wasn’t completed before the execution timeout expired. Execution timeouts count as a failure, which will send a non-zero reply and Systems Manager will exit the attempt to run the command automation, and report a failure status.</td>
</tr>
<tr>
<td>Status</td>
<td>Details MAX-ERRORS LIMIT</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>Failed</td>
<td>The command wasn't successful on the managed node. For a plugin, this indicates that the result code wasn't zero. For a command invocation, this indicates that the result code for one or more plugins wasn't zero. Invocation failures count against the <strong>max-errors</strong> limit of the parent command. This is a terminal state.</td>
</tr>
<tr>
<td>Cancelled</td>
<td>The command was canceled before it was completed. This is a terminal state.</td>
</tr>
<tr>
<td>Undeliverable</td>
<td>The command can't be delivered to the managed node. The node might not exist or it might not be responding. Undeliverable invocations don't count against the parent command's <strong>max-errors</strong> limit, but they do contribute to whether the parent command status is Success or Incomplete. For example, if all invocations in a command have the status Undeliverable, then the command status returned is Failed. However, if a command has five invocations, four of which return the status Undeliverable and one of which returns the status Success, then the parent command's status is Success. This is a terminal state.</td>
</tr>
<tr>
<td>Terminated</td>
<td>The parent command exceeded its <strong>max-errors</strong> limit and subsequent command invocations were canceled by the system. This is a terminal state.</td>
</tr>
<tr>
<td>Status</td>
<td>Details</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>InvalidPlatform</td>
<td>The command was sent to a managed node that didn't match the required platforms specified by the chosen document. Invalid Platform doesn't count against the parent command's max-errors limit, but it does contribute to whether the parent command status is Success or Failed. For example, if all invocations in a command have the status Invalid Platform, then the command status returned is Failed. However, if a command has five invocations, four of which return the status Invalid Platform and one of which returns the status Success, then the parent command's status is Success. This is a terminal state.</td>
</tr>
<tr>
<td>AccessDenied</td>
<td>The AWS Identity and Access Management (IAM) user or role initiating the command doesn't have access to the targeted managed node. Access Denied doesn't count against the parent command's max-errors limit, but it does contribute to whether the parent command status is Success or Failed. For example, if all invocations in a command have the status Access Denied, then the command status returned is Failed. However, if a command has five invocations, four of which return the status Access Denied and one of which returns the status Success, then the parent command's status is Success. This is a terminal state.</td>
</tr>
</tbody>
</table>
## Detailed status for a command

<table>
<thead>
<tr>
<th>Status</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pending</td>
<td>The command wasn't yet received by an agent on any managed nodes.</td>
</tr>
<tr>
<td>InProgress</td>
<td>The command has been sent to at least one managed node but hasn't reached a final state on all nodes.</td>
</tr>
<tr>
<td>Delayed</td>
<td>The system attempted to send the command to the node but wasn't successful. The system retries again.</td>
</tr>
<tr>
<td>Success</td>
<td>The command was received by SSM Agent on all specified or targeted managed nodes and returned an exit code of zero. All command invocations have reached a terminal state, and the value of max-errors wasn't reached. This status <em>doesn't</em> mean the command was successfully processed on all specified or targeted managed nodes. This is a terminal state.</td>
</tr>
</tbody>
</table>

**Note**

To troubleshoot errors or get more information about the command execution, send a command that handles errors or exceptions by returning appropriate exit codes (non-zero exit codes for command failure).
<table>
<thead>
<tr>
<th>Status</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delivery Timed Out</td>
<td>The command wasn't successful on the managed node. The value of max-errors or more command invocations shows a status of Failed. This is a terminal state.</td>
</tr>
<tr>
<td>Failed</td>
<td>The command was attempted on all managed nodes and one or more of the invocations doesn't have a value of Success. However, not enough invocations failed for the status to be Failed. This is a terminal state.</td>
</tr>
<tr>
<td>Incomplete</td>
<td>The command was canceled before it was completed. This is a terminal state.</td>
</tr>
<tr>
<td>Cancelled</td>
<td>The command was canceled before it was completed. This is a terminal state.</td>
</tr>
<tr>
<td>RateExceeded</td>
<td>The number of managed nodes targeted by the command exceeded the account quota for pending invocations. The system has canceled the command before executing it on any node. This is a terminal state.</td>
</tr>
<tr>
<td>Status</td>
<td>Details</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AccessDenied</td>
<td>The user or role initiating the command doesn't have access to the targeted resource group. AccessDenied doesn't count against the parent command's max-errors limit, but does contribute to whether the parent command status is Success or Failed. (For example, if all invocations in a command have the status AccessDenied, then the command status returned is Failed. However, if a command has 5 invocations, 4 of which return the status AccessDenied and 1 of which returns the status Success, then the parent command's status is Success.) This is a terminal state.</td>
</tr>
<tr>
<td>No Instances In Tag</td>
<td>The tag key-pair value or resource group targeted by the command doesn't match any managed nodes. This is a terminal state.</td>
</tr>
</tbody>
</table>

### Understanding command timeout values

Systems Manager enforces the following timeout values when running commands.

**Total Timeout**

In the Systems Manager console, you specify the timeout value in the **Timeout (seconds)** field. After a command is sent, Run Command checks whether the command has expired or not. If a command reaches the command expiration limit (total timeout), it changes status to DeliveryTimedOut for all invocations that have the status InProgress, Pending or Delayed.
On a more technical level, total timeout (Timeout (seconds)) is a combination of two timeout values, as shown here:

Total timeout = "Timeout(seconds)" from the console + "timeoutSeconds": "{{ executionTimeout }}" from your SSM document

For example, the default value of Timeout (seconds) in the Systems Manager console is 600 seconds. If you run a command by using the AWS-RunShellScript SSM document, the default value of timeoutSeconds: "{{ executionTimeout }}" is 3600 seconds, as shown in the following document sample:

```
"executionTimeout": {
   "type": "String",
   "default": "3600",

"runtimeConfig": {
   "aws:runShellScript": {
      "properties": [
      { "timeoutSeconds": "{{ executionTimeout }}"
```

This means the command runs for 4,200 seconds (70 minutes) before the system sets the command status to DeliveryTimedOut.
Execution Timeout

In the Systems Manager console, you specify the execution timeout value in the **Execution Timeout** field, if available. Not all SSM documents require that you specify an execution timeout. The **Execution Timeout** field is only displayed when a corresponding input parameter has been defined in the SSM document. If specified, the command must complete within this time period.

¡Note

Run Command relies on the SSM Agent document terminal response to determine whether or not the command was delivered to the agent. SSM Agent must send an **ExecutionTimedOut** signal for an invocation or command to be marked as **ExecutionTimedOut**.

**Default Execution Timeout**

If a SSM document doesn't require that you explicitly specify an execution timeout value, then Systems Manager enforces the hard-coded default execution timeout.

**How Systems Manager reports timeouts**

If Systems Manager receives an **execution timeout** reply from SSM Agent on a target, then Systems Manager marks the command invocation as **executionTimeout**.

If Run Command doesn't receive a document terminal response from SSM Agent, the command invocation is marked as **deliveryTimeout**.

To determine timeout status on a target, SSM Agent combines all parameters and the content of the SSM document to calculate for **executionTimeout**. When SSM Agent determines that a command has timed out, it sends **executionTimeout** to the service.

The default for **Timeout (seconds)** is 3600 seconds. The default for **Execution Timeout** is also 3600 seconds. Therefore, the total default timeout for a command is 7200 seconds.
Note

SSM Agent processes execution Timeout differently depending on the type of SSM document and the document version.

Run Command walkthroughs

The walkthroughs in this section show you how to run commands with Run Command, a capability of AWS Systems Manager, using either the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell.

Contents

- Updating software using Run Command
- Walkthrough: Use the AWS CLI with Run Command
- Walkthrough: Use the AWS Tools for Windows PowerShell with Run Command

You can also view sample commands in the following references.

- Systems Manager AWS CLI Reference
- AWS Tools for Windows PowerShell - AWS Systems Manager

Updating software using Run Command

The following procedures describe how to update software on your managed nodes.

Updating the SSM Agent using Run Command

The following procedure describes how to update the SSM Agent running on your managed nodes. You can update to either the latest version of SSM Agent or downgrade to an older version. When you run the command, the system downloads the version from AWS, installs it, and then uninstalls the version that existed before the command was run. If an error occurs during this process, the system rolls back to the version on the server before the command was run and the command status shows that the command failed.
If an instance is running macOS version 11.0 (Big Sur) or later, the instance must have the SSM Agent version 3.1.941.0 or higher to run the AWS-UpdateSSMAgent document. If the instance is running a version of SSM Agent released before 3.1.941.0, you can update your SSM Agent to run the AWS-UpdateSSMAgent document by running `brew update` and `brew upgrade amazon-ssm-agent` commands.

To be notified about SSM Agent updates, subscribe to the [SSM Agent Release Notes](https://github.com/aws/ssm-agent) page on GitHub.

**To update SSM Agent using Run Command**

2. In the navigation pane, choose Run Command.
3. Choose Run command.
4. In the Command document list, choose AWS-UpdateSSMAgent.
5. In the Command parameters section, specify values for the following parameters, if you want:
   a. (Optional) For Version, enter the version of SSM Agent to install. You can install older versions of the agent. If you don't specify a version, the service installs the latest version.
   b. (Optional) For Allow Downgrade, choose true to install an earlier version of SSM Agent. If you choose this option, specify the earlier version number. Choose false to install only the newest version of the service.
6. In the Targets section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

**Tip**

If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

7. For Other parameters:
   - For Comment, enter information about this command.
• For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:

• For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

![Note]

If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

• For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

![Note]

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.
For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

Updating PowerShell using Run Command

The following procedure describes how to update PowerShell to version 5.1 on your Windows Server 2012 and 2012 R2 managed nodes. The script provided in this procedure downloads the Windows Management Framework (WMF) version 5.1 update, and starts the installation of the update. The node reboots during this process because this is required when installing WMF 5.1. The download and installation of the update takes approximately five minutes to complete.

To update PowerShell using Run Command

2. In the navigation pane, choose Run Command.
3. Choose Run command.
4. In the Command document list, choose AWS-RunPowerShellScript.
5. In the Commands section, paste the following commands for your operating system.

Windows Server 2012 R2

```
Set-Location -Path "C:\Windows\Temp"

Invoke-WebRequest "https://go.microsoft.com/fwlink/?linkid=839516" -OutFile "Win8.1AndW2K12R2-KB3191564-x64.msu"

Start-Process -FilePath "$env:systemroot\system32\wusa.exe" -Verb RunAs -ArgumentList ('Win8.1AndW2K12R2-KB3191564-x64.msu', '/quiet')
```

Windows Server 2012

```
Set-Location -Path "C:\Windows\Temp"

Invoke-WebRequest "https://go.microsoft.com/fwlink/?linkid=839513" -OutFile "W2K12-KB3191565-x64.msu"
```
6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   **Tip**
   
   If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

7. For **Other parameters**:
   - For **Comment**, enter information about this command.
   - For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:
   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**
   
   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.
Note

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the SNS notifications section, if you want notifications sent about the status of the command execution, select the Enable SNS notifications check box.

   For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

After the managed node reboots and the installation of the update is complete, connect to your node to confirm that PowerShell successfully upgraded to version 5.1. To check the version of PowerShell on your node, open PowerShell and enter $PSVersionTable. The PSVersion value in the output table shows 5.1 if the upgrade was successful.

If the PSVersion value is different than 5.1, for example 3.0 or 4.0, review the Setup logs in Event Viewer under Windows Logs. These logs indicate why the update installation failed.

Walkthrough: Use the AWS CLI with Run Command

The following sample walkthrough shows you how to use the AWS Command Line Interface (AWS CLI) to view information about commands and command parameters, how to run commands, and how to view the status of those commands.

Important

Only trusted administrators should be allowed to use AWS Systems Manager pre-configured documents shown in this topic. The commands or scripts specified in Systems Manager documents run with administrative permissions on your managed nodes. If a user
has permission to run any of the pre-defined Systems Manager documents (any document that begins with AWS-), then that user also has administrator access to the node. For all other users, you should create restrictive documents and share them with specific users.

**Topics**

- Step 1: Getting started
- Step 2: Run shell scripts to view resource details
- Step 3: Send simple commands using the AWS-RunShellScript document
- Step 4: Run a simple Python script using Run Command
- Step 5: Run a Bash script using Run Command

**Step 1: Getting started**

You must either have administrator permissions on the managed node you want to configure or you must have been granted the appropriate permission in AWS Identity and Access Management (IAM). Also note, this example uses the US East (Ohio) Region (us-east-2). Run Command is available in the AWS Regions listed in Systems Manager service endpoints in the Amazon Web Services General Reference. For more information, see Setting up AWS Systems Manager.

**To run commands using the AWS CLI**

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven’t already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. List all available documents.

   This command lists all of the documents available for your account based on IAM permissions.

   ```
   aws ssm list-documents
   ```

3. Verify that an managed node is ready to receive commands.

   The output of the following command shows if managed nodes are online.

   **Linux & macOS**

   ```
   aws ssm describe-instance-information \
   ```
4. Run the following command to view details about a particular managed node.

```bash
aws ssm describe-instance-information
```

**Note**

To run the commands in this walkthrough, replace the instance and command IDs. For managed AWS IoT Greengrass core devices, use the `mi-ID_number` for instance ID. The command ID is returned as a response to `send-command`. Instance IDs are available from Fleet Manager, a capability of AWS Systems Manager.

**Linux & macOS**

```bash
aws ssm describe-instance-information
```

**Windows**

```bash
aws ssm describe-instance-information
```

Step 2: Run shell scripts to view resource details

Using Run Command and the AWS-RunShellScript document, you can run any command or script on a managed node as if you were logged on locally.

**View the description and available parameters**

Run the following command to view a description of the Systems Manager JSON document.

**Linux & macOS**

```bash
aws ssm describe-document
```
--name "AWS-RunShellScript" \
--query "[Document.Name,Document.Description]"

Windows

aws ssm describe-document ^
   --name "AWS-RunShellScript" ^
   --query "[Document.Name,Document.Description]"

Run the following command to view the available parameters and details about those parameters.

Linux & macOS

aws ssm describe-document \
   --name "AWS-RunShellScript" \
   --query "Document.Parameters[*]"

Windows

aws ssm describe-document ^
   --name "AWS-RunShellScript" ^
   --query "Document.Parameters[*]"

Step 3: Send simple commands using the AWS-RunShellScript document

Run the following command to get IP information for a Linux managed node.

If you're targeting a Windows Server managed node, change the document-name to AWS-RunPowerShellScript and change the command from ifconfig to ipconfig.

Linux & macOS

aws ssm send-command \
   --instance-ids "instance-ID" \
   --document-name "AWS-RunShellScript" \
   --comment "IP config" \ 
   --parameters commands=ifconfig \
   --output text
Windows

```bash
aws ssm send-command ^
    --instance-ids "instance-ID" ^
    --document-name "AWS-RunShellScript" ^
    --comment "IP config" ^
    --parameters commands=ipconfig ^
    --output text
```

Get command information with response data

The following command uses the Command ID that was returned from the previous command to get the details and response data of the command execution. The system returns the response data if the command completed. If the command execution shows "Pending" or "InProgress" you run this command again to see the response data.

Linux & macOS

```bash
aws ssm list-command-invocations \
    --command-id $sh-command-id \
    --details
```

Windows

```bash
aws ssm list-command-invocations ^
    --command-id $sh-command-id ^
    --details
```

Identify user

The following command displays the default user running the commands.

Linux & macOS

```bash
sh_command_id=$(aws ssm send-command \
    --instance-ids "instance-ID" \
    --document-name "AWS-RunShellScript" \
    --comment "Demo run shell script on Linux managed node" \
    --parameters commands=whoami \
    --output text \
```

Run Command walkthroughs
**Get command status**

The following command uses the Command ID to get the status of the command execution on the managed node. This example uses the Command ID that was returned in the previous command.

**Linux & macOS**

```bash
aws ssm list-commands
   --command-id "command-ID"
```

**Windows**

```bash
aws ssm list-commands ^
   --command-id "command-ID"
```

**Get command details**

The following command uses the Command ID from the previous command to get the status of the command execution on a per managed node basis.

**Linux & macOS**

```bash
aws ssm list-command-invocations
   --command-id "command-ID" ^
   --details
```

**Windows**

```bash
aws ssm list-command-invocations ^
   --command-id "command-ID" ^
   --details
```

**Get command information with response data for a specific managed node**

The following command returns the output of the original `aws ssm send-command` request for a specific managed node.
**Linux & macOS**

```bash
aws ssm list-command-invocations \
  --instance-id instance-ID \
  --command-id "command-ID" \
  --details
```

**Windows**

```bash
aws ssm list-command-invocations ^
  --instance-id instance-ID ^
  --command-id "command-ID" ^
  --details
```

**Display Python version**

The following command returns the version of Python running on a node.

**Linux & macOS**

```bash
sh_command_id=$(aws ssm send-command \
  --instance-ids "instance-ID" \
  --document-name "AWS-RunShellScript" \
  --comment "Demo run shell script on Linux Instances" \
  --parameters commands='python -V' \
  --output text --query "Command.CommandId") \
sh -c 'aws ssm list-command-invocations \
  --command-id "$sh_command_id" \
  --details \
  --query "CommandInvocations[].CommandPlugins[].{Status:Status,Output:Output}"'
```

**Step 4: Run a simple Python script using Run Command**

The following command runs a simple Python "Hello World" script using Run Command.

**Linux & macOS**

```bash
sh_command_id=$(aws ssm send-command \
  --instance-ids "instance-ID" \
  --document-name "AWS-RunShellScript" \
  --parameters commands='python -c "print("Hello World")"' \
  --output text --query "Command.CommandId") \
sh -c 'aws ssm list-command-invocations \
  --command-id "$sh_command_id" \
  --details \
  --query "CommandInvocations[].CommandPlugins[].{Status:Status,Output:Output}"'
```
### Step 5: Run a Bash script using Run Command

The examples in this section demonstrate how to run the following bash script using Run Command.

For examples of using Run Command to run scripts stored in remote locations, see [Running scripts from Amazon S3](#) and [Running scripts from GitHub](#).

```bash
#!/bin/bash
yum -y update
yum install -y ruby
cd /home/ec2-user
chmod +x ./install
./install auto
```

This script installs the AWS CodeDeploy agent on Amazon Linux and Red Hat Enterprise Linux (RHEL) instances, as described in [Create an Amazon EC2 instance for CodeDeploy](#) in the AWS CodeDeploy User Guide.

The script installs the CodeDeploy agent from an AWS managed S3 bucket in the US East (Ohio) Region (us-east-2), aws-codedeploy-us-east-2.

### Run a bash script in an AWS CLI command

The following sample demonstrates how to include the bash script in a CLI command using the `--parameters` option.

**Linux & macOS**

```bash
aws ssm send-command
```
Run a bash script in a JSON file

In the following example, the content of the bash script is stored in a JSON file, and the file is included in the command using the `--cli-input-json` option.

**Linux & macOS**

```
aws ssm send-command \
   --document-name "AWS-RunShellScript" \
   --targets "Key=InstanceIds,Values=${instance-id}" \
   --cli-input-json file://installCodeDeployAgent.json
```

**Windows**

```
aws ssm send-command ^
   --document-name "AWS-RunShellScript" ^
   --targets "Key=InstanceIds,Values=${instance-id}" ^
   --cli-input-json file://installCodeDeployAgent.json
```

The contents of the referenced `installCodeDeployAgent.json` file is shown in the following example.

```json
{
   "Parameters": {
      "commands": [
         "#!/bin/bash",
         "yum -y update",
         "yum install -y ruby",
         "cd /home/ec2-user",
         "chmod +x ./install",
         "../install auto"
      ]
   }
}
```
Walkthrough: Use the AWS Tools for Windows PowerShell with Run Command

The following examples show how to use the AWS Tools for Windows PowerShell to view information about commands and command parameters, how to run commands, and how to view the status of those commands. This walkthrough includes an example for each of the pre-defined AWS Systems Manager documents.

⚠️ Important

Only trusted administrators should be allowed to use Systems Manager pre-configured documents shown in this topic. The commands or scripts specified in Systems Manager documents run with administrative permission on your managed nodes. If a user has permission to run any of the predefined Systems Manager documents (any document that begins with AWS), then that user also has administrator access to the node. For all other users, you should create restrictive documents and share them with specific users.

Topics

- Configure AWS Tools for Windows PowerShell session settings
- List all available documents
- Run PowerShell commands or scripts
- Install an application using the AWS-InstallApplication document
- Install a PowerShell module using the AWS-InstallPowerShellModule JSON document
- Join a managed node to a Domain using the AWS-JoinDirectoryServiceDomain JSON document
- Send Windows metrics to Amazon CloudWatch Logs using the AWS-ConfigureCloudWatch document
- Update EC2Config using the AWS-UpdateEC2Config document
- Turn on or turn off Windows automatic update using the AWS-ConfigureWindowsUpdate document
- Manage Windows updates using Run Command

Configure AWS Tools for Windows PowerShell session settings

Specify your credentials
Open **Tools for Windows PowerShell** on your local computer and run the following command to specify your credentials. You must either have administrator permissions on the managed nodes you want to configure or you must have been granted the appropriate permission in AWS Identity and Access Management (IAM). For more information, see [Setting up AWS Systems Manager](#).

```
Set-AWSCredentials -AccessKey key-name -SecretKey key-name
```

**Set a default AWS Region**

Run the following command to set the region for your PowerShell session. The example uses the US East (Ohio) Region (us-east-2). Run Command is available in the AWS Regions listed in [Systems Manager service endpoints](#) in the [Amazon Web Services General Reference](#).

```
Set-DefaultAWSRegion -Region us-east-2
```

**List all available documents**

This command lists all documents available for your account.

```
Get-SSMDocumentList
```

**Run PowerShell commands or scripts**

Using Run Command and the AWS-RunPowerShell document, you can run any command or script on a managed node as if you were logged on locally. You can issue commands or enter a path to a local script to run the command.

**Note**

For information about rebooting managed nodes when using Run Command to call scripts, see [Handling reboots when running commands](#).

```
Get-SSMDocumentDescription -Name "AWS-RunPowerShellScript"
```

**View the description and available parameters**

```
Get-SSMDocumentDescription -Name "AWS-RunPowerShellScript"
```

**View more information about parameters**
Get-SSMDocumentDescription `  
   -Name "AWS-RunPowerShellScript" | Select -ExpandProperty Parameters

Send a command using the AWS-RunPowerShellScript document

The following command shows the contents of the "C:\Users" directory and the contents of the "C:\" directory on two managed nodes.

```
$runPSCommand = Send-SSMCommand `  
   -InstanceIds @("instance-ID-1", "instance-ID-2") `  
   -DocumentName "AWS-RunPowerShellScript" `  
   -Comment "Demo AWS-RunPowerShellScript with two instances" `  
   -Parameter @{'commands'=@('dir C:\Users', 'dir C:\')}
```

Get command request details

The following command uses the CommandId to get the status of the command execution on both managed nodes. This example uses the CommandId that was returned in the previous command.

```
Get-SSMCommand `  
   -CommandId $runPSCommand.CommandId
```

The status of the command in this example can be Success, Pending, or InProgress.

Get command information per managed node

The following command uses the CommandId from the previous command to get the status of the command execution on a per managed node basis.

```
Get-SSMCommandInvocation `  
   -CommandId $runPSCommand.CommandId
```

Get command information with response data for a specific managed node

The following command returns the output of the original Send-SSMCommand for a specific managed node.

```
Get-SSMCommandInvocation `  
   -CommandId $runPSCommand.CommandId `  
   -Details $true `  
   -InstanceId instance-ID | Select -ExpandProperty CommandPlugins
```
Cancel a command

The following command cancels the Send-SSMCommand for the AWS-RunPowerShellScript document.

```powershell
$cancelCommand = Send-SSMCommand `  -InstanceIds @("instance-ID-1","instance-ID-2") `  -DocumentName "AWS-RunPowerShellScript" `  -Comment "Demo AWS-RunPowerShellScript with two instances" `  -Parameter @{'commands'='Start-Sleep -Seconds 120; dir C:\'}

Stop-SSMCommand -CommandId $cancelCommand.CommandId
```

Check the command status

The following command checks the status of the Cancel command.

```powershell
Get-SSMCommand `  -CommandId $cancelCommand.CommandId
```

Install an application using the AWS-InstallApplication document

Using Run Command and the AWS-InstallApplication document, you can install, repair, or uninstall applications on managed nodes. The command requires the path or address to an MSI.

**Note**

For information about rebooting managed nodes when using Run Command to call scripts, see [Handling reboots when running commands](#).

View the description and available parameters

```powershell
Get-SSMDocumentDescription `  -Name "AWS-InstallApplication"
```

View more information about parameters

```powershell
Get-SSMDocumentDescription `  -Name "AWS-InstallApplication" | Select -ExpandProperty Parameters
```
Send a command using the AWS-InstallApplication document

The following command installs a version of Python on your managed node in unattended mode, and logs the output to a local text file on your C: drive.

```bash
$installAppCommand = Send-SSMCommand `  
  -InstanceId instance-ID `  
  -DocumentName "AWS-InstallApplication" `  
  -Parameter @{'source'='https://www.python.org/ftp/python/2.7.9/python-2.7.9.msi'; 'parameters'=''/norestart /quiet /log c:\pythoninstall.txt'}
```

Get command information per managed node

The following command uses the CommandId to get the status of the command execution.

```bash
Get-SSMCommandInvocation `  
  -CommandId $installAppCommand.CommandId `  
  -Details $true
```

Get command information with response data for a specific managed node

The following command returns the results of the Python installation.

```bash
Get-SSMCommandInvocation `  
  -CommandId $installAppCommand.CommandId `  
  -Details $true `  
  -InstanceId instance-ID | Select -ExpandProperty CommandPlugins
```

Install a PowerShell module using the AWS-InstallPowerShellModule JSON document

You can use Run Command to install PowerShell modules on managed nodes. For more information about PowerShell modules, see Windows PowerShell Modules.

View the description and available parameters

```bash
Get-SSMDocumentDescription `  
  -Name "AWS-InstallPowerShellModule"
```

View more information about parameters

```bash
Get-SSMDocumentDescription `
Install a PowerShell module

The following command downloads the EZOut.zip file, installs it, and then runs an additional command to install XPS viewer. Lastly, the output of this command is uploaded to an S3 bucket named "demo-ssm-output-bucket".

```
$installPSCommand = Send-SSMCommand `  
  -InstanceId instance-ID `  
  -DocumentName "AWS-InstallPowerShellModule" `  
  -Parameter @{'source='https://gallery.technet.microsoft.com/EZOut-33ae0fb7/file/110351/1/EZOut.zip';'commands'=@('Add-WindowsFeature -name XPS-Viewer -restart'))} `  
  -OutputS3BucketName demo-ssm-output-bucket
```

Get command information per managed node

The following command uses the CommandId to get the status of the command execution.

```
Get-SSMCommandInvocation `  
  -CommandId $installPSCommand.CommandId `  
  -Details $true
```

Get command information with response data for the managed node

The following command returns the output of the original Send-SSMCommand for the specific CommandId.

```
Get-SSMCommandInvocation `  
  -CommandId $installPSCommand.CommandId `  
  -Details $true | Select -ExpandProperty CommandPlugins
```

Join a managed node to a Domain using the AWS-JoinDirectoryServiceDomain JSON document

Using Run Command, you can quickly join a managed node to an AWS Directory Service domain. Before executing this command, create a directory. We also recommend that you learn more about the AWS Directory Service. For more information, see the AWS Directory Service Administration Guide.
You can only join a managed node to a domain. You can't remove a node from a domain.

⚠️ **Note**

For information about managed nodes when using Run Command to call scripts, see [Handling reboots when running commands](#).

### View the description and available parameters

```powershell
Get-SSMDocumentDescription
  -Name "AWS-JoinDirectoryServiceDomain"
```

### View more information about parameters

```powershell
Get-SSMDocumentDescription
  -Name "AWS-JoinDirectoryServiceDomain" | Select -ExpandProperty Parameters
```

### Join a managed node to a domain

The following command joins a managed node to the given AWS Directory Service domain and uploads any generated output to the example Amazon Simple Storage Service (Amazon S3) bucket.

```powershell
$domainJoinCommand = Send-SSMCommand
  -InstanceId *instance-ID*
  -DocumentName "AWS-JoinDirectoryServiceDomain"
  -Parameter @{'directoryId'='d-example01'; 'directoryName'='ssm.example.com'; 'dnsIpAddresses'=@('192.168.10.195', '192.168.20.97')} `.
  -OutputS3BucketName *demo-ssm-output-bucket*
```

### Get command information per managed node

The following command uses the CommandId to get the status of the command execution.

```powershell
Get-SSMCommandInvocation
  -CommandId $domainJoinCommand.CommandId
  -Details $true
```

### Get command information with response data for the managed node

---

Run Command walkthroughs
This command returns the output of the original Send-SSMCommand for the specific CommandId.

```powershell
Get-SSMCommandInvocation ' -CommandId $domainJoinCommand.CommandId ' -Details $true | Select -ExpandProperty CommandPlugins
```

**Send Windows metrics to Amazon CloudWatch Logs using the AWS-ConfigureCloudWatch document**

You can send Windows Server messages in the application, system, security, and Event Tracing for Windows (ETW) logs to Amazon CloudWatch Logs. When you allow logging for the first time, Systems Manager sends all logs generated within one (1) minute from the time that you start uploading logs for the application, system, security, and ETW logs. Logs that occurred before this time aren't included. If you turn off logging and then later turn logging back on, Systems Manager sends logs from the time it left off. For any custom log files and Internet Information Services (IIS) logs, Systems Manager reads the log files from the beginning. In addition, Systems Manager can also send performance counter data to CloudWatch Logs.

If you previously turned on CloudWatch integration in EC2Config, the Systems Manager settings override any settings stored locally on the managed node in the C:\Program Files\Amazon\EC2ConfigService\Settings\AWS.EC2.Windows.CloudWatch.json file. For more information about using EC2Config to manage performance counters and logs on a single managed node, see [Collecting metrics and logs from Amazon EC2 instances and on-premises servers with the CloudWatch agent](https://docs.aws.amazon.com/AmazonCloudWatch/latest/userguide/using-ec2-config.html) in the *Amazon CloudWatch User Guide*.

**View the description and available parameters**

```powershell
Get-SSMDocumentDescription ' -Name "AWS-ConfigureCloudWatch"
```

**View more information about parameters**

```powershell
Get-SSMDocumentDescription ' -Name "AWS-ConfigureCloudWatch" | Select -ExpandProperty Parameters
```

**Send application logs to CloudWatch**

The following command configures the managed node and moves Windows Applications logs to CloudWatch.
Get command information per managed node

The following command uses the CommandId to get the status of the command execution.

```
Get-SSMCommandInvocation
  -CommandId $cloudWatchCommand.CommandId
  -Details $true
```

Get command information with response data for a specific managed node

The following command returns the results of the Amazon CloudWatch configuration.

```
Get-SSMCommandInvocation
  -CommandId $cloudWatchCommand.CommandId
  -Details $true
  -InstanceId instance-ID | Select -ExpandProperty CommandPlugins
```

Send performance counters to CloudWatch using the AWS-ConfigureCloudWatch document

The following demonstration command uploads performance counters to CloudWatch. For more information, see the Amazon CloudWatch User Guide.

```
$cloudWatchMetricsCommand = Send-SSMCommand
  -InstanceID instance-ID
  -DocumentName "AWS-ConfigureCloudWatch"
  -Parameter @'properties'='"engineConfiguration": {"PollInterval":"00:00:15",
  "Components":[{"Id":"PerformanceCounter",
  "Parameters":{"CategoryName":"Memory", "CounterName":"Available
  MBytes", "InstanceName":"", "MetricName":"AvailableMemory",}]}'}
```
Update EC2Config using the AWS-UpdateEC2Config document

Using Run Command and the AWS-EC2ConfigUpdate document, you can update the EC2Config service running on your Windows Server managed nodes. This command can update the EC2Config service to the latest version or a version you specify.

View the description and available parameters

```powershell
Get-SSMDocumentDescription -Name "AWS-UpdateEC2Config"
```

View more information about parameters

```powershell
Get-SSMDocumentDescription -Name "AWS-UpdateEC2Config" | Select -ExpandProperty Parameters
```

Update EC2Config to the latest version

```powershell
$ec2ConfigCommand = Send-SSMCommand -InstanceId instance-ID -DocumentName "AWS-UpdateEC2Config"
```

Get command information with response data for the managed node

This command returns the output of the specified command from the previous Send-SSMCommand.

```powershell
Get-SSMCommandInvocation -CommandId $ec2ConfigCommand.CommandId -Details $true -InstanceId instance-ID | Select -ExpandProperty CommandPlugins
```

Update EC2Config to a specific version

The following command downgrades EC2Config to an older version.
Turn on or turn off Windows automatic update using the AWS-ConfigureWindowsUpdate document

Using Run Command and the AWS-ConfigureWindowsUpdate document, you can turn on or turn off automatic Windows updates on your Windows Server managed nodes. This command configures the Windows Update Agent to download and install Windows updates on the day and hour that you specify. If an update requires a reboot, the managed node reboots automatically 15 minutes after updates have been installed. With this command you can also configure Windows Update to check for updates but not install them. The AWS-ConfigureWindowsUpdate document is compatible with Windows Server 2008, 2008 R2, 2012, 2012 R2, and 2016.

View the description and available parameters

```
Get-SSMDocumentDescription
    -Name "AWS-ConfigureWindowsUpdate"
```

View more information about parameters

```
Get-SSMDocumentDescription
    -Name "AWS-ConfigureWindowsUpdate" | Select -ExpandProperty Parameters
```

Turn on Windows automatic update

The following command configures Windows Update to automatically download and install updates daily at 10:00 PM.

```
$configureWindowsUpdateCommand = Send-SSMCommand
    -InstanceId instance-ID
    -DocumentName "AWS-ConfigureWindowsUpdate"
    -Parameters @{
        'updateLevel'='InstallUpdatesAutomatically';
        'scheduledInstallDay'='Daily'; 'scheduledInstallTime'='22:00'}
```

View command status for allowing Windows automatic update

Run Command walkthroughs
The following command uses the CommandId to get the status of the command execution for allowing Windows automatic update.

```powershell
Get-SSMCommandInvocation -Details $true -CommandId $configureWindowsUpdateCommand.CommandId | Select -ExpandProperty CommandPlugins
```

**Turn off Windows automatic update**

The following command lowers the Windows Update notification level so the system checks for updates but doesn't automatically update the managed node.

```powershell
$configureWindowsUpdateCommand = Send-SSMCommand -InstanceId instance-ID -DocumentName "AWS-ConfigureWindowsUpdate" -Parameters @{'updateLevel'='NeverCheckForUpdates'}
```

**View command status for turning off Windows automatic update**

The following command uses the CommandId to get the status of the command execution for turning off Windows automatic update.

```powershell
Get-SSMCommandInvocation -Details $true -CommandId $configureWindowsUpdateCommand.CommandId | Select -ExpandProperty CommandPlugins
```

**Manage Windows updates using Run Command**

Using Run Command and the AWS-InstallWindowsUpdates document, you can manage updates for Windows Server managed nodes. This command scans for or installs missing updates on your managed nodes and optionally reboots following installation. You can also specify the appropriate classifications and severity levels for updates to install in your environment.

**Note**

For information about rebooting managed nodes when using Run Command to call scripts, see [Handling reboots when running commands.](#)
The following examples demonstrate how to perform the specified Windows Update management tasks.

**Search for all missing Windows updates**

```
Send-SSMCommand ' -InstanceId instance-ID ' -DocumentName "AWS-InstallWindowsUpdates" ' -Parameters @{'Action'='Scan'}
```

**Install specific Windows updates**

```
Send-SSMCommand ' -InstanceId instance-ID ' -DocumentName "AWS-InstallWindowsUpdates" ' -Parameters @{'Action'='Install';'IncludeKbs'='kb-ID-1,kb-ID-2,kb-ID-3';'AllowReboot'='True'}
```

**Install important missing Windows updates**

```
Send-SSMCommand ' -InstanceId instance-ID ' -DocumentName "AWS-InstallWindowsUpdates" ' -Parameters @{'Action'='Install';'SeverityLevels'='Important';'AllowReboot'='True'}
```

**Install missing Windows updates with specific exclusions**

```
Send-SSMCommand ' -InstanceId instance-ID ' -DocumentName "AWS-InstallWindowsUpdates" ' -Parameters @{'Action'='Install';'ExcludeKbs'='kb-ID-1,kb-ID-2';'AllowReboot'='True'}
```

**Troubleshooting Systems Manager Run Command**

Run Command, a capability of AWS Systems Manager, provides status details with each command execution. For more information about the details of command statuses, see Understanding command statuses. You can also use the information in this topic to help troubleshoot problems with Run Command.
**Topics**

- **Some of my managed nodes are missing**
- **A step in my script failed, but the overall status is 'succeeded'**
- **SSM Agent isn't running properly**

### Some of my managed nodes are missing

In the **Run a command** page, after you choose an SSM document to run and select **Manually selecting instances** in the **Targets** section, a list is displayed of managed nodes you can choose to run the command on.

If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

After you create, activate, reboot, or restart a managed node, install Run Command on a node, or attach an AWS Identity and Access Management (IAM) instance profile to a node, it can take a few minutes for the managed node to be added to the list.

### A step in my script failed, but the overall status is 'succeeded'

Using Run Command, you can define how your scripts handle exit codes. By default, the exit code of the last command run in a script is reported as the exit code for the entire script. You can, however, include a conditional statement to exit the script if any command before the final one fails. For information and examples, see [Specify exit codes in commands](#).

### SSM Agent isn't running properly

If you experience problems running commands using Run Command, there might be a problem with the SSM Agent. For information about investigating issues with SSM Agent, see [Troubleshooting SSM Agent](#).

---

**AWS Systems Manager State Manager**

State Manager, a capability of AWS Systems Manager, is a secure and scalable configuration management service that automates the process of keeping your managed nodes and other AWS resources in a state that you define. To get started with State Manager, open the [Systems Manager console](#). In the navigation pane, choose **State Manager**.
Note

State Manager and Maintenance Windows can perform some similar types of updates on your managed nodes. Which one you choose depends on whether you need to automate system compliance or perform high-priority, time-sensitive tasks during periods you specify.

For more information, see Choosing between State Manager and Maintenance Windows.

How can State Manager benefit my organization?

By using pre-configured Systems Manager documents (SSM documents), State Manager offers the following benefits for managing your nodes:

- Bootstrap nodes with specific software at start-up.
- Download and update agents on a defined schedule, including the SSM Agent.
- Configure network settings.
- Join nodes to a Microsoft Active Directory domain.
- Run scripts on Linux, macOS, and Windows managed nodes throughout their lifecycle.

To manage configuration drift across other AWS resources, you can use Automation, a capability of Systems Manager, with State Manager to perform the following types of tasks:

- Attach a Systems Manager role to Amazon Elastic Compute Cloud (Amazon EC2) instances to make them managed nodes.
- Enforce desired ingress and egress rules for a security group.
- Create or delete Amazon DynamoDB backups.
- Create or delete Amazon Elastic Block Store (Amazon EBS) snapshots.
- Turn off read and write permissions on Amazon Simple Storage Service (Amazon S3) buckets.
- Start, restart, or stop managed nodes and Amazon Relational Database Service (Amazon RDS) instances.
- Apply patches to Linux, macOS, and Window AMIs.

For information about using State Manager with Automation runbooks, see Scheduling automations with State Manager associations.
Who should use State Manager?

State Manager is appropriate for any AWS customer that wants to improve the management and governance of their AWS resources and reduce configuration drift.

What are the features of State Manager?

Key features of State Manager include the following:

- **State Manager associations**

  A State Manager *association* is a configuration that you assign to your AWS resources. The configuration defines the state that you want to maintain on your resources. For example, an association can specify that antivirus software must be installed and running on a managed node, or that certain ports must be closed.

  An association specifies a schedule for when to apply the configuration and the targets for the association. For example, an association for antivirus software might run once a day on all managed nodes in an AWS account. If the software isn't installed on a node, then the association could instruct State Manager to install it. If the software is installed, but the service isn't running, then the association could instruct State Manager to start the service.

- **Flexible scheduling options**

  State Manager offers the following options for scheduling when an association runs:

  - **Immediate or delayed processing**

    When you create an association, by default, the system immediately runs it on the specified resources. After the initial run, the association runs in intervals according to the schedule that you defined.

    You can instruct State Manager not to run an association immediately by using the **Apply association only at the next specified Cron interval** option in the console or the **ApplyOnlyAtCronInterval** parameter from the command line.

  - **Cron and rate expressions**

    When you create an association, you specify a schedule for when State Manager applies the configuration. State Manager supports most standard cron and rate expressions for scheduling when an association runs. State Manager also supports cron expressions that include a day of
the week and the number sign (#) to designate the \textit{n}th day of a month to run an association and the (L) sign to indicate the last \textit{X} day of the month.

\textbf{Note}

State Manager doesn’t currently support specifying months in cron expressions for associations.

To further control when an association runs, for example if you want to run an association two days after patch Tuesday, you can specify an offset. An \textit{offset} defines how many days to wait after the scheduled day to run an association.

For information about building cron and rate expressions, see Reference: Cron and rate expressions for Systems Manager.

- \textbf{Multiple targeting options}

An association also specifies the targets for the association. State Manager supports targeting AWS resources by using tags, AWS Resource Groups, individual node IDs, or all managed nodes in the current AWS Region and AWS account.

- \textbf{Amazon S3 support}

Store the command output from association runs in an Amazon S3 bucket of your choice. For more information, see Working with associations in Systems Manager.

- \textbf{EventBridge support}

This Systems Manager capability is supported as both an \textit{event} type and a \textit{target} type in Amazon EventBridge rules. For information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

\textbf{Is there a charge to use State Manager?}

State Manager is available at no additional charge.

\textbf{How do I get started with State Manager?}

Complete the following tasks to get started with State Manager.

- [AWS Systems Manager State Manager walkthroughs](#)

About State Manager

State Manager, a capability of AWS Systems Manager, is a secure and scalable service that automates the process of keeping managed nodes in a hybrid and multicloud infrastructure in a state that you define.

Here's how State Manager works:

1. **Determine the state you want to apply to your AWS resources.**

   Do you want to guarantee that your managed nodes are configured with specific applications, such as antivirus or malware applications? Do you want to automate the process of updating the SSM Agent or other AWS packages such as AWSPVDriver? Do you need to guarantee that specific ports are closed or open? To get started with State Manager, determine the state that you want to apply to your AWS resources. The state that you want to apply determines which SSM document you use to create a State Manager association.
A State Manager association is a configuration that you assign to your AWS resources. The configuration defines the state that you want to maintain on your resources. For example, an association can specify that antivirus software must be installed and running on a managed node, or that certain ports must be closed.

An association specifies a schedule for when to apply the configuration and the targets for the association. For example, an association for antivirus software might run once a day on all managed nodes in an AWS account. If the software isn't installed on a node, then the association could instruct State Manager to install it. If the software is installed, but the service isn't running, then the association could instruct State Manager to start the service.

2. Determine if a preconfigured SSM document can help you create the desired state on your AWS resources.

Systems Manager includes dozens of preconfigured SSM documents that you can use to create an association. Preconfigured documents are ready to perform common tasks like installing applications, configuring Amazon CloudWatch, running AWS Systems Manager automations, running PowerShell and Shell scripts, and joining managed nodes to a directory service domain for Active Directory.

You can view all SSM documents in the Systems Manager console. Choose the name of a document to learn more about each one. Here are two examples: AWS-ConfigureAWSPackage and AWS-InstallApplication.

3. Create an association.

You can create an association by using the Systems Manager console, the AWS Command Line Interface (AWS CLI), AWS Tools for Windows PowerShell (Tools for Windows PowerShell), or the Systems Manager API. When you create an association, you specify the following information:

- A name for the association.
- The parameters for the SSM document (for example, the path to the application to install or the script to run on the nodes).
- Targets for the association. You can target managed nodes by specifying tags, by choosing individual node IDs, or by choosing a group in AWS Resource Groups. You can also target all managed nodes in the current AWS Region and AWS account.
- A schedule for when or how often to apply the state. You can specify a cron or rate expression. For more information about creating schedules by using cron and rate expressions, see Cron and rate expressions for associations.
Note

State Manager doesn't currently support specifying months in cron expressions for associations.

When you run the command to create the association, Systems Manager binds the information you specified (schedule, targets, SSM document, and parameters) to the targeted resources. The status of the association initially shows "Pending" as the system attempts to reach all targets and immediately apply the state specified in the association.

Note

If you create a new association that is scheduled to run while an earlier association is still running, the earlier association times out and the new association runs.

Systems Manager reports the status of the request to create associations on the resources. You can view status details in the console or (for managed nodes) by using the DescribeInstanceAssociationsStatus API operation. If you choose to write the output of the command to Amazon Simple Storage Service (Amazon S3) when you create an association, you can also view the output in the Amazon S3 bucket you specified.

For more information, see Working with associations in Systems Manager.

Note

API operations that are initiated by the SSM document during an association run are not logged in AWS CloudTrail.

After you create the association, State Manager reapplies the configuration according to the schedule that you defined in the association. You can view the status of your associations on the State Manager page in the console or by directly calling the association ID generated by Systems Manager when you created the association. For more information, see Viewing association histories. You can update your association documents and reapply them as
necessary. You can also create multiple versions of an association. For more information, see Editing and creating a new version of an association.

When are associations applied to resources?

When you create an association, you specify an SSM document that defines the configuration, a list of target resources, and a schedule for applying the configuration. By default, State Manager runs the association when you create it and then according to your schedule. State Manager also attempts to run the association in the following situations:

- **Association edit** – State Manager runs the association after a user edits and saves their changes to any of the following association fields: DOCUMENT_VERSION, PARAMETERS, SCHEDULE_EXPRESSION, OUTPUT_S3_LOCATION.

- **Document edit** – State Manager runs the association after a user edits and saves changes to the SSM document that defines the association's configuration state. Specifically, the association runs after the following edits to the document:
  - A user specifies a new $DEFAULT document version and the association was created using the $DEFAULT version.
  - A user updates a document and the association was created using the $LATEST version.
  - A user deletes the document that was specified when the association was created.

- **Parameter Store parameter value change** – State Manager runs the association after a user edits the value of a parameter defined in the association.

- **Manual start** – State Manager runs the association when initiated by the user from either the Systems Manager console or programmatically.

- **Target changes** – State Manager runs the association after any of the following activity occurs on a target node:
  - A managed node comes online for the first time.
  - A managed node comes online after missing a scheduled association run.
  - A managed node comes online after being stopped for more than 30 days.

\[\text{Note}\]
Target updates don't affect associations created using Systems Manager Automation.
Working with associations in Systems Manager

This section describes how to create and manage State Manager associations by using the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), and AWS Tools for PowerShell.

- Working with associations using IAM

About targets and rate controls in State Manager associations

This topic describes State Manager, a capability of AWS Systems Manager, features that help you deploy an association to dozens or hundreds of nodes while controlling the number of nodes that run the association at the scheduled time.

Targets

When you create a State Manager association, you choose which nodes to configure with the association in the **Targets** section of the Systems Manager console, as shown here.
If you create an association by using a command line tool such as the AWS Command Line Interface (AWS CLI), then you specify the `targets` parameter. Targeting nodes allows you to configure tens, hundreds, or thousands of nodes with an association without having to specify or choose individual node IDs.

Each managed node can be targeted by a maximum of 20 associations.

State Manager includes the following target options when creating an association.

**Specify tags**

Use this option to specify a tag key and (optionally) a tag value assigned to your nodes. When you run the request, the system locates and attempts to create the association on all nodes that match the specified tag key and value. If you specified multiple tag values, the association targets any node with at least one of those tag values. When the system initially creates the association, it runs the association. After this initial run, the system runs the association according to the schedule you specified.

If you create new nodes and assign the specified tag key and value to those nodes, the system automatically applies the association, runs it immediately, and then runs it according to the schedule. This applies when the association uses a Command or Policy document and doesn't apply
if the association uses an Automation runbook. If you delete the specified tags from a node, the system no longer runs the association on those nodes.

Note

If you use Automation runbooks with State Manager and the tagging limitation prevents you from achieving a specific goal, consider using Automation runbooks with Amazon EventBridge. For more information, see Run automations based on events. For more information about using runbooks with State Manager, see Scheduling automations with State Manager associations.

As a best practice, we recommend using tags when creating associations that use a Command or Policy document. We also recommend using tags when creating associations to run Auto Scaling groups. For more information, see Running Auto Scaling groups with associations.

Note

Note the following information.

- While creating an association in the console, when targeting nodes by using tags, you can specify only one tag key. If you want to use the console and you want to target your nodes by using more than one tag key, assign the tag keys to an AWS Resource Groups group and add the nodes to it. You can then choose the Resource Group option in the Targets list when you create the State Manager association.

- You can specify a maximum of five tag keys by using the AWS CLI. If you use the AWS CLI, all tag keys specified in the create-association command must be currently assigned to the node. If they aren't, State Manager fails to target the node for an association. For information about assigning tags to your nodes, see Tagging Systems Manager resources.

Choose nodes manually

Use this option to manually select the nodes where you want to create the association. The Instances pane displays all Systems Manager managed nodes in the current AWS account and AWS Region. You can manually select as many nodes as you want. When the system initially creates the
association, it runs the association. After this initial run, the system runs the association according to the schedule you specified.

⚠️ Note
If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

Choose a resource group

Use this option to create an association on all nodes returned by an AWS Resource Groups tag-based or AWS CloudFormation stack-based query.

Below are details about targeting resource groups for an association.

- If you add new nodes to a group, the system automatically maps the nodes to the association that targets the resource group. The system applies the association to the nodes when it discovers the change. After this initial run, the system runs the association according to the schedule you specified.

- If you create an association that targets a resource group and the AWS::SSM::ManagedInstance resource type was specified for that group, then by design, the association runs on both Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 nodes in a hybrid and multicloud environment.

- If you create an association that targets a resource group, the resource group must not have more than five tag keys assigned to it or more than five values specified for any one tag key. If either of these conditions applies to the tags and keys assigned to your resource group, the association fails to run and returns an InvalidTarget error.

- If you delete a resource group, all instances in that group no longer run the association. As a best practice, delete associations targeting the group.

- At most you can target a single resource group for an association. Multiple or nested groups aren't supported.

- After you create an association, State Manager periodically updates the association with information about resources in the Resource Group. If you add new resources to a Resource Group, the schedule for when the system applies the association to the new resources depends on several factors. You can determine the status of the association in the State Manager page of the Systems Manager console.
Warning

An AWS Identity and Access Management (IAM) user, group, or role with permission to create an association that targets a resource group of Amazon EC2 instances automatically has root-level control of all instances in the group. Only trusted administrators should be permitted to create associations.

Choose all nodes

Use this option to target all nodes in the current AWS account and AWS Region. When you run the request, the system locates and attempts to create the association on all nodes in the current AWS account and AWS Region. When the system initially creates the association, it runs the association. After this initial run, the system runs the association according to the schedule you specified. If you create new nodes, the system automatically applies the association, runs it immediately, and then runs it according to the schedule.

Rate controls

You can control the execution of an association on your nodes by specifying a concurrency value and an error threshold. The concurrency value specifies how many nodes can run the association simultaneously. An error threshold specifies how many association executions can fail before Systems Manager sends a command to each node configured with that association to stop running the association. The command stops the association from running until the next scheduled execution. The concurrency and error threshold features are collectively called rate controls.
Concurrency helps to limit the impact on your nodes by allowing you to specify that only a certain number of nodes can process an association at one time. You can specify either an absolute number of nodes, for example 20, or a percentage of the target set of nodes, for example 10%.

State Manager concurrency has the following restrictions and limitations:

- If you choose to create an association by using targets, but you don’t specify a concurrency value, then State Manager automatically enforces a maximum concurrency of 50 nodes.

- If new nodes that match the target criteria come online while an association that uses concurrency is running, then the new nodes run the association if the concurrency value isn't exceeded. If the concurrency value is exceeded, then the nodes are ignored during the current association execution interval. The nodes run the association during the next scheduled interval while conforming to the concurrency requirements.

- If you update an association that uses concurrency, and one or more nodes are processing that association when it's updated, then any node that is running the association is allowed to complete. Those associations that haven't started are stopped. After running associations complete, all target nodes immediately run the association again because it was updated. When the association runs again, the concurrency value is enforced.

Error thresholds
An error threshold specifies how many association executions are allowed to fail before Systems Manager sends a command to each node configured with that association. The command stops the association from running until the next scheduled execution. You can specify either an absolute number of errors, for example 10, or a percentage of the target set, for example 10%.

If you specify an absolute number of three errors, for example, State Manager sends the stop command when the fourth error is returned. If you specify 0, then State Manager sends the stop command after the first error result is returned.

If you specify an error threshold of 10% for 50 associations, then State Manager sends the stop command when the sixth error is returned. Associations that are already running when an error threshold is reached are allowed to complete, but some of these associations might fail. To ensure that there aren't more errors than the number specified for the error threshold, set the **Concurrency** value to 1 so that associations proceed one at a time.

State Manager error thresholds have the following restrictions and limitations:

- Error thresholds are enforced for the current interval.
- Information about each error, including step-level details, is recorded in the association history.
- If you choose to create an association by using targets, but you don’t specify an error threshold, then State Manager automatically enforces a threshold of 100% failures.

**Creating associations**

State Manager, a capability of AWS Systems Manager, helps you keep your AWS resources in a state that you define and reduce configuration drift. To do this, State Manager uses associations. An *association* is a configuration that you assign to your AWS resources. The configuration defines the state that you want to maintain on your resources. For example, an association can specify that antivirus software must be installed and running on a managed node, or that certain ports must be closed.

An association specifies a schedule for when to apply the configuration and the targets for the association. For example, an association for antivirus software might run once a day on all managed nodes in an AWS account. If the software isn't installed on a node, then the association could instruct State Manager to install it. If the software is installed, but the service isn't running, then the association could instruct State Manager to start the service.
You can assign tags to an association when you create it by using a command line tool such as the AWS CLI or AWS Tools for PowerShell. Adding tags to an association by using the Systems Manager console isn't supported. For more information about tags, see Tagging Systems Manager resources.

The following procedures describe how to create an association that uses either a Command or a Policy document to target managed nodes. For information about creating an association that uses an Automation runbook to target nodes or other types of AWS resources, see Scheduling automations with State Manager associations.

Association targets and rate controls

An association specifies which managed nodes, or targets, should receive the association. State Manager includes several features to help you target your managed nodes and control how the association is deployed to those targets. For more information about targets and rate controls, see About targets and rate controls in State Manager associations.

Running associations

By default, State Manager runs an association immediately after you create it, and then according to the schedule that you've defined.

The system also runs associations according to the following rules:

- State Manager attempts to run the association on all specified or targeted nodes during an interval.
- If an association doesn't run during an interval (because, for example, a concurrency value limited the number of nodes that could process the association at one time), then State Manager attempts to run the association during the next interval.
- State Manager runs the association after changes to the association's configuration, target nodes, documents, or parameters. For more information, see When are associations applied to resources?
- State Manager records history for all skipped intervals. You can view the history on the Execution History tab.
Scheduling associations

You can schedule associations to run at basic intervals such as every 10 hours, or you can create more advanced schedules using custom cron and rate expressions. You can also prevent associations from running when you first create them.

Using cron and rate expressions to schedule association runs

In addition to standard cron and rate expressions, State Manager also supports cron expressions that include a day of the week and the number sign (#) to designate the nth day of a month to run an association. Here is an example that runs a cron schedule on the third Tuesday of every month at 23:30 UTC:

`cron(30 23 ? * TUE#3 *)`

Here is an example that runs on the second Thursday of every month at midnight UTC:

`cron(0 0 ? * THU#2 *)`

State Manager also supports the (L) sign to indicate the last X day of the month. Here is an example that runs a cron schedule on the last Tuesday of every month at midnight UTC:

`cron(0 0 ? * 3L *)`

To further control when an association runs, for example if you want to run an association two days after patch Tuesday, you can specify an offset. An offset defines how many days to wait after the scheduled day to run an association. For example, if you specified a cron schedule of `cron(0 0 ? * THU#2 *)`, you could specify the number 3 in the Schedule offset field to run the association each Sunday after the second Thursday of the month.

Note

To use offsets, you must either select Apply association only at the next specified Cron interval in the console or specify the ApplyOnlyAtCronInterval parameter from the command line. When either of these options are activated, State Manager doesn't run the association immediately after you create it.

For more information about cron and rate expressions, see Reference: Cron and rate expressions for Systems Manager.
Create an association (console)

The following procedure describes how to use the Systems Manager console to create a State Manager association.

⚠️ Warning
When you create an association, you can choose an AWS resource group of managed nodes as the target for the association. If an AWS Identity and Access Management (IAM) user, group, or role has permission to create an association that targets a resource group of managed nodes, then that user, group, or role automatically has root-level control of all nodes in the group. Permit only trusted administrators to create associations.

To create a State Manager association

2. In the navigation pane, choose State Manager.
3. Choose Create association.
4. In the Name field, specify a name.
5. In the Document list, choose the option next to a document name. Note the document type. This procedure applies to Command and Policy documents. For information about creating an association that uses an Automation runbook, see Scheduling automations with State Manager associations.

⚠️ Important
State Manager doesn't support running associations that use a new version of a document if that document is shared from another account. State Manager always runs the default version of a document if shared from another account, even though the Systems Manager console shows that a new version was processed. If you want to run an association using a new version of a document shared from another account, you must set the document version to default.

6. For Parameters, specify the required input parameters.
7. (Optional) Choose a CloudWatch alarm to apply to your association for monitoring.
Note

Note the following information about this step.

- The alarms list displays a maximum of 100 alarms. If you don't see your alarm in the list, use the AWS Command Line Interface to create the association. For more information, see Create an association (command line).

- To attach a CloudWatch alarm to your command, the IAM principal that creates the association must have permission for the iam:createServiceLinkedRole action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms.

- If your alarm activates, any pending command invocations or automations do not run.

8. For Targets, choose an option. For information about using targets, see About targets and rate controls in State Manager associations.

9. In the Specify schedule section, choose either On Schedule or No schedule. If you choose On Schedule, use the buttons provided to create a cron or rate schedule for the association.

   If you don't want the association to run immediately after you create it, choose Apply association only at the next specified Cron interval.

10. (Optional) In the Schedule offset field, specify a number between 1 and 6.

11. In the Advanced options section use Compliance severity to choose a severity level for the association and use Change Calendars to choose a change calendar for the association.

   Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you indicate here. For more information, see About State Manager association compliance.

   The change calendar determines when the association runs. If the calendar is closed, the association isn't applied. If the calendar is open, the association runs accordingly. For more information, see AWS Systems Manager Change Calendar.

12. In the Rate control section, choose options to control how the association runs on multiple nodes. For more information about using rate controls, see About targets and rate controls in State Manager associations.
In the **Concurrency** section, choose an option:

- Choose **targets** to enter an absolute number of targets that can run the association simultaneously.
- Choose **percentage** to enter a percentage of the target set that can run the association simultaneously.

In the **Error threshold** section, choose an option:

- Choose **errors** to enter an absolute number of errors that are allowed before State Manager stops running associations on additional targets.
- Choose **percentage** to enter a percentage of errors that are allowed before State Manager stops running associations on additional targets.

13. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

---

**Note**

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

Following are the minimal permissions required to turn on Amazon S3 output for an association. You can further restrict access by attaching IAM policies to users or roles within an account. At minimum, an Amazon EC2 instance profile should have an IAM role with the AmazonSSMManagedInstanceCore managed policy and the following inline policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```
For minimal permissions, the Amazon S3 bucket you export to must have the default settings defined by the Amazon S3 console. For more information about creating Amazon S3 buckets, see Creating a bucket in the Amazon S3 User Guide.

Note
API operations that are initiated by the SSM document during an association run are not logged in AWS CloudTrail.

Note
If you delete the association you created, the association no longer runs on any targets of that association.

Create an association (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or Tools for PowerShell to create a State Manager association. This section includes several examples that show how to use targets and rate controls. Targets and rate controls allow you to assign an association to dozens or hundreds of nodes while controlling the execution of those associations. For more information about targets and rate controls, see About targets and rate controls in State Manager associations.

Before you begin
The targets parameter is an array of search criteria that targets nodes using a Key,Value combination that you specify. If you plan to create an association on dozens or hundreds of node by using the targets parameter, review the following targeting options before you begin the procedure.

Target specific nodes by specifying IDs

```bash
--targets Key=InstanceIds,Values=instance-id-1,instance-id-2,instance-id-3
```

```bash
--targets Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE,i-07782c72faEXAMPLE
```

Target instances by using tags

```bash
--targets Key=tag:tag-key,Values=tag-value-1,tag-value-2,tag-value-3
```

```bash
--targets Key=tag:Environment,Values=Development,Test,Pre-production
```

Target nodes by using AWS Resource Groups

```bash
--targets Key=resource-groups:Name,Values=resource-group-name
```

```bash
--targets Key=resource-groups:Name,Values=WindowsInstancesGroup
```

Target all instances in the current AWS account and AWS Region

```bash
--targets Key=InstanceIds,Values=* 
```

**Note**

Note the following information.

- State Manager doesn't support running associations that use a new version of a document if that document is shared from another account. State Manager always runs the default version of a document if shared from another account, even though the Systems Manager console shows that a new version was processed. If you want to run an
association using a new version of a document shared form another account, you must set the document version to default.

- You can specify a maximum of five tag keys by using the AWS CLI. If you use the AWS CLI, all tag keys specified in the create-association command must be currently assigned to the node. If they aren't, State Manager fails to target the node for an association. For information about assigning tags to your nodes, see Tagging Systems Manager resources.

- When you create an association, you specify when the schedule runs. Specify the schedule by using a cron or rate expression. For more information about cron and rate expressions, see Cron and rate expressions for associations.

To create an association

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Use the following format to create a command that creates a State Manager association. Replace each example resource placeholder with your own information.

   Linux & macOS

   ```bash
   aws ssm create-association
     --name document_name
     --document-version version_of_document_applied
     --instance-id instances_to_apply_association_on
     --parameters (if any)
     --targets target_options
     --schedule-expression "cron_or_rate_expression"
     --apply-only-at-cron-interval required_parameter_for_schedule_offsets
     --schedule-offset number_between_1_and_6
     --output-location s3_bucket_to_store_output_details
     --association-name association_name
     --max-errors a_number_of_errors_or_a_percentage_of_target_set
     --max-concurrency a_number_of_instances_or_a_percentage_of_target_set
     --compliance-severity severity_level
     --calendar-names change_calendar_names
     --target-locations aws_region_or_account
   ```
Windows

```bash
aws ssm create-association
  --name document_name
  --document-version version_of_document_applied
  --instance-id instances_to_apply_association_on
  --parameters (if any)
  --targets target_options
  --schedule-expression "cron_or_rate_expression"
  --apply-only-at-cron-interval required_parameter_for_schedule_offsets
  --schedule-offset number_between_1_and_6
  --output-location s3_bucket_to_store_output_details
  --association-name association_name
  --max-errors a_number_of_errors_or_a_percentage_of_target_set
  --max-concurrency a_number_of_instances_or_a_percentage_of_target_set
  --compliance-severity severity_level
  --calendar-names change_calendar_names
  --target-locations aws_region_or_account
  --tags "Key=tag_key,Value=tag_value"
```

PowerShell

```powershell
New-SSMAssociation
  -Name document_name
  -DocumentVersion version_of_document_applied
  -InstanceId instances_to_apply_association_on
  -Parameters (if any)
  -Target target_options
  -ScheduleExpression "cron_or_rate_expression"
  -ApplyOnlyAtCronInterval required_parameter_for_schedule_offsets
  -ScheduleOffset number_between_1_and_6
  -OutputLocation s3_bucket_to_store_output_details
  -AssociationName association_name
  -MaxError a_number_of_errors_or_a_percentage_of_target_set
  -MaxConcurrency a_number_of_instances_or_a_percentage_of_target_set
  -ComplianceSeverity severity_level
  -CalendarNames change_calendar_names
  -TargetLocations aws_region_or_account
  -Tags "Key=tag_key,Value=tag_value"
```

Working with associations
The following example creates an association on nodes tagged with "Environment,Linux". The association uses the AWS-UpdateSSMAgent document to update the SSM Agent on the targeted nodes at 2:00 UTC every Sunday morning. This association runs simultaneously on 10 nodes maximum at any given time. Also, this association stops running on more nodes for a particular execution interval if the error count exceeds 5. For compliance reporting, this association is assigned a severity level of Medium.

Linux & macOS

```bash
aws ssm create-association
    --association-name Update_SSM_Agent_Linux
    --targets Key=tag:Environment,Values=Linux
    --name AWS-UpdateSSMAgent
    --compliance-severity "MEDIUM"
    --schedule-expression "cron(0 2 ? * SUN *)"
    --max-errors "5"
    --max-concurrency "10"
```

Windows

```bash
aws ssm create-association
    --association-name Update_SSM_Agent_Linux
    --targets Key=tag:Environment,Values=Linux
    --name AWS-UpdateSSMAgent
    --compliance-severity "MEDIUM"
    --schedule-expression "cron(0 2 ? * SUN *)"
    --max-errors "5"
    --max-concurrency "10"
```

PowerShell

```powershell
New-SSMAssociation
    -AssociationName Update_SSM_Agent_Linux
    -Name AWS-UpdateSSMAgent
    -Target @(
        "Key"="tag:Environment"
        "Values"="Linux"
    )
    -ComplianceSeverity MEDIUM
    -ScheduleExpression "cron(0 2 ? * SUN *)"
```
The following example targets node IDs by specifying a wildcard value (*). This allows Systems Manager to create an association on all nodes in the current AWS account and AWS Region. This association runs simultaneously on 10 nodes maximum at any given time. Also, this association stops running on more nodes for a particular execution interval if the error count exceeds 5. For compliance reporting, this association is assigned a severity level of Medium. This association uses a schedule offset, which means it runs two days after the specified cron schedule. It also includes the ApplyOnlyAtCronInterval parameter, which is required to use the schedule offset and which means the association won't run immediately after it is created.

Linux & macOS

```bash
aws ssm create-association
  --association-name Update_SSM_Agent_Linux
  --name "AWS-UpdateSSMAgent"
  --targets "Key=instanceids,Values=*"
  --compliance-severity "MEDIUM"
  --schedule-expression "cron(0 2 ? * SUN#2 *)"
  --apply-only-at-cron-interval
  --schedule-offset 2
  --max-errors "5"
  --max-concurrency "10"
```

Windows

```bash
aws ssm create-association
  --association-name Update_SSM_Agent_Linux
  --name "AWS-UpdateSSMAgent"
  --targets "Key=instanceids,Values=*"
  --compliance-severity "MEDIUM"
  --schedule-expression "cron(0 2 ? * SUN#2 *)"
  --apply-only-at-cron-interval
  --schedule-offset 2
  --max-errors "5"
  --max-concurrency "10"
```
The following example creates an association on nodes in Resource Groups. The group is named "HR-Department". The association uses the AWS-UpdateSSMAgent document to update SSM Agent on the targeted nodes at 2:00 UTC every Sunday morning. This association runs simultaneously on 10 nodes maximum at any given time. Also, this association stops running on more nodes for a particular execution interval if the error count exceeds 5. For compliance reporting, this association is assigned a severity level of Medium. This association runs at the specified cron schedule. It doesn't run immediately after the association is created.

**Linux & macOS**

```bash
aws ssm create-association \
  --association-name Update_SSM_Agent_Linux \
  --targets Key=resource-groups:Name,Values=HR-Department \
  --name AWS-UpdateSSMAgent \
  --compliance-severity "MEDIUM" \
  --schedule-expression "cron(0 2 ? * SUN#2 *)" \
  --max-errors "5" \
  --max-concurrency "10" \
  --apply-only-at-cron-interval
```
Windows

```
aws ssm create-association ^
  --association-name Update_SSM_Agent_Linux ^
  --targets Key=resource-groups:Name,Values=HR-Department ^
  --name AWS-UpdateSSMAgent ^
  --compliance-severity "MEDIUM" ^
  --schedule-expression "cron(0 2 ? * SUN *)" ^
  --max-errors "5" ^
  --max-concurrency "10" ^
  --apply-only-at-cron-interval
```

PowerShell

```
New-SSMAssociation `
  -AssociationName Update_SSM_Agent_Linux `
  -Name AWS-UpdateSSMAgent `
  -Target @{ `
    "Key"="resource-groups:Name" `
    "Values"="HR-Department" `
  } `
  -ScheduleExpression "cron(0 2 ? * SUN *)" `
  -MaxConcurrency "10" `
  -MaxError "5" `
  -ComplianceSeverity MEDIUM `
  -ApplyOnlyAtCronInterval
```

The following example creates an association that runs on nodes tagged with a specific node ID. The association uses the SSM Agent document to update SSM Agent on the targeted nodes once when the change calendar is open. The association checks the calendar state when it runs. If the calendar is closed at launch time and the association is only run once, it won't run again because the association run window has passed. If the calendar is open, the association runs accordingly.
Note

If you add new nodes to the tags or resource groups that an association acts on when the change calendar is closed, the association is applied to those nodes once the change calendar opens.

Linux & macOS

```
aws ssm create-association
    --association-name CalendarAssociation
    --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f"
    --name AWS-UpdateSSMAgent
    --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
    --schedule-expression "rate(1day)"
```

Windows

```
aws ssm create-association
    --association-name CalendarAssociation
    --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f"
    --name AWS-UpdateSSMAgent
    --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
    --schedule-expression "rate(1day)"
```

PowerShell

```
New-SSMAssociation
    -AssociationName CalendarAssociation
    -Target @{
        "Key"="tag:instanceids"
        "Values"="i-0cb2b964d3e14fd9f"
    }
    -Name AWS-UpdateSSMAgent
    -CalendarNames "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1"
    -ScheduleExpression "rate(1day)"
```
The following example creates an association that runs on nodes tagged with a specific node ID. The association uses the SSM Agent document to update SSM Agent on the targeted nodes on the targeted nodes at 2:00 AM every Sunday. This association runs only at the specified cron schedule when the change calendar is open. When the association is created, it checks the calendar state. If the calendar is closed, the association isn't applied. When the interval to apply the association starts at 2:00 AM on Sunday, the association checks to see if the calendar is open. If the calendar is open, the association runs accordingly.

**Note**

If you add new nodes to the tags or resource groups that an association acts on when the change calendar is closed, the association is applied to those nodes once the change calendar opens.

**Linux & macOS**

```
aws ssm create-association \
  --association-name MultiCalendarAssociation \
  --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f" \
  --name AWS-UpdateSSMAgent \
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1" \
  "arn:aws:ssm:us-east-2:123456789012:document/testCalendar2" \
  --schedule-expression "cron(0 2 ? * SUN *)"
```

**Windows**

```
aws ssm create-association ^
  --association-name MultiCalendarAssociation ^
  --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f" ^
  --name AWS-UpdateSSMAgent ^
  --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1" \
  --schedule-expression "cron(0 2 ? * SUN *)"
```

**PowerShell**

```
New-SSMAssociation \
```
-AssociationName MultiCalendarAssociation \
-Name AWS-UpdateSSMAgent \
-Target @{ \n  "Key"="tag:instanceids" \n  "Values"="i-0cb2b964d3e14fd9f" \n} \
-ScheduleExpression "cron(0 2 ? * SUN *)"

**Note**

If you delete the association you created, the association no longer runs on any targets of that association. Also, if you specified the `apply-only-at-cron-interval` parameter, you can reset this option. To do so, specify the `no-apply-only-at-cron-interval` parameter when you update the association from the command line. This parameter forces the association to run immediately after updating the association and according to the interval specified.

**Editing and creating a new version of an association**

You can edit a State Manager association to specify a new name, schedule, severity level, or targets. You can also choose to write the output of the command to an Amazon Simple Storage Service (Amazon S3) bucket. After you edit an association, State Manager creates a new version. You can view different versions after editing, as described in the following procedures.

The following procedures describe how to edit and create a new version of an association using the Systems Manager console, AWS Command Line Interface (AWS CLI), and AWS Tools for PowerShell (Tools for PowerShell).

**Important**

State Manager doesn't support running associations that use a new version of a document if that document is shared from another account. State Manager always runs the default version of a document if shared from another account, even though the Systems Manager console shows that a new version was processed. If you want to run an association using
a new version of a document shared from another account, you must set the document version to default.

Edit an association (console)

The following procedure describes how to use the Systems Manager console to edit and create a new version of an association.

**Note**

This procedure requires that you have write access to an existing Amazon S3 bucket. If you haven't used Amazon S3 before, be aware that you will incur charges for using Amazon S3. For information about how to create a bucket, see [Create a Bucket](#).

To edit a State Manager association

2. In the navigation pane, choose **State Manager**.
3. Choose the association you created in [Create an association (command line)](#) and then choose **Edit**.
4. In the **Name** field, enter a new name.
5. In the **Specify schedule** section, choose a new option.
6. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

**Note**

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.
7. Choose **Edit association**. Configure the association to meet your current requirements.

8. In the **Associations** page, choose the name of the association you edited, and then choose the **Versions** tab. The system lists each version of the association you created and edited.

10. Choose the name of the Amazon S3 bucket you specified for storing command output, and then choose the folder named with the ID of the node that ran the association. (If you chose to store output in a folder in the bucket, open it first.)

11. Drill down several levels, through the `awsrunPowerShell` folder, to the `stdout` file.

12. Choose **Open** or **Download** to view the host name.

---

### Edit an association (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to edit and create a new version of an association.

#### To edit a State Manager association

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

   For information, see [Installing or updating the latest version of the AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/installing.html) and [Installing the AWS Tools for PowerShell](https://docs.aws.amazon.com/sms/latest/userguide/sms-powershell.html).

2. Use the following format to create a command to edit and create a new version of an existing State Manager association. Replace each *example resource placeholder* with your own information.

   ```
   Important
   When you call UpdateAssociation, the system drops all optional parameters from the request and overwrites the association with null values for those parameters. This is by design. You must specify all optional parameters in the call, even if you are not changing the parameters. This includes the Name parameter. Before calling this API action, we recommend that you call the DescribeAssociation API operation and make a note of all optional parameters required for your UpdateAssociation call.
   ```
### Linux & macOS

```bash
aws ssm update-association \
  --name document_name \
  --document-version version_of_document_applied \
  --instance-id instances_to_apply_association_on \
  --parameters (if any) \
  --targets target_options \
  --schedule-expression "cron_or_rate_expression" \
  --schedule-offset "number_between_1_and_6" \
  --output-location s3_bucket_to_store_output_details \
  --association-name association_name \
  --max-errors a_number_of_errors_or_a_percentage_of_target_set \
  --max-concurrency a_number_of_instances_or_a_percentage_of_target_set \
  --compliance-severity severity_level \
  --calendar-names change_calendar_names \
  --target-locations aws_region_or_account
```

### Windows

```bash
aws ssm update-association ^
  --name document_name ^
  --document-version version_of_document_applied ^
  --instance-id instances_to_apply_association_on ^
  --parameters (if any) ^
  --targets target_options ^
  --schedule-expression "cron_or_rate_expression" ^
  --schedule-offset "number_between_1_and_6" ^
  --output-location s3_bucket_to_store_output_details ^
  --association-name association_name ^
  --max-errors a_number_of_errors_or_a_percentage_of_target_set ^
  --max-concurrency a_number_of_instances_or_a_percentage_of_target_set ^
  --compliance-severity severity_level ^
  --calendar-names change_calendar_names ^
  --target-locations aws_region_or_account
```

### PowerShell

```powershell
Update-SSMAssociation `
  -Name document_name `
  -DocumentVersion version_of_document_applied `
The following example updates an existing association to change the name to TestHostnameAssociation2. The new association version runs every hour and writes the output of commands to the specified Amazon S3 bucket.

**Linux & macOS**

```bash
aws ssm update-association \
    --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE \
    --association-name TestHostnameAssociation2 \
    --parameters commands="echo Association" \
    --output-location S3Location='{OutputS3Region=us-east-1,OutputS3BucketName=DOC-EXAMPLE-BUCKET,OutputS3KeyPrefix=logs}' \
    --schedule-expression "cron(0 */1 * * ? *)"
```

**Windows**

```bash
aws ssm update-association ^
    --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE ^
    --association-name TestHostnameAssociation2 ^
    --parameters commands="echo Association" ^
    --output-location S3Location='{OutputS3Region=us-east-1,OutputS3BucketName=DOC-EXAMPLE-BUCKET,OutputS3KeyPrefix=logs}' ^
    --schedule-expression "cron(0 */1 * * ? *)"
```

**PowerShell**

```powershell
Update-SSMAssociation \
    -AssociationId b85ccafe-9f02-4812-9b81-01234EXAMPLE \
```

---

**Working with associations**
The following example updates an existing association to change the name to `CalendarAssociation`. The new association runs when the calendar is open and writes command output to the specified Amazon S3 bucket.

**Linux & macOS**

```bash
aws ssm update-association
    --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE
    --association-name CalendarAssociation
    --parameters commands="echo Association"
    --output-location S3Location='{OutputS3Region=us-east-1,OutputS3BucketName=DOC-EXAMPLE-BUCKET,OutputS3KeyPrefix=logs}'
    --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar2"
```

**Windows**

```bash
aws ssm update-association ^
    --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE ^
    --association-name CalendarAssociation ^
    --parameters commands="echo Association" ^
    --output-location S3Location='{OutputS3Region=us-east-1,OutputS3BucketName=DOC-EXAMPLE-BUCKET,OutputS3KeyPrefix=logs}' ^
    --calendar-names "arn:aws:ssm:us-east-1:123456789012:document/testCalendar2"
```

**PowerShell**

```bash
Update-SSMAssociation
    -AssociationId b85ccafe-9f02-4812-9b81-01234EXAMPLE
    -AssociationName CalendarAssociation
    -AssociationName OneTimeAssociation
    -Parameter @{"commands="echo Association"}]
    -S3Location_OutputS3BucketName DOC-EXAMPLE-BUCKET
    -CalendarNames "arn:aws:ssm:us-east-1:123456789012:document/testCalendar2"
```
The following example updates an existing association to change the name to MultiCalendarAssociation. The new association runs when the calendars are open and writes command output to the specified Amazon S3 bucket.

**Linux & macOS**

```bash
aws ssm update-association \\   --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE \\
   --association-name MultiCalendarAssociation \\
   --parameters commands="echo Association" \\
   --output-location S3Location='{OutputS3Region=us-east-1,OutputS3BucketName=DOC-EXAMPLE-BUCKET,OutputS3KeyPrefix=logs}' \\
```

**Windows**

```bash
aws ssm update-association ^
   --association-id 8dfe3659-4309-493a-8755-01234EXAMPLE ^
   --association-name MultiCalendarAssociation ^
   --parameters commands="echo Association" ^
   --output-location S3Location='{OutputS3Region=us-east-1,OutputS3BucketName=DOC-EXAMPLE-BUCKET,OutputS3KeyPrefix=logs}' ^
```

**PowerShell**

```powershell
Update-SSMAssociation `   -AssociationId b85ccafe-9f02-4812-9b81-01234EXAMPLE `   -AssociationName MultiCalendarAssociation `   -Parameter @{"commands"="echo Association"} `   -S3Location_OutputS3BucketName DOC-EXAMPLE-BUCKET `   -CalendarNames "arn:aws:ssm:us-east-1:123456789012:document/testCalendar1" "arn:aws:ssm:us-east-2:123456789012:document/testCalendar2"
```

3. To view the new version of the association, run the following command.
Linux & macOS

```
aws ssm describe-association \
--association-id b85ccafe-9f02-4812-9b81-01234EXAMPLE
```

Windows

```
aws ssm describe-association ^
--association-id b85ccafe-9f02-4812-9b81-01234EXAMPLE
```

PowerShell

```
Get-SSMAssociation `
-AssociationId b85ccafe-9f02-4812-9b81-01234EXAMPLE | Select-Object *
```

The system returns information like the following.

Linux & macOS

```
{
  "AssociationDescription": {
    "ScheduleExpression": "cron(0 */1 * * ? *)",
    "OutputLocation": {
      "S3Location": {
        "OutputS3KeyPrefix": "logs",
        "OutputS3BucketName": "DOC-EXAMPLE-BUCKET",
        "OutputS3Region": "us-east-1"
      }
    },
    "Name": "AWS-RunPowerShellScript",
    "Parameters": {
      "commands": [
        "echo Association"
      ]
    },
    "LastExecutionDate": 1559316400.338,
    "Overview": {
      "Status": "Success",
      "DetailedStatus": "Success",
      "AssociationStatusAggregatedCount": {}
    }
  }
}
```
Windows

{
   "AssociationDescription": {
      "ScheduleExpression": "cron(0 */1 * * ? *)",
      "OutputLocation": {
         "S3Location": {
            "OutputS3KeyPrefix": "logs",
            "OutputS3BucketName": "DOC-EXAMPLE-BUCKET",
            "OutputS3Region": "us-east-1"
         }

Deleting associations

The following procedure describes how to delete a State Manager association by using the AWS Systems Manager console.

Delete an association

Use the following procedure to delete an association by using the AWS Systems Manager console.

To delete an association

2. In the navigation pane, choose State Manager.
3. Select an association and then choose Delete.

Running Auto Scaling groups with associations

The best practice when using associations to run Auto Scaling groups is to use tag targets. Not using tags might cause you to reach the association limit.

If all nodes are tagged with the same key and value, you only need one association to run your Auto Scaling group. The following procedure describes how to create such an association.

To create an association that runs Auto Scaling groups

1. Ensure all nodes in the Auto Scaling group are tagged with the same key and value. For more instructions on tagging nodes, see Tagging Auto Scaling groups and instances in the AWS Auto Scaling User Guide.
2. Create an association by using the procedure in Working with associations in Systems Manager.

   If you're working in the console, choose Specify instance tags in the Targets field. For Instance tags, enter the Tag key and value for your Auto Scaling group.

   If you're using the AWS Command Line Interface (AWS CLI), specify --targets Key=tag:tag-key,Values=tag-value where the key and value match what you tagged your nodes with.
Viewing association histories

You can view all executions for a specific association ID by using the DescribeAssociationExecutions API operation. Use this operation to see the status, detailed status, results, last execution time, and more information for a State Manager association. State Manager is a capability of AWS Systems Manager. This API operation also includes filters to help you locate associations according to the criteria you specify. For example, you can specify an exact date and time, and use a GREATERTHAN filter to view executions processed after the specified date and time.

If, for example, an association execution failed, you can drill down into the details of a specific execution by using the DescribeAssociationExecutionTargets API operation. This operation shows you the resources, such as node IDs, where the association ran and the various association statuses. You can then see which resource or node failed to run an association. With the resource ID you can then view the command execution details to see which step in a command failed.

The examples in this section also include information about how to use the StartAssociationsOnce API operation to run an association once at the time of creation. You can use this API operation when you investigate failed association executions. If you see that an association failed, you can make a change on the resource, and then immediately run the association to see if the change on the resource allows the association to run successfully.

⚠️ Note

API operations that are initiated by the SSM document during an association run are not logged in AWS CloudTrail.

Viewing association histories (console)

Use the following procedure to view the execution history for a specific association ID and then view execution details for one or more resources.

To view execution history for a specific association ID

2. Choose State Manager.
3. In the Association id field, choose an association for which you want to view the history.
4. Choose the **View details** button.
5. Choose the **Execution history** tab.
6. Choose an association for which you want to view resource-level execution details. For example, choose an association that shows a status of **Failed**. You can then view the execution details for the nodes that failed to run the association.

   Use the search box filters to locate the execution for which you want to view details.

![Association executions](image)

7. Choose an execution ID. The **Association execution targets** page opens. This page shows all the resources that ran the association.
8. Choose a resource ID to view specific information about that resource.

   Use the search box filters to locate the resource for which you want to view details.

![Association execution targets](image)

9. If you're investigating an association that failed to run, you can use the **Apply association now** button to run an association once at the time of creation. After you made changes on the resource where the association failed to run, choose the **Association ID** link in the navigation breadcrumb.
10. Choose the **Apply association now** button. After the execution is complete, verify that the association execution succeeded.

**Viewing association histories (command line)**

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) (on Linux or Windows) or AWS Tools for PowerShell to view the execution history for a specific association ID. Following this, the procedure describes how to view execution details for one or more resources.

**To view execution history for a specific association ID**

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.
For information, see Installing or updating the latest version of the AWS CLI and Installing the AWS Tools for PowerShell.

2. Run the following command to view a list of executions for a specific association ID.

**Linux & macOS**

```bash
aws ssm describe-association-executions \
  --association-id ID \
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN
```

**Note**

This command includes a filter to limit the results to only those executions that occurred after a specific date and time. If you want to view all executions for a specific association ID, remove the `--filters` parameter and `Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN` value.

**Windows**

```bash
aws ssm describe-association-executions ^
  --association-id ID ^
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN
```

**Note**

This command includes a filter to limit the results to only those executions that occurred after a specific date and time. If you want to view all executions for a specific association ID, remove the `--filters` parameter and `Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN` value.

**PowerShell**

```powershell
Get-SSMAssociationExecution `n```

Working with associations
-AssociationId ID
-Filter
@{"Key":"CreatedTime","Value":"2019-06-01T19:15:38.372Z","Type":"GREATER_THAN"}

### Note

This command includes a filter to limit the results to only those executions that occurred after a specific date and time. If you want to view all executions for a specific association ID, remove the -Filter parameter and @{"Key":"CreatedTime","Value":"2019-06-01T19:15:38.372Z","Type":"GREATER_THAN"} value.

The system returns information like the following.

Linux & macOS

```json
{
  "AssociationExecutions": [
    {

You can limit the results by using one or more filters. The following example returns all associations that were run before a specific date and time.

**Linux & macOS**

```
aws ssm describe-association-executions \
  --association-id ID \
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=LESS_THAN
```

**Windows**

```
aws ssm describe-association-executions ^
  --association-id ID ^
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=LESS_THAN
```

**PowerShell**

```
Get-SSMAssociationExecution \
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE \
```
The following returns all associations that were successfully run after a specific date and time.

**Linux & macOS**

```bash
cat
aws ssm describe-association-executions \
  --association-id ID \
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN 
  Key=Status,Value=Success,Type=EQUAL
```

**Windows**

```bash
cat
aws ssm describe-association-executions ^ \
  --association-id ID ^ \
  --filters Key=CreatedTime,Value="2018-04-10T19:15:38.372Z",Type=GREATER_THAN 
  Key=Status,Value=Success,Type=EQUAL
```

**PowerShell**

```powershell
Get-SSMAssociationExecution ` 
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE ` 
  -Filter @{
    "Key"="CreatedTime";
    "Value"="2019-06-01T19:15:38.372Z";
    "Type"="GREATER_THAN"
  },
  @{
    "Key"="Status";
    "Value"="Success";
    "Type"="EQUAL"
  }
```

3. Run the following command to view all targets where the specific execution ran.

**Linux & macOS**

```bash
cat
aws ssm describe-association-execution-targets \
  --association-id ID \
```

Working with associations

1700
Windows

```
aws ssm describe-association-execution-targets 
  --association-id ID 
  --execution-id ID
```

PowerShell

```
Get-SSMAssociationExecutionTarget ` 
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE ` 
  -ExecutionId 76a5a04f-caf6-490c-b448-92c02EXAMPLE
```

You can limit the results by using one or more filters. The following example returns information about all targets where the specific association failed to run.

Linux & macOS

```
aws ssm describe-association-execution-targets 
  --association-id ID 
  --execution-id ID 
  --filters Key=Status,Value="Failed"
```

Windows

```
aws ssm describe-association-execution-targets 
  --association-id ID 
  --execution-id ID 
  --filters Key=Status,Value="Failed"
```

PowerShell

```
Get-SSMAssociationExecutionTarget ` 
  -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE ` 
  -ExecutionId 76a5a04f-caf6-490c-b448-92c02EXAMPLE ` 
  -Filter @{
    "Key"="Status";
    "Value"="Failed"
```

Working with associations

1701
The following example returns information about a specific managed node where an association failed to run.

**Linux & macOS**

```bash
aws ssm describe-association-execution-targets \
   --association-id ID \
   --execution-id ID \
   --filters Key=Status,Value=Failed Key=ResourceId,Value="i-02573cafcfEXAMPLE" Key=ResourceType,Value=ManagedInstance
```

**Windows**

```bash
aws ssm describe-association-execution-targets ^
   --association-id ID ^
   --execution-id ID ^
   --filters Key=Status,Value=Failed Key=ResourceId,Value="i-02573cafcfEXAMPLE" Key=ResourceType,Value=ManagedInstance
```

**PowerShell**

```powershell
Get-SSMAssociationExecutionTarget ` 
   -AssociationId 14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE ` 
   -ExecutionId 76a5a04f-caf6-490c-b448-92c02EXAMPLE ` 
   -Filter @{
       "Key"="Status";
       "Value"="Success"
   },
   @{
       "Key"="ResourceId";
       "Value"="i-02573cafcfEXAMPLE"
   },
   @{
       "Key"="ResourceType";
       "Value"="ManagedInstance"
}
```

4. If you're investigating an association that failed to run, you can use the `StartAssociationsOnce` API operation to run an association immediately and only one time. After you change the
resource where the association failed to run, run the following command to run the association immediately and only one time.

**Linux & macOS**

```
aws ssm start-associations-once \
   --association-id ID
```

**Windows**

```
aws ssm start-associations-once ^
   --association-id ID
```

**PowerShell**

```
Start-SSMAssociationsOnce ` 
   -AssociationId ID
```

**Working with associations using IAM**

State Manager, a capability of AWS Systems Manager, uses **targets** to choose which instances you configure your associations with. Originally, associations were created by specifying a document name (**Name**) and instance ID (**InstanceId**). This created an association between a document and an instance or managed node. Associations used to be identified by these parameters. These parameters are now deprecated, but they're still supported. The resources instance and managed-instance were added as resources to actions with **Name** and **InstanceId**.

AWS Identity and Access Management (IAM) policy enforcement behavior depends on the type of resource specified. Resources for State Manager operations are only enforced based on the passed-in request. State Manager doesn't perform a deep check for the properties of resources in your account. A request is only validated against policy resources if the request parameter contains the specified policy resources. For example, if you specify an instance in the resource block, the policy is enforced if the request uses the **InstanceId** parameter. The **Targets** parameter for each resource in the account isn't checked for that **InstanceId**.

Following are some cases with confusing behavior:
DescribeAssociation, DeleteAssociation, and UpdateAssociation use instance, managed-instance, and document resources to specify the deprecated way of referring to associations. This includes all associations created with the deprecated InstanceId parameter.

CreateAssociation, CreateAssociationBatch, and UpdateAssociation use instance and managed-instance resources to specify the deprecated way of referring to associations. This includes all associations created with the deprecated InstanceId parameter. The document resource type is part of the deprecated way of referring to associations and is an actual property of an association. This means you can construct IAM policies with Allow or Deny permissions for both Create and Update actions based on document name.

For more information about using IAM policies with Systems Manager, see Identity and access management for AWS Systems Manager or Actions, resources, and condition keys for AWS Systems Manager in the Service Authorization Reference.

AWS Systems Manager State Manager walkthroughs

The following walkthroughs demonstrate how to create and configure State Manager associations by using the Systems Manager console or the AWS Command Line Interface (AWS CLI). The walkthroughs also demonstrate how to automatically perform common administrative tasks by using State Manager, a capability of AWS Systems Manager.

Topics

- Walkthrough: Creating associations that run MOF files
- Walkthrough: Creating associations that run Ansible playbooks
- Walkthrough: Creating associations that run Chef recipes
- Walkthrough: Automatically update SSM Agent (CLI)
- Walkthrough: Automatically update PV drivers on EC2 instances for Windows Server (console)

Walkthrough: Creating associations that run MOF files

You can run Managed Object Format (MOF) files to enforce a desired state on Windows Server managed nodes with State Manager, a capability of AWS Systems Manager, by using the AWS-ApplyDSCMofs SSM document. The AWS-ApplyDSCMofs document has two execution modes. With the first mode, you can configure the association to scan and report if the managed nodes are in the desired state defined in the specified MOF files. In the second mode, you can run the MOF files and change the configuration of your nodes based on the resources and their values.
defined in the MOF files. The AWS-ApplyDSCMofs document allows you to download and run MOF configuration files from Amazon Simple Storage Service (Amazon S3), a local share, or from a secure website with an HTTPS domain.

State Manager logs and reports the status of each MOF file execution during each association run. State Manager also reports the output of each MOF file execution as a compliance event which you can view on the AWS Systems Manager Compliance page.

MOF file execution is built on Windows PowerShell Desired State Configuration (PowerShell DSC). PowerShell DSC is a declarative platform used for configuration, deployment, and management of Windows systems. PowerShell DSC allows administrators to describe, in simple text documents called DSC configurations, how they want a server to be configured. A PowerShell DSC configuration is a specialized PowerShell script that states what to do, but not how to do it. Running the configuration produces a MOF file. The MOF file can be applied to one or more servers to achieve the desired configuration for those servers. PowerShell DSC resources do the actual work of enforcing configuration. For more information, see Windows PowerShell Desired State Configuration Overview.

- Using tokens in MOF files
- Prerequisites
- Creating an association that runs MOF files
- Troubleshooting
- Viewing DSC resource compliance details

Using Amazon S3 to store artifacts

If you're using Amazon S3 to store PowerShell modules, MOF files, compliance reports, or status reports, then the AWS Identity and Access Management (IAM) role used by AWS Systems Manager SSM Agent must have GetObject and ListBucket permissions on the bucket. If you don't provide these permissions, the system returns an Access Denied error. Below is important information about storing artifacts in Amazon S3.

- If the bucket is in a different AWS account, create a bucket resource policy that grants the account (or the IAM role) GetObject and ListBucket permissions.
• If you want to use custom DSC resources, you can download these resources from an Amazon S3 bucket. You can also install them automatically from the PowerShell gallery.

• If you're using Amazon S3 as a module source, upload the module as a Zip file in the following case-sensitive format: `ModuleName_ModuleVersion.zip`. For example: `MyModule_1.0.0.zip`.

• All files must be in the bucket root. Folder structures aren't supported.

**Resolving credentials in MOF files**

Credentials are resolved by using [AWS Secrets Manager](https://aws.amazon.com/secretsmanager/) or [AWS Systems Manager Parameter Store](https://aws.amazon.com/systemsmanager/parameter-store/). This allows you to set up automatic credential rotation. This also allows DSC to automatically propagate credentials to your servers without redeploying MOFs.

To use an AWS Secrets Manager secret in a configuration, create a PSCredential object where the Username is the SecretId or SecretARN of the secret containing the credential. You can specify any value for the password. The value is ignored. Following is an example.

```
Configuration MyConfig
{
    $ss = ConvertTo-SecureString -String 'a_string' -AsPlaintext -Force
    $credential = New-Object PSCredential('a_secret_or_ARN', $ss)

    Node localhost
    {
        File file_name
        {
            DestinationPath = 'C:\MyFile.txt'
            SourcePath = '\FileServer\Share\MyFile.txt'
            Credential = $credential
        }
    }
}
```

Compile your MOF using the `PsAllowPlaintextPassword` setting in configuration data. This is OK because the credential only contains a label.

In Secrets Manager, ensure that the node has GetSecretValue access in an IAM Managed Policy, and optionally in the Secret Resource Policy if one exists. To work with DSC, the secret must be in the following format.

```
{ 'Username': 'a_name', 'Password': 'a_password' }
```
The secret can have other properties (for example, properties used for rotation), but it must at least have the username and password properties.

We recommended that you use a multi-user rotation method, where you have two different usernames and passwords, and the rotation AWS Lambda function flips between them. This method allows you to have multiple active accounts while eliminating the risk of locking out a user during rotation.

**Using tokens in MOF files**

Tokens give you the ability to modify resource property values *after* the MOF has been compiled. This allows you to reuse common MOF files on multiple servers that require similar configurations.

Token substitution only works for Resource Properties of type `String`. However, if your resource has a nested CIM node property, it also resolves tokens from `String` properties in that CIM node. You can't use token substitution for numerals or arrays.

For example, consider a scenario where you're using the `xComputerManagement` resource and you want to rename the computer using DSC. Normally you would need a dedicated MOF file for that machine. However, with token support, you can create a single MOF file and apply it to all your nodes. In the `ComputerName` property, instead of hardcoding the computer name into the MOF, you can use an Instance Tag type token. The value is resolved during MOF parsing. See the following example.

```configuration
Configuration MyConfig
{
  xComputer Computer
  {
    ComputerName = '{tag:ComputerName}'
  }
}
```

You then set a tag on either the managed node in the Systems Manager console, or an Amazon Elastic Compute Cloud (Amazon EC2) tag in the Amazon EC2 console. When you run the document, the script substitutes the `{tag:ComputerName}` token for the value of the instance tag.

You can also combine multiple tags into a single property, as shown in the following example.

```configuration
Configuration MyConfig
```
There are five different types of tokens you can use:

- **tag**: Amazon EC2 or managed node tags.
- **tagb64**: This is the same as tag, but the system uses base64 to decode the value. This allows you to use special characters in tag values.
- **env**: Resolves Environment variables.
- **ssm**: Parameter Store values. Only String and Secure String types are supported.
- **tagssm**: This is the same as tag, but if the tag isn't set on the node, the system tries to resolve the value from a Systems Manager parameter with the same name. This is useful in situations when you want a 'default global value' but you want to be able to override it on a single node (for example, one-box deployments).

Here is a Parameter Store example that uses the ssm token type.

```json
File MyFile
{
    DestinationPath = "C:\ProgramData\ConnectionData.txt"
    Content = "\{ssm:%servicePath%/ConnectionData\}"
}
```

Tokens play an important role in reducing redundant code by making MOF files generic and reusable. If you can avoid server-specific MOF file, then there's no need for a MOF building service. A MOF building service increases costs, slows provisioning time, and increases the risk of configuration drift between grouped nodes due to differing module versions being installed on the build server when their MOFs were compiled.

**Prerequisites**

Before you create an association that runs MOF files, verify that your managed nodes have the following prerequisites installed:
Creating an association that runs MOF files

To create an association that runs MOF files

2. In the navigation pane, choose State Manager.
3. Choose State Manager, and then choose Create association.
4. In the Name field, specify a name. This is optional, but recommended. A name can help you understand the purpose of the association when you created it. Spaces aren't allowed in the name.
5. In the Document list, choose AWS-ApplyDSCMofs.
6. In the Parameters section, specify your choices for the required and optional input parameters.

   a. Mofs To Apply: Specify one or more MOF files to run when this association runs. Use commas to separate a list of MOF files. You can specify the following options for locating MOF file.

      • An Amazon S3 bucket name. Bucket names must use lowercase letters. Specify this information by using the following format.

      s3:DOC-EXAMPLE-BUCKET:MOF_file_name.mof

      If you want to specify an AWS Region, then use the following format.

      s3:bucket.Region:DOC-EXAMPLE-BUCKET:MOF_file_name.mof

      • A secure website. Specify this information by using the following format.

      https://domain_name/MOF_file_name.mof
Here is an example.

https://www.example.com/TestMOF.mof

• A file system on a local share. Specify this information by using the following format.

\server_name\shared_folder_name\MOF_file_name.mof

Here is an example.

\StateManagerAssociationsBox\MOFs_folder\MyMof.mof

b. **Service Path**: (Optional) A service path is either an Amazon S3 bucket prefix where you want to write reports and status information. Or, a service path is a path for Parameter Store parameter-based tags. When resolving parameter-based tags, the system uses {ssm: %servicePath%/parameter_name} to inject the servicePath value into the parameter name. For example, if your service path is "WebServers/Production" then the system resolves the parameter as: WebServers/Production/parameter_name. This is useful for when you're running multiple environments in the same account.

c. **Report Bucket Name**: (Optional) Enter the name of an Amazon S3 bucket where you want to write compliance data. Reports are saved in this bucket in JSON format.

![Note]

You can prefix the bucket name with a Region where the bucket is located. Here's an example: us-west-2:MyMOFBucket. If you're using a proxy for Amazon S3 endpoints in a specific Region that doesn't include us-east-1, prefix the bucket name with a Region. If the bucket name isn't prefixed, it automatically discovers the bucket Region by using the us-east-1 endpoint.

d. **Mof Operation Mode**: Choose State Manager behavior when running the AWS-\ApplyDSCMofs association:

• **Apply**: Correct node configurations that aren't compliant.

• **ReportOnly**: Don't correct node configurations, but instead log all compliance data and report nodes that aren't compliant.
e. **Status Bucket Name**: (Optional) Enter the name of an Amazon S3 bucket where you want to write MOF execution status information. These status reports are singleton summaries of the most recent compliance run of a node. This means that the report is overwritten the next time the association runs MOF files.

   **Note**
   
   You can prefix the bucket name with a Region where the bucket is located. Here's an example: `us-west-2:DOC-EXAMPLE-BUCKET`. If you're using a proxy for Amazon S3 endpoints in a specific Region that doesn't include us-east-1, prefix the bucket name with a Region. If the bucket name isn't prefixed, it automatically discovers the bucket Region using the us-east-1 endpoint.

f. **Module Source Bucket Name**: (Optional) Enter the name of an Amazon S3 bucket that contains PowerShell module files. If you specify **None**, choose **True** for the next option, **Allow PS Gallery Module Source**.

   **Note**
   
   You can prefix the bucket name with a Region where the bucket is located. Here's an example: `us-west-2:DOC-EXAMPLE-BUCKET`. If you're using a proxy for Amazon S3 endpoints in a specific Region that doesn't include us-east-1, prefix the bucket name with a Region. If the bucket name isn't prefixed, it automatically discovers the bucket Region using the us-east-1 endpoint.

g. **Allow PS Gallery Module Source**: (Optional) Choose **True** to download PowerShell modules from [https://www.powershellgallery.com/](https://www.powershellgallery.com/). If you choose **False**, specify a source for the previous option, **ModuleSourceBucketName**.

h. **Proxy Uri**: (Optional) Use this option to download MOF files from a proxy server.

i. **Reboot Behavior**: (Optional) Specify one of the following reboot behaviors if your MOF file execution requires rebooting:

   - **AfterMof**: Reboots the node after all MOF executions are complete. Even if multiple MOF executions request reboots, the system waits until all MOF executions are complete to reboot.

   - **Immediately**: Reboots the node whenever a MOF execution requests it. If running multiple MOF files that request reboots, then the nodes are rebooted multiple times.
• **Never**: Nodes aren't rebooted, even if the MOF execution explicitly requests a reboot.

j. **Use Computer Name For Reporting**: (Optional) Turn on this option to use the name of the computer when reporting compliance information. The default value is **false**, which means that the system uses the node ID when reporting compliance information.

k. **Turn on Verbose Logging**: (Optional) We recommend that you turn on verbose logging when deploying MOF files for the first time.

![Important]

When allowed, verbose logging writes more data to your Amazon S3 bucket than standard association execution logging. This might result in slower performance and higher storage charges for Amazon S3. To mitigate storage size issues, we recommend that you turn on lifecycle policies on your Amazon S3 bucket. For more information, see [How Do I Create a Lifecycle Policy for an S3 Bucket?](#) in the *Amazon Simple Storage Service User Guide*.

l. **Turn on Debug Logging**: (Optional) We recommend that you turn on debug logging to troubleshoot MOF failures. We also recommend that you deactivate this option for normal use.

![Important]

When allowed, debug logging writes more data to your Amazon S3 bucket than standard association execution logging. This might result in slower performance and higher storage charges for Amazon S3. To mitigate storage size issues, we recommend that you turn on lifecycle policies on your Amazon S3 bucket. For more information, see [How Do I Create a Lifecycle Policy for an S3 Bucket?](#) in the *Amazon Simple Storage Service User Guide*.

m. **Compliance Type**: (Optional) Specify the compliance type to use when reporting compliance information. The default compliance type is **Custom:DSC**. If you create multiple associations that run MOF files, then be sure to specify a different compliance type for each association. If you don't, each additional association that uses **Custom:DSC** overwrites the existing compliance data.

n. **Pre Reboot Script**: (Optional) Specify a script to run if the configuration has indicated that a reboot is necessary. The script runs before the reboot. The script must be a single line. Separate additional lines by using semicolons.
7. In the **Targets** section, choose either **Specifying tags** or **Manually Selecting Instance**. If you choose to target resources by using tags, then enter a tag key and a tag value in the fields provided. For more information about using targets, see [About targets and rate controls in State Manager associations](#).

8. In the **Specify schedule** section, choose either **On Schedule** or **No schedule**. If you choose **On Schedule**, then use the buttons provided to create a cron or rate schedule for the association.

9. In the **Advanced options** section:
   - In **Compliance severity**, choose a severity level for the association. Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you indicate here. For more information, see [About State Manager association compliance](#).

10. In the **Rate control** section, configure options for running State Manager associations across of fleet of managed nodes. For more information about these options, see [About targets and rate controls in State Manager associations](#).

In the **Concurrency** section, choose an option:
   - Choose **targets** to enter an absolute number of targets that can run the association simultaneously.
   - Choose **percentage** to enter a percentage of the target set that can run the association simultaneously.

In the **Error threshold** section, choose an option:
   - Choose **errors** to enter an absolute number of errors allowed before State Manager stops running associations on additional targets.
   - Choose **percentage** to enter a percentage of errors allowed before State Manager stops running associations on additional targets.

11. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

    **Note**

    The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see [Configure instance permissions](#).
required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

12. Choose **Create Association**.

State Manager creates and immediately runs the association on the specified nodes or targets. After the initial execution, the association runs in intervals according to the schedule that you defined and according to the following rules:

- State Manager runs associations on nodes that are online when the interval starts and skips offline nodes.
- State Manager attempts to run the association on all configured nodes during an interval.
- If an association isn't run during an interval (because, for example, a concurrency value limited the number of nodes that could process the association at one time), then State Manager attempts to run the association during the next interval.
- State Manager records history for all skipped intervals. You can view the history on the **Execution History** tab.

**Note**

The **AWS-App1yDSCMofS** is a Systems Manager Command document. This means that you can also run this document by using Run Command, a capability of AWS Systems Manager. For more information, see [AWS Systems Manager Run Command](#).

**Troubleshooting**

This section includes information to help you troubleshoot issues creating associations that run MOF files.

**Turn on enhanced logging**

As a first step to troubleshooting, turn on enhanced logging. More specifically, do the following:
1. Verify that the association is configured to write command output to either Amazon S3 or Amazon CloudWatch Logs (CloudWatch).

2. Set the **Enable Verbose Logging** parameter to True.

3. Set the **Enable Debug Logging** parameter to True.

With verbose and debug logging turned on, the **Stdout** output file includes details about the script execution. This output file can help you identify where the script failed. The **Stderr** output file contains errors that occurred during the script execution.

**Common problems**

This section includes information about common problems that can occur when creating associations that run MOF files and steps to troubleshoot these issues.

**My MOF wasn't applied**

If State Manager failed to apply the association to your nodes, then start by reviewing the **Stderr** output file. This file can help you understand the root cause of the issue. Also, verify the following:

- The node has the required access permissions to all MOF-related Amazon S3 buckets. Specifically:
  - **s3:GetObject permissions**: This is required for MOF files in private Amazon S3 buckets and custom modules in Amazon S3 buckets.
  - **s3:PutObject permission**: This is required to write compliance reports and compliance status to Amazon S3 buckets.
- If you're using tags, then ensure that the node has the required IAM policy. Using tags requires the instance IAM role to have a policy allowing the `ec2:DescribeInstances` and `ssm:ListTagsForResource` actions.
- Ensure that the node has the expected tags or SSM parameters assigned.
- Ensure that the tags or SSM parameters aren't misspelled.
- Try applying the MOF locally on the node to make sure there isn't an issue with the MOF file itself.

**My MOF seemed to fail, but the Systems Manager execution was successful**

If the `AWS-ApplyDSCMofs` document successfully ran, then the Systems Manager execution status shows **Success**. This status doesn't reflect the compliance status of your node against the
configuration requirements in the MOF file. To view the compliance status of your nodes, view the compliance reports. You can view a JSON report in the Amazon S3 Report Bucket. This applies to Run Command and State Manager executions. Also, for State Manager, you can view compliance details on the Systems Manager Compliance page.

**Stderr states: Name resolution failure attempting to reach service**

This error indicates that the script can't reach a remote service. Most likely, the script can't reach Amazon S3. This issue most often occurs when the script attempts to write compliance reports or compliance status to the Amazon S3 bucket supplied in the document parameters. Typically, this error occurs when a computing environment uses a firewall or transparent proxy that includes an allow list. To resolve this issue:

- Use Region-specific bucket syntax for all Amazon S3 bucket parameters. For example, the **Mofs to Apply** parameter should be formatted as follows:

  s3:bucket-region:bucket-name:mof-file-name.mof.

  Here is an example: s3:us-west-2:DOC-EXAMPLE-BUCKET:my-mof.mof

  The Report, Status, and Module Source bucket names should be formatted as follows.

  **bucket-region:bucket-name**. Here is an example: us-west-1:DOC-EXAMPLE-BUCKET;

- If Region-specific syntax doesn't fix the problem, then make sure that the targeted nodes can access Amazon S3 in the desired Region. To verify this:

  1. Find the endpoint name for Amazon S3 in the appropriate Amazon S3 Region. For information, see [Amazon S3 Service Endpoints](https://docs.aws.amazon.com/AmazonS3/latest/userguide/service-regions.html) in the Amazon Web Services General Reference.

  2. Log on to the target node and run the following ping command.

    ```bash
    ping s3.s3-region.amazonaws.com
    ```

    If the ping failed, it means that either Amazon S3 is down, or a firewall/transparent proxy is blocking access to the Amazon S3 Region, or the node can't access the internet.

**Viewing DSC resource compliance details**

Systems Manager captures compliance information about DSC resource failures in the Amazon S3 **Status Bucket** you specified when you ran the **AWS-ApplyDSCMofs** document. Searching for
information about DSC resource failures in an Amazon S3 bucket can be time consuming. Instead, you can view this information in the Systems Manager **Compliance** page.

The **Compliance resources summary** section displays a count of resources that failed. In the following example, the **ComplianceType** is **Custom:DSC** and one resource is noncompliant.

![Compliance resources summary](image)

**Note**

Custom:DSC is the default **ComplianceType** value in the AWS-ApplyDSCMofs document. This value is customizable.

The **Details overview for resources** section displays information about the AWS resource with the noncompliant DSC resource. This section also includes the MOF name, script execution steps, and (when applicable) a **View output** link to view detailed status information.
The **View output** link displays the last 4,000 characters of the detailed status. Systems Manager starts with the exception as the first element, and then scans back through the verbose messages and prepends as many as it can until it reaches the 4,000 character quota. This process displays the log messages that were output before the exception was thrown, which are the most relevant messages for troubleshooting.
For information about how to view compliance information, see AWS Systems Manager Compliance.

**Situations that affect compliance reporting**

If the State Manager association fails, then no compliance data is reported. More specifically, if a MOF fails to process, then Systems Manager doesn’t report any compliance items because the associations fails. For example, if Systems Manager attempts to download a MOF from an Amazon S3 bucket that the node doesn't have permission to access, then the association fails and no compliance data is reported.

If a resource in a second MOF fails, then Systems Manager *does* report compliance data. For example, if a MOF tries to create a file on a drive that doesn’t exist, then Systems Manager reports compliance because the AWS-ApplyDSCMofs document is able to process completely, which means the association successfully runs.

**Walkthrough: Creating associations that run Ansible playbooks**

You can create State Manager associations that run Ansible playbooks by using the AWS-ApplyAnsiblePlaybooks SSM document. State Manager is a capability of AWS Systems Manager. This document offers the following benefits for running playbooks:
Support for running complex playbooks

Support for downloading playbooks from GitHub and Amazon Simple Storage Service (Amazon S3)

Support for compressed playbook structure

Enhanced logging

Ability to specify which playbook to run when playbooks are bundled

**Note**

Systems Manager includes two SSM documents that allow you to create State Manager associations that run Ansible playbooks: AWS-RunAnsiblePlaybook and AWS-ApplyAnsiblePlaybooks. The AWS-RunAnsiblePlaybook document is deprecated. It remains available in Systems Manager for legacy purposes. We recommend that you use the AWS-ApplyAnsiblePlaybooks document because of the enhancements described here.

Associations that run Ansible playbooks aren't supported on macOS.

**Support for running complex playbooks**

The AWS-ApplyAnsiblePlaybooks document supports bundled, complex playbooks because it copies the entire file structure to a local directory before executing the specified main playbook. You can provide source playbooks in Zip files or in a directory structure. The Zip file or directory can be stored in GitHub or Amazon S3.

**Support for downloading playbooks from GitHub**

The AWS-ApplyAnsiblePlaybooks document uses the aws:downloadContent plugin to download playbook files. Files can be stored in GitHub in a single file or as a combined set of playbook files. To download content from GitHub, specify information about your GitHub repository in JSON format. Here is an example.

```json
{
   "owner": "TestUser",
   "repository": "GitHubTest",
   "path": "scripts/python/test-script",
   "getOptions": "branch:master",
   "tokenInfo": "{{ssm-secure:secure-string-token}}"
}
```
Support for downloading playbooks from Amazon S3

You can also store and download Ansible playbooks in Amazon S3 as either a single .zip file or a directory structure. To download content from Amazon S3, specify the path to the file. Here are two examples.

Example 1: Download a specific playbook file

```json
{
   "path":"https://s3.amazonaws.com/DOC-EXAMPLE-BUCKET/playbook.yml"
}
```

Example 2: Download the contents of a directory

```json
{
   "path":"https://s3.amazonaws.com/DOC-EXAMPLE-BUCKET/ansible/webservers/
```

⚠️ Important

If you specify Amazon S3, then the AWS Identity and Access Management (IAM) instance profile on your managed nodes must be configured with the AmazonS3ReadOnlyAccess policy. For more information, see Configure instance permissions required for Systems Manager.

Support for compressed playbook structure

The AWS-ApplyAnsiblePlaybooks document allows you to run compressed .zip files in the downloaded bundle. The document checks if the downloaded files contain a compressed file in .zip format. If a .zip is found, the document automatically decompresses the file and then runs the specified Ansible automation.

Enhanced logging

The AWS-ApplyAnsiblePlaybooks document includes an optional parameter for specifying different levels of logging. Specify -v for low verbosity, -vv or -vvv for medium verbosity, and -vvvv for debug level logging. These options directly map to Ansible verbosity options.
Ability to specify which playbook to run when playbooks are bundled

The AWS-ApplyAnsiblePlaybooks document includes a required parameter for specifying which playbook to run when multiple playbooks are bundled. This option provides flexibility for running playbooks to support different use cases.

Installed dependencies

If you specify True for the InstallDependencies parameter, then Systems Manager verifies that your nodes have the following dependencies installed:

- **Ubuntu Server/Debian Server**: Apt-get (Package Management), Python 3, Ansible, Unzip
- **Amazon Linux**: Ansible
- **RHEL**: Python 3, Ansible, Unzip

If one or more of these dependencies aren't found, then Systems Manager automatically installs them.

Create an association that runs Ansible playbooks (console)

The following procedure describes how to use the Systems Manager console to create a State Manager association that runs Ansible playbooks by using the AWS-ApplyAnsiblePlaybooks document.

To create an association that runs Ansible playbooks (console)

2. In the navigation pane, choose State Manager.
3. Choose State Manager, and then choose Create association.
4. For Name, specify a name that helps you remember the purpose of the association.
5. In the Document list, choose AWS-ApplyAnsiblePlaybooks.
6. In the Parameters section, for Source Type, choose either GitHub or S3.

**GitHub**

If you choose GitHub, enter repository information in the following format.

```
If you choose **S3**, enter path information in the following format.

```json
{
    "path":"https://s3.amazonaws.com/path_to_directory_or_playbook_to_download"
}
```

7. For **Install Dependencies**, choose an option.
8. (Optional) For **Playbook File**, enter a file name. If a Zip file contains the playbook, specify a relative path to the Zip file.
9. (Optional) For **Extra Variables**, enter variables that you want State Manager to send to Ansible at runtime.
10. (Optional) For **Check**, choose an option.
11. (Optional) For **Verbose**, choose an option.
12. For **Targets**, choose an option. For information about using targets, see [About targets and rate controls in State Manager associations](#).
13. In the **Specify schedule** section, choose either **On schedule** or **No schedule**. If you choose **On schedule**, then use the buttons provided to create a cron or rate schedule for the association.
14. In the **Advanced options** section, for **Compliance severity**, choose a severity level for the association. Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you indicate here. For more information, see [About State Manager association compliance](#).
15. In the **Rate control** section, configure options to run State Manager associations across a fleet of managed nodes. For information about using rate controls, see [About targets and rate controls in State Manager associations](#).

In the **Concurrency** section, choose an option:

- Choose **targets** to enter an absolute number of targets that can run the association simultaneously.
• Choose **percentage** to enter a percentage of the target set that can run the association simultaneously.

In the **Error threshold** section, choose an option:

• Choose **errors** to enter an absolute number of errors that are allowed before State Manager stops running associations on additional targets.

• Choose **percentage** to enter a percentage of errors that are allowed before State Manager stops running associations on additional targets.

16. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

**Note**

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#).

In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

17. Choose **Create Association**.

**Note**

If you use tags to create an association on one or more target nodes, and then you remove the tags from a node, that node no longer runs the association. The node is disassociated from the State Manager document.

---

**Create an association that runs Ansible playbooks (CLI)**

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) to create a State Manager association that runs Ansible playbooks by using the `AWS-ApplyAnsiblePlaybooks` document.
To create an association that runs Ansible playbooks (CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven’t already.

   For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run one of the following commands to create an association that runs Ansible playbooks by targeting nodes using tags. Replace each example resource placeholder with your own information. Command (A) specifies GitHub as the source type. Command (B) specifies Amazon S3 as the source type.

   **(A) GitHub source**

   **Linux & macOS**

   ```
   aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" 
   --targets Key=tag:TagKey,Values=TagValue 
   --parameters '{"SourceType":"GitHub","SourceInfo":
   ["{"owner":"owner_name", "repository": "name",
   "getOptions": "branch:master"}"],"InstallDependencies":
   ["True_or_False"],"PlaybookFile": ["file_name.yml"],"ExtraVariables": ["key/value_pairs_separated_by_a_space"],"Check": ["True_or_False"],"Verbose": ["-v,-vv,-vvv, or -vvvv"],"TimeoutSeconds": ["3600"]}' 
   --association-name "name" 
   --schedule-expression "cron_or_rate_expression"
   ```

   **Windows**

   ```
   aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" ^ 
   --targets Key=tag:TagKey,Values=TagValue ^ 
   --parameters '{"SourceType":"GitHub","SourceInfo":
   ["{"owner":"owner_name", "repository": "name",
   "getOptions": "branch:master"}"],"InstallDependencies":
   ["True_or_False"],"PlaybookFile": ["file_name.yml"],"ExtraVariables": ["key/value_pairs_separated_by_a_space"],"Check": ["True_or_False"],"Verbose": ["-v,-vv,-vvv, or -vvvv"], "TimeoutSeconds": ["3600"]}' ^ 
   --association-name "name" ^ 
   --schedule-expression "cron_or_rate_expression"
   ```

Here is an example.
aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" \
   --targets "Key=tag:OS,Values=Linux" \
   --parameters '{"SourceType": ["GitHub"], "SourceInfo": [{"owner": "ansibleDocumentTest", "repository": "Ansible", "getOptions": {"branch": "master"}}, "InstallDependencies": ["True"], "PlaybookFile": ["hello-world-playbook.yml"], "ExtraVariables": ["SSM=True"], "Check": ["False"], "Verbose": ["-v"]}' \
   --association-name "AnsibleAssociation" \
   --schedule-expression "cron(0 2 ? * SUN *)"

(B) S3 source

Linux & macOS

aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" \
   --targets Key=tag:TagKey,Values=TagValue \
   --parameters '{"SourceType": ["S3"], "SourceInfo": [{"path": "https://s3.amazonaws.com/path_to_Zip_file,_directory,_or_playbook_to_download"}], "InstallDependencies": ["True_or_False"], "PlaybookFile": ["file_name.yml"], "ExtraVariables": ["key/value_pairs_separated_by_a_space"], "Check": ["True_or_False"], "Verbose": ["-v,-vv,-vvv, or -vvvv"]}' \
   --association-name "name" \
   --schedule-expression "cron_or_rate_expression"

Windows

aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" ^ \
   --targets Key=tag:TagKey,Values=TagValue ^ \
   --parameters '{"SourceType": ["S3"], "SourceInfo": [{"path": "https://s3.amazonaws.com/path_to_Zip_file,_directory,_or_playbook_to_download"}], "InstallDependencies": ["True_or_False"], "PlaybookFile": ["file_name.yml"], "ExtraVariables": ["key/value_pairs_separated_by_a_space"], "Check": ["True_or_False"], "Verbose": ["-v,-vv,-vvv, or -vvvv"]}' ^ \
   --association-name "name" ^ \
   --schedule-expression "cron_or_rate_expression"

Here is an example.

aws ssm create-association --name "AWS-ApplyAnsiblePlaybooks" \

Note

State Manager associations don't support all cron and rate expressions. For more information about creating cron and rate expressions for associations, see Reference: Cron and rate expressions for Systems Manager.

The system attempts to create the association on the nodes and immediately apply the state.

3. Run the following command to view an updated status of the association you just created.

```bash
aws ssm describe-association --association-id "ID"
```

Walkthrough: Creating associations that run Chef recipes

You can create State Manager associations that run Chef recipes by using the AWS-ApplyChefRecipes SSM document. State Manager is a capability of AWS Systems Manager. You can target Linux-based Systems Manager managed nodes with the AWS-ApplyChefRecipes SSM document. This document offers the following benefits for running Chef recipes:

- Supports multiple releases of Chef (Chef 11 through Chef 18).
- Automatically installs the Chef client software on target nodes.
- Optionally runs Systems Manager compliance checks on target nodes, and stores the results of compliance checks in an Amazon Simple Storage Service (Amazon S3) bucket.
- Runs multiple cookbooks and recipes in a single run of the document.
- Optionally runs recipes in why-run mode, to show which recipes change on target nodes without making changes.
- Optionally applies custom JSON attributes to chef-client runs.
Optionally applies custom JSON attributes from a source file that is stored at a location that you specify.

You can use Git, GitHub, HTTP, or Amazon S3 buckets as download sources for Chef cookbooks and recipes that you specify in an AWS-ApplyChefRecipes document.

**Note**

Associations that run Chef recipes aren't supported on macOS.

### Prerequisites: Set up your association, repository, and cookbooks

Before you create an AWS-ApplyChefRecipes document, prepare your Chef cookbooks and cookbook repository. If you don't already have a Chef cookbook that you want to use, you can get started by using a test HelloWorld cookbook that AWS has prepared for you. The AWS-ApplyChefRecipes document already points to this cookbook by default. Your cookbooks should be set up similarly to the following directory structure. In the following example, jenkins and nginx are examples of Chef cookbooks that are available in the Chef Supermarket on the Chef website.

Though AWS can't officially support cookbooks on the Chef Supermarket website, many of them work with the AWS-ApplyChefRecipes document. The following are examples of criteria to determine when you're testing a community cookbook:

- The cookbook should support the Linux-based operating systems of the Systems Manager managed nodes that you're targeting.
- The cookbook should be valid for the Chef client version (Chef 11 through Chef 18) that you use.
- The cookbook is compatible with Chef Infra Client, and, doesn't require a Chef server.

Verify that you can reach the Chef.io website, so that any cookbooks you specify in your run list can be installed when the Systems Manager document (SSM document) runs. Using a nested cookbooks folder is supported, but not required; you can store cookbooks directly under the root level.

```bash
<Top-level directory, or the top level of the archive file (ZIP or tgz or tar.gz)>
### cookbooks (optional level)
```
### jenkins

#   ### metadata.rb
#   ### recipes
### nginx
### metadata.rb
### recipes

⚠️ **Important**

Before you create a State Manager association that runs Chef recipes, be aware that the document run installs the Chef client software on your Systems Manager managed nodes, unless you set the value of **Chef client version** to None. This operation uses an installation script from Chef to install Chef components on your behalf. Before you run an AWS-ApplyChefRecipes document, be sure your enterprise can comply with any applicable legal requirements, including license terms applicable to the use of Chef software. For more information, see the [Chef website](https://www.chef.io).  

Systems Manager can deliver compliance reports to an S3 bucket, the Systems Manager console, or make compliance results available in response to Systems Manager API commands. To run Systems Manager compliance reports, the instance profile attached to Systems Manager managed nodes must have permissions to write to the S3 bucket. The instance profile must have permissions to use the Systems Manager PutComplianceItem API. For more information about Systems Manager compliance, see [AWS Systems Manager Compliance](https://docs.aws.amazon.com/systems-manager/latest/userguide/compliance.html).

**Logging the document run**

When you run a Systems Manager document (SSM document) by using a State Manager association, you can configure the association to choose the output of the document run, and you can send the output to Amazon S3 or Amazon CloudWatch Logs (CloudWatch Logs). To help ease troubleshooting when an association has finished running, verify that the association is configured to write command output to either an Amazon S3 bucket or CloudWatch Logs. For more information, see [Working with associations in Systems Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/working-with-associations.html).

**Applying JSON attributes to targets when running a recipe**

You can specify JSON attributes for your Chef client to apply to target nodes during an association run. When setting up the association, you can provide raw JSON or provide the path to a JSON file stored in Amazon S3.
Use JSON attributes when you want to customize how the recipe is run without having to modify the recipe itself, for example:

- **Overriding a small number of attributes**

  Use custom JSON to avoid having to maintain multiple versions of a recipe to accommodate minor differences.

- **Providing variable values**

  Use custom JSON to specify values that may change from run-to-run. For example, if your Chef cookbooks configure a third-party application that accepts payments, you might use custom JSON to specify the payment endpoint URL.

### Specifying attributes in raw JSON

The following is an example of the format you can use to specify custom JSON attributes for your Chef recipe.

```json
{"filepath":"/tmp/example.txt", "content":"Hello, World!"}
```

### Specifying a path to a JSON file

The following is an example of the format you can use to specify the path to custom JSON attributes for your Chef recipe.

```json
{"sourceType":"s3", "sourceInfo":"someS3URL1"}, {"sourceType":"s3", "sourceInfo":"someS3URL2"}
```

### Use Git as a cookbook source

The AWS-ApplyChefRecipes document uses the `aws:downloadContent` plugin to download Chef cookbooks. To download content from Git, specify information about your Git repository in JSON format as in the following example. Replace each `example-resource-placeholder` with your own information.

```json
{
    "repository":"GitCookbookRepository",
    "privateSSHKey"{{ssm-secure:ssh-key-secure-string-parameter}}",
    "skipHostKeyChecking":"false",
```
Use GitHub as a cookbook source

The AWS-ApplyChefRecipes document uses the `aws:downloadContent` plugin to download cookbooks. To download content from GitHub, specify information about your GitHub repository in JSON format as in the following example. Replace each `example-resource-placeholder` with your own information.

```json
{
    "owner": "TestUser",
    "repository": "GitHubCookbookRepository",
    "path": "cookbooks/HelloWorld",
    "getOptions": "branch:refs/head/main",
    "tokenInfo": "{{ssm-secure:token-secure-string-parameter}}"
}
```

Use HTTP as a cookbook source

You can store Chef cookbooks at a custom HTTP location as either a single `.zip` or `.tar.gz` file, or a directory structure. To download content from HTTP, specify the path to the file or directory in JSON format as in the following example. Replace each `example-resource-placeholder` with your own information.

```json
{
    "url": "https://my.website.com/chef-cookbooks/HelloWorld.zip",
    "allowInsecureDownload": "false",
    "authMethod": "Basic",
    "username": "{{ssm-secure:username-secure-string-parameter}}",
    "password": "{{ssm-secure:password-secure-string-parameter}}"
}
```

Use Amazon S3 as a cookbook source

You can also store and download Chef cookbooks in Amazon S3 as either a single `.zip` or `.tar.gz` file, or a directory structure. To download content from Amazon S3, specify the path to the file in JSON format as in the following examples. Replace each `example-resource-placeholder` with your own information.
Example 1: Download a specific cookbook

```json
{
   "path": "https://s3.amazonaws.com/chef-cookbooks/HelloWorld.zip"
}
```

Example 2: Download the contents of a directory

```json
{
   "path": "https://s3.amazonaws.com/chef-cookbooks-test/HelloWorld"
}
```

⚠️ **Important**

If you specify Amazon S3, the AWS Identity and Access Management (IAM) instance profile on your managed nodes must be configured with the AmazonS3ReadOnlyAccess policy. For more information, see [Configure instance permissions required for Systems Manager](#).

**Topics**

- [Create an association that runs Chef recipes (console)](#)
- [Create an association that runs Chef recipes (CLI)](#)
- [Viewing Chef resource compliance details](#)

**Create an association that runs Chef recipes (console)**

The following procedure describes how to use the Systems Manager console to create a State Manager association that runs Chef cookbooks by using the `AWS-ApplyChefRecipes` document.

2. In the navigation pane, choose **State Manager**.
3. Choose **State Manager**, and then choose **Create association**.
4. For **Name**, enter a name that helps you remember the purpose of the association.
5. In the **Document** list, choose `AWS-ApplyChefRecipes`. 
6. In **Parameters**, for **Source Type**, select either **Git**, **GitHub**, **HTTP**, or **S3**.

7. For **Source info**, enter cookbook source information using the appropriate format for the **Source Type** that you selected in step 6. For more information, see the following topics:
   - [the section called “Use Git as a cookbook source”](#)
   - [the section called “Use GitHub as a cookbook source”](#)
   - [the section called “Use HTTP as a cookbook source”](#)
   - [the section called “Use Amazon S3 as a cookbook source”](#)

8. In **Run list**, list the recipes that you want to run in the following format, separating each recipe with a comma as shown. Don't include a space after the comma. Replace each `example-resource-placeholder` with your own information.

   ```
   recipe[cookbook-name1::recipe-name],recipe[cookbook-name2::recipe-name]
   ```

9. (Optional) Specify custom JSON attributes that you want the Chef client to pass to your target nodes.
   
   a. In **JSON attributes content**, add any attributes that you want the Chef client to pass to your target nodes.
   
   b. In **JSON attributes sources**, add the paths to any attributes that you want the Chef client to pass to your target nodes.

   For more information, see [the section called “Applying JSON attributes to targets when running a recipe”](#).

10. For **Chef client version**, specify a Chef version. Valid values are 11 through 18, or None. If you specify a number between 11 18 (inclusive), Systems Manager installs the correct Chef client version on your target nodes. If you specify None, Systems Manager doesn't install the Chef client on target nodes before running the document's recipes.

11. (Optional) For **Chef client arguments**, specify additional arguments that are supported for the version of Chef you're using. To learn more about supported arguments, run `chef-client -h` on a node that is running the Chef client.

12. (Optional) Turn on **Why-run** to show changes made to target nodes if the recipes are run, without actually changing target nodes.

13. For **Compliance severity**, choose the severity of Systems Manager Compliance results that you want reported. Compliance reporting indicates whether the association state is compliant or
Compliance scans measure drift between configuration that is specified in your Chef recipes and node resources. Valid values are Critical, High, Medium, Low, Informational, Unspecified, or None. To skip compliance reporting, choose None.

14. For **Compliance type**, specify the compliance type for which you want results reported. Valid values are Association for State Manager associations, or Custom: `custom-type`. The default value is Custom:Chef.

15. For **Compliance report bucket**, enter the name of an S3 bucket in which to store information about every Chef run performed by this document, including resource configuration and Compliance results.

16. In **Rate control**, configure options to run State Manager associations across a fleet of managed nodes. For information about using rate controls, see [About targets and rate controls in State Manager associations](#).

In **Concurrency**, choose an option:

- Choose **targets** to enter an absolute number of targets that can run the association simultaneously.

- Choose **percentage** to enter a percentage of the target set that can run the association simultaneously.

In **Error threshold**, choose an option:

- Choose **errors** to enter an absolute number of errors that are allowed before State Manager stops running associations on additional targets.

- Choose **percentage** to enter a percentage of errors that are allowed before State Manager stops running associations on additional targets.

17. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

---

**Note**

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user.
performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#).

In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

18. Choose **Create Association**.

### Create an association that runs Chef recipes (CLI)

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) to create a State Manager association that runs Chef cookbooks by using the AWS-ApplyChefRecipes document.

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run one of the following commands to create an association that runs Chef cookbooks on target nodes that have the specified tags. Use the command that is appropriate for your cookbook source type and operating system. Replace each `example-resource-placeholder` with your own information.

   a. **Git source**

      Linux & macOS

      ```bash
      aws ssm create-association --name "AWS-ApplyChefRecipes" \
         --targets Key=tag:TagKey,Values=TagValue \
         --parameters '{"SourceType":"Git","SourceInfo":{"repository":"repository-name","getOptions":"branch:branch-name","username":"
                                 {{{ ssm-secure:username-secure-string-parameter }}"}, "password":
                                 "{{ ssm-secure:password-secure-string-parameter }}"}, "RunList":
                                 ["{"recipe[cookbook-name-1::recipe-name]","recipe[cookbook-name-2::recipe-name]"}]", "JsonAttributesContent": [{"custom-json-content"}], "JsonAttributesSources": "{\"sourceType\":"s3\", \"sourceInfo\":\"s3-bucket-endpoint-1\"}, {\"sourceType\":\"s3\", \"sourceInfo\":\"s3-bucket-endpoint-2\"}, "ChefClientVersion": ["version-number"], "ChefClientArguments": [{\"chef-client-arguments\"]}, "WhyRun": boolean, "ComplianceSeverity": ["severity-value"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": ["s3-bucket-name"]}' 
      ```
Windows

aws ssm create-association --name "AWS-ApplyChefRecipes" ^
--targets Key=tag:TagKey,Values=TagValue ^
--parameters '{"SourceType": "Git", "SourceInfo": "{"repository": "repository-name", "getOptions": "branch:branch-name", "username": "{{ ssm-secure:username-secure-string-parameter }}", "password": "{{ ssm-secure:password-secure-string-parameter }}"}, "RunList": [
{"recipe[cookbook-name-1::recipe-name]", "recipe[cookbook-name-2::recipe-name]"}], "JsonAttributesContent": [{"custom-json"]}, "JsonAttributesSources": [{"sourceType": "s3", "sourceInfo": "s3-bucket-endpoint-1"}, {"sourceType": "s3", "sourceInfo": "s3-bucket-endpoint-2"}], "ChefClientVersion": [{"version-number"]}, "ChefClientArguments": [{"chef-client-arguments"]}, "WhyRun": boolean, "ComplianceSeverity": [{"severity-value"]}, "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": [{"s3-bucket-name"]}' ^
--association-name "name" ^
--schedule-expression "cron-or-rate-expression"

b. GitHub source

Linux & macOS

aws ssm create-association --name "AWS-ApplyChefRecipes" \
--targets Key=tag:TagKey,Values=TagValue \
--parameters '{"SourceType": "GitHub", "SourceInfo": "{"owner": "owner-name", "repository": "name", "path": "path-to-directory-or-cookbook-to-download", "getOptions": "branch:branch-name"", "RunList": [{"recipe[cookbook-name-1::recipe-name]", "recipe[cookbook-name-2::recipe-name]"}], "JsonAttributesContent": [{"custom-json"]}, "ChefClientVersion": [{"version-number"]}, "ChefClientArguments": [{"chef-client-arguments"]}, "WhyRun": boolean, "ComplianceSeverity": [{"severity-value"]}, "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": [{"s3-bucket-name"]}' \
--association-name "name" \
--schedule-expression "cron-or-rate-expression"
Here is an example.

**Linux & macOS**

```bash
aws ssm create-association --name "AWS-ApplyChefRecipes" \
    --targets Key=tag:OS,Values=Linux \n    --parameters "{"SourceType":"GitHub","SourceInfo":{""owner":"ChefRecipeTest","repository":"ChefCookbooks","path":"cookbooks/HelloWorld"},"getOptions": "branch:master"}, "RunList": ["{"recipe[HelloWorld::HelloWorldRecipe]"", "recipe[HelloWorld::InstallApp]"}], "JsonAttributesContent": ["{"state": "visible","colors": {"foreground": "light-blue","background": "dark-gray"}}"], "ChefClientVersion": ["14"], "ChefClientArguments": ["--fips"], "WhyRun": false, "ComplianceSeverity": ["Medium"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": ["ChefComplianceResultsBucket"]}' \
    --association-name "MyChefAssociation" \
    --schedule-expression "cron(0 2 ? * SUN *)"
```

**Windows**

```bash
aws ssm create-association --name "AWS-ApplyChefRecipes" \
    --targets Key=tag:OS,Values=Linux \n    --parameters "{"SourceType":"GitHub","SourceInfo":{""owner":"ChefRecipeTest","repository":"ChefCookbooks","path":"cookbooks/HelloWorld"},"getOptions": "branch:master"}, "RunList": ["{"recipe[HelloWorld::HelloWorldRecipe]"", "recipe[HelloWorld::InstallApp]"}], "JsonAttributesContent": ["{"state": "visible","colors": {"foreground": "light-blue","background": "dark-gray"}}"], "ChefClientVersion": ["14"], "ChefClientArguments": ["--fips"], "WhyRun": false, "ComplianceSeverity": ["Medium"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": ["ChefComplianceResultsBucket"]}' \
    --association-name "MyChefAssociation" \
    --schedule-expression "cron(0 2 ? * SUN *)"
```
c. **HTTP source**

Linux & macOS

```bash
aws ssm create-association --name "AWS-ApplyChefRecipes" \
  --targets Key=tag:TagKey,Values=TagValue \
  --parameters '{"SourceType": ["HTTP"], "SourceInfo": ["{\"url\": "url-to-zip-file|directory|cookbook\", \"authMethod\": \"auth-method\", \"username\": \"{{ ss3-secure:username-secure-string-parameter }\"}, \"password\": \"{{ ss3-secure:password-secure-string-parameter }\"}]}, \"RunList\": ["{\"recipe[cookbook-name-1::recipe-name]\", \"recipe[cookbook-name-2::recipe-name]\"]}, \"JsonAttributesContent\": ["{\"custom-json-content\"]}, \"JsonAttributesSources\": ["\"s3\", \"sourceInfo\": "s3-bucket-endpoint-1"}, \"sourceType\": "s3\", \"sourceInfo\": "s3-bucket-endpoint-2"}]", \"ChefClientVersion\": ["version-number"], \"ChefClientArguments\": ["{chef-client-arguments}\"]}, \"WhyRun\": boolean, \"ComplianceSeverity\": ["severity-value"], \"ComplianceType\": ["Custom:Chef"], \"ComplianceReportBucket\": ["s3-bucket-name"]}' \
  --association-name "MyChefAssociation" ^ \
  --schedule-expression "cron(0 2 * * SUN *)"
```

Windows

```bash
aws ssm create-association --name "AWS-ApplyChefRecipes" ^ \
  --targets Key=tag:TagKey,Values=TagValue ^ \
  --parameters '{"SourceType": ["HTTP"], "SourceInfo": ["{\"url\": "url-to-zip-file|directory|cookbook\", \"authMethod\": \"auth-method\", \"username\": \"{{ ss3-secure:username-secure-string-parameter }\"}, \"password\": \"{{ ss3-secure:password-secure-string-parameter }\"}]}, \"RunList\": ["{\"recipe[cookbook-name-1::recipe-name]\", \"recipe[cookbook-name-2::recipe-name]\"]}, \"JsonAttributesContent\": ["{\"custom-json-content\"]}, \"JsonAttributesSources\": ["\"s3\", \"sourceInfo\"]}]
```

State Manager walkthroughs 1738
d. **Amazon S3 source**

**Linux & macOS**

```bash
aws ssm create-association --name "AWS-ApplyChefRecipes" \
   --targets Key=tag:TagKey,Values=TagValue \
   --parameters '{"SourceType":"S3","SourceInfo":{"\"path\":\"https://s3.amazonaws.com/path_to_Zip_file,_directory,_or_cookbook_to_download\"\"}}', "RunList":['{"recipe[cookbook_name1::recipe_name]"}, "recipe[cookbook_name2::recipe_name]"'], "JsonAttributesContent": ["{Custom_JSON}"], "ChefClientVersion": ["version_number"], "ChefClientArguments": [{chef-client-arguments}], "WhyRun": boolean, "ComplianceSeverity": ["severity-value"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": ["s3-bucket-name"],' \
   --association-name "name" ^ \
   --schedule-expression "cron-or-rate-expression"
```

**Windows**

```bash
aws ssm create-association --name "AWS-ApplyChefRecipes" ^ \
   --targets Key=tag:TagKey,Values=TagValue ^ \
   --parameters '{"SourceType":"S3","SourceInfo":{"\"path\":\"https://s3.amazonaws.com/path_to_Zip_file,_directory,_or_cookbook_to_download\"\"}}', "RunList":['{"recipe[cookbook_name1::recipe_name]"}, "recipe[cookbook_name2::recipe_name]"'], "JsonAttributesContent": ["{Custom_JSON}"], "ChefClientVersion": ["version_number"], "ChefClientArguments": [{chef-client-arguments}], "WhyRun": boolean, "ComplianceSeverity": ["severity-value"], "ComplianceType": ["Custom:Chef"], "ComplianceReportBucket": ["DOC-EXAMPLE-BUCKET"],' ^ \
   --association-name "name" ^ \
   --schedule-expression "cron-or_rate_expression"
```

Here is an example.
### Linux & macOS

```bash
aws ssm create-association --name "AWS-ApplyChefRecipes" \
  --targets "Key=tag:OS,Values= Linux" \
  --parameters '{"SourceType": ["S3"], "SourceInfo": ["{\"path\": "https://s3.amazonaws.com/DOC-EXAMPLE-BUCKET/HelloWorld\"}]}, "RunList": ["{\"recipe[HelloWorld::HelloWorldRecipe]\", \
  recipe[HelloWorld::InstallApp]\"}], "JsonAttributesContent": 
  ["{\"state\": \"visible\", \"colors\": \"foreground\": \"light-blue \", \"background\": \"dark-gray\"]}], 
  "ChefClientVersion": ["14"], 
  "ChefClientArguments": ["--fips"], 
  "WhyRun": false, 
  "ComplianceSeverity": ["Medium"], 
  "ComplianceType": ["Custom:Chef"], 
  "ComplianceReportBucket": ["ChefComplianceResultsBucket"]}' \
  --association-name "name" \
  --schedule-expression "cron(0 2 ? * SUN *)"
```

### Windows

```bash
aws ssm create-association --name "AWS-ApplyChefRecipes" ^ \
  --targets "Key=tag:OS,Values= Linux" ^ \
  --parameters '{"SourceType": ["S3"], "SourceInfo": ["{\"path\": "https://s3.amazonaws.com/DOC-EXAMPLE-BUCKET/HelloWorld\"}]}, "RunList": ["{\"recipe[HelloWorld::HelloWorldRecipe]\", \
  recipe[HelloWorld::InstallApp]\"}], "JsonAttributesContent": 
  ["{\"state\": \"visible\", \"colors\": \"foreground\": \"light-blue \", \"background\": \"dark-gray\"]}], 
  "ChefClientVersion": ["14"], 
  "ChefClientArguments": ["--fips"], 
  "WhyRun": false, 
  "ComplianceSeverity": ["Medium"], 
  "ComplianceType": ["Custom:Chef"], 
  "ComplianceReportBucket": ["ChefComplianceResultsBucket"]}' ^ \
  --association-name "name" ^ \
  --schedule-expression "cron(0 2 ? * SUN *)"
```

The system creates the association, and unless your specified cron or rate expression prevents it, the system runs the association on the target nodes.
3. Run the following command to view the status of the association you just created.

```
aws ssm describe-association --association-id "ID"
```

**Viewing Chef resource compliance details**

Systems Manager captures compliance information about Chef-managed resources in the Amazon S3 Compliance report bucket value that you specified when you ran the AWS-ApplyChefRecipes document. Searching for information about Chef resource failures in an S3 bucket can be time consuming. Instead, you can view this information on the Systems Manager Compliance page.

A Systems Manager Compliance scan collects information about resources on your managed nodes that were created or checked in the most recent Chef run. The resources can include files, directories, systemd services, yum packages, templated files, gem packages, and dependent cookbooks, among others.

The Compliance resources summary section displays a count of resources that failed. In the following example, the ComplianceType is Custom:Chef and one resource is noncompliant.

**Note**

Custom:Chef is the default ComplianceType value in the AWS-ApplyChefRecipes document. This value is customizable.
The **Details overview for resources** section shows information about the AWS resource that isn't in compliance. This section also includes the Chef resource type against which compliance was run, severity of issue, compliance status, and links to more information when applicable.

### Details overview for resources

</tbody>
</table>

**View output** shows the last 4,000 characters of the detailed status. Systems Manager starts with the exception as the first element, finds verbose messages, and shows them until it reaches the 4,000 character quota. This process displays the log messages that were output before the exception was thrown, which are the most relevant messages for troubleshooting.

For information about how to view compliance information, see [AWS Systems Manager Compliance](#).
Association failures affect compliance reporting

If the State Manager association fails, no compliance data is reported. For example, if Systems Manager attempts to download a Chef cookbook from an S3 bucket that the node doesn't have permission to access, the association fails, and Systems Manager reports no compliance data.

Walkthrough: Automatically update SSM Agent (CLI)

The following procedure walks you through the process of creating a State Manager association using the AWS Command Line Interface. The association automatically updates the SSM Agent according to a schedule that you specify. For more information about SSM Agent, see Working with SSM Agent. To customize the update schedule for SSM Agent using the console, see Automatically updating SSM Agent.

To be notified about SSM Agent updates, subscribe to the SSM Agent Release Notes page on GitHub.

Before you begin

Before you complete the following procedure, verify that you have at least one running Amazon Elastic Compute Cloud (Amazon EC2) instance for Linux, macOS, or Windows Server that is configured for Systems Manager. For more information, see Setting up AWS Systems Manager.

If you create an association by using either the AWS CLI or AWS Tools for Windows PowerShell, use the --Targets parameter to target instances, as shown in the following example. Don't use the --InstanceId parameter. The --InstanceId parameter is a legacy parameter.

To create an association for automatically updating SSM Agent

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.
   
   For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command to create an association by targeting instances using Amazon Elastic Compute Cloud (Amazon EC2) tags. Replace each example resource placeholder with your own information. The Schedule parameter sets a schedule to run the association every Sunday morning at 2:00 a.m. (UTC).

   State Manager associations don't support all cron and rate expressions. For more information about creating cron and rate expressions for associations, see Reference: Cron and rate expressions for Systems Manager.
Linux & macOS

```bash
aws ssm create-association \
--targets Key=tag:tag_key,Values=tag_value \
--name AWS-UpdateSSMAgent \n--schedule-expression "cron(0 2 ? * SUN *)"
```

Windows

```bash
aws ssm create-association ^
--targets Key=tag:tag_key,Values=tag_value ^
--name AWS-UpdateSSMAgent ^
--schedule-expression "cron(0 2 ? * SUN *)"
```

You can target multiple instances by specifying instances IDs in a comma-separated list.

Linux & macOS

```bash
aws ssm create-association \
--targets Key=instanceids,Values=instance_ID,instance_ID,instance_ID \n--name AWS-UpdateSSMAgent \n--schedule-expression "cron(0 2 ? * SUN *)"
```

Windows

```bash
aws ssm create-association ^
--targets Key=instanceids,Values=instance_ID,instance_ID,instance_ID ^
--name AWS-UpdateSSMAgent ^
--schedule-expression "cron(0 2 ? * SUN *)"
```

You can specify the version of the SSM Agent you want to update to.

Linux & macOS

```bash
aws ssm create-association \
--targets Key=instanceids,Values=instance_ID,instance_ID,instance_ID \n--name AWS-UpdateSSMAgent \n--schedule-expression "cron(0 2 ? * SUN *)"
```
--parameters version=ssm_agent_version_number

Windows

aws ssm create-association ^
--targets Key=instanceids,Values=instance_ID,instance_ID,instance_ID ^
--name AWS-UpdateSSMAgent ^
--schedule-expression "cron(0 2 ? * SUN *)" ^
--parameters version=ssm_agent_version_number

The system returns information like the following.

```json
{
   "AssociationDescription": {
      "ScheduleExpression": "cron(0 2 ? * SUN *)",
      "Name": "AWS-UpdateSSMAgent",
      "Overview": {
         "Status": "Pending",
         "DetailedStatus": "Creating"
      },
      "AssociationId": "123..............",
      "DocumentVersion": "$DEFAULT",
      "LastUpdateAssociationDate": 1504034257.98,
      "Date": 1504034257.98,
      "AssociationVersion": "1",
      "Targets": [
         {
            "Values": [
               "TagValue"
            ],
            "Key": "tag:TagKey"
         }
      ]
   }
}
```

The system attempts to create the association on the instance(s) and applies the state following creation. The association status shows Pending.

3. Run the following command to view an updated status of the association you created.
If your instances aren't running the most recent version of the SSM Agent, the status shows Failed. When a new version of SSM Agent is published, the association automatically installs the new agent, and the status shows Success.

Walkthrough: Automatically update PV drivers on EC2 instances for Windows Server (console)

Amazon Windows Amazon Machine Images (AMIs) contain a set of drivers to permit access to virtualized hardware. These drivers are used by Amazon Elastic Compute Cloud (Amazon EC2) to map instance store and Amazon Elastic Block Store (Amazon EBS) volumes to their devices. We recommend that you install the latest drivers to improve stability and performance of your EC2 instances for Windows Server. For more information about PV drivers, see AWS PV Drivers.

The following walkthrough shows you how to configure a State Manager association to automatically download and install new AWS PV drivers when the drivers become available. State Manager is a capability of AWS Systems Manager.

Before you begin

Before you complete the following procedure, verify that you have at least one Amazon EC2 instance for Windows Server running that is configured for Systems Manager. For more information, see Setting up AWS Systems Manager.

To create a State Manager association that automatically updates PV drivers

2. In the navigation pane, choose State Manager.
3. Choose Create association.
4. In the Name field, enter a descriptive name for the association.
5. In the Document list, choose AWS-ConfigureAWSPackage.
6. In the Parameters area, do the following:
   - For Action, choose Install.
For **Installation type**, choose **Uninstall and reinstall**.

**Note**
In-place upgrades are not supported for this package. It must be uninstalled and reinstalled.

For **Name**, enter **AWSPVDriver**.

You don't need to enter anything for **Version** and **Additional Arguments**.

7. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

**Tip**
If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

**Note**
If you choose to target instances by using tags, and you specify tags that map to Linux instances, the association succeeds on the Windows instance but fails on the Linux instances. The overall status of the association shows **Failed**.

8. In the **Specify schedule** area, choose whether to run the association on a schedule that you configure, or just once. Updated PV drivers are released a several times a year, so you can schedule the association to run once a month, if you want.

9. In the **Advanced options** area, for **Compliance severity**, choose a severity level for the association. Compliance reporting indicates whether the association state is compliant or noncompliant, along with the severity level you indicate here. For more information, see [About State Manager association compliance](#).

10. For **Rate control**:

    - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.
If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- **For Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

11. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](https://docs.aws.amazon.com/systemsmanager/latest/userguide/sysmgmt-instancepermissions.html) or [Create an IAM service role for a hybrid environment](https://docs.aws.amazon.com/systemsmanager/latest/userguide/sysmgmt-servicepermissions.html).

In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

12. (Optional) In the **CloudWatch alarm** section, for **Alarm name**, choose a CloudWatch alarm to apply to your association for monitoring.

Note the following information about this step.

- The alarms list displays a maximum of 100 alarms. If you don't see your alarm in the list, use the AWS Command Line Interface to create the association. For more information, see [Create an association (command line)](https://docs.aws.amazon.com/systemsmanager/latest/userguide/sysmgmt-cli-createassociation.html).
- To attach a CloudWatch alarm to your command, the IAM principal that creates the association must have permission for the `iam:createServiceLinkedRole` action.
For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms.

- If your alarm activates, any pending command invocations or automations do not run.

13. Choose **Create association**, and then choose **Close**. The system attempts to create the association on the instances and immediately apply the state.

If you created the association on one or more Amazon EC2 instances for Windows Server, the status changes to **Success**. If your instances aren't configured for Systems Manager, or if you inadvertently targeted Linux instances, the status shows **Failed**.

If the status is **Failed**, choose the association ID, choose the **Resources** tab, and then verify that the association was successfully created on your EC2 instances for Windows Server. If EC2 instances for Windows Server show a status of **Failed**, verify that the SSM Agent is running on the instance, and verify that the instance is configured with an AWS Identity and Access Management (IAM) role for Systems Manager. For more information, see Setting up AWS Systems Manager.

**AWS Systems Manager Patch Manager**

Patch Manager, a capability of AWS Systems Manager, automates the process of patching managed nodes with both security-related updates and other types of updates.

⚠️ **Important**

Beginning December 22, 2022, Systems Manager provides support for **patch policies**, which are the new and recommended method for configuring your patching operations. Using a single patch policy configuration, you can define patching for all accounts in all Regions in your organization, for only the accounts and Regions you choose, or for a single account-Region pair. For more information, see Using Quick Setup patch policies.

You can use Patch Manager to apply patches for both operating systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.)

You can use Patch Manager to install Service Packs on Windows nodes and perform minor version upgrades on Linux nodes. You can patch fleets of Amazon Elastic Compute Cloud (Amazon EC2)
instances, edge devices, on-premises servers, and virtual machines (VMs) by operating system type. This includes supported versions of several operating systems, as listed in Patch Manager prerequisites. You can scan instances to see only a report of missing patches, or you can scan and automatically install all missing patches. To get started with Patch Manager, open the Systems Manager console. In the navigation pane, choose Patch Manager.

---

**Note**

AWS doesn't test patches before making them available in Patch Manager. Also, Patch Manager doesn't support upgrading major versions of operating systems, such as Windows Server 2016 to Windows Server 2019, or SUSE Linux Enterprise Server (SLES) 12.0 to SLES 15.0.

For Linux-based operating system types that report a severity level for patches, Patch Manager uses the severity level reported by the software publisher for the update notice or individual patch. Patch Manager doesn't derive severity levels from third-party sources, such as the Common Vulnerability Scoring System (CVSS), or from metrics released by the National Vulnerability Database (NVD).

---

**Patch baselines**

Patch Manager uses *patch baselines*, which include rules for auto-approving patches within days of their release, in addition to optional lists of approved and rejected patches. When a patching operation runs, Patch Manager compares the patches currently applied to a managed node to those that should be applied according to the rules set up in the patch baseline. You can choose for Patch Manager to show you only a report of missing patches (a Scan operation), or you can choose for Patch Manager to automatically install all patches it find are missing from a managed node (a Scan and install operation).

**Patching operation methods**

Patch Manager currently offers four methods for running Scan and Scan and install operations:

- **(Recommended) A patch policy configured in Quick Setup** – Based on integration with AWS Organizations, a single patch policy can define patching schedules and patch baselines for an entire organization, including multiple AWS accounts and all AWS Regions those accounts operate in. A patch policy can also target only some organizational units (OUs) in an
organization. You can use a single patch policy to scan and install on different schedules. For more information, see Patch Manager organization patching configuration and Using Quick Setup patch policies.

- **A Host Management option configured in Quick Setup** – Host Management configurations are also supported by integration with AWS Organizations, making it possible to run a patching operation for up to an entire Organization. However, this option is limited to scanning for missing patches using the current default patch baseline and providing results in compliance reports. This operation method can't install patches. For more information, see Amazon EC2 host management.

- **A maintenance window to run a patch Scan or Install task** – A maintenance window, which you set up in the Systems Manager capability called Maintenance Windows, can be configured to run different types of tasks on a schedule you define. A Run Command-type task can be used to run Scan or Scan and Install tasks a set of managed nodes that you choose. Each maintenance window task can target managed nodes in only a single AWS account-AWS Region pair. For more information, see Walkthrough: Creating a maintenance window for patching (console).

- **An on-demand 'Patch now' operation in Patch Manager** – The Patch now option lets you bypass schedule setups when you need to patch managed nodes as quickly as possible. Using Patch now, you specify whether to run Scan or Scan and Install operation and which managed nodes to run the operation on. You can also choose to running Systems Manager documents (SSM documents) as lifecycle hooks during the patching operation. Each Patch now operation can target managed nodes in only a single AWS account-AWS Region pair. For more information, see Patching managed nodes on demand.

**Compliance reporting**

After a Scan operation, you can use the Systems Manager console to view information about which of your managed nodes are out of patch compliance, and which patches are missing from each of those nodes. You can also generate patch compliance reports in .csv format that are sent to an Amazon Simple Storage Service (Amazon S3) bucket of your choice. You can generate one-time reports, or generate reports on a regular schedule. For a single managed node, reports include details of all patches for the node. For a report on all managed nodes, only a summary of how many patches are missing is provided. After a report is generated, you can use a tool like Amazon QuickSight to import and analyze the data. For more information, see Working with patch compliance reports.
Note

A compliance item generated through the use of a patch policy has an execution type of PatchPolicy. A compliance item not generated in a patch policy operation has an execution type of Command.

Integrations

Patch Manager integrates with the following other AWS services:

- **AWS Identity and Access Management (IAM)** – Use IAM to control which users, groups, and roles have access to Patch Manager operations. For more information, see [How AWS Systems Manager works with IAM](#) and [Configure instance permissions required for Systems Manager](#).

- **AWS CloudTrail** – Use CloudTrail to record an auditable history of patching operation events initiated by users, roles, or groups. For more information, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#).

- **AWS Security Hub** – Patch compliance data from Patch Manager can be sent to AWS Security Hub. Security Hub gives you a comprehensive view of your high-priority security alerts and compliance status. It also monitors the patching status of your fleet. For more information, see [Integrating Patch Manager with AWS Security Hub](#).

- **AWS Config** – Set up recording in AWS Config to view Amazon EC2 instance management data in the Patch Manager Dashboard. For more information, see [Viewing patch Dashboard summaries](#).

Troubleshooting Patch Manager

Using Quick Setup patch policies

Beginning December 22, 2022, Patch Manager offers a new, recommended method to configure patching for your organization and AWS accounts through the use of patch policies.

A patch policy is a configuration you set up using Quick Setup, a capability of AWS Systems Manager. Patch policies provide more extensive and more centralized control over your patching operations than is available with previous methods of configuring patching. Patch policies can be used with all operating systems supported by Patch Manager, including supported versions of Linux, macOS, and Windows Server. For information about creating a patch policy, see Patch Manager organization patching configuration.

Major features of patch policies

Instead of using other methods of patching your nodes, use a patch policy to take advantage of these major features:

- **Single setup** – Setting up patching operations using a maintenance window or State Manager association can require multiple tasks in different parts of the Systems Manager console. Using a patch policy, all your patching operations can be set up in a single wizard.

- **Multi-account/Multi-Region support** – Using a maintenance window, a State Manager association, or the Patch now feature in Patch Manager, you're limited to targeting managed nodes in a single AWS account-AWS Region pair. If you use multiple accounts and multiple Regions, your setup and maintenance tasks can require a great deal of time, because you must perform setup tasks in each account-Region pair. However, if you use AWS Organizations, you can set up one patch policy that applies to all your managed nodes in all AWS Regions in all your AWS accounts. Or, if you choose, a patch policy can apply to only some organizational units (OUs) in the accounts and Regions you choose. A patch policy can also apply to a single local account, if you choose.

- **Installation support at the organizational level** – The existing Host Management configuration option in Quick Setup provides support for a daily scan of your managed nodes for patch compliance. However, this scan is done at a predetermined time and results in patch compliance information only. No patch installations are performed. Using a patch policy, you can specify different schedules for scanning and installing. You can also choose the frequency and time of these operations by using custom CRON or Rate expressions. For example, you could scan for
missing patches every day to provide you with regularly updated compliance information. But, your installation schedule could be just once a week to avoid unwanted downtime.

- **Simplified patch baseline selection** – Patch policies still incorporate patch baselines, and there are no changes to the way patch baselines are configured. However, when you create or update a patch policy, you can select the AWS managed or custom baseline you want to use for each operating system (OS) type in a single list. It's not necessary to specify the default baseline for each OS type in separate tasks.

**Note**

When patching operations based on a patch policy run, they use the AWS-RunPatchBaseline SSM document. For more information, see [About the AWS-RunPatchBaseline SSM document](#).

**Related information**

[Centrally deploy patching operations across your AWS Organization using Systems Manager Quick Setup](#) (AWS Cloud Operations and Migrations Blog)

**Other differences with patch policies**

Here are some other differences to note when using patch policies instead of previous methods of configuring patching:

- **No patch groups required** – In previous patching operations, you could tag multiple nodes to belong to a patch group, and then specify the patch baseline to use for that patch group. If no patch group was defined, Patch Manager patched instances with the current default patch baseline for the OS type. Using patch policies, it's no longer necessary to set up and maintain patch groups.

- **‘Configure patching’ page removed** – Before the release of patch policies, you could specify defaults for which nodes to patch, a patching schedule, and a patching operation on a Configure patching page. This page has been removed from Patch Manager. These options are now specified in patch policies.

- **No ‘Patch now’ support** – The ability to patch nodes on demand is still limited to a single AWS account-AWS Region pair at a time. For information, see [Patching managed nodes on demand](#).
• **Patch policies and compliance information** – When your managed nodes are scanned for compliance according to a patching policy configuration, compliance data is made available to you. You can view and work with the data in the same way as with other methods of compliance scanning. Although you can set up a patch policy for an entire organization or multiple organizational units, compliance information is reported individually for each AWS account-AWS Region pair. For more information, see [Working with patch compliance reports](#).

• **Association compliance status and patch policies** – The patching status for a managed node that's under a Quick Setup patch policy matches the status of the State Manager association execution for that node. If the association execution status is **Compliant**, the patching status for the managed node is also marked **Compliant**. If the association execution status is **Non-Compliant**, the patching status for the managed node is also marked **Non-Compliant**.

### AWS Regions supported for patch policies

Patch policy configurations in Quick Setup are currently supported in the following Regions:

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (N. California) (us-west-1)
- US West (Oregon) (us-west-2)
- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Canada (Central) (ca-central-1)
- Europe (Frankfurt) (eu-central-1)
- Europe (Ireland) (eu-west-1)
- Europe (London) (eu-west-2)
- Europe (Paris) (eu-west-3)
- Europe (Stockholm) (eu-north-1)
- South America (São Paulo) (sa-east-1)
Patch Manager prerequisites

Make sure that you have met the required prerequisites before using Patch Manager, a capability of AWS Systems Manager.

Topics

- **SSM Agent version**
- **Python version**
- **Connectivity to the patch source**
- **S3 endpoint access**
- **Supported operating systems for Patch Manager**

SSM Agent version

Version 2.0.834.0 or later of SSM Agent is running on the managed node you want to manage with Patch Manager.

**Note**

An updated version of SSM Agent is released whenever new capabilities are added to Systems Manager or updates are made to existing capabilities. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager capabilities and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Python version

For macOS and most Linux operating systems (OSs), Patch Manager currently supports Python versions 2.6 - 3.10. The AlmaLinux, Debian Server, Raspberry Pi OS, and Ubuntu Server OSs require a supported version of Python 3 (3.0 - 3.10).

Connectivity to the patch source

If your managed nodes don't have a direct connection to the Internet and you're using an Amazon Virtual Private Cloud (Amazon VPC) with a VPC endpoint, you must ensure that the nodes have
access to the source patch repositories (repos). On Linux nodes, patch updates are typically
downloaded from the remote repos configured on the node. Therefore, the node must be able to
connect to the repos so the patching can be performed. For more information, see [How security patches are selected](#).

Windows Server managed nodes must be able to connect to the Windows Update Catalog or
Windows Server Update Services (WSUS). Confirm that your nodes have connectivity to the
Microsoft Update Catalog through an internet gateway, NAT gateway, or NAT instance. If you are
using WSUS, confirm that the node has connectivity to the WSUS server in your environment. For
more information, see [Issue: managed node doesn't have access to Windows Update Catalog or WSUS](#).

**S3 endpoint access**

Whether your managed nodes operate in a private or public network, without access to the
required AWS managed Amazon Simple Storage Service (Amazon S3) buckets, patching operations
fail. For information about the S3 buckets your managed nodes must be able to access, see [SSM Agent communications with AWS managed S3 buckets](#) and [Improve the security of EC2 instances by using VPC endpoints for Systems Manager](#).

**Supported operating systems for Patch Manager**

The Patch Manager capability doesn't support all the same operating systems versions that are
supported by other Systems Manager capabilities. For example, Patch Manager doesn't support
CentOS 6.3 or Raspberry Pi OS 8 (Jessie). (For the full list of Systems Manager-supported operating
systems, see [Supported operating systems for Systems Manager](#).) Therefore, ensure that the
managed nodes you want to use with Patch Manager are running one of the operating systems
listed in the following table.

---

**Note**

Patch Manager relies on the patch repositories that are configured on a managed node,
such as Windows Update Catalog and Windows Server Update Services for Windows,
to retrieve available patches to install. Therefore, for end of life (EOL) operating system
versions, if no new updates are available, Patch Manager might not be able to report on the
new updates. This can be because no new updates are released by the Linux distribution
maintainer, Microsoft, or Apple, or because the managed node does not have the proper
license to access the new updates.
Patch Manager reports compliance status against the available patches on the managed node. Therefore, if an instance is running an EOL operating system, and no updates are available, Patch Manager might report the node as Compliant, depending on the patch baselines configured for the patching operation.

<table>
<thead>
<tr>
<th>Operating system</th>
<th>Details</th>
</tr>
</thead>
</table>
| Linux            | • AlmaLinux 8.3–8.9, 9.0–9.2

<tbody>
<tr>
<td>14.0 (Sonoma)</td>
<td></td>
</tr>
</tbody>
</table>

**macOS OS updates**

Patch Manager doesn't support operating system (OS) updates or upgrades for macOS, such as from 12.x to 13.x or 13.1 to 13.2. To perform OS version updates on macOS, we recommend using Apple's built-in OS upgrade mechanisms. For more information, see [Device Management](https://developer.apple.com/documentation/device_management) on the Apple Developer Documentation website.

**Homebrew support**

The Homebrew open-source software package management system has discontinued support for macOS 10.14.x (Mojave) and 10.15.x (Catalina). As a result, patching operations on these versions are not currently supported.

**Region support**

macOS is not supported in all AWS Regions. For more information about Amazon EC2 support for macOS, see [Amazon EC2 Mac instances](https://docs.aws.amazon.com/AWSEC2/latest/userguide/mac-inst.html) in the *Amazon EC2 User Guide*.

**macOS edge devices**

SSM Agent for AWS IoT Greengrass core devices is not supported on macOS. You can't use Patch Manager to patch macOS edge devices.
### Operating system

<table>

</tbody>
</table>

**Note**

SSM Agent for AWS IoT Greengrass core devices is not supported on Windows 10. You can't use Patch Manager to patch Windows 10 edge devices.

### About Windows Server 2008 support

As of January 14, 2020, Windows Server 2008 is no longer supported for feature or security updates from Microsoft. Legacy Amazon Machine Images (AMIs) for Windows Server 2008 and 2008 R2 still include version 2 of SSM Agent preinstalled, but Systems Manager no longer officially supports 2008 versions and no longer updates the agent for these versions of Windows Server. In addition, SSM Agent version 3 might not be compatible with all operations on Windows Server 2008 and 2008 R2. The final officially supported version of SSM Agent for Windows Server 2008 versions is 2.3.1644.0.

### About Windows Server 2012 and 2012 R2 support

Windows Server 2012 and 2012 R2 reached end of support on October 10, 2023. To use Patch Manager with these versions, we recommend also using Extended Security

### How Patch Manager operations work

This section provides technical details that explain how Patch Manager, a capability of AWS Systems Manager, determines which patches to install and how it installs them on each supported operating system. For Linux operating systems, it also provides information about specifying a source repository, in a custom patch baseline, for patches other than the default configured on a managed node. This section also provides details about how patch baseline rules work on different distributions of the Linux operating system.

#### Note

The information in the following topics applies no matter which method or type of configuration you are using for your patching operations:

- A patch policy configured in Quick Setup
- A Host Management option configured in Quick Setup
- A maintenance window to run a patch Scan or Install task
- An on-demand Patch now operation

#### Topics

- How package release dates and update dates are calculated
- How security patches are selected
- How to specify an alternative patch source repository (Linux)
- How patches are installed
- How patch baseline rules work on Linux-based systems
- Key differences between Linux and Windows patching
How package release dates and update dates are calculated

Important

The information on this page applies to the Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022, and Amazon Linux 2023 operating systems (OSs) for Amazon Elastic Compute Cloud (Amazon EC2) instances. The packages for these OS types are created and maintained by Amazon Web Services. How the manufacturers of other operating systems manage their packages and repositories affect how their release dates and update dates are calculated. For OSs besides Amazon Linux, Amazon Linux 2, Amazon Linux 2022, and Amazon Linux 2023, such as Red Hat Enterprise Linux (RHEL) and SUSE Linux Enterprise Server (SLES), refer to the manufacturer's documentation for information about how their packages are updated and maintained.

In the settings for custom patch baselines you create, for most OS types, you can specify that patches are auto-approved for installation after a certain number of days. AWS provides several predefined patch baselines that include auto-approval dates of 7 days.

An auto-approval delay is the number of days to wait after the patch was released, before the patch is automatically approved for patching. For example, you create a rule using the CriticalUpdates classification and configure it for 7 days auto-approval delay. As a result, a new critical patch with a release date or last update date of July 7 is automatically approved on July 14.

To avoid unexpected results with auto-approval delays on Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022, and Amazon Linux 2023, it's important to understand how their release dates and update dates are calculated.

In most cases, the auto-approval wait time before patches are installed is calculated from an Updated Date value in updateinfo.xml, not a Release Date value. The following are important details about these date calculations:

- The Release Date is the date a notice is released. It does not mean the package is necessarily available in the associated repositories yet.
- The Update Date is the last date the notice was updated. An update to a notice can represent something as small as a text or description update. It does not mean the package was released from that date or is necessarily available in the associated repositories yet.
This means that a package could have an Update Date value of July 7 but not be available for installation until (for example) July 13. Suppose for this case that a patch baseline that specifies a 7-day auto-approval delay runs in an Install operation on July 14. Because the Update Date value is 7 days prior to the run date, the patches and updates in the package are installed on July 14. The installation happens even though only 1 day has passed since the package became available for actual installation.

- A package containing operating system or application patches can be updated more than once after initial release.
- A package can be released into the AWS managed repositories but then rolled back if issues are later discovered with it.

In some patching operations, these factors might not be important. For example, if a patch baseline is configured to install a patch with severity values of Low and Medium, and a classification of Recommended, any auto-approval delay might have little impact on your operations.

However, in cases where the timing of critical or high-severity patches is more important, you might want to exercise more control over when patches are installed. The recommended method for doing this is to use alternative patch source repositories instead of the default repositories for patching operations on a managed node.

You can specify alternative patch source repositories when you create a custom patch baseline. In each custom patch baseline, you can specify patch source configurations for up to 20 versions of a supported Linux operating system. For more information, see How to specify an alternative patch source repository (Linux).

**How security patches are selected**

The primary focus of Patch Manager, a capability of AWS Systems Manager, is on installing operating systems security-related updates on managed nodes. By default, Patch Manager doesn’t install all available patches, but rather a smaller set of patches focused on security.

For Linux-based operating system types that report a severity level for patches, Patch Manager uses the severity level reported by the software publisher for the update notice or individual patch. Patch Manager doesn’t derive severity levels from third-party sources, such as the Common Vulnerability Scoring System (CVSS), or from metrics released by the National Vulnerability Database (NVD).
Note

On all Linux-based systems supported by Patch Manager, you can choose a different source repository configured for the managed node, typically to install nonsecurity updates. For information, see How to specify an alternative patch source repository (Linux).

The remainder of this section explains how Patch Manager selects security patches for the different supported operating systems.

Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022, and Amazon Linux 2023

Preconfigured repositories are handled differently on Amazon Linux 1 and Amazon Linux 2 than on Amazon Linux 2022 and Amazon Linux 2023.

On Amazon Linux 1 and Amazon Linux 2, the Systems Manager patch baseline service uses preconfigured repositories on the managed node. There are usually two preconfigured repositories (repos) on a node:

On Amazon Linux 1

- **Repo ID**: amzn-main/latest
  
  **Repo name**: amzn-main-Base

- **Repo ID**: amzn-updates/latest
  
  **Repo name**: amzn-updates-Base

On Amazon Linux 2

- **Repo ID**: amzn2-core/2/architecture
  
  **Repo name**: Amazon Linux 2 core repository

- **Repo ID**: amzn2extra-docker/2/architecture
  
  **Repo name**: Amazon Extras repo for docker
Amazon Linux 2023 (AL2023) instances initially contain the updates that were available in the version of AL2023 and the chosen AMI. By default, your AL2023 instance doesn't automatically receive additional critical and important security updates at launch. Instead, with the deterministic upgrades through versioned repositories feature in AL2023, which is turned on by default, you can apply updates based on a schedule that meets your specific needs. For more information, see Deterministic upgrades through versioned repositories in the Amazon Linux 2023 User Guide.

On Amazon Linux 2022, the preconfigured repositories are tied to locked versions of package updates. When new Amazon Machine Images (AMIs) for Amazon Linux 2022 are released, they are locked to a specific version. For patch updates, Patch Manager retrieves the latest locked version of the patch update repository and then updates packages on the managed node based on the content of that locked version.

On AL2023, the preconfigured repository is the following:

- **Repo ID**: amazonlinux
  
  **Repo name**: Amazon Linux 2023 repository

On Amazon Linux 2022 (preview release), the preconfigured repositories are tied to locked versions of package updates. When new Amazon Machine Images (AMIs) for Amazon Linux 2022 are released, they are locked to a specific version. For patch updates, Patch Manager retrieves the latest locked version of the patch update repository and then updates packages on the managed node based on the content of that locked version.

On Amazon Linux 2022, the preconfigured repository is the following:

- **Repo ID**: amazonlinux
  
  **Repo name**: Amazon Linux 2022 repository
All updates are downloaded from the remote repos configured on the managed node. Therefore, the node must have outbound access to the internet in order to connect to the repos so the patching can be performed.

Amazon Linux 1 and Amazon Linux 2 managed nodes use Yum as the package manager. Amazon Linux 2022 and Amazon Linux 2023 use DNF as the package manager.

Both package managers use the concept of an update notice as a file named updateinfo.xml. An update notice is simply a collection of packages that fix specific problems. All packages that are in an update notice are considered Security by Patch Manager. Individual packages aren’t assigned classifications or severity levels. For this reason, Patch Manager assigns the attributes of an update notice to the related packages.

If you select the Include non-security updates check box in the Create patch baseline page, then packages that aren’t classified in an updateinfo.xml file (or a package that contains a file without properly formatted Classification, Severity, and Date values) can be included in the prefiltered list of patches. However, in order for a patch to be applied, the patch must still meet the user-specified patch baseline rules.

CentOS and CentOS Stream

On CentOS and CentOS Stream, the Systems Manager patch baseline service uses preconfigured repositories (repos) on the managed node. The following list provides examples for a fictitious CentOS 8.2 Amazon Machine Image (AMI):

- **Repo ID**: example-centos-8.2-base
  - **Repo name**: Example CentOS-8.2 - Base
- **Repo ID**: example-centos-8.2-extras
  - **Repo name**: Example CentOS-8.2 - Extras
- **Repo ID**: example-centos-8.2-updates
Repo name: Example CentOS-8.2 - Updates
• Repo ID: example-centos-8.x-examplerepo

Repo name: Example CentOS-8.x - Example Repo Packages

Note
All updates are downloaded from the remote repos configured on the managed node. Therefore, the node must have outbound access to the internet in order to connect to the repos so the patching can be performed.

CentOS 6 and 7 managed nodes use Yum as the package manager. CentOS 8 and CentOS Stream nodes use DNF as the package manager. Both package managers use the concept of an update notice. An update notice is simply a collection of packages that fix specific problems.

However, CentOS and CentOS Stream default repos aren't configured with an update notice. This means that Patch Manager doesn't detect packages on default CentOS and CentOS Stream repos. To allow Patch Manager to process packages that aren't contained in an update notice, you must turn on the EnableNonSecurity flag in the patch baseline rules.

Note
CentOS and CentOS Stream update notices are supported. Repos with update notices can be downloaded after launch.

Debian Server and Raspberry Pi OS

On Debian Server and Raspberry Pi OS (formerly Raspbian), the Systems Manager patch baseline service uses preconfigured repositories (repos) on the instance. These preconfigured repos are used to pull an updated list of available package upgrades. For this, Systems Manager performs the equivalent of a `sudo apt-get update` command.

Packages are then filtered from `debian-security codename` repos. This means that on each version of Debian Server, Patch Manager only identifies upgrades that are part of the associated repo for that version, as follows:
- Debian Server 8: debian-security jessie
- Debian Server 9: debian-security stretch
- Debian Server 10: debian-security buster
- Debian Server 11: debian-security bullseye
- Debian Server 12: debian-security bookworm

**Note**

On Debian Server 8 only: Because some Debian Server 8.* managed nodes refer to an obsolete package repository (jessie-backports), Patch Manager performs additional steps to ensure that patching operations succeed. For more information, see [How patches are installed](#).

Oracle Linux

On Oracle Linux, the Systems Manager patch baseline service uses preconfigured repositories (repos) on the managed node. There are usually two preconfigured repos on a node.

**Oracle Linux 7:**

- **Repo ID:** ol7_UEKR5/x86_64
  
  **Repo name:** Latest Unbreakable Enterprise Kernel Release 5 for Oracle Linux 7 Server (x86_64)

- **Repo ID:** ol7_latest/x86_64
  
  **Repo name:** Oracle Linux 7 Server Latest (x86_64)

**Oracle Linux 8:**

- **Repo ID:** ol8_baseos_latest
  
  **Repo name:** Oracle Linux 8 BaseOS Latest (x86_64)

- **Repo ID:** ol8_appstream
  
  **Repo name:** Oracle Linux 8 Application Stream (x86_64)
- **Repo ID**: ol8_UEKR6

  **Repo name**: Latest Unbreakable Enterprise Kernel Release 6 for Oracle Linux 8 (x86_64)

**Oracle Linux 9:**

- **Repo ID**: ol9_baseos_latest

  **Repo name**: Oracle Linux 9 BaseOS Latest (x86_64)

- **Repo ID**: ol9_appstream

  **Repo name**: Oracle Linux 9 Application Stream Packages(x86_64)

- **Repo ID**: ol9_UEKR7

  **Repo name**: Oracle Linux UEK Release 7 (x86_64)

---

**Note**

All updates are downloaded from the remote repos configured on the managed node. Therefore, the node must have outbound access to the internet in order to connect to the repos so the patching can be performed.

---

Oracle Linux managed nodes use Yum as the package manager, and Yum uses the concept of an update notice as a file named `updateinfo.xml`. An update notice is simply a collection of packages that fix specific problems. Individual packages aren't assigned classifications or severity levels. For this reason, Patch Manager assigns the attributes of an update notice to the related packages and installs packages based on the Classification filters specified in the patch baseline.

---

**Note**

If you select the **Include non-security updates** check box in the **Create patch baseline** page, then packages that aren't classified in an `updateinfo.xml` file (or a package that contains a file without properly formatted Classification, Severity, and Date values) can...
AlmaLinux, RHEL, and Rocky Linux

On AlmaLinux, Red Hat Enterprise Linux, and Rocky Linux the Systems Manager patch baseline service uses preconfigured repositories (repos) on the managed node. There are usually three preconfigured repos on a node.

All updates are downloaded from the remote repos configured on the managed node. Therefore, the node must have outbound access to the internet in order to connect to the repos so the patching can be performed.

**Note**

If you select the Include non-security updates check box in the Create patch baseline page, then packages that aren't classified in an updateinfo.xml file (or a package that contains a file without properly formatted Classification, Severity, and Date values) can be included in the prefiltered list of patches. However, in order for a patch to be applied, the patch must still meet the user-specified patch baseline rules.

Red Hat Enterprise Linux 7 managed nodes use Yum as the package manager. AlmaLinux, Red Hat Enterprise Linux 8, and Rocky Linux managed nodes use DNF as the package manager. Both package managers use the concept of an update notice as a file named updateinfo.xml. An update notice is simply a collection of packages that fix specific problems. Individual packages aren't assigned classifications or severity levels. For this reason, Patch Manager assigns the attributes of an update notice to the related packages and installs packages based on the Classification filters specified in the patch baseline.

**RHEL 7**

**Note**

The following repo IDs are associated with RHUI 2. RHUI 3 launched in December 2019 and introduced a different naming scheme for Yum repository IDs. Depending on the RHEL-7 AMI you create your managed nodes from, you might need to update...
your commands. For more information, see Repository IDs for RHEL 7 in AWS Have Changed on the Red Hat Customer Portal.

- **Repo ID**: rhui-REGION-client-config-server-7/x86_64
  - **Repo name**: Red Hat Update Infrastructure 2.0 Client Configuration Server 7

- **Repo ID**: rhui-REGION-rhel-server-releases/7Server/x86_64
  - **Repo name**: Red Hat Enterprise Linux Server 7 (RPMs)

- **Repo ID**: rhui-REGION-rhel-server-rh-common/7Server/x86_64
  - **Repo name**: Red Hat Enterprise Linux Server 7 RH Common (RPMs)

- **Repo ID**: rhui-client-config-server-8
  - **Repo name**: Red Hat Update Infrastructure 3 Client Configuration Server 8

AlmaLinux, 8 RHEL 8, and Rocky Linux 8

- **Repo ID**: rhel-8-appstream-rhui-rpms
  - **Repo name**: Red Hat Enterprise Linux 8 for x86_64 - AppStream from RHUI (RPMs)

- **Repo ID**: rhel-8-baseos-rhui-rpms
  - **Repo name**: Red Hat Enterprise Linux 8 for x86_64 - BaseOS from RHUI (RPMs)

- **Repo ID**: rhui-client-config-server-9
  - **Repo name**: Red Hat Update Infrastructure 3 Client Configuration Server 9

AlmaLinux 9, RHEL 9, and Rocky Linux 9

- **Repo ID**: rhel-9-appstream-rhui-rpms
  - **Repo name**: Red Hat Enterprise Linux 9 for x86_64 - AppStream from RHUI (RPMs)

- **Repo ID**: rhel-9-baseos-rhui-rpms
  - **Repo name**: Red Hat Enterprise Linux 9 for x86_64 - BaseOS from RHUI (RPMs)

- **Repo ID**: rhui-client-config-server-9
**Repo name:** Red Hat Enterprise Linux 9 Client Configuration

**SLES**

On SUSE Linux Enterprise Server (SLES) managed nodes, the ZYPP library gets the list of available patches (a collection of packages) from the following locations:

- List of repositories: `etc/zypp/repos.d/*`
- Package information: `/var/cache/zypp/raw/*`

SLES managed nodes use Zypper as the package manager, and Zypper uses the concept of a patch. A patch is simply a collection of packages that fix a specific problem. Patch Manager handles all packages referenced in a patch as security-related. Because individual packages aren't given classifications or severity, Patch Manager assigns the packages the attributes of the patch that they belong to.

**Ubuntu Server**

On Ubuntu Server, the Systems Manager patch baseline service uses preconfigured repositories (repos) on the managed node. These preconfigured repos are used to pull an updated list of available package upgrades. For this, Systems Manager performs the equivalent of a `sudo apt-get update` command.

Packages are then filtered from `codename-security` repos, where the codename is unique to the release version, such as `trusty` for Ubuntu Server 14. Patch Manager only identifies upgrades that are part of these repos:

- Ubuntu Server 14.04 LTS: `trusty-security`
- Ubuntu Server 16.04 LTS: `xenial-security`
- Ubuntu Server 18.04 LTS: `bionic-security`
- Ubuntu Server 20.04 LTS: `focal-security`
- Ubuntu Server 20.10 STR: `groovy-security`
- Ubuntu Server 22.04 LTS (jammy-security)
- Ubuntu Server 23.04 (lunar-security)
Windows Server

On Microsoft Windows operating systems, Patch Manager retrieves a list of available updates that Microsoft publishes to Microsoft Update and are automatically available to Windows Server Update Services (WSUS).

Patch Manager continually monitors for new updates in every AWS Region. The list of available updates is refreshed in each Region at least once per day. When the patch information from Microsoft is processed, Patch Manager removes updates that were replaced by later updates from its patch list. Therefore, only the most recent update is displayed and made available for installation. For example, if KB4012214 replaces KB3135456, only KB4012214 is made available as an update in Patch Manager.

Patch Manager only makes available patches for Windows Server operating system versions that are supported for Patch Manager. For example, Patch Manager can’t be used to patch Windows RT.

Note

In some cases, Microsoft releases patches for applications that don’t specify an updated date and time. In these cases, an updated date and time of 01/01/1970 is supplied by default.

How to specify an alternative patch source repository (Linux)

When you use the default repositories configured on a managed node for patching operations, Patch Manager, a capability of AWS Systems Manager, scans for or installs security-related patches. This is the default behavior for Patch Manager. For complete information about how Patch Manager selects and installs security patches, see How security patches are selected.

On Linux systems, however, you can also use Patch Manager to install patches that aren’t related to security, or that are in a different source repository than the default one configured on the managed node. You can specify alternative patch source repositories when you create a custom patch baseline. In each custom patch baseline, you can specify patch source configurations for up to 20 versions of a supported Linux operating system.

For example, suppose that your Ubuntu Server fleet includes both Ubuntu Server 14.04 and Ubuntu Server 16.04 managed nodes. In this case, you can specify alternate repositories for each
version in the same custom patch baseline. For each version, you provide a name, specify the operating system version type (product), and provide a repository configuration. You can also specify a single alternative source repository that applies to all versions of a supported operating system.

Note

Running a custom patch baseline that specifies alternative patch repositories for a managed node doesn't make them the new default repositories on the operating system. After the patching operation is complete, the repositories previously configured as the defaults for the node's operating system remain the defaults.

For a list of example scenarios for using this option, see Sample uses for alternative patch source repositories later in this topic.

For information about default and custom patch baselines, see About predefined and custom patch baselines.

Example: Using the console

To specify alternative patch source repositories when you're working in the Systems Manager console, use the Patch sources section on the Create patch baseline page. For information about using the Patch sources options, see Creating a custom patch baseline (Linux).

Example: Using the AWS CLI

For an example of using the --sources option with the AWS Command Line Interface (AWS CLI), see Create a patch baseline with custom repositories for different OS versions.

Topics

- Important considerations for alternative repositories
- Sample uses for alternative patch source repositories

Important considerations for alternative repositories

Keep in mind the following points as you plan your patching strategy using alternative patch repositories.
Only specified repositories are used for patching

Specifying alternative repositories doesn't mean specifying additional repositories. You can choose to specify repositories other than those configured as defaults on a managed node. However, you must also specify the default repositories as part of the alternative patch source configuration if you want their updates to be applied.

For example, on Amazon Linux 2 managed nodes, the default repositories are amzn2-core and amzn2extra-docker. If you want to include the Extra Packages for Enterprise Linux (EPEL) repository in your patching operations, you must specify all three repositories as alternative repositories.

**Note**

Running a custom patch baseline that specifies alternative patch repositories for a managed node doesn't make them the new default repositories on the operating system. After the patching operation is complete, the repositories previously configured as the defaults for the node's operating system remain the defaults.

Patching behavior for YUM-based distributions depends on the updateinfo.xml manifest

When you specify alternative patch repositories for YUM-based distributions, such as Amazon Linux 1 or Amazon Linux 2, Red Hat Enterprise Linux, or CentOS, patching behavior depends on whether the repository includes an update manifest in the form of a complete and correctly formatted updateinfo.xml file. This file specifies the release date, classifications, and severities of the various packages. Any of the following will affect the patching behavior:

- If you filter on **Classification** and **Severity**, but they aren't specified in updateinfo.xml, the package won't be included by the filter. This also means that packages without an updateinfo.xml file won't be included in patching.
- If you filter on **ApprovalAfterDays**, but the package release date isn't in Unix Epoch format (or has no release date specified), the package won't be included by the filter.
- There is an exception if you select the **Include non-security updates** check box in the **Create patch baseline** page. In this case, packages without an updateinfo.xml file (or that contains this file without properly formatted **Classification**, **Severity**, and **Date** values) will be included in the prefiltered list of patches. (They must still meet the other patch baseline rule requirements in order to be installed.)
Sample uses for alternative patch source repositories

Example 1 – Nonsecurity Updates for Ubuntu Server

You’re already using Patch Manager to install security patches on a fleet of Ubuntu Server managed nodes using the AWS-provided predefined patch baseline AWS-UbuntuDefaultPatchBaseline. You can create a new patch baseline that is based on this default, but specify in the approval rules that you want nonsecurity related updates that are part of the default distribution to be installed as well. When this patch baseline is run against your nodes, patches for both security and nonsecurity issues are applied. You can also choose to approve nonsecurity patches in the patch exceptions you specify for a baseline.

Example 2 - Personal Package Archives (PPA) for Ubuntu Server

Your Ubuntu Server managed nodes are running software that is distributed through a Personal Package Archives (PPA) for Ubuntu. In this case, you create a patch baseline that specifies a PPA repository that you have configured on the managed node as the source repository for the patching operation. Then use Run Command to run the patch baseline document on the nodes.

Example 3 – Internal Corporate Applications on Amazon Linux

You need to run some applications needed for industry regulatory compliance on your Amazon Linux managed nodes. You can configure a repository for these applications on the nodes, use YUM to initially install the applications, and then update or create a new patch baseline to include this new corporate repository. After this you can use Run Command to run the AWS-RunPatchBaseline document with the Scan option to see if the corporate package is listed among the installed packages and is up to date on the managed node. If it isn't up to date, you can run the document again using the Install option to update the applications.

How patches are installed

Patch Manager, a capability of AWS Systems Manager, uses the appropriate built-in mechanism for an operating system type to install updates on a managed node. For example, on Windows Server, the Windows Update API is used, and on Amazon Linux 2 the yum package manager is used.

The remainder of this section explains how Patch Manager installs patches on an operating system.

Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022, and Amazon Linux 2023

On Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022, and Amazon Linux 2023 managed nodes, the patch installation workflow is as follows:
1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the InstallOverrideList parameter for the AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation documents, the listed patches are installed and steps 2-7 are skipped.

2. Apply **GlobalFilters** as specified in the patch baseline, keeping only the qualified packages for further processing.

3. Apply **ApprovalRules** as specified in the patch baseline. Each approval rule can define a package as approved.

   Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

   If nonsecurity updates are included, patches from other repositories are considered as well.

4. Apply **ApprovedPatches** as specified in the patch baseline. The approved patches are approved for update even if they're discarded by **GlobalFilters** or if no approval rule specified in **ApprovalRules** grants it approval.

5. Apply **RejectedPatches** as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.

6. If multiple versions of a patch are approved, the latest version is applied.

7. The YUM update API (Amazon Linux 1, Amazon Linux 2) or the DNF update API (Amazon Linux 2022, Amazon Linux 2023) is applied to approved patches as follows:

   - For predefined default patch baselines provided by AWS, only patches specified in updateinfo.xml are applied (security updates only). This is because the **Include nonsecurity updates** check box is not selected. The predefined baselines are equivalent to a custom baseline with the following:
     - The **Include nonsecurity updates** check box is not selected
     - A SEVERITY list of [Critical, Important]
     - A CLASSIFICATION list of [Security, Bugfix]

   For Amazon Linux 1 and Amazon Linux 2, the equivalent yum command for this workflow is:
For Amazon Linux 2022 and Amazon Linux 2023, the equivalent dnf command for this workflow is:

```
sudo dnf upgrade-minimal --sec-severity=critical --sec-severity=important --bugfix -y
```

If the **Include nonsecurity updates** check box is selected, patches in `updateinfo.xml` and those not in `updateinfo.xml` are all applied (security and nonsecurity updates).

For Amazon Linux 1 and Amazon Linux 2, if a baseline with **Include nonsecurity updates** is selected, has a SEVERITY list of [Critical, Important] and a CLASSIFICATION list of [Security, Bugfix], the equivalent yum command is:

```
sudo yum update --security --sec-severity=critical,important --bugfix -y
```

For Amazon Linux 2022, and Amazon Linux 2023, the equivalent dnf command is:

```
sudo dnf upgrade --security --sec-severity=critical --sec-severity=important --bugfix -y
```

---

**Note**

For Amazon Linux 2022 and Amazon Linux 2023, a patch severity level of Medium is equivalent to a severity of Moderate that might be defined in some external repositories. If you include Medium severity patches in the patch baseline, Moderate severity patches from external patches are also installed on the instances.

When you query for compliance data using the API action `DescribeInstancePatches`, filtering for the severity level Medium reports patches with severity levels of both Medium and Moderate.

Amazon Linux 2022 and Amazon Linux 2023 also support the patch severity level None, which is recognized by the DNF package manager.
8. The managed node is rebooted if any updates were installed. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

CentOS and CentOS Stream

On CentOS and CentOS Stream managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the InstallOverrideList parameter for the AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation documents, the listed patches are installed and steps 2-7 are skipped.

   Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.

2. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

   Approval rules, however, are also subject to whether the Include nonsecurity updates check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

   If nonsecurity updates are included, patches from other repositories are considered as well.

3. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.

4. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.

5. If multiple versions of a patch are approved, the latest version is applied.

6. The YUM update API (on CentOS 6.x and 7.x versions) or the DNF update (on CentOS 8 and CentOS Stream) is applied to approved patches.

7. The managed node is rebooted if any updates were installed. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document,
the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

Debian Server and Raspberry Pi OS

On Debian Server and Raspberry Pi OS (formerly Raspbian) instances, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the InstallOverrideList parameter for the AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation documents, the listed patches are installed and steps 2-7 are skipped.

2. If an update is available for python3-apt (a Python library interface to libapt), it is upgraded to the latest version. (This nonsecurity package is upgraded even if you did not select the Include nonsecurity updates option.)

⚠️ Important

On Debian Server 8 only: Because some Debian Server 8.* managed nodes refer to an obsolete package repository (jessie-backports), Patch Manager performs the following additional steps to ensure that patching operations succeed:

a. On your managed node, the reference to the jessie-backports repository is commented out from the source location list (/etc/apt/sources.list.d/jessie-backports). As a result, no attempt is made to download patches from that location.

b. A Stretch security update signing key is imported. This key provides the necessary permissions for the update and install operations on Debian Server 8.* distributions.

c. The apt-get operation is run at this point to ensure that the latest version of python3-apt is installed before the patching process begins.

d. After the installation process is complete, the reference to the jessie-backports repository is restored and the signing key is removed from the apt sources keyring. This is done to leave the system configuration as it was before the patching operation.

The next time Patch Manager updates the system, the same process is repeated.
3. Apply **GlobalFilters** as specified in the patch baseline, keeping only the qualified packages for further processing.

4. Apply **ApprovalRules** as specified in the patch baseline. Each approval rule can define a package as approved.

   **Note**

   Because it isn't possible to reliably determine the release dates of update packages for Debian Server, the auto-approval options aren't supported for this operating system.

   Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

   If nonsecurity updates are included, patches from other repositories are considered as well.

   **Note**

   For Debian Server and Raspberry Pi OS, patch candidate versions are limited to patches included in debian-security.

5. Apply **ApprovedPatches** as specified in the patch baseline. The approved patches are approved for update even if they're discarded by **GlobalFilters** or if no approval rule specified in **ApprovalRules** grants it approval.

6. Apply **RejectedPatches** as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.

7. The APT library is used to upgrade packages.

   **Note**

   Patch Manager does not support using the APT Pin-Priority option to assign priorities to packages. Patch Manager aggregates available updates from all enabled...
8. The managed node is rebooted if any updates were installed. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

macOS

On macOS managed nodes, the patch installation workflow is as follows:

1. The /Library/Receipts/InstallHistory.plist property list is a record of software that has been installed and upgraded using the softwareupdate and installer package managers. Using the pkgutil command line tool (for installer) and the softwareupdate package manager, CLI commands are run to parse this list.

   For installer, the response to the CLI commands includes package name, version, volume, location, and install-time details, but only the package name and version are used by Patch Manager.

   For softwareupdate, the response to the CLI commands includes the package name (display name), version, and date, but only the package name and version are used by Patch Manager.

   For Brew and Brew Cask, Homebrew doesn't support its commands running under the root user. As a result, Patch Manager queries for and runs Homebrew commands as either the owner of the Homebrew directory or as a valid user belonging to the Homebrew directory's owner group. The commands are similar to softwareupdate and installer and are run through a Python subprocess to gather package data, and the output is parsed to identify package names and versions.

2. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.

3. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.
4. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.

5. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.

6. If multiple versions of a patch are approved, the latest version is applied.

7. Invokes the appropriate package CLI on the managed node to process approved patches as follows:

   - For predefined default patch baselines provided by AWS, and for custom patch baselines where the Include non-security updates check box is not selected, only security updates are applied.
   - For custom patch baselines where the Include non-security updates check box is selected, both security and nonsecurity updates are applied.

8. The managed node is rebooted if any updates were installed. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

Oracle Linux

On Oracle Linux managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the InstallOverrideList parameter for the AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation documents, the listed patches are installed and steps 2-7 are skipped.

2. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.
3. Apply **ApprovalRules** as specified in the patch baseline. Each approval rule can define a package as approved.

Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

If nonsecurity updates are included, patches from other repositories are considered as well.

4. Apply **ApprovedPatches** as specified in the patch baseline. The approved patches are approved for update even if they're discarded by **GlobalFilters** or if no approval rule specified in **ApprovalRules** grants it approval.

5. Apply **RejectedPatches** as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.

6. If multiple versions of a patch are approved, the latest version is applied.

7. On version 7 managed nodes, the YUM update API is applied to approved patches as follows:

   - For predefined default patch baselines provided by AWS, and for custom patch baselines where the **Include non-security updates** check box is **not** selected, only patches specified in updateinfo.xml are applied (security updates only).

     The equivalent yum command for this workflow is:

     ```
     sudo yum update-minimal --sec-severity=Important,Moderate --bugfix -y
     ```

   - For custom patch baselines where the **Include non-security updates** check box is **selected**, both patches in updateinfo.xml and those not in updateinfo.xml are applied (security and nonsecurity updates).

     The equivalent yum command for this workflow is:

     ```
     sudo yum update --security --bugfix -y
     ```

On version 8 and 9 managed nodes, the DNF update API is applied to approved patches as follows:
• For predefined default patch baselines provided by AWS, and for custom patch baselines where the Include non-security updates check box is not selected, only patches specified in updateinfo.xml are applied (security updates only).

The equivalent yum command for this workflow is:

```
sudo dnf upgrade-minimal --security --sec-severity=Moderate --sec-severity=Important
```

• For custom patch baselines where the Include non-security updates check box is selected, both patches in updateinfo.xml and those not in updateinfo.xml are applied (security and nonsecurity updates).

The equivalent yum command for this workflow is:

```
sudo dnf upgrade --security --bugfix
```

8. The managed node is rebooted if any updates were installed. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

AlmaLinux, RHEL, and Rocky Linux

On AlmaLinux, Red Hat Enterprise Linux, and Rocky Linux managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the InstallOverrideList parameter for the AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation documents, the listed patches are installed and steps 2-7 are skipped.

2. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.

3. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

Approval rules, however, are also subject to whether the Include nonsecurity updates check box was selected when creating or last updating a patch baseline.
If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

If nonsecurity updates are included, patches from other repositories are considered as well.

4. Apply **ApprovedPatches** as specified in the patch baseline. The approved patches are approved for update even if they're discarded by **GlobalFilters** or if no approval rule specified in **ApprovalRules** grants it approval.

5. Apply **RejectedPatches** as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.

6. If multiple versions of a patch are approved, the latest version is applied.

7. The YUM update API (on RHEL 7) or the DNF update API (on AlmaLinux 8 and 9, RHEL 8 and 9, and Rocky Linux 8 and 9) is applied to approved patches as follows:

   - For predefined default patch baselines provided by AWS, and for custom patch baselines where the **Include non-security updates** check box is not selected, only patches specified in `updateinfo.xml` are applied (security updates only).

   For RHEL 7, the equivalent yum command for this workflow is:

   ```
sudo yum update-minimal --sec-severity=Critical,Important --bugfix -y
   ```

   For AlmaLinux, RHEL 8, and Rocky Linux, the equivalent dnf commands for this workflow are:

   ```
sudo dnf update-minimal --sec-severity=Critical --bugfix -y ; \
sudo dnf update-minimal --sec-severity=Important --bugfix -y
   ```

   - For custom patch baselines where the **Include non-security updates** check box is selected, both patches in `updateinfo.xml` and those not in `updateinfo.xml` are applied (security and nonsecurity updates).

   For RHEL 7, the equivalent yum command for this workflow is:

   ```
sudo yum update --security --bugfix -y
   ```
For AlmaLinux 8 and 9, RHEL 8 and 9, and Rocky Linux 8 and 9, the equivalent dnf command for this workflow is:

```
sudo dnf update --security --bugfix -y
```

8. The managed node is rebooted if any updates were installed. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

SLES

On SUSE Linux Enterprise Server (SLES) managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the InstallOverrideList parameter for the AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation documents, the listed patches are installed and steps 2-7 are skipped.

2. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.

3. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

   Approval rules, however, are also subject to whether the Include nonsecurity updates check box was selected when creating or last updating a patch baseline.

   If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.

   If nonsecurity updates are included, patches from other repositories are considered as well.

4. Apply ApprovedPatches as specified in the patch baseline. The approved patches are approved for update even if they're discarded by GlobalFilters or if no approval rule specified in ApprovalRules grants it approval.

5. Apply RejectedPatches as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.
6. If multiple versions of a patch are approved, the latest version is applied.

7. The Zypper update API is applied to approved patches.

8. The managed node is rebooted if any updates were installed. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

Ubuntu Server

On Ubuntu Server managed nodes, the patch installation workflow is as follows:

1. If a list of patches is specified using an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL using the InstallOverrideList parameter for the AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation documents, the listed patches are installed and steps 2-7 are skipped.

2. If an update is available for python3-apt (a Python library interface to libapt), it is upgraded to the latest version. (This nonsecurity package is upgraded even if you did not select the Include nonsecurity updates option.)

3. Apply GlobalFilters as specified in the patch baseline, keeping only the qualified packages for further processing.

4. Apply ApprovalRules as specified in the patch baseline. Each approval rule can define a package as approved.

Note

Because it's not possible to reliably determine the release dates of update packages for Ubuntu Server, the auto-approval options aren't supported for this operating system.

Approval rules, however, are also subject to whether the Include nonsecurity updates check box was selected when creating or last updating a patch baseline.

If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo.
If nonsecurity updates are included, patches from other repositories are considered as well. Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

**Note**

For each version of Ubuntu Server, patch candidate versions are limited to patches that are part of the associated repo for that version, as follows:

- Ubuntu Server 14.04 LTS: `trusty-security`
- Ubuntu Server 16.04 LTS: `xenial-security`
- Ubuntu Server 18.04 LTS: `bionic-security`
- Ubuntu Server 20.04 LTS: `focal-security`
- Ubuntu Server 20.10 STR: `groovy-security`
- Ubuntu Server 22.04 LTS: `jammy-security`
- Ubuntu Server 23.04: `lunar-lobster`

5. Apply [ApprovedPatches](#) as specified in the patch baseline. The approved patches are approved for update even if they're discarded by [GlobalFilters](#) or if no approval rule specified in [ApprovalRules](#) grants it approval.

6. Apply [RejectedPatches](#) as specified in the patch baseline. The rejected patches are removed from the list of approved patches and won't be applied.

7. The APT library is used to upgrade packages.

**Note**

Patch Manager does not support using the APT Pin-Priority option to assign priorities to packages. Patch Manager aggregates available updates from all enabled repositories and selects the most recent update that matches the baseline for each installed package.

8. The managed node is rebooted if any updates were installed. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see [Parameter name: RebootOption](#).)
Windows Server

When a patching operation is performed on a Windows Server managed node, the node requests a snapshot of the appropriate patch baseline from Systems Manager. This snapshot contains the list of all updates available in the patch baseline that were approved for deployment. This list of updates is sent to the Windows Update API, which determines which of the updates are applicable to the managed node and installs them as needed. If any updates are installed, the managed node is rebooted afterwards, as many times as necessary to complete all necessary patching. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

The summary of the patching operation can be found in the output of the Run Command request. Additional logs can be found on the managed node in the %PROGRAMDATA%\Amazon\PatchBaselineOperations\Logs folder.

Because the Windows Update API is used to download and install patches, all Group Policy settings for Windows Update are respected. No Group Policy settings are required to use Patch Manager, but any settings that you have defined will be applied, such as to direct managed nodes to a Windows Server Update Services (WSUS) server.

Note

By default, Windows downloads all patches from Microsoft's Windows Update site because Patch Manager uses the Windows Update API to drive the download and installation of patches. As a result, the managed node must be able to reach the Microsoft Windows Update site or patching will fail. Alternatively, you can configure a WSUS server to serve as a patch repository and configure your managed nodes to target that WSUS server using Group Policies.

How patch baseline rules work on Linux-based systems

The rules in a patch baseline for Linux distributions operate differently based on the distribution type. Unlike patch updates on Windows Server managed nodes, rules are evaluated on each node to take the configured repos on the instance into consideration. Patch Manager, a capability of AWS Systems Manager, uses the native package manager to drive the installation of patches approved by the patch baseline.
For Linux-based operating system types that report a severity level for patches, Patch Manager uses the severity level reported by the software publisher for the update notice or individual patch. Patch Manager doesn't derive severity levels from third-party sources, such as the Common Vulnerability Scoring System (CVSS), or from metrics released by the National Vulnerability Database (NVD).

How patch baseline rules work on Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022 and Amazon Linux 2023

On Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022 and Amazon Linux 2023, the patch selection process is as follows:

1. On the managed node, the YUM library (Amazon Linux 1 and, Amazon Linux 2) or the DNF library (Amazon Linux 2022 and Amazon Linux 2023) accesses the updateinfo.xml file for each configured repo.

   ![Note](image)

   If no updateinfo.xml file is found, whether patches are installed depend on settings for Include non-security updates and Auto-approval. For example, if non-security updates are permitted, they're installed when the auto-approval time arrives.

2. Each update notice in updateinfo.xml includes several attributes that denote the properties of the packages in the notice, as described in the following table.
## Update notice attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Corresponds to the value of the Classification key attribute in the patch baseline's PatchFilter data type. Denotes the type of package included in the update notice. You can view the list of supported values by using the AWS CLI command <code>describe-patch-properties</code> or the API operation <code>DescribePatchProperties</code>. You can also view the list in the Approval rules area of the Create patch baseline page or Edit patch baseline page in the Systems Manager console.</td>
</tr>
<tr>
<td>severity</td>
<td>Corresponds to the value of the Severity key attribute in the patch baseline's PatchFilter data type. Denotes the severity of the packages included in the update notice. Usually only applicable for Security update notices. You can view the list of supported values by using the AWS CLI command <code>describe-patch-properties</code> or the API operation <code>DescribePatchProperties</code>. You can also view the list in the Approval rules area of the Create patch baseline page or Edit patch baseline page in the Systems Manager console.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>update_id</td>
<td>Denotes the advisory ID, such as ALAS-2017-867. The advisory ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.</td>
</tr>
<tr>
<td>references</td>
<td>Contains additional information about the update notice, such as a CVE ID (format: CVE-2017-1234567). The CVE ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.</td>
</tr>
<tr>
<td>updated</td>
<td>Corresponds to ApproveAfterDays in the patch baseline. Denotes the released date (updated date) of the packages included in the update notice. A comparison between the current timestamp and the value of this attribute plus the ApproveAfterDays is used to determine if the patch is approved for deployment.</td>
</tr>
</tbody>
</table>

**Note**

For information about accepted formats for lists of approved patches and rejected patches, see About package name formats for approved and rejected patch lists.

3. The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline's PatchFilter data type.

4. Packages are selected for the update according to the following guidelines.

<table>
<thead>
<tr>
<th>Security option</th>
<th>Patch selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-defined default patch baselines provided by AWS and custom patch baselines where updateinf o.xm l, the patch baseline is used as a filter, allowing only the qualified packages to be</td>
<td></td>
</tr>
<tr>
<td>Security option</td>
<td>Patch selection</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------------</td>
</tr>
<tr>
<td>the <strong>Include non-security updates</strong> is <em>not</em> selected</td>
<td>included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used.</td>
</tr>
</tbody>
</table>

For Amazon Linux 1 and Amazon Linux 2, the equivalent yum command for this workflow is:

```bash
sudo yum update-minimal --sec-severity=Critical,Important --bugfix -y
```

For Amazon Linux 2022 and Amazon Linux 2023, the equivalent dnf command for this workflow is:

```bash
sudo dnf upgrade-minimal --sec-severity=Critical --sec-severity=Important --bugfix -y
```
Custom patch baselines where the **Include non-security updates** check box is selected with a SEVERITY list of [Critical, Important] and a CLASSIFICATION list of [Security, Bugfix]

In addition to applying the security updates that were selected from updateinfo.xml, Patch Manager applies nonsecurity updates that otherwise meet the patch filtering rules.

For Amazon Linux and Amazon Linux 2, the equivalent yum command for this workflow is:

```
sudo yum update-minimal --security --sec-severity=Critical,Important --bugfix -y
```

For Amazon Linux 2022 and Amazon Linux 2023, the equivalent dnf command for this workflow is:

```
sudo dnf upgrade-minimal --security --sec-severity=Critical --sec-severity=Important --bugfix -y
```

For information about patch compliance status values, see [Understanding patch compliance state values](#).

### How patch baseline rules work on CentOS and CentOS Stream

The CentOS and CentOS Stream default repositories do not include an updateinfo.xml file. However, custom repositories that you create or use might include this file. In this topic, references to updateinfo.xml apply only to these custom repositories.

On CentOS and CentOS Stream, the patch selection process is as follows:

1. On the managed node, the YUM library (on CentOS 6.x and 7.x versions) or the DNF library (on CentOS 8.x and CentOS Stream) accesses the updateinfo.xml file, if it exists in a custom repository, for each configured repo.
If there is no `updateinfo.xml` found, which always includes the default repos, whether patches are installed depends on settings for **Include non-security updates** and **Auto-approval**. For example, if non-security updates are permitted, they're installed when the auto-approval time arrives.

2. If `updateinfo.xml` is present, each update notice in the file includes several attributes that denote the properties of the packages in the notice, as described in the following table.

**Update notice attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Corresponds to the value of the Classification key attribute in the patch baseline's <code>PatchFilter</code> data type. Denotes the type of package included in the update notice. You can view the list of supported values by using the AWS CLI command <code>describe-patch-properties</code> or the API operation <code>DescribePatchProperties</code>. You can also view the list in the <code>Approval rules</code> area of the Create patch baseline page or Edit patch baseline page in the Systems Manager console.</td>
</tr>
<tr>
<td>severity</td>
<td>Corresponds to the value of the Severity key attribute in the patch baseline's <code>PatchFilter</code> data type. Denotes the severity of the packages included in the update notice. Usually only applicable for <code>Security</code> update notices. You can view the list of supported values by using the AWS CLI command <code>describe-patch-properties</code> or the API operation <code>DescribePatchProperties</code>. You can also view the list in the <code>Approval rules</code> area of the</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Create patch baseline page or Edit patch baseline page in the Systems Manager console.</td>
<td></td>
</tr>
<tr>
<td>update_id</td>
<td>Denotes the advisory ID, such as CVE-2019-17055. The advisory ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.</td>
</tr>
<tr>
<td>references</td>
<td>Contains additional information about the update notice, such as a CVE ID (format: CVE-2019-17055) or a Bugzilla ID (format: 1463241). The CVE ID and Bugzilla ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.</td>
</tr>
<tr>
<td>updated</td>
<td>Corresponds to ApproveAfterDays in the patch baseline. Denotes the released date (updated date) of the packages included in the update notice. A comparison between the current timestamp and the value of this attribute plus the ApproveAfterDays is used to determine if the patch is approved for deployment.</td>
</tr>
</tbody>
</table>

**Note**
For information about accepted formats for lists of approved patches and rejected patches, see About package name formats for approved and rejected patch lists.

3. In all cases, the product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline's PatchFilter data type.

4. Packages are selected for the update according to the following guidelines.
<table>
<thead>
<tr>
<th>Security option</th>
<th>Patch selection</th>
</tr>
</thead>
</table>
| Pre-defined default patch baselines provided by AWS and custom patch baselines where the Include non-security updates is not selected | For each update notice in updateinfo.xml, if it exists in a custom repository, the patch baseline is used as a filter, allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used. For CentOS 6 and 7 where updateinfo.xml is present, the equivalent yum command for this workflow is:  
```
sudo yum update-minimal --sec-severity=Critical,Important --bugfix -y
```
For CentOS 8 and CentOS Stream where updateinfo.xml is present, the equivalent dnf command for this workflow is:  
```
sudo dnf upgrade-minimal --sec-severity=Critical --sec-severity=Important --bugfix -y
```
Custom patch baselines where the **Include non-security updates** check box is selected with a SEVERITY list of [Critical, Important] and a CLASSIFICATION list of [Security, Bugfix] in addition to applying the security updates that were selected from updateinfo.xml, if it exists in a custom repository, Patch Manager applies nonsecurity updates that otherwise meet the patch filtering rules.

For CentOS 6 and 7 where updateinfo.xml is present, the equivalent yum command for this workflow is:

```
sudo yum update --sec-severity=Critical,Important --bugfix -y
```

For CentOS 8 and CentOS Stream where updateinfo.xml is present, the equivalent dnf command for this workflow is:

```
sudo dnf upgrade --security --sec-severity=Critical --sec-severity=Important --bugfix -y
```

For default repos and custom repos without updateinfo.xml, you must select the **Include non-security updates** check box in order to update operating system (OS) packages.

For information about patch compliance status values, see **Understanding patch compliance state values**.

### How patch baseline rules work on Debian Server and Raspberry Pi OS

On Debian Server and Raspberry Pi OS (formerly Raspbian), the patch baseline service offers filtering on the **Priority** and **Section** fields. These fields are typically present for all Debian Server and Raspberry Pi OS packages. To determine whether a patch is selected by the patch baseline, Patch Manager does the following:
1. On Debian Server and Raspberry Pi OS systems, the equivalent of `sudo apt-get update` is run to refresh the list of available packages. Repos aren't configured and the data is pulled from repos configured in a `sources` list.

2. If an update is available for `python3-apt` (a Python library interface to `libapt`), it is upgraded to the latest version. (This nonsecurity package is upgraded even if you did not select the **Include nonsecurity updates** option.)

   **Important**

   On Debian Server 8 only: Because Debian Server 8.* operating systems refer to an obsolete package repository (`jessie-backports`), Patch Manager performs the following additional steps to ensure that patching operations succeed:

   a. On your managed node, the reference to the `jessie-backports` repository is commented out from the source location list (`/etc/apt/sources.list.d/jessie-backports`). As a result, no attempt is made to download patches from that location.

   b. A Stretch security update signing key is imported. This key provides the necessary permissions for the update and install operations on Debian Server 8.* distributions.

   c. The `apt-get` operation is run at this point to ensure that the latest version of `python3-apt` is installed before the patching process begins.

   d. After the installation process is complete, the reference to the `jessie-backports` repository is restored and the signing key is removed from the apt sources keyring. This is done to leave the system configuration as it was before the patching operation.

3. Next, the **GlobalFilters**, **ApprovalRules**, **ApprovedPatches** and **RejectedPatches** lists are applied.

   **Note**

   Because it isn't possible to reliably determine the release dates of update packages for Debian Server, the auto-approval options aren't supported for this operating system.

   Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.
If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo. In this case, for Debian Server, patch candidate versions are limited to patches included in the following repos:

These repos are named as follows:

- Debian Server 8: debian-security jessie
- Debian Server and Raspberry Pi OS 9: debian-security stretch
- Debian Server 10: debian-security buster
- Debian Server 11: debian-security bullseye
- Debian Server 12: debian-security bookworm

If nonsecurity updates are included, patches from other repositories are considered as well.

**Note**
For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

To view the contents of the *Priority* and *Section* fields, run the following `aptitude` command:

![Note]

You might need to first install Aptitude on Debian Server systems.

```
aptitude search -F '%p %P %s %t %V#' '~U'
```

In the response to this command, all upgradable packages are reported in this format:

```
name, priority, section, archive, candidate version
```

For information about patch compliance status values, see [Understanding patch compliance state values](#).
How patch baseline rules work on macOS

On macOS, the patch selection process is as follows:

1. On the managed node, Patch Manager accesses the parsed contents of the InstallHistory.plist file and identifies package names and versions.

   For details about the parsing process, see the macOS section in How patches are installed.

2. The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline’s PatchFilter data type.

3. Packages are selected for the update according to the following guidelines.

<table>
<thead>
<tr>
<th>Security option</th>
<th>Patch selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-defined default patch baselines provided by AWS and custom patch baselines where the <strong>Include non-security updates</strong> is <strong>not</strong> selected</td>
<td>For each available package update, the patch baseline is used as a filter, allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used.</td>
</tr>
<tr>
<td>Custom patch baselines where the <strong>Include non-security updates</strong> is <strong>selected</strong></td>
<td>In addition to applying the security updates that were identified by using InstallHistory.plist, Patch Manager applies nonsecurity updates that otherwise meet the patch filtering rules.</td>
</tr>
</tbody>
</table>

For information about patch compliance status values, see Understanding patch compliance state values.

How patch baseline rules work on Oracle Linux

On Oracle Linux, the patch selection process is as follows:

1. On the managed node, the YUM library accesses the updateinfo.xml file for each configured repo.
Note

The `updateinfo.xml` file might not be available if the repo isn't one managed by Oracle. If there is no `updateinfo.xml` found, whether patches are installed depend on settings for Include non-security updates and Auto-approval. For example, if non-security updates are permitted, they're installed when the auto-approval time arrives.

2. Each update notice in `updateinfo.xml` includes several attributes that denote the properties of the packages in the notice, as described in the following table.

## Update notice attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Corresponds to the value of the Classification key attribute in the patch baseline's <code>PatchFilter</code> data type. Denotes the type of package included in the update notice. You can view the list of supported values by using the AWS CLI command <code>describe-patch-properties</code> or the API operation <code>DescribePatchProperties</code>. You can also view the list in the Approval rules area of the Create patch baseline page or Edit patch baseline page in the Systems Manager console.</td>
</tr>
<tr>
<td>severity</td>
<td>Corresponds to the value of the Severity key attribute in the patch baseline's <code>PatchFilter</code> data type. Denotes the severity of the packages included in the update notice. Usually only applicable for Security update notices. You can view the list of supported values by using the AWS CLI command <code>describe-patch-properties</code> or the API operation <code>DescribePatchProperties</code>.</td>
</tr>
</tbody>
</table>
### Attribute | Description
--- | ---
**DescribePatchProperties.** You can also view the list in the **Approval rules** area of the **Create patch baseline** page or **Edit patch baseline** page in the Systems Manager console.

**update_id** | Denotes the advisory ID, such as **CVE-2019-17055**. The advisory ID can be used in the **ApprovedPatches** or **RejectedPatches** attribute in the patch baseline.

**references** | Contains additional information about the update notice, such as a CVE ID (format: **CVE-2019-17055**) or a Bugzilla ID (format: **1463241**). The CVE ID and Bugzilla ID can be used in the **ApprovedPatches** or **RejectedPatches** attribute in the patch baseline.

**updated** | Corresponds to **ApproveAfterDays** in the patch baseline. Denotes the released date (updated date) of the packages included in the update notice. A comparison between the current timestamp and the value of this attribute plus the **ApproveAfterDays** is used to determine if the patch is approved for deployment.

---

**Note**
For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

3. The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline's **PatchFilter** data type.

4. Packages are selected for the update according to the following guidelines.
<table>
<thead>
<tr>
<th>Security option</th>
<th>Patch selection</th>
<th></th>
</tr>
</thead>
</table>
| Pre-defined default patch baselines provided by AWS and custom patch baselines where the **Include non-security updates** is *not* selected | For each update notice in `updateinfo.xml`, the patch baseline is used as a filter, allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used. For version 7 managed nodes, the equivalent `yum` command for this workflow is:  
  ```bash
  sudo yum update-minimal --sec-severity=Important,Moderate --bugfix -y
  ```  
|                                                                                 |                                                                                                                                                                                                                 |   |
|                                                                                 | For version 8 and 9 managed nodes, the equivalent `dnf` command for this workflow is:  
  ```bash
  sudo dnf upgrade-minimal --security --sec-severity=Moderate --sec-severity=Important
  ```  |   |
### Security option

Custom patch baselines where the **Include non-security updates** is selected with a **SEVERITY** list of [Critical, Important] and a **CLASSIFICATION** list of [Security, Bugfix]

<table>
<thead>
<tr>
<th>Patch selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>In addition to applying the security updates that were selected from updateinfo.xml, Patch Manager applies nonsecurity updates that otherwise meet the patch filtering rules.</td>
</tr>
<tr>
<td>For version 7 managed nodes, the equivalent yum command for this workflow is:</td>
</tr>
<tr>
<td><code>sudo yum update --security --sec-severity=Critical,Important --bugfix -y</code></td>
</tr>
<tr>
<td>For version 8 and 9 managed nodes, the equivalent dnf command for this workflow is:</td>
</tr>
<tr>
<td><code>sudo dnf upgrade --security --sec-severity=Critical, --sec-severity=Important --bugfix y</code></td>
</tr>
</tbody>
</table>

For information about patch compliance status values, see [Understanding patch compliance state values](#).

### How patch baseline rules work on AlmaLinux, RHEL, and Rocky Linux

On AlmaLinux, Red Hat Enterprise Linux (RHEL), and Rocky Linux, the patch selection process is as follows:

1. On the managed node, the YUM library (RHEL 7) or the DNF library (AlmaLinux 8 and 9, RHEL 8 and 9, and Rocky Linux 8 and 9) accesses the `updateinfo.xml` file for each configured repo.

**Note**

The `updateinfo.xml` file might not be available if the repo isn't one managed by Red Hat. If there is no `updateinfo.xml` found, no patch will be applied.
2. Each update notice in `updateinfo.xml` includes several attributes that denote the properties of the packages in the notice, as described in the following table.

### Update notice attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>type</strong></td>
<td>Corresponds to the value of the Classification key attribute in the patch baseline's <code>PatchFilter</code> data type. Denotes the type of package included in the update notice. You can view the list of supported values by using the AWS CLI command <code>describe-patch-properties</code> or the API operation <code>DescribePatchProperties</code>. You can also view the list in the <strong>Approval rules</strong> area of the Create patch baseline page or Edit patch baseline page in the Systems Manager console.</td>
</tr>
<tr>
<td><strong>severity</strong></td>
<td>Corresponds to the value of the Severity key attribute in the patch baseline's <code>PatchFilter</code> data type. Denotes the severity of the packages included in the update notice. Usually only applicable for <strong>Security</strong> update notices. You can view the list of supported values by using the AWS CLI command <code>describe-patch-properties</code> or the API operation <code>DescribePatchProperties</code>. You can also view the list in the <strong>Approval rules</strong> area of the Create patch baseline page or Edit patch baseline page in the Systems Manager console.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>update_id</td>
<td>Denotes the advisory ID, such as RHSA-2017:0864. The advisory ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.</td>
</tr>
<tr>
<td>references</td>
<td>Contains additional information about the update notice, such as a CVE ID (format: CVE-2017-1000371) or a Bugzilla ID (format: 1463241). The CVE ID and Bugzilla ID can be used in the ApprovedPatches or RejectedPatches attribute in the patch baseline.</td>
</tr>
<tr>
<td>updated</td>
<td>Correlates to ApproveAfterDays in the patch baseline. Denotes the released date (updated date) of the packages included in the update notice. A comparison between the current timestamp and the value of this attribute plus the ApproveAfterDays is used to determine if the patch is approved for deployment.</td>
</tr>
</tbody>
</table>

**Note**
For information about accepted formats for lists of approved patches and rejected patches, see About package name formats for approved and rejected patch lists.

3. The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the Product key attribute in the patch baseline's PatchFilter data type.

4. Packages are selected for the update according to the following guidelines.

<table>
<thead>
<tr>
<th>Security option</th>
<th>Patch selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-defined default patch baselines provided by AWS and custom patch baselines where</td>
<td>For each update notice in updateinfo.xml, the patch baseline is used as a filter,</td>
</tr>
<tr>
<td>Security option</td>
<td>Patch selection</td>
</tr>
<tr>
<td>---------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>the <strong>Include non-security updates</strong> check box is <em>not</em> selected in any rule</td>
<td>allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used.</td>
</tr>
</tbody>
</table>

For RHEL 7, the equivalent yum command for this workflow is:

```bash
sudo yum update-minimal --sec-severity=Critical,Important --bugfix -y
```

For AlmaLinux 8 and 9, RHEL 8 and 9, and Rocky Linux 8 and 9, the equivalent dnf command for this workflow is:

```bash
sudo dnf upgrade-minimal --sec-severity=Critical --sec-severity=Important --bugfix -y
```
### Security option

Custom patch baselines where the **Include non-security updates** check box is selected with a SEVERITY list of [Critical, Important] and a CLASSIFICATION list of [Security, Bugfix] cannot include non-security updates that otherwise meet the patch filtering rules.

### Patch selection

In addition to applying the security updates that were selected from updateinfo.xml, Patch Manager applies nonsecurity updates that otherwise meet the patch filtering rules.

For RHEL 7, the equivalent `yum` command for this workflow is:

```
sudo yum update --security --sec-severity=Critical,Important --bugfix -y
```

For AlmaLinux 8 and 9, RHEL 8 and 9, and Rocky Linux 8 and 9, the equivalent `dnf` command for this workflow is:

```
sudo dnf upgrade --sec-severity=Critical --sec-severity=Important --bugfix -y
```

For information about patch compliance status values, see [Understanding patch compliance state values](#).

### How patch baseline rules work on SUSE Linux Enterprise Server

On SLES, each patch includes the following attributes that denote the properties of the packages in the patch:

- **Category**: Corresponds to the value of the **Classification** key attribute in the patch baseline's **PatchFilter** data type. Denotes the type of patch included in the update notice.

You can view the list of supported values by using the AWS CLI command `describe-patch-properties` or the API operation `DescribePatchProperties`. You can also view the list in the **Approval rules** area of the [Create patch baseline](#) page or [Edit patch baseline](#) page in the Systems Manager console.
• **Severity:** Corresponds to the value of the **Severity** key attribute in the patch baseline's PatchFilter data type. Denotes the severity of the patches.

You can view the list of supported values by using the AWS CLI command `describe-patch-properties` or the API operation `DescribePatchProperties`. You can also view the list in the Approval rules area of the Create patch baseline page or Edit patch baseline page in the Systems Manager console.

The product of the managed node is determined by SSM Agent. This attribute corresponds to the value of the **Product** key attribute in the patch baseline's PatchFilter data type.

For each patch, the patch baseline is used as a filter, allowing only the qualified packages to be included in the update. If multiple packages are applicable after applying the patch baseline definition, the latest version is used.

⚠️ **Note**

For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

**How patch baseline rules work on Ubuntu Server**

On Ubuntu Server, the patch baseline service offers filtering on the **Priority** and **Section** fields. These fields are typically present for all Ubuntu Server packages. To determine whether a patch is selected by the patch baseline, Patch Manager does the following:

1. On Ubuntu Server systems, the equivalent of `sudo apt-get update` is run to refresh the list of available packages. Repos aren't configured and the data is pulled from repos configured in a sources list.

2. If an update is available for `python3-apt` (a Python library interface to `libapt`), it is upgraded to the latest version. (This nonsecurity package is upgraded even if you did not select the Include nonsecurity updates option.)

3. Next, the **GlobalFilters**, **ApprovalRules**, **ApprovedPatches** and **RejectedPatches** lists are applied.
Because it's not possible to reliably determine the release dates of update packages for Ubuntu Server, the auto-approval options aren't supported for this operating system.

Approval rules, however, are also subject to whether the **Include nonsecurity updates** check box was selected when creating or last updating a patch baseline.

If nonsecurity updates are excluded, an implicit rule is applied in order to select only packages with upgrades in security repos. For each package, the candidate version of the package (which is typically the latest version) must be part of a security repo. In this case, for Ubuntu Server, patch candidate versions are limited to patches included in the following repos:

- Ubuntu Server 14.04 LTS: trusty-security
- Ubuntu Server 16.04 LTS: xenial-security
- Ubuntu Server 18.04 LTS: bionic-security
- Ubuntu Server 20.04 LTS: focal-security
- Ubuntu Server 20.10 STR: groovy-security
- Ubuntu Server 22.04 LTS (jammy-security)
- Ubuntu Server 23.04 (lunar-security)

If nonsecurity updates are included, patches from other repositories are considered as well.

For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

To view the contents of the **Priority** and **Section** fields, run the following `aptitude` command:

You might need to first install Aptitude on Ubuntu Server 16 systems.
aptitude search -F '%p %P %s %t %V#' '~U'

In the response to this command, all upgradable packages are reported in this format:

name, priority, section, archive, candidate version

For information about patch compliance status values, see Understanding patch compliance state values.

**Key differences between Linux and Windows patching**

This topic describes important differences between Linux and Windows patching in Patch Manager, a capability of AWS Systems Manager.

ℹ️ **Note**

To patch Linux managed nodes, your nodes must be running SSM Agent version 2.0.834.0 or later.

An updated version of SSM Agent is released whenever new capabilities are added to Systems Manager or updates are made to existing capabilities. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager capabilities and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see [Automating updates to SSM Agent](#). Subscribe to the [SSM Agent Release Notes](#) page on GitHub to get notifications about SSM Agent updates.

**Difference 1: Patch evaluation**

**Linux**

For Linux patching, Systems Manager evaluates patch baseline rules and the list of approved and rejected patches on each managed node. Systems Manager must evaluate patching on each node because the service retrieves the list of known patches and updates from the repositories that are configured on the managed node.

**Windows**

Patch Manager uses different processes on Windows managed nodes and Linux managed nodes in order to evaluate which patches should be present. For Windows patching, Systems Manager
evaluates patch baseline rules and the list of approved and rejected patches *directly in the service*. It can do this because Windows patches are pulled from a single repository (Windows Update).

**Difference 2: Not Applicable patches**

Due to the large number of available packages for Linux operating systems, Systems Manager doesn't report details about patches in the *Not Applicable* state. A *Not Applicable* patch is, for example, a patch for Apache software when the instance doesn't have Apache installed. Systems Manager does report the number of *Not Applicable* patches in the summary, but if you call the `DescribeInstancePatches` API for a managed node, the returned data doesn't include patches with a state of *Not Applicable*. This behavior is different from Windows.

**Difference 3: SSM document support**

The `AWS-ApplyPatchBaseline` Systems Manager document (SSM document) doesn't support Linux managed nodes. For applying patch baselines to Linux, macOS, and Windows Server managed nodes, the recommended SSM document is `AWS-RunPatchBaseline`. For more information, see [About SSM documents for patching managed nodes](#) and [About the AWS-RunPatchBaseline SSM document](#).

**Difference 4: Application patches**

The primary focus of Patch Manager is applying patches to operating systems. However, you can also use Patch Manager to apply patches to some applications on your managed nodes.

**Linux**

On Linux operating systems, Patch Manager uses the configured repositories for updates, and doesn't differentiate between operating systems and application patches. You can use Patch Manager to define which repositories to fetch updates from. For more information, see [How to specify an alternative patch source repository (Linux)](#).

**Windows**

On Windows Server managed nodes, you can apply approval rules, as well as *Approved* and *Rejected* patch exceptions, for applications released by Microsoft, such as Microsoft Word 2016 and Microsoft Exchange Server 2016. For more information, see [Working with custom patch baselines](#).
About SSM documents for patching managed nodes

This topic describes the nine Systems Manager documents (SSM documents) available to help you keep your managed nodes patched with the latest security-related updates.

We recommend using just five of these documents in your patching operations. Together, these five SSM documents provide you with a full range of patching options using AWS Systems Manager. Four of these documents were released later than the four legacy SSM documents they replace and represent expansions or consolidations of functionality.

Recommended SSM documents for patching

We recommend using the following five SSM documents in your patching operations.

• AWS-ConfigureWindowsUpdate
• AWS-InstallWindowsUpdates
• AWS-RunPatchBaseline
• AWS-RunPatchBaselineAssociation
• AWS-RunPatchBaselineWithHooks

Legacy SSM documents for patching

The following four legacy SSM documents are still available for use in some AWS Regions but are no longer updated, can't be guaranteed to work in all scenarios, and might no longer be supported in the future. We recommend that you do not use them in your patching operations.

• AWS-ApplyPatchBaseline
• AWS-FindWindowsUpdates
• AWS-InstallMissingWindowsUpdates
• AWS-InstallSpecificWindowsUpdates

Refer to the following sections for more information about using these SSM documents in your patching operations.

Topics

• SSM documents recommended for patching managed nodes
• Legacy SSM documents for patching managed nodes
• About the AWS-RunPatchBaseline SSM document
• About the AWS-RunPatchBaselineAssociation SSM document
• About the AWS-RunPatchBaselineWithHooks SSM document
• Sample scenario for using the InstallOverrideList parameter in AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation
• Using the BaselineOverride parameter

SSM documents recommended for patching managed nodes

The following five SSM documents are recommended for use in your managed node patching operations.

Recommended SSM documents
• AWS-ConfigureWindowsUpdate
• AWS-InstallWindowsUpdates
• AWS-RunPatchBaseline
• AWS-RunPatchBaselineAssociation
• AWS-RunPatchBaselineWithHooks

AWS-ConfigureWindowsUpdate

Supports configuring basic Windows Update functions and using them to install updates automatically (or to turn off automatic updates). Available in all AWS Regions.

This SSM document prompts Windows Update to download and install the specified updates and reboot managed nodes as needed. Use this document with State Manager, a capability of AWS Systems Manager, to ensure Windows Update maintains its configuration. You can also run it manually using Run Command, a capability of AWS Systems Manager, to change the Windows Update configuration.

The available parameters in this document support specifying a category of updates to install (or whether to turn off automatic updates), as well as specifying the day of the week and time of day to run patching operations. This SSM document is most useful if you don’t need strict control over Windows updates and don’t need to collect compliance information.
Replaces legacy SSM documents:

- None

**AWS-InstallWindowsUpdates**

Installs updates on a Windows Server managed node. Available in all AWS Regions.

This SSM document provides basic patching functionality in cases where you either want to install a specific update (using the `Include Kbs` parameter), or want to install patches with specific classifications or categories but don't need patch compliance information.

Replaces legacy SSM documents:

- AWS-FindWindowsUpdates
- AWS-InstallMissingWindowsUpdates
- AWS-InstallSpecificWindowsUpdates

The three legacy documents perform different functions, but you can achieve the same results by using different parameter settings with the newer SSM document `AWS-InstallWindowsUpdates`. These parameter settings are described in Legacy SSM documents for patching managed nodes.

**AWS-RunPatchBaseline**

Installs patches on your managed nodes or scans nodes to determine whether any qualified patches are missing. Available in all AWS Regions.

`AWS-RunPatchBaseline` allows you to control patch approvals using the patch baseline specified as the "default" for an operating system type. Reports patch compliance information that you can view using the Systems Manager Compliance tools. These tools provide you with insights on the patch compliance state of your managed nodes, such as which nodes are missing patches and what those patches are. When you use `AWS-RunPatchBaseline`, patch compliance information is recorded using the `PutInventory` API command. For Linux operating systems, compliance information is provided for patches from both the default source repository configured on a managed node and from any alternative source repositories you specify in a custom patch baseline. For more information about alternative source repositories, see How to specify an alternative patch source repository (Linux). For more information about the Systems Manager Compliance tools, see AWS Systems Manager Compliance.
Replaces legacy documents:

- AWS-ApplyPatchBaseline

The legacy document AWS-ApplyPatchBaseline applies only to Windows Server managed nodes, and doesn’t provide support for application patching. The newer AWS-RunPatchBaseline provides the same support for both Windows and Linux systems. Version 2.0.834.0 or later of SSM Agent is required in order to use the AWS-RunPatchBaseline document.

For more information about the AWS-RunPatchBaseline SSM document, see About the AWS-RunPatchBaseline SSM document.

AWS-RunPatchBaselineAssociation

Installs patches on your instances or scans instances to determine whether any qualified patches are missing. Available in all commercial AWS Regions.

AWS-RunPatchBaselineAssociation differs from AWS-RunPatchBaseline in a few important ways:

- AWS-RunPatchBaselineAssociation is intended for use primarily with State Manager associations created using Quick Setup, a capability of AWS Systems Manager. Specifically, when you use the Quick Setup Host Management configuration type, if you choose the option Scan instances for missing patches daily, the system uses AWS-RunPatchBaselineAssociation for the operation.

In most cases, however, when setting up your own patching operations, you should choose AWS-RunPatchBaseline or AWS-RunPatchBaselineWithHooks instead of AWS-RunPatchBaselineAssociation.

For more information, see the following topics:

- AWS Systems Manager Quick Setup
- About the AWS-RunPatchBaselineAssociation SSM document

AWS-RunPatchBaselineAssociation supports the use of tags to identify which patch baseline to use with a set of targets when it runs.

For patching operations that use AWS-RunPatchBaselineAssociation, patch compliance data is compiled in terms of a specific State Manager association. The patch compliance data collected when AWS-RunPatchBaselineAssociation runs is recorded using the
PutComplianceItems API command instead of the PutInventory command. This prevents compliance data that isn't associated with this particular association from being overwritten.

For Linux operating systems, compliance information is provided for patches from both the default source repository configured on an instance and from any alternative source repositories you specify in a custom patch baseline. For more information about alternative source repositories, see How to specify an alternative patch source repository (Linux).

For more information about the Systems Manager Compliance tools, see AWS Systems Manager Compliance.

Replaces legacy documents:

- None

For more information about the AWS-RunPatchBaselineAssociation SSM document, see About the AWS-RunPatchBaselineAssociation SSM document.

AWS-RunPatchBaselineWithHooks

Installs patches on your managed nodes or scans nodes to determine whether any qualified patches are missing, with optional hooks you can use to run SSM documents at three points during the patching cycle. Available in all commercial AWS Regions.

AWS-RunPatchBaselineWithHooks differs from AWS-RunPatchBaseline in its Install operation.

AWS-RunPatchBaselineWithHooks supports lifecycle hooks that run at designated points during managed node patching. Because patch installations sometimes require managed nodes to reboot, the patching operation is divided into two events, for a total of three hooks that support custom functionality. The first hook is before the Install with NoReboot operation. The second hook is after the Install with NoReboot operation. The third hook is available after the reboot of the node.

Replaces legacy documents:

- None

For more information about the AWS-RunPatchBaselineWithHooks SSM document, see About the AWS-RunPatchBaselineWithHooks SSM document.
Legacy SSM documents for patching managed nodes

The following four SSM documents are still available in some AWS Regions. However, they are no longer updated and might be no longer supported in the future, so we don't recommend their use. Instead, use the documents described in SSM documents recommended for patching managed nodes.

Legacy SSM Documents

- AWS-ApplyPatchBaseline
- AWS-FindWindowsUpdates
- AWS-InstallMissingWindowsUpdates
- AWS-InstallSpecificWindowsUpdates

AWS-ApplyPatchBaseline

Supports only Windows Server managed nodes, but doesn't include support for patching applications that is found in its replacement, AWS-RunPatchBaseline. Not available in AWS Regions launched after August 2017.

Note

The replacement for this SSM document, AWS-RunPatchBaseline, requires version 2.0.834.0 or a later version of SSM Agent. You can use the AWS-UpdateSSMAgent document to update your managed nodes to the latest version of the agent.

AWS-FindWindowsUpdates

Replaced by AWS-InstallWindowsUpdates, which can perform all the same actions. Not available in AWS Regions launched after April 2017.

To achieve the same result that you would from this legacy SSM document, use the following parameter configuration with the recommended replacement document, AWS-InstallWindowsUpdates:

- Action = Scan
- Allow Reboot = False
AWS-InstallMissingWindowsUpdates

Replaced by AWS-InstallWindowsUpdates, which can perform all the same actions. Not available in any AWS Regions launched after April 2017.

To achieve the same result that you would from this legacy SSM document, use the following parameter configuration with the recommended replacement document, AWS-InstallWindowsUpdates:

- Action = Install
- Allow Reboot = True

AWS-InstallSpecificWindowsUpdates

Replaced by AWS-InstallWindowsUpdates, which can perform all the same actions. Not available in any AWS Regions launched after April 2017.

To achieve the same result that you would from this legacy SSM document, use the following parameter configuration with the recommended replacement document, AWS-InstallWindowsUpdates:

- Action = Install
- Allow Reboot = True
- Include Kbs = comma-separated list of KB articles

About the AWS-RunPatchBaseline SSM document

AWS Systems Manager supports AWS-RunPatchBaseline, a Systems Manager document (SSM document) for Patch Manager, a capability of AWS Systems Manager. This SSM document performs patching operations on managed nodes for both security related and other types of updates. When the document is run, it uses the patch baseline specified as the "default" for an operating system type if no patch group is specified. Otherwise, it uses the patch baseline that is associated with the patch group. For information about patch groups, see About patch groups.

You can use the document AWS-RunPatchBaseline to apply patches for both operating systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.)
This document supports Linux, macOS, and Windows Server managed nodes. The document will perform the appropriate actions for each platform.

**Note**

Patch Manager also supports the legacy SSM document `AWS-ApplyPatchBaseline`. However, this document supports patching on Windows managed nodes only. We encourage you to use `AWS-RunPatchBaseline` instead because it supports patching on Linux, macOS, and Windows Server managed nodes. Version 2.0.834.0 or later of SSM Agent is required in order to use the `AWS-RunPatchBaseline` document.

**Windows Server**

On Windows Server managed nodes, the `AWS-RunPatchBaseline` document downloads and invokes a PowerShell module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. This patch baseline snapshot contains a list of approved patches that is compiled by querying the patch baseline against a Windows Server Update Services (WSUS) server. This list is passed to the Windows Update API, which controls downloading and installing the approved patches as appropriate.

**Linux**

On Linux managed nodes, the `AWS-RunPatchBaseline` document invokes a Python module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. This patch baseline snapshot uses the defined rules and lists of approved and blocked patches to drive the appropriate package manager for each node type:

- Amazon Linux 1, Amazon Linux 2, CentOS, Oracle Linux, and RHEL 7 managed nodes use YUM. For YUM operations, Patch Manager requires Python 2.6 or a later supported version (2.6 - 3.10).
- RHEL 8 managed nodes use DNF. For DNF operations, Patch Manager requires a supported version of Python 2 or Python 3 (2.6 - 3.10). (Neither version is installed by default on RHEL 8. You must install one or the other manually.)
- Debian Server, Raspberry Pi OS, and Ubuntu Server instances use APT. For APT operations, Patch Manager requires a supported version of Python 3 (3.0 - 3.10).
- SUSE Linux Enterprise Server managed nodes use Zypper. For Zypper operations, Patch Manager requires Python 2.6 or a later supported version (2.6 - 3.10).
macOS

On macOS managed nodes, the AWS-RunPatchBaseline document invokes a Python module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. Next, a Python subprocess invokes the AWS Command Line Interface (AWS CLI) on the node to retrieve the installation and update information for the specified package managers and to drive the appropriate package manager for each update package.

Each snapshot is specific to an AWS account, patch group, operating system, and snapshot ID. The snapshot is delivered through a presigned Amazon Simple Storage Service (Amazon S3) URL, which expires 24 hours after the snapshot is created. After the URL expires, however, if you want to apply the same snapshot content to other managed nodes, you can generate a new presigned Amazon S3 URL up to 3 days after the snapshot was created. To do this, use the `get-deployable-patch-snapshot-for-instance` command.

After all approved and applicable updates have been installed, with reboots performed as necessary, patch compliance information is generated on a managed node and reported back to Patch Manager.

Note

If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.

For information about viewing patch compliance data, see About patch compliance.

AWS-RunPatchBaseline parameters

AWS-RunPatchBaseline supports five parameters. The Operation parameter is required. The InstallOverrideList, BaselineOverride, and RebootOption parameters are optional. Snapshot-ID is technically optional, but we recommend that you supply a custom value for it when you run AWS-RunPatchBaseline outside of a maintenance window. Patch Manager can supply the custom value automatically when the document is run as part of a maintenance window operation.

Parameters
Parameter name: **Operation**

**Usage**: Required.

**Options**: Scan | Install.

**Scan**

When you choose the Scan option, AWS-RunPatchBaseline determines the patch compliance state of the managed node and reports this information back to Patch Manager. Scan doesn't prompt updates to be installed or managed nodes to be rebooted. Instead, the operation identifies where updates are missing that are approved and applicable to the node.

**Install**

When you choose the Install option, AWS-RunPatchBaseline attempts to install the approved and applicable updates that are missing from the managed node. Patch compliance information generated as part of an Install operation doesn't list any missing updates, but might report updates that are in a failed state if the installation of the update didn't succeed for any reason. Whenever an update is installed on a managed node, the node is rebooted to ensure the update is both installed and active. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaseline document, the managed node isn't rebooted after Patch Manager runs. For more information, see **Parameter name: RebootOption**.)

---

**Note**

If a patch specified by the baseline rules is installed *before* Patch Manager updates the managed node, the system might not reboot as expected. This can happen when a patch is installed manually by a user or installed automatically by another program, such as the unattended-upgrades package on Ubuntu Server.
Parameter name: AssociationId

Usage: Optional.

AssociationId is the ID of an existing association in State Manager, a capability of AWS Systems Manager. It's used by Patch Manager to add compliance data to a specified association. This association is related to a patching operation that's set up in a patch policy in Quick Setup.

Note

With the AWS-RunPatchBaseline, if an AssociationId value is provided along with a patch policy baseline override, patching is done as a PatchPolicy operation and the ExecutionType value reported in AWS:ComplianceItem is also PatchPolicy. If no AssociationId value is provided, patching is done as a Command operation and the ExecutionType value report in on the AWS:ComplianceItem submitted is also Command.

If you don't already have an association you want to use, you can create one by running create-association the command.

Parameter name: Snapshot ID

Usage: Optional.

Snapshot ID is a unique ID (GUID) used by Patch Manager to ensure that a set of managed nodes that are patched in a single operation all have the exact same set of approved patches. Although the parameter is defined as optional, our best practice recommendation depends on whether or not you're running AWS-RunPatchBaseline in a maintenance window, as described in the following table.

AWS-RunPatchBaseline best practices

<table>
<thead>
<tr>
<th>Mode</th>
<th>Best practice</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Running AWS-RunPatchBaseline inside a maintenance window</td>
<td>Don't supply a Snapshot ID. Patch Manager will supply it for you.</td>
<td>If you use a maintenance window to run AWS-RunPatchBaseline, you shouldn't provide your own generated Snapshot ID. In this</td>
</tr>
<tr>
<td>Mode</td>
<td>Best practice</td>
<td>Details</td>
</tr>
<tr>
<td>------</td>
<td>---------------</td>
<td>---------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>scenario, Systems Manager provides a GUID value based on the maintenance window execution ID. This ensures that a correct ID is used for all the invocations of AWS-RunPatchBaseline in that maintenance window. If you do specify a value in this scenario, note that the snapshot of the patch baseline might not remain in place for more than 3 days. After that, a new snapshot will be generated even if you specify the same ID after the snapshot expires.</td>
</tr>

<td>Running AWS-RunPatchBaseline outside of a</td>
<td>Generate and specify a custom GUID value for the Snapshot ID.¹</td>
<td>When you aren't using a maintenance window to run AWS-RunPatchBaseline, we recommend that you generate and specify a unique Snapshot ID for each patch baseline, particularly if you're running the AWS-RunPatchBaseline document on multiple managed nodes in the same operation. If you don't specify an ID in this scenario, Systems Manager generates a different Snapshot ID for each managed node the command is sent to. This might result in varying sets of patches being specified among the managed nodes. For instance, say that you're running the AWS-RunPatchBaseline document directly through Run Command, a capability of AWS Systems Manager, and targeting a group of 50 managed nodes. Specifying a custom Snapshot ID results in the generation of a single baseline snapshot that is used to evaluate and patch all the nodes.</td>
</tr>

<tr>
<td></td>
<td></td>
<td>nodes, ensuring that they end up in a consistent state.</td>
</tr>
</tbody>
</table>

¹ You can use any tool capable of generating a GUID to generate a value for the Snapshot ID parameter. For example, in PowerShell, you can use the `New-Guid` cmdlet to generate a GUID in the format of `12345699-9405-4f69-bc5e-9315aEXAMPLE`.

**Parameter name: InstallOverrideList**

**Usage:** Optional.

Using `InstallOverrideList`, you specify an https URL or an Amazon S3 path-style URL to a list of patches to be installed. This patch installation list, which you maintain in YAML format, overrides the patches specified by the current default patch baseline. This provides you with more granular control over which patches are installed on your managed nodes.

The patching operation behavior when using the `InstallOverrideList` parameter differs between Linux & macOS managed nodes and Windows Server managed nodes. On Linux & macOS, Patch Manager attempts to apply patches included in the `InstallOverrideList` patch list that are present in any repository enabled on the node, whether or not the patches match the patch baseline rules. On Windows Server nodes, however, patches in the `InstallOverrideList` patch list are applied only if they also match the patch baseline rules.

Be aware that compliance reports reflect patch states according to what’s specified in the patch baseline, not what you specify in an `InstallOverrideList` list of patches. In other words, Scan operations ignore the `InstallOverrideList` parameter. This is to ensure that compliance reports consistently reflect patch states according to policy rather than what was approved for a specific patching operation.

For a description of how you might use the `InstallOverrideList` parameter to apply different types of patches to a target group, on different maintenance window schedules, while still using a single patch baseline, see [Sample scenario for using the InstallOverrideList parameter in AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation](#).

**Valid URL formats**
**Note**

If your file is stored in a publicly available bucket, you can specify either an https URL format or an Amazon S3 path-style URL. If your file is stored in a private bucket, you must specify an Amazon S3 path-style URL.

- **https URL format:**
  
  https://s3.aws-api-domain/DOC-EXAMPLE-BUCKET/my-windows-override-list.yaml

- **Amazon S3 path-style URL:**
  
  s3://DOC-EXAMPLE-BUCKET/my-windows-override-list.yaml

### Valid YAML content formats

The formats you use to specify patches in your list depends on the operating system of your managed node. The general format, however, is as follows:

```yaml
patches:
  -
    id: '{patch-d}'
    title: '{patch-title}'
    {additional-fields}:{values}
```

Although you can provide additional fields in your YAML file, they're ignored during patch operations.

In addition, we recommend verifying that the format of your YAML file is valid before adding or updating the list in your S3 bucket. For more information about the YAML format, see [yaml.org](https://yaml.org). For validation tool options, perform a web search for "yaml format validators".

**Linux**

**id**

The `id` field is required. Use it to specify patches using the package name and architecture. For example: 'dhclient.x86_64'. You can use wildcards in id to indicate multiple packages. For example: 'dhcp*' and 'dhcp*1.*'.

---

*About SSM documents for patching managed nodes*
**Title**

The **title** field is optional, but on Linux systems it does provide additional filtering capabilities. If you use **title**, it should contain the package version information in the one of the following formats:

**YUM/SUSE Linux Enterprise Server (SLES):**

```
{name}.{architecture}:{epoch}:{version}-{release}
```

**APT**

```
{name}.{architecture}:{version}
```

For Linux patch titles, you can use one or more wildcards in any position to expand the number of package matches. For example: `'*32:9.8.2-0.*.rc1.57.amzn1'`.

For example:

- apt package version 1.2.25 is currently installed on your managed node, but version 1.2.27 is now available.
- You add apt.amd64 version 1.2.27 to the patch list. It depends on apt utils.amd64 version 1.2.27, but apt-utils.amd64 version 1.2.25 is specified in the list.

In this case, apt version 1.2.27 will be blocked from installation and reported as “Failed-NonCompliant.”

**Windows Server**

**id**

The **id** field is required. Use it to specify patches using Microsoft Knowledge Base IDs (for example, KB2736693) and Microsoft Security Bulletin IDs (for example, MS17-023).

Any other fields you want to provide in a patch list for Windows are optional and are for your own informational use only. You can use additional fields such as **title**, **classification**, **severity**, or anything else for providing more detailed information about the specified patches.

**macOS**

**id**
The **id** field is required. The value for the **id** field can be supplied using either a `{package-name}.{package-version}` format or a `{package_name}` format.

Sample patch lists

- **Amazon Linux**

```json
patches:
  - id: 'kernel.x86_64'
  - id: 'bind*.x86_64'
    title: '32:9.8.2-0.62.rc1.57.amzn1'
  - id: 'glibc*'
    - id: 'dhclient*'
      title: '*12:4.1.1-53.P1.28.amzn1'
    - id: 'dhcp*'
```

- **CentOS**

```json
patches:
  - id: 'kernel.x86_64'
  - id: 'bind*.x86_64'
    title: '32:9.8.2-0.62.rc1.57.amzn1'
  - id: 'glibc*'
    - id: 'dhclient*'
      title: '*12:4.1.1-53.P1.28.amzn1'
    - id: 'dhcp*'
```

- **Debian Server**

```json
patches:
```

  - id: 'KB4338814'

**Parameter name: RebootOption**

**Usage:** Optional.

**Options:** RebootIfNeeded | NoReboot

**Default:** RebootIfNeeded
⚠️ **Warning**

The default option is RebootIfNeeded. Be sure to select the correct option for your use case. For example, if your managed nodes must reboot immediately to complete a configuration process, choose RebootIfNeeded. Or, if you need to maintain managed node availability until a scheduled reboot time, choose NoReboot.

⚠️ **Important**

We don’t recommend using Patch Manager for patching cluster instances in Amazon EMR (previously called Amazon Elastic MapReduce). In particular, don’t select the RebootIfNeeded option for the RebootOption parameter. (This option is available in the SSM Command documents for patching AWS-RunPatchBaseline, AWS-RunPatchBaselineAssociation, and AWS-RunPatchBaselineWithHooks.)

The underlying commands for patching using Patch Manager use `yum` and `dnf` commands. Therefore, the operations result in incompatibilities because of how packages are installed. For information about the preferred methods for updating software on Amazon EMR clusters, see [Using the default AMI for Amazon EMR](https://docs.aws.amazon.com/emr/latest/managementguide/using-default-ami-emr.html) in the *Amazon EMR Management Guide*.

---

**RebootIfNeeded**

When you choose the RebootIfNeeded option, the managed node is rebooted in either of the following cases:

- **Patch Manager installed one or more patches.**
  
  Patch Manager doesn’t evaluate whether a reboot is *required* by the patch. The system is rebooted even if the patch doesn't require a reboot.

- **Patch Manager detects one or more patches with a status of INSTALLED_PENDING_REBOOT during the Install operation.**

  The INSTALLED_PENDING_REBOOT status can mean that the option NoReboot was selected the last time the Install operation was run, or that a patch was installed outside of Patch Manager since the last time the managed node was rebooted.
Rebooting managed nodes in these two cases ensures that updated packages are flushed from memory and keeps patching and rebooting behavior consistent across all operating systems.

NoReboot

When you choose the NoReboot option, Patch Manager doesn't reboot a managed node even if it installed patches during the Install operation. This option is useful if you know that your managed nodes don't require rebooting after patches are applied, or you have applications or processes running on a node that shouldn't be disrupted by a patching operation reboot. It's also useful when you want more control over the timing of managed node reboots, such as by using a maintenance window.

Note

If you choose the NoReboot option and a patch is installed, the patch is assigned a status of InstalledPendingReboot. The managed node itself, however, is marked as Non-Compliant. After a reboot occurs and a Scan operation is run, the managed node status is updated to Compliant.

Patch installation tracking file: To track patch installation, especially patches that were installed since the last system reboot, Systems Manager maintains a file on the managed node.

Important

Don't delete or modify the tracking file. If this file is deleted or corrupted, the patch compliance report for the managed node is inaccurate. If this happens, reboot the node and run a patch Scan operation to restore the file.

This tracking file is stored in the following locations on your managed nodes:

- Linux operating systems:
  - /var/log/amazon/ssm/patch-configuration/patch-states-configuration.json
  - /var/log/amazon/ssm/patch-configuration/patch-inventory-from-last-operation.json
- Windows Server operating system:
Parameter name: BaselineOverride

**Usage:** Optional.

You can define patching preferences at runtime using the BaselineOverride parameter. This baseline override is maintained as a JSON object in an S3 bucket. It ensures patching operations use the provided baselines that match the host operating system instead of applying the rules from the default patch baseline.

For more information about how to use the BaselineOverride parameter, see Using the BaselineOverride parameter.

About the AWS-RunPatchBaselineAssociation SSM document

Like the AWS-RunPatchBaseline document, AWS-RunPatchBaselineAssociation performs patching operations on instances for both security related and other types of updates. You can also use the document AWS-RunPatchBaselineAssociation to apply patches for both operating systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.)

This document supports Amazon Elastic Compute Cloud (Amazon EC2) instances for Linux, macOS, and Windows Server. It does not support non-EC2 nodes in a hybrid and multicloud environment. The document will perform the appropriate actions for each platform, invoking a Python module on Linux and macOS instances, and a PowerShell module on Windows instances.

AWS-RunPatchBaselineAssociation, however, differs from AWS-RunPatchBaseline in the following ways:

- AWS-RunPatchBaselineAssociation is intended for use primarily with State Manager associations created using Quick Setup, a capability of AWS Systems Manager. Specifically, when you use the Quick Setup Host Management configuration type, if you choose the option Scan instances for missing patches daily, the system uses AWS-RunPatchBaselineAssociation for the operation.
In most cases, however, when setting up your own patching operations, you should choose AWS-RunPatchBaseline or AWS-RunPatchBaselineWithHooks instead of AWS-RunPatchBaselineAssociation.

- When you use the AWS-RunPatchBaselineAssociation document, you can specify a tag key pair in the document's BaselineTags parameter field. If a custom patch baseline in your AWS account shares these tags, Patch Manager, a capability of AWS Systems Manager, uses that tagged baseline when it runs on the target instances instead of the currently specified "default" patch baseline for the operating system type.

⚠️ **Important**

If you choose to use AWS-RunPatchBaselineAssociation in patching operations other than those set up using Quick Setup, and you want to use its optional BaselineTags parameter, you must provide some additional permissions to the instance profile for Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information, see Parameter name: BaselineTags.

Both of the following formats are valid for your BaselineTags parameter:

Key=tag-key, Values=tag-value

Key=tag-key, Values=tag-value1, tag-value2, tag-value3

- When AWS-RunPatchBaselineAssociation runs, the patch compliance data it collects is recorded using the PutComplianceItems API command instead of the PutInventory command, which is used by AWS-RunPatchBaseline. This difference means that the patch compliance information that is stored and reported per a specific association. Patch compliance data generated outside of this association isn't overwritten.

- The patch compliance information reported after running AWS-RunPatchBaselineAssociation indicates whether or not an instance is in compliance. It doesn't include patch-level details, as demonstrated by the output of the following AWS Command Line Interface (AWS CLI) command. The command filters on Association as the compliance type:

```
aws ssm list-compliance-items \
  --resource-ids "i-02573cafcfEXAMPLE"
```
The system returns information like the following.

```json
{
  "ComplianceItems": [
    {
      "Status": "NON_COMPLIANT",
      "Severity": "UNSPECIFIED",
      "Title": "MyPatchAssociation",
      "ResourceType": "ManagedInstance",
      "ResourceId": "i-02573cafcfEXAMPLE",
      "ComplianceType": "Association",
      "Details": {
        "DocumentName": "AWS-RunPatchBaselineAssociation",
        "PatchBaselineId": "pb-0c10e65780EXAMPLE",
        "DocumentVersion": "1"
      },
      "ExecutionSummary": {
        "ExecutionTime": 1590698771.0
      },
      "Id": "3e5d5694-cd07-40f0-bbea-040e6EXAMPLE"
    }
  ]
}
```

If a tag key pair value has been specified as a parameter for the `AWS-RunPatchBaselineAssociation` document, Patch Manager searches for a custom patch baseline that matches the operating system type and has been tagged with that same tag-key pair. This search isn't limited to the current specified default patch baseline or the baseline assigned to a patch group. If no baseline is found with the specified tags, Patch Manager next looks for a patch group, if one was specified in the command that runs `AWS-RunPatchBaselineAssociation`. If no patch group is matched, Patch Manager falls back to the current default patch baseline for the operating system account.

If more than one patch baseline is found with the tags specified in the `AWS-RunPatchBaselineAssociation` document, Patch Manager returns an error message indicating
that only one patch baseline can be tagged with that key-value pair in order for the operation to proceed.

**Note**

On Linux instances, the appropriate package manager for each instance type is used to install packages:

- Amazon Linux 1, Amazon Linux 2, CentOS, Oracle Linux, and RHEL instances use YUM. For YUM operations, Patch Manager requires Python 2.6 or a later supported version (2.6 - 3.10).
- Debian Server, Raspberry Pi OS, and Ubuntu Server instances use APT. For APT operations, Patch Manager requires a supported version of Python 3 (3.0 - 3.10).
- SUSE Linux Enterprise Server instances use Zypper. For Zypper operations, Patch Manager requires Python 2.6 or a later supported version (2.6 - 3.10).

After a scan is complete, or after all approved and applicable updates have been installed, with reboots performed as necessary, patch compliance information is generated on an instance and reported back to the Patch Compliance service.

**Note**

If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaselineAssociation document, the instance isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.

For information about viewing patch compliance data, see About patch compliance.

**AWS-RunPatchBaselineAssociation parameters**

AWS-RunPatchBaselineAssociation supports four parameters. The Operation and AssociationId parameters are required. The InstallOverrideList, RebootOption, and BaselineTags parameters are optional.

**Parameters**

- Parameter name: Operation
Parameter name: BaselineTags

Parameter name: AssociationId

Parameter name: InstallOverrideList

Parameter name: RebootOption

**Parameter name: Operation**

**Usage:** Required.

**Options:** Scan | Install.

**Scan**

When you choose the Scan option, AWS-RunPatchBaselineAssociation determines the patch compliance state of the instance and reports this information back to Patch Manager. Scan doesn't prompt updates to be installed or instances to be rebooted. Instead, the operation identifies where updates are missing that are approved and applicable to the instance.

**Install**

When you choose the Install option, AWS-RunPatchBaselineAssociation attempts to install the approved and applicable updates that are missing from the instance. Patch compliance information generated as part of an Install operation doesn't list any missing updates, but might report updates that are in a failed state if the installation of the update didn't succeed for any reason. Whenever an update is installed on an instance, the instance is rebooted to ensure the update is both installed and active. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaselineAssociation document, the instance isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

**Note**

If a patch specified by the baseline rules is installed before Patch Manager updates the instance, the system might not reboot as expected. This can happen when a patch is installed manually by a user or installed automatically by another program, such as the unattended-upgrades package on Ubuntu Server.
Parameter name: BaselineTags

Usage: Optional.

BaselineTags is a unique tag key-value pair that you choose and assign to an individual custom patch baseline. You can specify one or more values for this parameter. Both of the following formats are valid:

Key=tag-key, Values=tag-value

Key=tag-key, Values=tag-value1, tag-value2, tag-value3

The BaselineTags value is used by Patch Manager to ensure that a set of instances that are patched in a single operation all have the exact same set of approved patches. When the patching operation runs, Patch Manager checks to see if a patch baseline for the operating system type is tagged with the same key-value pair you specify for BaselineTags. If there is a match, this custom patch baseline is used. If there isn't a match, a patch baseline is identified according to any patch group specified for the patching operating. If there is none, the AWS managed predefined patch baseline for that operating system is used.

Additional permission requirements

If you use AWS-RunPatchBaselineAssociation in patching operations other than those set up using Quick Setup, and you want to use the optional BaselineTags parameter, you must add the following permissions to the instance profile for Amazon Elastic Compute Cloud (Amazon EC2) instances.

```
{
  "Effect": "Allow",
  "Action": [
    "ssm:DescribePatchBaselines",
    "tag:GetResources"
  ],
  "Resource": "*"
},
```

About SSM documents for patching managed nodes

Quick Setup and AWS-RunPatchBaselineAssociation don't support on-premises servers and virtual machines (VMs).
```
{
    "Effect": "Allow",
    "Action": [
        "ssm:GetPatchBaseline",
        "ssm:DescribeEffectivePatchesForPatchBaseline"
    ],
    "Resource": "patch-baseline-arn"
}
```

Replace `patch-baseline-arn` with the Amazon Resource Name (ARN) of the patch baseline to which you want to provide access, in the format `arn:aws:ssm:us-east-2:123456789012:patchbaseline/pb-0c10e65780EXAMPLE`.

**Parameter name: AssociationId**

**Usage:** Required.

AssociationId is the ID of an existing association in State Manager, a capability of AWS Systems Manager. It's used by Patch Manager to add compliance data to a specified association. This association is related to a patch Scan operation enabled in a Host Management configuration created in Quick Setup. By sending patching results as association compliance data instead of inventory compliance data, existing inventory compliance information for your instances isn't overwritten after a patching operation, nor for other association IDs. If you don't already have an association you want to use, you can create one by running `create-association` the command. For example:

**Linux & macOS**

```
aws ssm create-association \
    --name "AWS-RunPatchBaselineAssociation" \
    --association-name "MyPatchHostConfigAssociation" \
    --targets "Key=instanceids,Values=[i-02573cafcfEXAMPLE,i-07782c72faEXAMPLE,i-07782c72faEXAMPLE]"
    --parameters "Operation=Scan" \
    --schedule-expression "cron(0 */30 * * * ? *)" \
    --sync-compliance "MANUAL" \
    --region us-east-2
```

**Windows Server**

```
aws ssm create-association ^
```
Parameter name: InstallOverrideList

Usage: Optional.

Using InstallOverrideList, you specify an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL to a list of patches to be installed. This patch installation list, which you maintain in YAML format, overrides the patches specified by the current default patch baseline. This provides you with more granular control over which patches are installed on your instances.

The patching operation behavior when using the InstallOverrideList parameter differs between Linux & macOS managed nodes and Windows Server managed nodes. On Linux & macOS, Patch Manager attempts to apply patches included in the InstallOverrideList patch list that are present in any repository enabled on the node, whether or not the patches match the patch baseline rules. On Windows Server nodes, however, patches in the InstallOverrideList patch list are applied only if they also match the patch baseline rules.

Be aware that compliance reports reflect patch states according to what's specified in the patch baseline, not what you specify in an InstallOverrideList list of patches. In other words, Scan operations ignore the InstallOverrideList parameter. This is to ensure that compliance reports consistently reflect patch states according to policy rather than what was approved for a specific patching operation.

Valid URL formats

ℹ️ Note

If your file is stored in a publicly available bucket, you can specify either an https URL format or an Amazon S3 path-style URL. If your file is stored in a private bucket, you must specify an Amazon S3 path-style URL.
Valid YAML content formats

The formats you use to specify patches in your list depends on the operating system of your instance. The general format, however, is as follows:

```
patches:
  -
    id: '{patch-d}'
    title: '{patch-title}'
    {additional-fields}:{values}
```

Although you can provide additional fields in your YAML file, they're ignored during patch operations.

In addition, we recommend verifying that the format of your YAML file is valid before adding or updating the list in your S3 bucket. For more information about the YAML format, see [yaml.org](http://yaml.org). For validation tool options, perform a web search for "yaml format validators".

- **Microsoft Windows**

  **id**

  The **id** field is required. Use it to specify patches using Microsoft Knowledge Base IDs (for example, KB2736693) and Microsoft Security Bulletin IDs (for example, MS17-023).

  Any other fields you want to provide in a patch list for Windows are optional and are for your own informational use only. You can use additional fields such as **title**, **classification**, **severity**, or anything else for providing more detailed information about the specified patches.

- **Linux**

  **id**
The **id** field is required. Use it to specify patches using the package name and architecture. For example: 'dhclient.x86_64'. You can use wildcards in id to indicate multiple packages. For example: 'dhcp*' and 'dhcp*1.*'.

**title**

The **title** field is optional, but on Linux systems it does provide additional filtering capabilities. If you use **title**, it should contain the package version information in the one of the following formats:

YUM/SUSE Linux Enterprise Server (SLES):

```
{name}.{architecture}:{epoch}:{version}-{release}
```

**APT**

```
{name}.{architecture}:{version}
```

For Linux patch titles, you can use one or more wildcards in any position to expand the number of package matches. For example: '*32:9.8.2-*rc1.57.amzn1'.

For example:

- apt package version 1.2.25 is currently installed on your instance, but version 1.2.27 is now available.
- You add apt.amd64 version 1.2.27 to the patch list. It depends on apt-utils.amd64 version 1.2.27, but apt-utils.amd64 version 1.2.25 is specified in the list.

In this case, apt version 1.2.27 will be blocked from installation and reported as “Failed-NonCompliant.”

**Other fields**

Any other fields you want to provide in a patch list for Linux are optional and are for your own informational use only. You can use additional fields such as **classification**, **severity**, or anything else for providing more detailed information about the specified patches.

**Sample patch lists**
• **Windows**

```json
patches:
  - id: 'KB4284819'
    title: '2018-06 Cumulative Update for Windows Server 2016 (1709) for x64-based Systems (KB4284819)'
  - id: 'KB4284833'
  - id: 'KB4284835'
    title: '2018-06 Cumulative Update for Windows Server 2016 (1803) for x64-based Systems (KB4284835)'
  - id: 'KB4284880'
  - id: 'KB4338814'
```

• **APT**

```json
patches:
  - id: 'apparmor.amd64'
    title: '2.10.95-0ubuntu2.9'
  - id: 'cryptsetup.amd64'
    title: '*2:1.6.6-5ubuntu2.1'
  - id: 'cryptsetup-bin.*'
    title: '*2:1.6.6-5ubuntu2.1'
  - id: 'apt.amd64'
    title: '*1.2.27'
  - id: 'apt-utils.amd64'
    title: '*1.2.25'
```

• **Amazon Linux**

  - id: 'KB4338814'
Parameter name: RebootOption

Usage: Optional.

Options: RebootIfNeeded | NoReboot

Default: RebootIf Needed

⚠️ Warning

The default option is RebootIfNeeded. Be sure to select the correct option for your use case. For example, if your instances must reboot immediately to complete a configuration process, choose RebootIfNeeded. Or, if you need to maintain instances availability until a scheduled reboot time, choose NoReboot.

⚠️ Important

We don’t recommend using Patch Manager for patching cluster instances in Amazon EMR (previously called Amazon Elastic MapReduce). In particular, don’t select the RebootIfNeeded option for the RebootOption parameter. (This option is available in the SSM Command documents for patching AWS-RunPatchBaseline, AWS-RunPatchBaselineAssociation, and AWS-RunPatchBaselineWithHooks.) The underlying commands for patching using Patch Manager use yum and dnf commands. Therefore, the operations result in incompatibilities because of how packages are installed. For information about the preferred methods for updating software on Amazon EMR clusters, see Using the default AMI for Amazon EMR in the Amazon EMR Management Guide.

RebootIfNeeded

When you choose the RebootIfNeeded option, the instance is rebooted in either of the following cases:

- Patch Manager installed one or more patches.

Patch Manager doesn't evaluate whether a reboot is required by the patch. The system is rebooted even if the patch doesn't require a reboot.
Patch Manager detects one or more patches with a status of INSTALLED_PENDING_REBOOT during the Install operation.

The INSTALLED_PENDING_REBOOT status can mean that the option NoReboot was selected the last time the Install operation was run, or that a patch was installed outside of Patch Manager since the last time the managed node was rebooted.

Rebooting instances in these two cases ensures that updated packages are flushed from memory and keeps patching and rebooting behavior consistent across all operating systems.

NoReboot

When you choose the NoReboot option, Patch Manager doesn't reboot an instance even if it installed patches during the Install operation. This option is useful if you know that your instances don't require rebooting after patches are applied, or you have applications or processes running on an instance that shouldn't be disrupted by a patching operation reboot. It's also useful when you want more control over the timing of instance reboots, such as by using a maintenance window.

**Patch installation tracking file:** To track patch installation, especially patches that have been installed since the last system reboot, Systems Manager maintains a file on the managed instance.

**Important**

Don't delete or modify the tracking file. If this file is deleted or corrupted, the patch compliance report for the instance is inaccurate. If this happens, reboot the instance and run a patch Scan operation to restore the file.

This tracking file is stored in the following locations on your managed instances:

- **Linux operating systems:**
  - `/var/log/amazon/ssm/patch-configuration/patch-states-configuration.json`
  - `/var/log/amazon/ssm/patch-configuration/patch-inventory-from-last-operation.json`

- **Windows Server operating system:**
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchStatesConfiguration.json`
AWS Systems Manager supports AWS-RunPatchBaselineWithHooks, a Systems Manager document (SSM document) for Patch Manager, a capability of AWS Systems Manager. This SSM document performs patching operations on managed nodes for both security related and other types of updates.

AWS-RunPatchBaselineWithHooks differs from AWS-RunPatchBaseline in the following ways:

- **A wrapper document** – AWS-RunPatchBaselineWithHooks is a wrapper for AWS-RunPatchBaseline and relies on AWS-RunPatchBaseline for some of its operations.

- **The Install operation** – AWS-RunPatchBaselineWithHooks supports lifecycle hooks that run at designated points during managed node patching. Because patch installations sometimes require managed nodes to reboot, the patching operation is divided into two events, for a total of three hooks that support custom functionality. The first hook is before the Install with NoReboot operation. The second hook is after the Install with NoReboot operation. The third hook is available after the reboot of the managed node.

- **No custom patch list support** – AWS-RunPatchBaselineWithHooks doesn't support the InstallOverrideList parameter.

- **SSM Agent support** – AWS-RunPatchBaselineWithHooks requires that SSM Agent 3.0.502 or later be installed on the managed node to patch.

When the document is run, it uses the patch baseline currently specified as the "default" for an operating system type if no patch group is specified. Otherwise, it uses the patch baselines that is associated with the patch group. For information about patch groups, see [About patch groups](#).

You can use the document AWS-RunPatchBaselineWithHooks to apply patches for both operating systems and applications. (On Windows, application support is limited to updates for applications released by Microsoft.)

This document supports Linux, macOS, and Windows Server managed nodes. The document will perform the appropriate actions for each platform.
Linux

On Linux managed nodes, the AWS-RunPatchBaselineWithHooks document invokes a Python module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. This patch baseline snapshot uses the defined rules and lists of approved and blocked patches to drive the appropriate package manager for each node type:

- Amazon Linux 1, Amazon Linux 2, CentOS, Oracle Linux, and RHEL 7 managed nodes use YUM. For YUM operations, Patch Manager requires Python 2.6 or a later supported version (2.6 - 3.10).
- RHEL 8 managed nodes use DNF. For DNF operations, Patch Manager requires a supported version of Python 2 or Python 3 (2.6 - 3.10). (Neither version is installed by default on RHEL 8. You must install one or the other manually.)
- Debian Server, Raspberry Pi OS, and Ubuntu Server instances use APT. For APT operations, Patch Manager requires a supported version of Python 3 (3.0 - 3.10).
- SUSE Linux Enterprise Server managed nodes use Zypper. For Zypper operations, Patch Manager requires Python 2.6 or a later supported version (2.6 - 3.10).

macOS

On macOS managed nodes, the AWS-RunPatchBaselineWithHooks document invokes a Python module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. Next, a Python subprocess invokes the CLI on the node to retrieve the installation and update information for the specified package managers and to drive the appropriate package manager for each update package.

Windows Server

On Windows Server managed nodes, the AWS-RunPatchBaselineWithHooks document downloads and invokes a PowerShell module, which in turn downloads a snapshot of the patch baseline that applies to the managed node. This patch baseline snapshot contains a list of approved patches that is compiled by querying the patch baseline against a Windows Server Update Services (WSUS) server. This list is passed to the Windows Update API, which controls downloading and installing the approved patches as appropriate.

Each snapshot is specific to an AWS account, patch group, operating system, and snapshot ID. The snapshot is delivered through a presigned Amazon Simple Storage Service (Amazon S3) URL, which expires 24 hours after the snapshot is created. After the URL expires, however, if you want to apply
the same snapshot content to other managed nodes, you can generate a new presigned Amazon S3 URL up to three days after the snapshot was created. To do this, use the `get-deployable-patch-snapshot-for-instance` command.

After all approved and applicable updates have been installed, with reboots performed as necessary, patch compliance information is generated on an managed node and reported back to Patch Manager.

### Note

If the `RebootOption` parameter is set to `NoReboot` in the AWS-RunPatchBaselineWithHooks document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.

For information about viewing patch compliance data, see About patch compliance.

**AWS-RunPatchBaselineWithHooks operational steps**

When the AWS-RunPatchBaselineWithHooks runs, the following steps are performed:

1. **Scan** - A Scan operation using AWS-RunPatchBaseline is run on the managed node, and a compliance report is generated and uploaded.

2. **Verify local patch states** - A script is run to determine what steps will be performed based on the selected operation and Scan result from Step 1.
   a. If the selected operation is `Scan`, the operation is marked complete. The operation concludes.
   b. If the selected operation is `Install`, Patch Manager evaluates the Scan result from Step 1 to determine what to run next:
      i. If no missing patches are detected, and no pending reboots required, the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped.
      ii. If no missing patches are detected, but there are pending reboots required and the selected reboot option is `NoReboot`, the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped.
      iii. Otherwise, the operation proceeds to the next step.

3. **Pre-patch hook operation** - The SSM document you have provided for the first lifecycle hook, PreInstallHookDocName, is run on the managed node.
4. **Install with NoReboot** - An Install operation with the reboot option of NoReboot using AWS-RunPatchBaseline is run on the managed node, and a compliance report is generated and uploaded.

5. **Post-install hook operation** - The SSM document you have provided for the second lifecycle hook, PostInstallHookDocName, is run on the managed node.

6. **Verify reboot** - A script runs to determine whether a reboot is needed for the managed node and what steps to run:
   
a. If the selected reboot option is NoReboot, the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped.
   
b. If the selected reboot option is RebootIfNeeded, Patch Manager checks whether there are any pending reboots required from the inventory collected in Step 4. This means that the operation continues to Step 7 and the managed node is rebooted in either of the following cases:
      
i. Patch Manager installed one or more patches. (Patch Manager doesn't evaluate whether a reboot is required by the patch. The system is rebooted even if the patch doesn't require a reboot.)
      
ii. Patch Manager detects one or more patches with a status of INSTALLED_PENDING_REBOOT during the Install operation. The INSTALLED_PENDING_REBOOT status can mean that the option NoReboot was selected the last time the Install operation was run, or that a patch was installed outside of Patch Manager since the last time the managed node was rebooted.

   If no patches meeting these criteria are found, the managed node patching operation is complete, and the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped.

7. **Reboot and report** - An installation operation with the reboot option of RebootIfNeeded runs on the managed node using AWS-RunPatchBaseline, and a compliance report is generated and uploaded.

8. **Post-reboot hook operation** - The SSM document you have provided for the third lifecycle hook, OnExitHookDocName, is run on the managed node.

For a Scan operation, if Step 1 fails, the process of running the document stops and the step is reported as failed, although subsequent steps are reported as successful.
For an Install operation, if any of the aws:runDocument steps fail during the operation, those steps are reported as failed, and the operation proceeds directly to the final step (Step 8), which includes a hook you have provided. Any steps in between are skipped. This step is reported as failed, the last step reports the status of its operation result, and all steps in between are reported as successful.

**AWS-RunPatchBaselineWithHooks parameters**

AWS-RunPatchBaselineWithHooks supports six parameters.

The Operation parameter is required.

The RebootOption, PreInstallHookDocName, PostInstallHookDocName, and OnExitHookDocName parameters are optional.

Snapshot-ID is technically optional, but we recommend that you supply a custom value for it when you run AWS-RunPatchBaselineWithHooks outside of a maintenance window. Let Patch Manager supply the value automatically when the document is run as part of a maintenance window operation.

**Parameters**

- **Parameter name: Operation**
- **Parameter name: Snapshot ID**
- **Parameter name: RebootOption**
- **Parameter name: PreInstallHookDocName**
- **Parameter name: PostInstallHookDocName**
- **Parameter name: OnExitHookDocName**

**Parameter name: Operation**

**Usage:** Required.

**Options:** Scan | Install.

**Scan**

When you choose the Scan option, the systems uses the AWS-RunPatchBaseline document to determine the patch compliance state of the managed node and reports this information back to Patch Manager. Scan doesn't prompt updates to be installed or managed nodes to be
rebooted. Instead, the operation identifies where updates are missing that are approved and applicable to the node.

Install

When you choose the Install option, AWS-RunPatchBaselineWithHooks attempts to install the approved and applicable updates that are missing from the managed node. Patch compliance information generated as part of an Install operation doesn't list any missing updates, but might report updates that are in a failed state if the installation of the update didn't succeed for any reason. Whenever an update is installed on a managed node, the node is rebooted to ensure the update is both installed and active. (Exception: If the RebootOption parameter is set to NoReboot in the AWS-RunPatchBaselineWithHooks document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: RebootOption.)

Note

If a patch specified by the baseline rules is installed before Patch Manager updates the managed node, the system might not reboot as expected. This can happen when a patch is installed manually by a user or installed automatically by another program, such as the unattended-upgrades package on Ubuntu Server.

Parameter name: Snapshot ID

Usage: Optional.

Snapshot ID is a unique ID (GUID) used by Patch Manager to ensure that a set of managed nodes that are patched in a single operation all have the exact same set of approved patches. Although the parameter is defined as optional, our best practice recommendation depends on whether or not you're running AWS-RunPatchBaselineWithHooks in a maintenance window, as described in the following table.

AWS-RunPatchBaselineWithHooks best practices

<table>
<thead>
<tr>
<th>Mode</th>
<th>Best practice</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Running AWS-RunPatchBaselineWithHooks</td>
<td>Don't supply a Snapshot ID. Patch Manager will supply it for you.</td>
<td>If you use a maintenance window to run AWS-RunPatchBaselineWithHooks</td>
</tr>
</tbody>
</table>
### Mode | Best practice | Details
--- | --- | ---
``inside a maintenance window`` | | `ks`, you shouldn't provide your own generated Snapshot ID. In this scenario, Systems Manager provides a GUID value based on the maintenance window execution ID. This ensures that a correct ID is used for all the invocations of `AWS-RunPatchBaselineWithHooks` in that maintenance window.

If you do specify a value in this scenario, note that the snapshot of the patch baseline might not remain in place for more than 3 days. After that, a new snapshot will be generated even if you specify the same ID after the snapshot expires.
<table>
<thead>
<tr>
<th>Mode</th>
<th>Best practice</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Running AWS-RunPatchBaselineWithHooks outside of a maintenance window</td>
<td>Generate and specify a custom GUID value for the Snapshot ID.¹</td>
<td>When you aren't using a maintenance window to run AWS-RunPatchBaselineWithHooks, we recommend that you generate and specify a unique Snapshot ID for each patch baseline, particularly if you're running the AWS-RunPatchBaselineWithHooks document on multiple managed nodes in the same operation. If you don't specify an ID in this scenario, Systems Manager generates a different Snapshot ID for each managed node the command is sent to. This might result in varying sets of patches being specified among the nodes. For instance, say that you're running the AWS-RunPatchBaselineWithHooks document directly through Run Command, a capability of AWS Systems Manager, and targeting a group of 50 managed nodes. Specifying a custom Snapshot ID results in the generation of a single baseline snapshot that is used to evaluate and patch all the managed nodes,</td>
</tr>
</tbody>
</table>
You can use any tool capable of generating a GUID to generate a value for the Snapshot ID parameter. For example, in PowerShell, you can use the `New-Guid` cmdlet to generate a GUID in the format of `12345699-9405-4f69-bc5e-9315aEXAMPLE`.

### Parameter name: RebootOption

**Usage:** Optional.

**Options:** RebootIfNeeded | NoReboot

**Default:** RebootIfNeeded

⚠️ **Warning**

The default option is RebootIfNeeded. Be sure to select the correct option for your use case. For example, if your managed nodes must reboot immediately to complete a configuration process, choose RebootIfNeeded. Or, if you need to maintain managed node availability until a scheduled reboot time, choose NoReboot.

⚠️ **Important**

We don't recommend using Patch Manager for patching cluster instances in Amazon EMR (previously called Amazon Elastic MapReduce). In particular, don't select the RebootIfNeeded option for the RebootOption parameter. (This option is available in the SSM Command documents for patching AWS-RunPatchBaseline, AWS-RunPatchBaselineAssociation, and AWS-RunPatchBaselineWithHooks.) The underlying commands for patching using Patch Manager use `yum` and `dnf` commands. Therefore, the operations result in incompatibilities because of how packages are installed. For information about the preferred methods for updating software on Amazon EMR clusters, see [Using the default AMI for Amazon EMR](#) in the *Amazon EMR Management Guide*. 

About SSM documents for patching managed nodes
RebootIfNeeded

When you choose the `RebootIfNeeded` option, the managed node is rebooted in either of the following cases:

- Patch Manager installed one or more patches.

  Patch Manager doesn't evaluate whether a reboot is *required* by the patch. The system is rebooted even if the patch doesn't require a reboot.

- Patch Manager detects one or more patches with a status of `INSTALLED_PENDING_REBOOT` during the `Install` operation.

  The `INSTALLED_PENDING_REBOOT` status can mean that the option `NoReboot` was selected the last time the `Install` operation was run, or that a patch was installed outside of Patch Manager since the last time the managed node was rebooted.

Rebooting managed nodes in these two cases ensures that updated packages are flushed from memory and keeps patching and rebooting behavior consistent across all operating systems.

NoReboot

When you choose the `NoReboot` option, Patch Manager doesn't reboot a managed node even if it installed patches during the `Install` operation. This option is useful if you know that your managed nodes don't require rebooting after patches are applied, or you have applications or processes running on a node that shouldn't be disrupted by a patching operation reboot. It's also useful when you want more control over the timing of managed node reboots, such as by using a maintenance window.

**Note**

If you choose the `NoReboot` option and a patch is installed, the patch is assigned a status of `InstalledPendingReboot`. The managed node itself, however, is marked as `Non-Compliant`. After a reboot occurs and a `Scan` operation is run, the node status is updated to `Compliant`.

**Patch installation tracking file:** To track patch installation, especially patches that were installed since the last system reboot, Systems Manager maintains a file on the managed node.
**Important**

Don't delete or modify the tracking file. If this file is deleted or corrupted, the patch compliance report for the managed node is inaccurate. If this happens, reboot the node and run a patch Scan operation to restore the file.

This tracking file is stored in the following locations on your managed nodes:

- **Linux operating systems:**
  - `/var/log/amazon/ssm/patch-configuration/patch-states-configuration.json`
  - `/var/log/amazon/ssm/patch-configuration/patch-inventory-from-last-operation.json`

- **Windows Server operating system:**
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchStatesConfiguration.json`
  - `C:\ProgramData\Amazon\PatchBaselineOperations\State\PatchInventoryFromLastOperation.json`

**Parameter name:** PreInstallHookDocName

**Usage:** Optional.

**Default:** AWS-Noop.

The value to provide for the PreInstallHookDocName parameter is the name or Amazon Resource Name (ARN) of an SSM document of your choice. You can provide the name of an AWS managed document or the name or ARN of a custom SSM document that you have created or that has been shared with you. (For an SSM document that has been shared with you from a different AWS account, you must specify the full resource ARN, such as `arn:aws:ssm:us-east-2:123456789012:document/MySharedDocument`.)

The SSM document you specify is run before the Install operation and performs any actions supported by SSM Agent, such as a shell script to check application health check before patching is performed on the managed node. (For a list of actions, see [Command document plugin reference](#)). The default SSM document name is AWS-Noop, which doesn't perform any operation on the managed node.
For information about creating a custom SSM document, see Creating SSM document content.

**Parameter name: PostInstallHookDocName**

**Usage:** Optional.

**Default:** AWS-Noop.

The value to provide for the PostInstallHookDocName parameter is the name or Amazon Resource Name (ARN) of an SSM document of your choice. You can provide the name of an AWS managed document or the name or ARN of a custom SSM document that you have created or that has been shared with you. (For an SSM document that has been shared with you from a different AWS account, you must specify the full resource ARN, such as arn:aws:ssm:us-east-2:123456789012:document/MySharedDocument.)

The SSM document you specify is run after the Install with NoReboot operation and performs any actions supported by SSM Agent, such as a shell script for installing third party updates before reboot. (For a list of actions, see Command document plugin reference). The default SSM document name is AWS-Noop, which doesn't perform any operation on the managed node.

For information about creating a custom SSM document, see Creating SSM document content.

**Parameter name: OnExitHookDocName**

**Usage:** Optional.

**Default:** AWS-Noop.

The value to provide for the OnExitHookDocName parameter is the name or Amazon Resource Name (ARN) of an SSM document of your choice. You can provide the name of an AWS managed document or the name or ARN of a custom SSM document that you have created or that has been shared with you. (For an SSM document that has been shared with you from a different AWS account, you must specify the full resource ARN, such as arn:aws:ssm:us-east-2:123456789012:document/MySharedDocument.)

The SSM document you specify is run after the managed node reboot operation and performs any actions supported by SSM Agent, such as a shell script to verify node health after the patching operation is complete. (For a list of actions, see Command document plugin reference). The default SSM document name is AWS-Noop, which doesn't perform any operation on the managed node.

For information about creating a custom SSM document, see Creating SSM document content.
Sample scenario for using the InstallOverrideList parameter in AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation

You can use the InstallOverrideList parameter when you want to override the patches specified by the current default patch baseline in Patch Manager, a capability of AWS Systems Manager. This topic provides examples that show how to use this parameter to achieve the following:

- Apply different sets of patches to a target group of managed nodes.
- Apply these patch sets on different frequencies.
- Use the same patch baseline for both operations.

Say that you want to install two different categories of patches on your Amazon Linux 2 managed nodes. You want to install these patches on different schedules using maintenance windows. You want one maintenance window to run every week and install all Security patches. You want another maintenance window to run once a month and install all available patches, or categories of patches other than Security.

However, only one patch baseline at a time can be defined as the default for an operating system. This requirement helps avoid situations where one patch baseline approves a patch while another blocks it, which can lead to issues between conflicting versions.

With the following strategy, you use the InstallOverrideList parameter to apply different types of patches to a target group, on different schedules, while still using the same patch baseline:

1. In the default patch baseline, ensure that only Security updates are specified.
2. Create a maintenance window that runs AWS-RunPatchBaseline or AWS-RunPatchBaselineAssociation each week. Don't specify an override list.
3. Create an override list of the patches of all types that you want to apply on a monthly basis and store it in an Amazon Simple Storage Service (Amazon S3) bucket.
4. Create a second maintenance window that runs once a month. However, for the Run Command task you register for this maintenance window, specify the location of your override list.

The result: Only Security patches, as defined in your default patch baseline, are installed each week. All available patches, or whatever subset of patches you define, are installed each month.
For more information and sample lists, see Parameter name: InstallOverrideList.

Using the BaselineOverride parameter

You can define patching preferences at runtime using the baseline override feature in Patch Manager, a capability of AWS Systems Manager. Do this by specifying an Amazon Simple Storage Service (Amazon S3) bucket containing a JSON object with a list of patch baselines. The patching operation uses the baselines provided in the JSON object that match the host operating system instead of applying the rules from the default patch baseline.

Note

Except when a patching operation uses a patch policy, using the BaselineOverride parameter doesn't overwrite the patch compliance of the baseline provided in the parameter. The output results are recorded in the Stdout logs from Run Command, a capability of AWS Systems Manager. The results only print out packages that are marked as NON_COMPLIANT. This means the package is marked as Missing, Failed, InstalledRejected, or InstalledPendingReboot. When a patch operation uses a patch policy, however, the system passes the override parameter from the associated S3 bucket, and the compliance value is updated for the managed node. For more information about patch policy behaviors, see Using Quick Setup patch policies.

Using the patch baseline override with Snapshot Id or Install Override List parameters

There are two cases where the patch baseline override has noteworthy behavior.

Using baseline override and Snapshot Id at the same time

Snapshot Ids ensure that all managed nodes in a particular patching command all apply the same thing. For example, if you patch 1,000 nodes at one time, the patches will be the same.

When using both a Snapshot Id and a patch baseline override, the Snapshot Id takes precedence over the patch baseline override. The baseline override rules will still be used, but they will only be evaluated once. In the earlier example, the patches across your 1,000 managed nodes will still always be the same. If, midway through the patching operation, you changed the JSON file in the referenced S3 bucket to be something different, the patches applied will still be the same. This is because the Snapshot Id was provided.
Using baseline override and Install Override List at the same time

You can't use these two parameters at the same time. The patching document fails if both parameters are supplied, and it doesn't perform any scans or installs on the managed node.

Code examples

The following code example for Python shows how to generate the patch baseline override.

```python
import boto3
import json

ssm = boto3.client('ssm')
s3 = boto3.resource('s3')
s3_bucket_name = 'my-baseline-override-bucket'
s3_file_name = 'MyBaselineOverride.json'
baseline_ids_to_export = ['pb-0000000000000000', 'pb-0000000000000001']

baseline_overrides = []
for baseline_id in baseline_ids_to_export:
    baseline_overrides.append(ssm.get_patch_baseline(BaselineId=baseline_id))

json_content = json.dumps(baseline_overrides, indent=4, sort_keys=True, default=str)
s3.Object(bucket_name=s3_bucket_name, key=s3_file_name).put(Body=json_content)
```

This produces a patch baseline override like the following.

```

About patch baselines

The topics in this section provide information about how patch baselines work in Patch Manager, a capability of AWS Systems Manager, when you run a Scan or Install operation on your managed nodes.

Topics
About predefined and custom patch baselines

Patch Manager, a capability of AWS Systems Manager, provides predefined patch baselines for each of the operating systems supported by Patch Manager. You can use these baselines as they are currently configured (you can't customize them) or you can create your own custom patch baselines. Custom patch baselines allows you greater control over which patches are approved or rejected for your environment. Also, the predefined baselines assign a compliance level of Unspecified to all patches installed using those baselines. For compliance values to be assigned, you can create a copy of a predefined baseline and specify the compliance values you want to assign to patches. For more information, see About custom baselines and Working with custom patch baselines.

Note

The information in this topic applies no matter which method or type of configuration you are using for your patching operations:

- A patch policy configured in Quick Setup
- A Host Management option configured in Quick Setup
- A maintenance window to run a patch Scan or Install task
- An on-demand Patch now operation

- About predefined baselines
- About custom baselines

About predefined baselines

The following table describes the predefined patch baselines provided with Patch Manager.
For information about which versions of each operating system Patch Manager supports, see [Patch Manager prerequisites](#).

<table>
<thead>
<tr>
<th>Name</th>
<th>Supported operating system</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS-AlmaLinuxDefaultPatchBaseline</td>
<td>AlmaLinux</td>
<td>Approves all operating system patches that are classified as &quot;Security&quot; and that have a severity level of &quot;Critical&quot; or &quot;Important&quot;. Also approves all patches that are classified as &quot;Bugfix&quot;. Patches are auto-approved 7 days after they are released or updated.¹</td>
</tr>
<tr>
<td>AWS-AmazonLinuxDefaultPatchBaseline</td>
<td>Amazon Linux 1</td>
<td>Approves all operating system patches that are classified as &quot;Security&quot; and that have a severity level of &quot;Critical&quot; or &quot;Important&quot;. Also auto-approves all patches with a classification of &quot;Bugfix&quot;. Patches are auto-approved 7 days after they are released or updated.¹</td>
</tr>
<tr>
<td>AWS-AmazonLinux2DefaultPatchBaseline</td>
<td>Amazon Linux 2</td>
<td>Approves all operating system patches that are classified as &quot;Security&quot; and that have a severity level of &quot;Critical&quot; or &quot;Important&quot;. Also approves all patches with a classification of &quot;Bugfix&quot;. Patches are auto-approved 7 days after release.¹</td>

</thead>
<tbody>
<tr>
<td>AWS-WindowsPredefinedPatchBaseline-OS</td>
<td>Windows Server</td>
<td>Approves all Windows Server operating system patches that are classified as &quot;CriticalUpdates&quot; or &quot;Security Updates&quot; and that have an MSRC severity of &quot;Critical&quot; or &quot;Important&quot;. Patches are auto-approved 7 days after they are released or updated.²</td>
</tr>
<tr>
<td>AWS-WindowsPredefinedPatchBaseline-OS-Applications</td>
<td>Windows Server</td>
<td>For the Windows Server operating system, approves all patches that are classified as &quot;CriticalUpdates&quot; or &quot;SecurityUpdates&quot; and that have an MSRC severity of &quot;Critical&quot; or &quot;Important&quot;. For applications released by Microsoft, approves all patches. Patches for both OS and applications are auto-approved 7 days after they are released or updated.²</td>
</tr>
</tbody>
</table>

¹ For Amazon Linux 1 and Amazon Linux 2, the 7-day wait before patches are auto-approved is calculated from an Updated Date value in updateinfo.xml, not a Release Date value. Various factors can affect the Updated Date value. Other operating systems handle release and update dates differently. For information to help you avoid unexpected results with auto-approval delays, see [How package release dates and update dates are calculated](#).

² For Windows Server, default baselines include a 7-day auto-approval delay. To install a patch within 7 days after release, you must create a custom baseline.
About custom baselines

If you create your own patch baseline, you can choose which patches to auto-approve by using the following categories.

- Operating system: Windows Server, Amazon Linux, Ubuntu Server, and so on.
- Product name (for operating systems): For example, RHEL 6.5, Amazon Linux 2014.09, Windows Server 2012, Windows Server 2012 R2, and so on.
- Product name (for applications released by Microsoft on Windows Server only): For example, Word 2016, BizTalk Server, and so on.
- Classification: For example, critical updates, security updates, and so on.
- Severity: For example, critical, important, and so on.

For each approval rule that you create, you can choose to specify an auto-approval delay or specify a patch approval cutoff date.

***Note***

Because it's not possible to reliably determine the release dates of update packages for Ubuntu Server, the auto-approval options aren't supported for this operating system.

An auto-approval delay is the number of days to wait after the patch was released or last updated, before the patch is automatically approved for patching. For example, if you create a rule using the CriticalUpdates classification and configure it for 7 days auto-approval delay, then a new critical patch released on July 7 is automatically approved on July 14.

***Note***

If a Linux repository doesn't provide release date information for packages, Systems Manager uses the build time of the package as the auto-approval delay for Amazon Linux 1, Amazon Linux 2, RHEL, and CentOS. If the system isn't able to find the build time of the package, Systems Manager treats the auto-approval delay as having a value of zero.
When you specify an auto-approval cutoff date, Patch Manager automatically applies all patches released or last updated on or before that date. For example, if you specify July 7, 2023 as the cutoff date, no patches released or last updated on or after July 8, 2023 are installed automatically.

**Note**  
When you create a custom patch baseline, you can specify a compliance severity level for patches approved by that patch baseline, such as Critical or High. If the patch state of any approved patch is reported as Missing, then the patch baseline's overall reported compliance severity is the severity level you specified.

Keep the following in mind when you create a patch baseline:

- Patch Manager provides one predefined patch baseline for each supported operating system. These predefined patch baselines are used as the default patch baselines for each operating system type unless you create your own patch baseline and designate it as the default for the corresponding operating system type.

**Note**  
For Windows Server, three predefined patch baselines are provided. The patch baselines AWS-DefaultPatchBaseline and AWS-WindowsPredefinedPatchBaseline-OS support only operating system updates on the Windows operating system itself. AWS-DefaultPatchBaseline is used as the default patch baseline for Windows Server managed nodes unless you specify a different patch baseline. The configuration settings in these two patch baselines are the same. The newer of the two, AWS-WindowsPredefinedPatchBaseline-OS, was created to distinguish it from the third predefined patch baseline for Windows Server. That patch baseline, AWS-WindowsPredefinedPatchBaseline-OS-Applications, can be used to apply patches to both the Windows Server operating system and supported applications released by Microsoft.

- For on-premises servers and virtual machines (VMs), Patch Manager attempts to use your custom default patch baseline. If no custom default patch baseline exists, the system uses the predefined patch baseline for the corresponding operating system.
- If a patch is listed as both approved and rejected in the same patch baseline, the patch is rejected.
• A managed node can have only one patch baseline defined for it.

• The formats of package names you can add to lists of approved patches and rejected patches for a patch baseline depend on the type of operating system you're patching.

For information about accepted formats for lists of approved patches and rejected patches, see About package name formats for approved and rejected patch lists.

• If you are using a patch policy configuration in Quick Setup, updates you make to custom patch baselines are synchronized with Quick Setup once an hour.

If a custom patch baseline that was referenced in a patch policy is deleted, a banner displays on the Quick Setup Configuration details page for your patch policy. The banner informs you that the patch policy references a patch baseline that no longer exists, and that subsequent patching operations will fail. In this case, return to the Quick Setup Configurations page, select the Patch Manager configuration, and choose Actions, Edit configuration. The deleted patch baseline name is highlighted, and you must select a new patch baseline for the affected operating system.

For information about creating a patch baseline, see Working with custom patch baselines and Tutorial: Patch a server environment (AWS CLI).

About package name formats for approved and rejected patch lists

The formats of package names you can add to lists of approved patches and rejected patches depend on the type of operating system you're patching.

Package name formats for Linux operating systems

The formats you can specify for approved and rejected patches in your patch baseline vary by Linux type. More specifically, the formats that are supported depend on the package manager used by the type of Linux operating system.

Topics

• Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022, Amazon Linux 2023, CentOS, Oracle Linux, and Red Hat Enterprise Linux (RHEL)

• Debian Server, Raspberry Pi OS (formerly Raspbian), and Ubuntu Server

• SUSE Linux Enterprise Server (SLES)
Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022, Amazon Linux 2023, CentOS, Oracle Linux, and Red Hat Enterprise Linux (RHEL)

Package manager: YUM, except for Amazon Linux 2022, Amazon Linux 2023, RHEL 8, and CentOS 8, which use DNF as the package manager

Approved patches: For approved patches, you can specify any of the following:

- Bugzilla IDs, in the format 1234567 (The system processes numbers-only strings as Bugzilla IDs.)
- CVE IDs, in the format CVE-2018-1234567
- Advisory IDs, in formats such as RHSA-2017:0864 and ALAS-2018-123
- Full package names, in formats such as:
  - example-pkg-0.710.10-2.7.abcd.x86_64
  - pkg-example-EE-20180914-2.2.amzn1.noarch
- Package-names with a single wildcard, in formats such as:
  - example-pkg-*.abcd.x86_64
  - example-pkg-*-20180914-2.2.amzn1.noarch
  - example-pkg-EE-2018*.amzn1.noarch

Rejected patches: For rejected patches, you can specify any of the following:

- Full package names, in formats such as:
  - example-pkg-0.710.10-2.7.abcd.x86_64
  - pkg-example-EE-20180914-2.2.amzn1.noarch
- Package-names with a single wildcard, in formats such as:
  - example-pkg-*.abcd.x86_64
  - example-pkg-*-20180914-2.2.amzn1.noarch
  - example-pkg-EE-2018*.amzn1.noarch

Debian Server, Raspberry Pi OS (formerly Raspbian), and Ubuntu Server

Package manager: APT

Approved patches and rejected patches: For both approved and rejected patches, specify the following:
- Package names, in the format `ExamplePkg33`

**Note**

For Debian Server lists, Raspberry Pi OS lists, and Ubuntu Server lists, don't include elements such as architecture or versions. For example, you specify the package name `ExamplePkg33` to include all the following in a patch list:

- `ExamplePkg33.x86.1`
- `ExamplePkg33.x86.2`
- `ExamplePkg33.x64.1`
- `ExamplePkg33.3.2.5-364.noarch`

**SUSE Linux Enterprise Server (SLES)**

**Package manager:** Zypper

**Approved patches** and **rejected patches:** For both approved and rejected patch lists, you can specify any of the following:

- Full package names, in formats such as:
  - `SUSE-SLE-Example-Package-12-2018-123`
  - `example-pkg-2018.11.4-46.17.1.x86_64.rpm`
- Package names with a single wildcard, such as:
  - `SUSE-SLE-Example-Package-12-2018-*`
  - `example-pkg-2018.11.4-46.17.1.*.rpm`

**Package name formats for macOS**

**Supported package managers:** softwareupdate, installer, Brew, Brew Cask

**Approved patches** and **rejected patches:** For both approved and rejected patch lists, you specify full package names, in formats such as:

- `XProtectPlistConfigData`
- `MRTConfigData`

About patch baselines
Wildcards aren't supported in approved and rejected patch lists for macOS.

### Package name formats for Windows operating systems

For Windows operating systems, specify patches using Microsoft Knowledge Base IDs and Microsoft Security Bulletin IDs; for example:

```
KB2032276,KB2124261,MS10-048
```

### About patch groups

⚠️ **Important**

Patch groups are not used in patching operations that are based on *patch policies*. For information about working with patch policies, see [Using Quick Setup patch policies](#).

You can use a *patch group* to associate managed nodes with a specific patch baseline in Patch Manager, a capability of AWS Systems Manager. Patch groups help ensure that you're deploying the appropriate patches, based on the associated patch baseline rules, to the correct set of nodes. Patch groups can also help you avoid deploying patches before they have been adequately tested. For example, you can create patch groups for different environments (such as Development, Test, and Production) and register each patch group to an appropriate patch baseline.

When you run `AWS-RunPatchBaseline`, you can target managed nodes using their ID or tags. SSM Agent and Patch Manager then evaluate which patch baseline to use based on the patch group value that you added to the managed node.

You create a patch group by using Amazon Elastic Compute Cloud (Amazon EC2) tags. Unlike other tagging scenarios across Systems Manager, a patch group *must* be defined with the either the tag key *Patch Group* or *PatchGroup*. The key is case-sensitive. You can specify any value to help you identify and target the resources in that group, for example "web servers" or "US-EAST-PROD", but the key must be *Patch Group* or *PatchGroup*.

After you create a patch group and tag managed nodes, you can register the patch group with a patch baseline. Registering the patch group with a patch baseline ensures that the nodes within the patch group use the rules defined in the associated patch baseline.

For more information about how to create a patch group and associate the patch group to a patch baseline, see [Working with patch groups](#) and [Add a patch group to a patch baseline](#).
To view an example of creating a patch baseline and patch groups by using the AWS Command Line Interface (AWS CLI), see Tutorial: Patch a server environment (AWS CLI). For more information about Amazon EC2 tags, see Tag your Amazon EC2 resources in the Amazon EC2 User Guide.

How it works

When the system runs the task to apply a patch baseline to a managed node, SSM Agent verifies that a patch group value is defined for the node. If the node is assigned to a patch group, Patch Manager then verifies which patch baseline is registered to that group. If a patch baseline is found for that group, Patch Manager notifies SSM Agent to use the associated patch baseline. If a node isn't configured for a patch group, Patch Manager automatically notifies SSM Agent to use the currently configured default patch baseline.

⚠️ Important
A managed node can only be in one patch group.
A patch group can be registered with only one patch baseline for each operating system type.
You can't apply the Patch Group tag (with a space) to an Amazon EC2 instance if the Allow tags in instance metadata option is enabled on the instance. Allowing tags in instance metadata prevents tag key names from containing spaces. If you have allowed tags in EC2 instance metadata, you must use the tag key PatchGroup (without a space).

The following diagram shows a general example of the processes that Systems Manager performs when sending a Run Command task to your fleet of servers to patch using Patch Manager. A similar process is used when a maintenance window is configured to send a command to patch using Patch Manager.

In this example, we have three groups of EC2 instances for Windows Server with the following tags applied:

<table>
<thead>
<tr>
<th>EC2 instances group</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group 1</td>
<td>key=OS,value=Windows</td>
</tr>
<tr>
<td></td>
<td>key=PatchGroup,value=DEV</td>
</tr>
<tr>
<td>Group 2</td>
<td>key=OS,value=Windows</td>
</tr>
</tbody>
</table>

About patch baselines
For this example, we also have these two Windows Server patch baselines:

<table>
<thead>
<tr>
<th>Patch baseline ID</th>
<th>Default</th>
<th>Associated patch group</th>
</tr>
</thead>
<tbody>
<tr>
<td>pb-0123456789abcdef0</td>
<td>Yes</td>
<td>Default</td>
</tr>
<tr>
<td>pb-9876543210abcdef0</td>
<td>No</td>
<td>DEV</td>
</tr>
</tbody>
</table>

**Diagram 1: General example of patching operations process flow**

The following diagram shows how Patch Manager determines which patch baselines to use in patching operations.
The general process to scan or install patches using Run Command, a capability of AWS Systems Manager, and Patch Manager is as follows:
1. **Send a command to patch:** Use the Systems Manager console, SDK, AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell to send a Run Command task using the document AWS-RunPatchBaseline. The diagram shows a Run Command task to patch managed instances by targeting the tag `key=OS,value=Windows`.

2. **Patch baseline determination:** SSM Agent verifies the patch group tags applied to the EC2 instance and queries Patch Manager for the corresponding patch baseline.

   - **Matching patch group value associated with patch baseline:**

     1. SSM Agent, which is installed on EC2 instances in group one, receives the command issued in Step 1 to begin a patching operation. SSM Agent validates that the EC2 instances have the patch group tag-value `DEV` applied and queries Patch Manager for an associated patch baseline.

     2. Patch Manager verifies that patch baseline `pb-9876543210abcdef0` has the patch group `DEV` associated and notifies SSM Agent.

     3. SSM Agent retrieves a patch baseline snapshot from Patch Manager based on the approval rules and exceptions configured in `pb-9876543210abcdef0` and proceeds to the next step.

   - **No patch group tag added to instance:**

     1. SSM Agent, which is installed on EC2 instances in group two, receives the command issued in Step 1 to begin a patching operation. SSM Agent validates that the EC2 instances don't have a `Patch Group` or `PatchGroup` tag applied and as a result, SSM Agent queries Patch Manager for the default Windows patch baseline.

     2. Patch Manager verifies that the default Windows Server patch baseline is `pb-0123456789abcdef0` and notifies SSM Agent.

     3. SSM Agent retrieves a patch baseline snapshot from Patch Manager based on the approval rules and exceptions configured in the default patch baseline `pb-0123456789abcdef0` and proceeds to the next step.

   - **No matching patch group value associated with a patch baseline:**

     1. SSM Agent, which is installed on EC2 instances in group three, receives the command issued in Step 1 to begin a patching operation. SSM Agent validates that the EC2 instances have the patch group tag-value `QA` applied and queries Patch Manager for an associated patch baseline.

     2. Patch Manager doesn't find a patch baseline that has the patch group `QA` associated.
3. Patch Manager notifies SSM Agent to use the default Windows patch baseline pb-0123456789abcdef0.

4. SSM Agent retrieves a patch baseline snapshot from Patch Manager based on the approval rules and exceptions configured in the default patch baseline pb-0123456789abcdef0 and proceeds to the next step.

3. **Patch scan or install**: After determining the appropriate patch baseline to use, SSM Agent begins either scanning for or installing patches based on the operation value specified in Step 1. The patches that are scanned for or installed are determined by the approval rules and patch exceptions defined in the patch baseline snapshot provided by Patch Manager.

**More info**

- [Understanding patch compliance state values](#)

### About patching applications released by Microsoft on Windows Server

Use the information in this topic to help you prepare to patch applications on Windows Server using Patch Manager, a capability of AWS Systems Manager.

**Microsoft application patching**

Patching support for applications on Windows Server managed nodes is limited to applications released by Microsoft.

**Note**

In some cases, Microsoft releases patches for applications that don't specify an updated date and time. In these cases, an updated date and time of 01/01/1970 is supplied by default.

### Patch baselines to patch applications released by Microsoft

For Windows Server, three predefined patch baselines are provided. The patch baselines AWS-DefaultPatchBaseline and AWS-WindowsPredefinedPatchBaseline-OS support only operating system updates on the Windows operating system itself. **AWS-DefaultPatchBaseline** is used as the default patch baseline for Windows Server managed nodes unless you specify a
different patch baseline. The configuration settings in these two patch baselines are the same. The newer of the two, AWS-WindowsPredefinedPatchBaseline-OS, was created to distinguish it from the third predefined patch baseline for Windows Server. That patch baseline, AWS-WindowsPredefinedPatchBaseline-OS-Applications, can be used to apply patches to both the Windows Server operating system and supported applications released by Microsoft.

You can also create a custom patch baseline to update applications released by Microsoft on Windows Server machines.

Support for patching applications released by Microsoft on on-premises servers, edge devices, VMs, and other non-EC2 nodes

To patch applications released by Microsoft on virtual machines (VMs) and other non-EC2 managed nodes, you must turn on the advanced-instances tier. There is a charge to use the advanced-instances tier. **However, there is no additional charge to patch applications released by Microsoft on Amazon Elastic Compute Cloud (Amazon EC2) instances.** For more information, see [Configuring instance tiers](#).

Windows update option for "other Microsoft products"

In order for Patch Manager to be able to patch applications released by Microsoft on your Windows Server managed nodes, the Windows Update option **Give me updates for other Microsoft products when I update Windows** must be activated on the managed node.

For information about allowing this option on a single managed node, see [Update Office with Microsoft Update](#) on the Microsoft Support website.

For a fleet of managed nodes running Windows Server 2016 and later, you can use a Group Policy Object (GPO) to turn on the setting. In the Group Policy Management Editor, go to **Computer Configuration, Administrative Templates, Windows Components, Windows Updates**, and choose **Install updates for other Microsoft products**. We also recommend configuring the GPO with additional parameters that prevent unplanned automatic updates and reboots outside of Patch Manager. For more information, see [Configuring Automatic Updates in a Non-Active Directory Environment](#) on the Microsoft technical documentation website.

For a fleet of managed nodes running Windows Server 2012 or 2012 R2, you can turn on the option by using a script, as described in [Enabling and Disabling Microsoft Update in Windows 7 via Script](#) on the Microsoft Docs Blog website. For example, you could do the following:

1. Save the script from the blog post in a file.
2. Upload the file to an Amazon Simple Storage Service (Amazon S3) bucket or other accessible location.

3. Use Run Command, a capability of AWS Systems Manager, to run the script on your managed nodes using the Systems Manager document (SSM document) AWS-RunPowerShellScript with a command similar to the following.

```powershell
Invoke-WebRequest -Uri "https://s3.aws-api-domain/DOC-EXAMPLE-BUCKET/script.vbs" -Outfile "C:\script.vbs" cscript c:\script.vbs
```

Minimum parameter requirements

To include applications released by Microsoft in your custom patch baseline, you must, at a minimum, specify the product that you want to patch. The following AWS Command Line Interface (AWS CLI) command demonstrates the minimal requirements to patch a product, such as Microsoft Office 2016.

Linux & macOS

```bash
aws ssm create-patch-baseline \
  --name "My-Windows-App-Baseline" \
  --approval-rules " PatchRules=[ { PatchFilterGroup= { PatchFilters= [ { Key=PRODUCT, Values='Office 2016' }, { Key=PATCH_SET, Values='APPLICATION' } ] }, ApproveAfterDays=5 } ]"
```

Windows Server

```bash
aws ssm create-patch-baseline ^
  --name "My-Windows-App-Baseline" ^
  --approval-rules " PatchRules=[ { PatchFilterGroup= { PatchFilters= [ { Key=PRODUCT, Values='Office 2016' }, { Key=PATCH_SET, Values='APPLICATION' } ] }, ApproveAfterDays=5 } ]"
```

If you specify the Microsoft application product family, each product you specify must be a supported member of the selected product family. For example, to patch the product "Active Directory Rights Management Services Client 2.0," you must specify its product family as "Active Directory" and not, for example, "Office" or "SQL Server." The following AWS CLI command demonstrates a matched pairing of product family and product.
Using Kernel Live Patching on Amazon Linux 2 managed nodes

Kernel Live Patching for Amazon Linux 2 allows you to apply security vulnerability and critical bug patches to a running Linux kernel without reboots or disruptions to running applications. This allows you to benefit from improved service and application availability, while keeping your infrastructure secure and up to date. Kernel Live Patching is supported on Amazon EC2 instances, AWS IoT Greengrass core devices, and on-premises virtual machines running Amazon Linux 2.

For general information about Kernel Live Patching, see Kernel Live Patching on Amazon Linux 2 in the Amazon EC2 User Guide.

After you turn on Kernel Live Patching on an Amazon Linux 2 managed node, you can use Patch Manager, a capability of AWS Systems Manager, to apply kernel live patches to the managed node. Using Patch Manager is an alternative to using existing yum workflows on the node to apply the updates.
Before you begin

To use Patch Manager to apply kernel live patches to your Amazon Linux 2 managed nodes, ensure your nodes are based on the correct architecture and kernel version. For information, see Supported configurations and prerequisites in the Amazon EC2 User Guide.

Topics

- About Kernel Live Patching and Patch Manager
- How it works
- Turning on Kernel Live Patching using Run Command
- Applying kernel live patches using Run Command
- Turning off Kernel Live Patching using Run Command

About Kernel Live Patching and Patch Manager

Updating the kernel version

You don't need to reboot a managed node after applying a kernel live patch update. However, AWS provides kernel live patches for an Amazon Linux 2 kernel version for up to three months after its release. After the three-month period, you must update to a later kernel version to continue to receive kernel live patches. We recommend using a maintenance window to schedule a reboot of your node at least once every three months to prompt the kernel version update.

Uninstalling kernel live patches

Kernel live patches can't be uninstalled using Patch Manager. Instead, you can turn off Kernel Live Patching, which removes the RPM packages for the applied kernel live patches. For more information, see Turning off Kernel Live Patching using Run Command.

Kernel compliance

In some cases, installing all CVE fixes from live patches for the current kernel version can bring that kernel into the same compliance state that a newer kernel version would have. When that happens, the newer version is reported as Installed, and the managed node reported as Compliant. No installation time is reported for newer kernel version, however.
One kernel live patch, multiple CVEs

If a kernel live patch addresses multiple CVEs, and those CVEs have various classification and severity values, only the highest classification and severity from among the CVEs is reported for the patch.

The remainder of this section describes how to use Patch Manager to apply kernel live patches to managed nodes that meet these requirements.

**How it works**

AWS releases two types of kernel live patches for Amazon Linux 2: security updates and bug fixes. To apply those types of patches, you use a patch baseline document that targets only the classifications and severities listed in the following table.

<table>
<thead>
<tr>
<th>Classification</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security</td>
<td>Critical, Important</td>
</tr>
<tr>
<td>Bugfix</td>
<td>All</td>
</tr>
</tbody>
</table>

You can create a custom patch baseline that targets only these patches, or use the predefined AWS-AmazonLinux2DefaultPatchBaseline patch baseline. In other words, you can use AWS-AmazonLinux2DefaultPatchBaseline with Amazon Linux 2 managed nodes on which Kernel Live Patching is turned on, and kernel live updates will be applied.

**Note**

The AWS-AmazonLinux2DefaultPatchBaseline configuration specifies a 7-day waiting period after a patch is released or last updated before it's installed automatically. If you don't want to wait 7 days for kernel live patches to be auto-approved, you can create and use a custom patch baseline. In your patch baseline, you can specify no auto-approval waiting period, or specify a shorter or longer one. For more information, see [Working with custom patch baselines](#).

We recommend the following strategy to patch your managed nodes with kernel live updates:
1. Turn on Kernel Live Patching on your Amazon Linux 2 managed nodes.

2. Use Run Command, a capability of AWS Systems Manager, to run a Scan operation on your managed nodes using the predefined AWS-AmazonLinux2DefaultPatchBaseline or a custom patch baseline that also targets only Security updates with severity classified as Critical and Important, and the Bugfix severity of All.

3. Use Compliance, a capability of AWS Systems Manager, to review whether non-compliance for patching is reported for any of the managed nodes that were scanned. If so, view the node compliance details to determine whether any kernel live patches are missing from the managed node.

4. To install missing kernel live patches, use Run Command with the same patch baseline you specified before, but this time run an Install operation instead of a Scan operation.

   Because kernel live patches are installed without the need to reboot, you can choose the NoReboot reboot option for this operation.

   **Note**

   You can still reboot the managed node if required for other types of patches installed on it, or if you want to update to a newer kernel. In these cases, choose the RebootIfNeeded reboot option instead.

   5. Return to Compliance to verify that the kernel live patches were installed.

### Turning on Kernel Live Patching using Run Command

To turn on Kernel Live Patching, you can either run `yum` commands on your managed nodes or use Run Command and a custom Systems Manager document (SSM document) that you create.

For information about turning on Kernel Live Patching by running `yum` commands directly on the managed node, see [Enable Kernel Live Patching](#) in the *Amazon EC2 User Guide*.

**Note**

When you turn on Kernel Live Patching, if the kernel already running on the managed node is *earlier* than `kernel-4.14.165-131.185.amzn2.x86_64` (the minimum supported version), the process installs the latest available kernel version and reboots the managed
node. If the node is already running `kernel-4.14.165-131.185.amzn2.x86_64` or later, the process doesn't install a newer version and doesn't reboot the node.

To turn on Kernel Live Patching using Run Command (console)

2. In the navigation pane, choose Run Command.
3. Choose Run command.
4. In the Command document list, choose the custom SSM document AWS-ConfigureKernelLivePatching.
5. In the Command parameters section, specify whether you want managed nodes to reboot as part of this operation.
6. For information about working with the remaining controls on this page, see Running commands from the console.
7. Choose Run.

To turn on Kernel Live Patching (AWS CLI)

- Run the following command on your local machine.

  **Linux & macOS**

  ```bash
  aws ssm send-command \
  --document-name "AWS-ConfigureKernelLivePatching" \
  --parameters "EnableOrDisable=Enable" \
  --targets "Key=instanceids,Values=instance-id"
  ```

  **Windows Server**

  ```bash
  aws ssm send-command ^
  --document-name "AWS-ConfigureKernelLivePatching" ^
  --parameters "EnableOrDisable=Enable" ^
  --targets "Key=instanceids,Values=instance-id"
  ```
Replace `instance-id` with the ID of the Amazon Linux 2 managed node on which you want to turn on the feature, such as i-02573cafcfEXAMPLE. To turn on the feature on multiple managed nodes, you can use either of the following formats.

- `--targets "Key=instanceids,Values=instance-id1,instance-id2"`
- `--targets "Key=tag:tag-key,Values=tag-value"`

For information about other options you can use in the command, see `send-command` in the AWS CLI Command Reference.

**Applying kernel live patches using Run Command**

To apply kernel live patches, you can either run `yum` commands on your managed nodes or use Run Command and the SSM document AWS-RunPatchBaseline.

For information about applying kernel live patches by running `yum` commands directly on the managed node, see Apply kernel live patches in the Amazon EC2 User Guide.

**To apply kernel live patches using Run Command (console)**

2. In the navigation pane, choose Run Command.
3. Choose Run command.
4. In the Command document list, choose the SSM document AWS-RunPatchBaseline.
5. In the Command parameters section, do one of the following:

   - If you're checking whether new kernel live patches are available, for Operation, choose Scan. For Reboot Option, if don't want your managed nodes to reboot after this operation, choose NoReboot. After the operation is complete, you can check for new patches and compliance status in Compliance.
   
   - If you checked patch compliance already and are ready to apply available kernel live patches, for Operation, choose Install. For Reboot Option, if you don't want your managed nodes to reboot after this operation, choose NoReboot.
6. For information about working with the remaining controls on this page, see Running commands from the console.

7. Choose Run.

To apply kernel live patches using Run Command (AWS CLI)

1. To perform a Scan operation before checking your results in Compliance, run the following command from your local machine.

   Linux & macOS
   
   ```bash
   aws ssm send-command  
   --document-name "AWS-RunPatchBaseline"  
   --targets "Key=InstanceIds,Values=instance-id"  
   --parameters '{"Operation": ["Scan"], "RebootOption": ["RebootIfNeeded"]}'
   ```

   Windows Server
   
   ```bash
   aws ssm send-command ^  
   --document-name "AWS-RunPatchBaseline" ^  
   --targets "Key=InstanceIds,Values=instance-id" ^  
   --parameters {"Operation": ["Scan"], "RebootOption": ["RebootIfNeeded"]}
   ```

For information about other options you can use in the command, see send-command in the AWS CLI Command Reference.

2. To perform an Install operation after checking your results in Compliance, run the following command from your local machine.

   Linux & macOS
   
   ```bash
   aws ssm send-command  
   --document-name "AWS-RunPatchBaseline"  
   --targets "Key=InstanceIds,Values=instance-id"  
   --parameters '{"Operation": ["Install"], "RebootOption": ["NoReboot"]}'
   ```
In both of the preceding commands, replace instance-id with the ID of the Amazon Linux 2 managed node on which you want to apply kernel live patches, such as i-02573cafcfEXAMPLE. To turn on the feature on multiple managed nodes, you can use either of the following formats.

- --targets "Key=instanceids,Values=instance-id1,instance-id2"
- --targets "Key=tag:tag-key,Values=tag-value"

For information about other options you can use in these commands, see send-command in the AWS CLI Command Reference.

### Turning off Kernel Live Patching using Run Command

To turn off Kernel Live Patching, you can either run yum commands on your managed nodes or use Run Command and the custom SSM document AWS-ConfigureKernelLivePatching.

#### Note

If you no longer need to use Kernel Live Patching, you can turn it off at any time. In most cases, turning off the feature isn't necessary.

For information about turning off Kernel Live Patching by running yum commands directly on the managed node, see Enable Kernel Live Patching in the Amazon EC2 User Guide.

#### Note

When you turn off Kernel Live Patching, the process uninstalls the Kernel Live Patching plugin and then reboots the managed node.
To turn off Kernel Live Patching using Run Command (console)

2. In the navigation pane, choose Run Command.
3. Choose Run command.
4. In the Command document list, choose the SSM document AWS-ConfigureKernelLivePatching.
5. In the Command parameters section, specify values for required parameters.
6. For information about working with the remaining controls on this page, see Running commands from the console.
7. Choose Run.

To turn off Kernel Live Patching (AWS CLI)

- Run a command similar to the following.

  Linux & macOS

  ```bash
  aws ssm send-command \\
  --document-name "AWS-ConfigureKernelLivePatching" \\
  --targets "Key=instanceIds,Values=instance-id" \\
  --parameters "EnableOrDisable=Disable"
  ```

  Windows Server

  ```bash
  aws ssm send-command ^
  --document-name "AWS-ConfigureKernelLivePatching" ^
  --targets "Key=instanceIds,Values=instance-id" ^
  --parameters "EnableOrDisable=Disable"
  ```

Replace `instance-id` with the ID of the Amazon Linux 2 managed node on which you want to turn off the feature, such as i-02573cafcfEXAMPLE. To turn off the feature on multiple managed nodes, you can use either of the following formats.

- `--targets "Key=instanceids,Values=instance-id1,instance-id2"`
- `--targets "Key=tag:tag-key,Values=tag-value"`
For information about other options you can use in the command, see `send-command` in the *AWS CLI Command Reference*.

**Working with Patch Manager (console)**

To use Patch Manager, a capability of AWS Systems Manager, complete the following tasks. These tasks are described in more detail in this section.

1. Verify that the AWS predefined patch baseline for each operating system type that you use meets your needs. If it doesn't, create a patch baseline that defines a standard set of patches for that managed node type and set it as the default instead.
2. Organize managed nodes into patch groups by using Amazon Elastic Compute Cloud (Amazon EC2) tags (optional, but recommended).
3. Do one of the following:
   - (Recommended) Configure a patch policy in Quick Setup, a capability of Systems Manager, that lets you install missing patches on a schedule for an entire organization, a subset of organizational units, or a single AWS account. For more information, see *Patch Manager organization patching configuration*.
   - Create a maintenance window that uses the Systems Manager document (SSM document) AWS-RunPatchBaseline in a Run Command task type. For more information, see *Walkthrough: Creating a maintenance window for patching (console)*.
   - Manually run AWS-RunPatchBaseline in a Run Command operation. For more information, see *Running commands from the console*.
   - Manually patch nodes on demand using the **Patch now** feature. For more information, see *Patching managed nodes on demand*.
4. Monitor patching to verify compliance and investigate failures.

**Topics**

- Creating a patch policy
- Viewing patch Dashboard summaries
- Working with patch compliance reports
- Patching managed nodes on demand
- Working with patch baselines
Creating a patch policy

A patch policy is a configuration you set up using Quick Setup, a capability of AWS Systems Manager. Patch policies provide more extensive and more centralized control over your patching operations than is available with other methods of configuring patching. A patch policy defines the schedule and baseline to use when automatically patching your nodes and applications.

For more information, see the following topics:

- [Using Quick Setup patch policies](#)
- [Patch Manager organization patching configuration](#)

Viewing patch Dashboard summaries

The **Dashboard** tab in Patch Manager provides you with a summary view in the console that you can use to monitor your patching operations in a consolidated view. Patch Manager is a capability of AWS Systems Manager. On the **Dashboard** tab, you can view the following:

- A snapshot of how many managed nodes are compliant and noncompliant with patching rules.
- A snapshot of the age of patch compliance results for your managed nodes.
- A linked count of how many noncompliant managed nodes there are for each of the most common reasons for noncompliance.
- A linked list of the most recent patching operations.
- A linked list of the recurring patching tasks that have been set up.

**To view patch Dashboard summaries**

2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Dashboard** tab.
4. Scroll to the section containing summary data that you want to view:

- Amazon EC2 instance management
- Compliance summary
- Noncompliance counts
- Compliance reports
- Non-patch policy-based operations
- Non-patch policy-based recurring tasks

**Working with patch compliance reports**

Use the information in the following topics to help you generate and work with patch compliance reports in Patch Manager, a capability of AWS Systems Manager.

The information in the following topics apply no matter which method or type of configuration you're using for your patching operations:

- A patch policy configured in Quick Setup
- A Host Management option configured in Quick Setup
- A maintenance window to run a patch Scan or Install task
- An on-demand **Patch now** operation

⚠️ **Important**

If you have multiple types of operations in place to scan your instances for patch compliance, note that each scan overwrites the patch compliance data of previous scans. As a result, you might end up with unexpected results in your patch compliance data. For more information, see [Avoiding unintentional patch compliance data overwrites](#).

To verify which patch baseline was used to generate the latest compliance information, navigate to the **Compliance reporting** tab in Patch Manager, locate the row for the managed node you want information about, and then choose the baseline ID in the **Baseline ID used** column.

**Topics**

- [Viewing patch compliance results](#)
Generating .csv patch compliance reports
Remediating noncompliant managed nodes with Patch Manager
Avoiding unintentional patch compliance data overwrites

Viewing patch compliance results

Use these procedures to view patch compliance information about your managed nodes.

This procedure applies to patch operations that use the AWS-RunPatchBaseline document. For information about viewing patch compliance information for patch operations that use the AWS-RunPatchBaselineAssociation document, see Identifying noncompliant managed nodes.

Note
The patch scanning operations for Quick Setup and Explorer use the AWS-RunPatchBaselineAssociation document. Quick Setup and Explorer are both capabilities of AWS Systems Manager.

Identify the patch solution for a specific CVE issue (Linux)

For many Linux-based operating systems, patch compliance results indicate which Common Vulnerabilities and Exposure (CVE) bulletin issues are resolved by which patches. This information can help you determine how urgently you need to install a missing or failed patch.

CVE details are included for supported versions of the following operating system types:

- AlmaLinux
- Amazon Linux 1
- Amazon Linux 2
- Amazon Linux 2022
- Amazon Linux 2023
- Oracle Linux
- Red Hat Enterprise Linux (RHEL)
- Rocky Linux
- SUSE Linux Enterprise Server (SLES)
By default, CentOS and CentOS Stream don't provide CVE information about updates. You can, however, allow this support by using third-party repositories such as the Extra Packages for Enterprise Linux (EPEL) repository published by Fedora. For information, see EPEL on the Fedora Wiki.

Currently, CVE ID values are reported only for patches with a status of Missing or Failed.

You can also add CVE IDs to your lists of approved or rejected patches in your patch baselines, as the situation and your patching goals warrant.

For information about working with approved and rejected patch lists, see the following topics:

- Working with custom patch baselines
- About package name formats for approved and rejected patch lists
- How patch baseline rules work on Linux-based systems
- How patches are installed

In some cases, Microsoft releases patches for applications that don't specify an updated date and time. In these cases, an updated date and time of 01/01/1970 is supplied by default.

### Viewing patching compliance results

Use the following procedures to view patch compliance results in the AWS Systems Manager console.

For information about generating patch compliance reports that are downloaded to an Amazon Simple Storage Service (Amazon S3) bucket, see [Generating .csv patch compliance reports](#).
To view patch compliance results

1. Do one of the following.

   **Option 1** (recommended) – Navigate from Patch Manager, a capability of AWS Systems Manager:
   - In the navigation pane, choose **Patch Manager**.
   - Choose the **Compliance reporting** tab.
   - In the **Node patching details** area, choose the node ID of the managed node for which you want to review patch compliance results.
   - In the **Details** area, in the **Properties** list, choose **Patches**.

   **Option 2** – Navigate from Compliance, a capability of AWS Systems Manager:
   - In the navigation pane, choose **Compliance**.
   - For **Compliance resources summary**, choose a number in the column for the types of patch resources you want to review, such as **Non-Compliant resources**.
   - Below, in the **Resource** list, choose the ID of the managed node for which you want to review patch compliance results.
   - In the **Details** area, in the **Properties** list, choose **Patches**.

   **Option 3** – Navigate from Fleet Manager, a capability of AWS Systems Manager.
   - In the navigation pane, choose **Fleet Manager**.
   - In the **Managed instances** area, choose the ID of the managed node for which you want to review patch compliance results.
   - In the **Details** area, in the **Properties** list, choose **Patches**.

2. (Optional) In the Search box
   - choose from the available filters.

   For example, for Red Hat Enterprise Linux (RHEL), choose from the following:
   - Name
   - Classification
• State
• Severity

For Windows Server, choose from the following:

• KB
• Classification
• State
• Severity

3. Choose one of the available values for the filter type you chose. For example, if you chose State, now choose a compliance state such as InstalledPendingReboot, Failed or Missing.

Note
Currently, CVE ID values are reported only for patches with a status of Missing or Failed.

4. Depending on the compliance state of the managed node, you can choose what action to take to remedy any noncompliant nodes.

For example, you can choose to patch your noncompliant managed nodes immediately. For information about patching your managed nodes on demand, see Patching managed nodes on demand.

For information about patch compliance states, see Understanding patch compliance state values.

Generating .csv patch compliance reports

You can use the AWS Systems Manager console to generate patch compliance reports that are saved as a .csv file to an Amazon Simple Storage Service (Amazon S3) bucket of your choice. You can generate a single on-demand report or specify a schedule for generating the reports automatically.

Reports can be generated for a single managed node or for all managed nodes in your selected AWS account and AWS Region. For a single node, a report contains comprehensive details,
including the IDs of patches related to a node being noncompliant. For a report on all managed nodes, only summary information and counts of noncompliant nodes’ patches are provided.

After a report is generated, you can use a tool like Amazon QuickSight to import and analyze the data. Amazon QuickSight is a business intelligence (BI) service you can use to explore and interpret information in an interactive visual environment. For more information, see the Amazon QuickSight User Guide.

Note

When you create a custom patch baseline, you can specify a compliance severity level for patches approved by that patch baseline, such as Critical or High. If the patch state of any approved patch is reported as Missing, then the patch baseline's overall reported compliance severity is the severity level you specified.

You can also specify an Amazon Simple Notification Service (Amazon SNS) topic to use for sending notifications when a report is generated.

Service roles for generating patch compliance reports

The first time you generate a report, Systems Manager creates an Automation assume role named AWS-SystemsManager-PatchSummaryExportRole to use for the export process to S3.

Note

If you are exporting compliance data to an encrypted S3 bucket, you must update its associated AWS KMS key policy to provide the necessary permissions for AWS-SystemsManager-PatchSummaryExportRole. For instance, add a permission similar to this to your S3 bucket's AWS KMS policy:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": "role-arn"
}
```
Replace `role-arn` with the Amazon Resource Name (ARN) of the created in your account, in the format `arn:aws:iam::111222333444:role/service-role/AWS-SystemsManager-PatchSummaryExportRole`. For more information, see Key policies in AWS KMS in the AWS Key Management Service Developer Guide.

The first time you generate a report on a schedule, Systems Manager creates another service role named AWS-EventBridge-Start-SSMAutomationRole, along with the service role AWS-SystemsManager-PatchSummaryExportRole (if not created already) to use for the export process. AWS-EventBridge-Start-SSMAutomationRole enables Amazon EventBridge to start an automation using the runbook AWS-ExportPatchReportToS3.

We recommend against attempting to modify these policies and roles. Doing so could cause patch compliance report generation to fail. For more information, see Troubleshooting patch compliance report generation.

Topics

- What's in a generated patch compliance report?
- Generating patch compliance reports for a single managed node
- Generating patch compliance reports for all managed nodes
- Viewing patch compliance reporting history
- Viewing patch compliance reporting schedules
- Troubleshooting patch compliance report generation

What's in a generated patch compliance report?

This topic provides information about the types of content included in the patch compliance reports that are generated and downloaded to a specified S3 bucket.

Report format for a single managed node

A report generated for a single managed node provides both summary and detailed information.

Download a sample report (single node)

Summary information for a single managed node includes the following:
• Index
• Instance ID
• Instance name
• Instance IP
• Platform name
• Platform version
• SSM Agent version
• Patch baseline
• Patch group
• Compliance status
• Compliance severity
• Noncompliant Critical severity patch count
• Noncompliant High severity patch count
• Noncompliant Medium severity patch count
• Noncompliant Low severity patch count
• Noncompliant Informational severity patch count
• Noncompliant Unspecified severity patch count

Detailed information for a single managed node includes the following:

• Index
• Instance ID
• Instance name
• Patch name
• KB ID/Patch ID
• Patch state
• Last report time
• Compliance level
• Patch severity
• Patch classification
• CVE ID
• Patch baseline
• Logs URL
• Instance IP
• Platform name
• Platform version
• SSM Agent version

**Note**

When you create a custom patch baseline, you can specify a compliance severity level for patches approved by that patch baseline, such as Critical or High. If the patch state of any approved patch is reported as Missing, then the patch baseline's overall reported compliance severity is the severity level you specified.

**Report format for all managed nodes**

A report generated for all managed nodes provides only summary information.

**Download a sample report (all managed nodes)**

Summary information for all managed nodes includes the following:

• Index
• Instance ID
• Instance name
• Instance IP
• Platform name
• Platform version
• SSM Agent version
• Patch baseline
• Patch group
• Compliance status
• Compliance severity
• Noncompliant Critical severity patch count
• Noncompliant High severity patch count
• Noncompliant Medium severity patch count
• Noncompliant Low severity patch count
• Noncompliant Informational severity patch count
• Noncompliant Unspecified severity patch count

Generating patch compliance reports for a single managed node

Use the following procedure to generate a patch summary report for a single managed node in your AWS account. The report for a single managed node provides details about each patch that is out of compliance, including patch names and IDs.

To generate patch compliance reports for a single managed node

2. In the navigation pane, choose Patch Manager.
3. Choose the Compliance reporting tab.
4. Choose the button for the row of the managed node for which you want to generate a report, and then choose View detail.
5. In the Patch summary section, choose Export to S3.
6. For Report name, enter a name to help you identify the report later.
7. For Reporting frequency, choose one of the following:
   • On demand – Create a one-time report. Skip to Step 9.
   • On a schedule – Specify a recurring schedule for automatically generating reports. Continue to Step 8.
8. For Schedule type, specify either a rate expression, such as every 3 days, or provide a cron expression to set the report frequency.

   For information about cron expressions, see Reference: Cron and rate expressions for Systems Manager.
9. For Bucket name, select the name of an S3 bucket where you want to store the .csv report files.
Important

If you're working in an AWS Region that was launched after March 20, 2019, you must select an S3 bucket in that same Region. Regions launched after that date were turned off by default. For more information and a list of these Regions, see Enabling a Region in the Amazon Web Services General Reference.

10. (Optional) To send notifications when the report is generated, expend the SNS topic section, and then choose an existing Amazon SNS topic from SNS topic Amazon Resource Name (ARN).

11. Choose Submit.

For information about viewing a history of generated reports, see Viewing patch compliance reporting history.

For information about viewing details of reporting schedules you have created, see Viewing patch compliance reporting schedules.

Generating patch compliance reports for all managed nodes

Use the following procedure to generate a patch summary report for all managed nodes in your AWS account. The report for all managed nodes indicates which nodes are out of compliance and the numbers of noncompliant patches. It doesn't provide the names or other identifiers of the patches. For these additional details, you can generate a patch compliance report for a single managed node. For information, see Generating patch compliance reports for a single managed node earlier in this topic.

To generate patch compliance reports for all managed nodes

2. In the navigation pane, choose Patch Manager.
3. Choose the Compliance reporting tab.
4. Choose Export to S3. (Don't select a node ID first.)
5. For Report name, enter a name to help you identify the report later.
6. For Reporting frequency, choose one of the following:
• **On demand** – Create a one-time report. Skip to Step 8.

• **On a schedule** – Specify a recurring schedule for automatically generating reports. Continue to Step 7.

7. For **Schedule type**, specify either a rate expression, such as every 3 days, or provide a cron expression to set the report frequency.

   For information about cron expressions, see Reference: Cron and rate expressions for Systems Manager.

8. For **Bucket name**, select the name of an S3 bucket where you want to store the .csv report files.

   **Important**

   If you’re working in an AWS Region that was launched after March 20, 2019, you must select an S3 bucket in that same Region. Regions launched after that date were turned off by default. For more information and a list of these Regions, see Enabling a Region in the Amazon Web Services General Reference.

9. (Optional) To send notifications when the report is generated, expend the **SNS topic** section, and then choose an existing Amazon SNS topic from SNS topic Amazon Resource Name (ARN).

10. Choose **Submit**.

For information about viewing a history of generated reports, see Viewing patch compliance reporting history.

For information about viewing details of reporting schedules you have created, see Viewing patch compliance reporting schedules.

**Viewing patch compliance reporting history**

Use the information in this topic to help you view details about the patch compliance reports generated in your AWS account.

**To view patch compliance reporting history**

2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Compliance reporting** tab.
4. Choose **View all S3 exports**, and then choose the **Export history** tab.

**Viewing patch compliance reporting schedules**

Use the information in this topic to help you view details about the patch compliance reporting schedules created in your AWS account.

**To view patch compliance reporting history**

2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Compliance reporting** tab.
4. Choose **View all S3 exports**, and then choose the **Report schedule rules** tab.

**Troubleshooting patch compliance report generation**

Use the following information to help you troubleshoot problems with generating patch compliance report generation in Patch Manager, a capability of AWS Systems Manager.

**Topics**

- [A message reports that the AWS-SystemsManager-PatchManagerExportRolePolicy policy is corrupted](#)
- [After deleting patch compliance policies or roles, scheduled reports aren't generated successfully](#)

**A message reports that the AWS-SystemsManager-PatchManagerExportRolePolicy policy is corrupted**

**Problem:** You receive an error message similar to the following, indicating the AWS-SystemsManager-PatchManagerExportRolePolicy is corrupted:

> An error occurred while updating the AWS-SystemsManager-PatchManagerExportRolePolicy policy. If you have edited the policy, you might need to delete the policy, and any role that uses it, then try again. Systems Manager recreates the roles and policies you have deleted.
• **Solution**: Use the Patch Manager console or AWS CLI to delete the affected roles and policies before generating a new patch compliance report.

**To delete the corrupt policy using the console**

2. Do one of the following:

   **On-demand reports** – If the problem occurred while generating a one-time on-demand report, in the left navigation, choose **Policies**, search for `AWS-SystemsManager-PatchManagerExportRolePolicy`, then delete the policy. Next, choose **Roles**, search for `AWS-SystemsManager-PatchSummaryExportRolePolicy`, then delete the role.

   **Scheduled reports** – If the problem occurred while generating a report on a schedule, in the left navigation, choose **Policies**, search one at a time for `AWS-EventBridge-Start-SSMAutomationRolePolicy` and `AWS-SystemsManager-PatchManagerExportRolePolicy`, and delete each policy. Next, choose **Roles**, search one at a time for `AWS-EventBridge-Start-SSMAutomationRole` and `AWS-SystemsManager-PatchSummaryExportRole`, and delete each role.

**To delete the corrupt policy using the AWS CLI**

Replace the *placeholder values* with your account ID.

- If the problem occurred while generating a one-time on-demand report, run the following commands:

  ```
  aws iam delete-policy --policy-arn arn:aws:iam::account-id:policy/AWS-SystemsManager-PatchManagerExportRolePolicy
  
  aws iam delete-role --role-name AWS-SystemsManager-PatchSummaryExportRole
  ```

- If the problem occurred while generating a report on a schedule, run the following commands:

  ```
  aws iam delete-policy --policy-arn arn:aws:iam::account-id:policy/AWS-EventBridge-Start-SSMAutomationRolePolicy
  ```
After completing either procedure, follow the steps to generate or schedule a new patch compliance report.

After deleting patch compliance policies or roles, scheduled reports aren’t generated successfully

**Problem:** The first time you generate a report, Systems Manager creates a service role and a policy to use for the export process (AWS-SystemsManager-PatchSummaryExportRole and AWS-SystemsManager-PatchManagerExportRolePolicy). The first time you generate a report on a schedule, Systems Manager creates another service role and a policy (AWS-EventBridge-Start-SSMAutomationRole and AWS-EventBridge-Start-SSMAutomationRolePolicy). These let Amazon EventBridge start an automation using the runbook [AWS-ExportPatchReportToS3](https://aws.amazon.com/)

If you delete any of these policies or roles, the connections between your schedule and your specified S3 bucket and Amazon SNS topic might be lost.

- **Solution:** To work around this problem, we recommend deleting the previous schedule and creating a new schedule to replace the one that was experiencing issues.

**Remediating noncompliant managed nodes with Patch Manager**

The topics in this section provide overviews of how to identify managed nodes that are out of patch compliance and how to bring nodes into compliance.

**Topics**

- [Identifying noncompliant managed nodes](#)
- [Understanding patch compliance state values](#)
Identifying noncompliant managed nodes

Out-of-compliance managed nodes are identified when either of two AWS Systems Manager documents (SSM documents) are run. These SSM documents reference the appropriate patch baseline for each managed node in Patch Manager, a capability of AWS Systems Manager. They then evaluate the patch state of the managed node and then make compliance results available to you.

There are two SSM documents that are used to identify or update noncompliant managed nodes: AWS-RunPatchBaseline and AWS-RunPatchBaselineAssociation. Each one is used by different processes, and their compliance results are available through different channels. The following table outlines the differences between these documents.

<table>
<thead>
<tr>
<th>Processes that use the document</th>
<th>AWS-RunPatchBaseline</th>
<th>AWS-RunPatchBaselineAssociation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patch on demand - You can scan or patch managed nodes on demand using the <strong>Patch now</strong> option. For information, see <a href="#">Patching managed nodes on demand</a>.</td>
<td>Systems Manager Quick Setup patch policies – You can create a patching configuration in Quick Setup, a capability of AWS Systems</td>
<td>Systems Manager Quick Setup Host Management – You can enable a Host Management configuration option in Quick Setup to scan your managed instances for patch compliance each day. For information, see <a href="#">Amazon EC2 host management</a>.</td>
</tr>
</tbody>
</table>

**Note**

Patch compliance data from Patch Manager can be sent to AWS Security Hub. Security Hub gives you a comprehensive view of your high-priority security alerts and compliance status. It also monitors the patching status of your fleet. For more information, see [Integrating Patch Manager with AWS Security Hub](#).
<table>
<thead>
<tr>
<th>AWS-RunPatchBaseline</th>
<th>AWS-RunPatchBaselineAssociation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manager, that can scan for or install missing patches on separate schedules for an entire organization, a subset of organizational units, or a single AWS account. For information, see Patch Manager organization patching configuration.</td>
<td>a capability of AWS Systems Manager, it regularly scans your managed instances for patch compliance and reports results in the Explorer dashboard.</td>
</tr>
</tbody>
</table>

**Run a command** – You can manually run AWS-RunPatchBaseline in an operation in Run Command, a capability of AWS Systems Manager. For information, see Running commands from the console.

**Maintenance window** – You can create a maintenance window that uses the SSM document AWS-RunPatchBaseline in a Run Command task type. For information, see Walkthrough: Creating a maintenance window for patching (console).
<p>| Format of the patch scan result data | AWS-RunPatchBaseline Association runs, Patch Manager sends an AWS:PatchSummary object to Inventory, a capability of AWS Systems Manager. | AWS-RunPatchBaselineAssociation runs, Patch Manager sends an AWS:ComplianceItem object to Systems Manager Inventory. |
| Viewing patch compliance reports in the console | You can view patch compliance information for processes that use AWS-RunPatchBaseline in Systems Manager Configuration Compliance and Working with managed nodes. For more information, see Viewing patch compliance results. | If you use Quick Setup to scan your managed instances for patch compliance, you can see the compliance report in Systems Manager State Manager, which is accessible using a View results button in Quick Setup. If you use Explorer to scan your managed instances for patch compliance, you can see the compliance report in both Explorer and Systems Manager OpsCenter. |</p>
<table>
<thead>
<tr>
<th>AWS CLI commands for viewing patch compliance results</th>
<th>For processes that use AWS-RunPatchBaseline, you can use the following AWS CLI commands to view summary information about patches on a managed node.</th>
</tr>
</thead>
</table>
|                                                      | • `describe-instance-patch-states`  
• `describe-instance-patch-states-for-patch-group`  
• `describe-patch-group-state` |
| Patching operations                                  | For processes that use AWS-RunPatchBaseline, you specify whether you want the operation to run a Scan operation only, or a Scan and install operation. |
|                                                      | If your goal is to identify noncompliant managed nodes and not remediate them, run only a Scan operation. |

|                                                      | For information about the various patch compliance states you might see reported, see Understanding patch compliance state values |
For information about remediating managed nodes that are out of patch compliance, see Patching noncompliant managed nodes.

Understanding patch compliance state values

The information about patches for a managed node include a report of the state, or status, of each individual patch.

Note
If you want to assign a specific patch compliance state to a managed node, you can use the put-compliance-items AWS Command Line Interface (AWS CLI) command or the PutComplianceItems API operation. Assigning compliance state isn't supported in the console.

Use the information in the following tables to help you identify why a managed node might be out of patch compliance.

Patch compliance values for Debian Server, Raspberry Pi OS, and Ubuntu Server

For Debian Server, Raspberry Pi OS, and Ubuntu Server, the rules for package classification into the different compliance states are described in the following table.

Note
Keep the following in mind when you're evaluating the Installed, Installed Other, and Missing status values: If you don't select the Include nonsecurity updates check box when creating or updating a patch baseline, patch candidate versions are limited to patches included in trusty-security (Ubuntu Server 14.04 LTS), xenial-security (Ubuntu Server 16.04 LTS), bionic-security (Ubuntu Server 18.04 LTS), focal-security (Ubuntu Server 20.04 LTS), groovy-security (Ubuntu Server 20.10 STR), jammy-security (Ubuntu Server 22.04 LTS), or debian-security (Debian Server and Raspberry Pi OS). If you do select the Include nonsecurity updates check box, patches from other repositories are considered as well.
<table>
<thead>
<tr>
<th>Patch state</th>
<th>Description</th>
<th>Compliance status</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSTALLED</td>
<td>The patch is listed in the patch baseline and is installed on the managed node. It could have been installed either manually by an individual or automatically by Patch Manager when the AWS-RunPatchBaseline document was run on the managed node.</td>
<td>Compliant</td>
</tr>
<tr>
<td>INSTALLED_OTHER</td>
<td>The patch isn't included in the baseline or isn't approved by the baseline but is installed on the managed node. The patch might have been installed manually, the package could be a required dependency of another approved patch, or the patch might have been included in an InstallOv errideList operation. If you don't specify Block as the Rejected patches action, Installed_Other patches also includes installed but rejected patches.</td>
<td>Compliant</td>
</tr>
<tr>
<td>INSTALLED_PENDING_REBOOT</td>
<td>INSTALLED_PENDING_REBOOT can mean either of two things:</td>
<td>Non-Compliant</td>
</tr>
</tbody>
</table>

- The Patch Manager Install operation
<table>
<thead>
<tr>
<th>Patch state</th>
<th>Description</th>
<th>Compliance status</th>

</thead>
<tbody>
<tr>
<td>INSTALLED_REJECTED</td>
<td>The patch is installed on the managed node but is specified in a Rejected patches list. This typically means the patch was installed before it was added to a list of rejected patches.</td>
<td>Non-Compliant</td>
</tr>
<tr>
<td>MISSING</td>
<td>Packages that are filtered through the baseline and not already installed.</td>
<td>Non-Compliant</td>
</tr>
<tr>
<td>FAILED</td>
<td>Packages that failed to install during the patch operation.</td>
<td>Non-Compliant</td>
</tr>
</tbody>
</table>

applied the patch to the managed node, but the node has not been rebooted since the patch was applied. This typically means the NoReboot option was selected for the RebootOption parameter when the AWS-RunPatchBaseline document was last run on the managed node. For more information, see [Parameter name: RebootOption](#).

- A patch was installed outside of Patch Manager since the last time the managed node was rebooted.
### Patch compliance values for other operating systems

For all operating systems besides Debian Server, Raspberry Pi OS, and Ubuntu Server, the rules for package classification into the different compliance states are described in the following table.

<table>
<thead>
<tr>
<th>Patch state</th>
<th>Description</th>
<th>Compliance value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>INSTALLED</strong></td>
<td>The patch is listed in the patch baseline and is installed on the managed node. It could have been installed either manually by an individual or automatically by Patch Manager when the AWS-RunPatchBaseline document was run on the node.</td>
<td>Compliant</td>
</tr>
<tr>
<td><strong>INSTALLED_OTHER</strong></td>
<td>The patch isn't in the baseline, but it is installed on the managed node. The patch might have been installed manually, or the package could be a required dependency of another approved patch. If you don't specify Block as the Rejected patches action, Installed_Other patches also includes installed but rejected patches.</td>
<td>Compliant</td>
</tr>
<tr>
<td><strong>INSTALLED_REJECTED</strong></td>
<td>The patch is installed on the managed node but is specified in a rejected patches list. This typically means the patch was installed before it was deemed compliant.</td>
<td>Non-Compliant</td>
</tr>
<tr>
<td>Patch state</td>
<td>Description</td>
<td>Compliance value</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td></td>
<td>was added to a list of rejected patches.</td>
<td></td>
</tr>
<tr>
<td>INSTALLED_PENDING_REBOOT</td>
<td>INSTALL_PENDING_REBOOT can mean either of two things:</td>
<td>Non-Compliant</td>
</tr>
<tr>
<td></td>
<td>• The Patch Manager Install operation applied the patch to the managed node, but the node has not been rebooted since the patch was applied. This typically means the NoReboot option was selected for the RebootOption parameter when the AWS-RunPatchBaseline document was last run on the managed node. For more information, see Parameter name: RebootOption.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• A patch was installed outside of Patch Manager since the last time the managed node was rebooted.</td>
<td></td>
</tr>
<tr>
<td>Patch state</td>
<td>Description</td>
<td>Compliance value</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>MISSING</td>
<td>The patch is approved in the baseline, but it isn't installed on the managed node. If you configure the AWS-RunPatchBaseline document task to scan (instead of install), the system reports this status for patches that were located during the scan but haven't been installed.</td>
<td>Non-Compliant</td>
</tr>
<tr>
<td>Patch state</td>
<td>Description</td>
<td>Compliance value</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>NOT_APPLICABLE ¹</td>
<td>The patch is approved in the baseline, but the service or feature that uses the patch isn't installed on the managed node. For example, a patch for a web server service such as Internet Information Services (IIS) would show NOT_APPLICABLE if it was approved in the baseline, but the web service isn't installed on the managed node. A patch can also be marked NOT_APPLICABLE if it has been superseded by a subsequent update. This means that the later update is installed and the NOT_APPLICABLE update is no longer required.</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

**Note**

This compliance state is only reported on Windows Server operating systems.
### Patching noncompliant managed nodes

Many of the same AWS Systems Manager tools and processes you can use to check managed nodes for patch compliance can be used to bring nodes into compliance with the patch rules that currently apply to them. To bring managed nodes into patch compliance, Patch Manager, a capability of AWS Systems Manager, must run a **Scan and install** operation. (If your goal is only to identify noncompliant managed nodes and not remediate them, run a **Scan** operation instead. For more information, see [Identifying noncompliant managed nodes](#).)

### Install patches using Systems Manager

You can choose from several tools to run a **Scan and install** operation:

- (Recommended) Configure a patch policy in Quick Setup, a capability of Systems Manager, that lets you install missing patches on a schedule for an entire organization, a subset of organizational units, or a single AWS account. For more information, see [Patch Manager organization patching configuration](#).

- Create a maintenance window that uses the Systems Manager document (SSM document) `AWS-RunPatchBaseline` in a Run Command task type. For information, see [Walkthrough: Creating a maintenance window for patching (console)](#).

---

1. For patches with the state **INSTALLED_OTHER** and **NOT_APPLICABLE**, Patch Manager omits some data from query results based on the `describe-instance-patches` command, such as the values for Classification and Severity. This is done to help prevent exceeding the data limit for individual nodes in Inventory, a capability of AWS Systems Manager. To view all patch details, you can use the `describe-available-patches` command.
• Manually run AWS-RunPatchBaseline in a Run Command operation. For information, see Running commands from the console.

• Install patches on demand using the Patch now option. For information, see Patching managed nodes on demand.

Avoiding unintentional patch compliance data overwrites

If you have multiple types of operations in place to scan your instances for patch compliance, each scan overwrites the patch compliance data of previous scans. As a result, you might end up with unexpected results in your patch compliance data.

For example, suppose you create a patch policy that scans for patch compliance each day at 2 AM local time. That patch policy uses a patch baseline that targets patches with severity marked as Critical, Important, and Moderate. This patch baseline also specifies a few specifically rejected patches.

Also suppose that you already had a maintenance window set up to scan the same set of managed nodes each day at 4 AM local time, which you don't delete or deactivate. That maintenance window's task uses a different patch baseline, one that targets only patches with a Critical severity and doesn't exclude any specific patches.

When this second scan is performed by the maintenance window, the patch compliance data from the first scan is deleted and replaced with patch compliance from the second scan.

Therefore, we strongly recommend using only one automated method for scanning and installing in your patching operations. If you're setting up patch policies, you should delete or deactivate other methods of scanning for patch compliance. For more information, see the following topics:

• To remove a patching operation task from a maintenance window – Updating or deregistering maintenance window tasks (console)
• To delete a State Manager association – Deleting associations.

To deactivate daily patch compliance scans in a Host Management configuration, do the following in Quick Setup:

1. In the navigation pane, choose Quick Setup.
2. Select the Host Management configuration to update.
3. Choose **Actions, Edit configuration**.
4. Clear the **Scan instances for missing patches daily** check box.
5. Choose **Update**.

![Note]

Using the **Patch now** option to scan a managed node for compliance also results in an overwrite of patch compliance data.

### Patching managed nodes on demand

Using the **Patch now** option in Patch Manager, a capability of AWS Systems Manager, you can run on-demand patching operations from the Systems Manager console. This means you don’t have to create a schedule in order to update the compliance status of your managed nodes or to install patches on noncompliant nodes. You also don’t need to switch the Systems Manager console between Patch Manager and Maintenance Windows, a capability of AWS Systems Manager, in order to set up or modify a scheduled patching window.

**Patch now** is especially useful when you must apply zero-day updates or install other critical patches on your managed nodes as soon as possible.

![Note]

Patching on demand is supported for a single AWS account-AWS Region pair at a time. It can’t be used with patching operations that are based on **patch policies**. We recommend using patch policies for keeping all your managed nodes in compliance. For more information about working with patch policies, see [Using Quick Setup patch policies](#).

### Topics
- **How 'Patch now' works**
- **Running 'Patch now'**

**How 'Patch now' works**

To run **Patch now**, you specify just two required settings:
• Whether to scan for missing patches only, or to scan and install patches on your managed nodes

• Which managed nodes to run the operation on

When the **Patch now** operation runs, it determines which patch baseline to use in the same way one is selected for other patching operations. If a managed node is associated with a patch group, the patch baseline specified for that group is used. If the managed node isn't associated with a patch group, the operation uses the patch baseline that is currently set as the default for the operating system type of the managed node. This can be a predefined baseline, or the custom baseline you have set as the default. For more information about patch baseline selection, see **About patch groups**.

Options you can specify for **Patch now** include choosing when, or whether, to reboot managed nodes after patching, specifying an Amazon Simple Storage Service (Amazon S3) bucket to store log data for the patching operation, and running Systems Manager documents (SSM documents) as lifecycle hooks during patching.

**Concurrency and error thresholds for 'Patch now'**

For **Patch now** operations, concurrency and error threshold options are handled by Patch Manager. You don't need to specify how many managed nodes to patch at once, nor how many errors are permitted before the operation fails. Patch Manager applies the concurrency and error threshold settings described in the following tables when you patch on demand.

⚠️ **Important**

The following thresholds apply to **Scan and install** operations only. For **Scan** operations, Patch Manager attempts to scan up to 1,000 nodes concurrently, and continue scanning until it has encountered up to 1,000 errors.

### Concurrency: Install operations

<table>
<thead>
<tr>
<th>Total number of managed nodes in the Patch now operation</th>
<th>Number of managed nodes scanned or patched at a time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fewer than 25</td>
<td>1</td>
</tr>
<tr>
<td>25-100</td>
<td>5%</td>
</tr>
</tbody>
</table>
### Total number of managed nodes in the Patch now operation

<table>
<thead>
<tr>
<th>Total number of managed nodes in the Patch now operation</th>
<th>Number of managed nodes scanned or patched at a time</th>
</tr>
</thead>
<tbody>
<tr>
<td>101 to 1,000</td>
<td>8%</td>
</tr>
<tr>
<td>More than 1,000</td>
<td>10%</td>
</tr>
</tbody>
</table>

### Error threshold: Install operations

<table>
<thead>
<tr>
<th>Total number of managed nodes in the Patch now operation</th>
<th>Number of errors permitted before the operation fails</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fewer than 25</td>
<td>1</td>
</tr>
<tr>
<td>25-100</td>
<td>5</td>
</tr>
<tr>
<td>101 to 1,000</td>
<td>10</td>
</tr>
<tr>
<td>More than 1,000</td>
<td>10</td>
</tr>
</tbody>
</table>

### Using 'Patch now' lifecycle hooks

**Patch now** provides you with the ability to run SSM Command documents as lifecycle hooks during an **Install** patching operation. You can use these hooks for tasks such as shutting down applications before patching or running health checks on your applications after patching or after a reboot.

For more information about using lifecycle hooks, see [About the AWS-RunPatchBaselineWithHooks SSM document](#).

The following table lists the lifecycle hooks available for each of the three **Patch now** reboot options, in addition to sample uses for each hook.
<table>
<thead>
<tr>
<th>Reboot option</th>
<th>Hook: Before installation</th>
<th>Hook: After installation</th>
<th>Hook: On exit</th>
<th>Hook: After scheduled reboot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reboot if needed</td>
<td>Run an SSM document before patching begins.</td>
<td>Run an SSM document at the end of the patching operation and before managed node reboot.</td>
<td>Run an SSM document after the patching operation is complete and instances are rebooted.</td>
<td>Not available</td>
</tr>
<tr>
<td></td>
<td>Example use: Safely shut down applications before the patching process begins.</td>
<td>Example use: Run operations such as installing third-party applications before a potential reboot.</td>
<td>Example use: Ensure that applications are running as expected after patching.</td>
<td></td>
</tr>
<tr>
<td>Do not reboot my instances</td>
<td>Same as above.</td>
<td>Run an SSM document at the end of the patching operation.</td>
<td>Not available</td>

<td>After a scheduled reboot is complete.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Example use: Ensure that applications are running as expected after the reboot.</td>
</tr>
</tbody>
</table>

Running 'Patch now'

Use the following procedure to patch your managed nodes on demand.

**To run 'Patch now'**

2. In the navigation pane, choose Patch Manager.
3. On either the **AWS Systems Manager Patch Manager** page or the **Patch baselines** page, depending on which one opens, choose **Patch now**.
4. For **Patching operation**, choose one of the following:
   - **Scan**: Patch Manager finds which patches are missing from your managed nodes but doesn’t install them. You can view the results in the Compliance dashboard or in other tools you use for viewing patch compliance.
   - **Scan and install**: Patch Manager finds which patches are missing from your managed nodes and installs them.
5. Use this step only if you chose **Scan and install** in the previous step. For **Reboot option**, choose one of the following:
• **Reboot if needed**: After installation, Patch Manager reboots managed nodes only if needed to complete a patch installation.

• **Don’t reboot my instances**: After installation, Patch Manager doesn’t reboot managed nodes. You can reboot nodes manually when you choose or manage reboots outside of Patch Manager.

• **Schedule a reboot time**: Specify the date, time, and UTC time zone for Patch Manager to reboot your managed nodes. After you run the **Patch now** operation, the scheduled reboot is listed as an association in State Manager with the name **AWS-PatchRebootAssociation**.

6. **For Instances to patch**, choose one of the following:

   • **Patch all instances**: Patch Manager runs the specified operation on all managed nodes in your AWS account in the current AWS Region.

   • **Patch only the target instances I specify**: You specify which managed nodes to target in the next step.

7. Use this step only if you chose **Patch only the target instances I specify** in the previous step. In the **Target selection** section, identify the nodes on which you want to run this operation by specifying tags, selecting nodes manually, or specifying a resource group.

   **Note**
   If a managed node you expect to see isn’t listed, see **Troubleshooting managed node availability** for troubleshooting tips.
   If you choose to target a resource group, note that resource groups that are based on an AWS CloudFormation stack must still be tagged with the default `aws:cloudformation:stack-id` tag. If it has been removed, Patch Manager might be unable to determine which managed nodes belong to the resource group.

8. **(Optional)** For **Patching log storage**, if you want to create and save logs from this patching operation, select the S3 bucket for storing the logs.

   **Note**
   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more
information, see Configure instance permissions required for Systems Manager or Create the IAM service role required for Systems Manager in hybrid and multicloud environments. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

9. (Optional) If you want to run SSM documents as lifecycle hooks during specific points of the patching operation, do the following:

- Choose Use lifecycle hooks.
- For each available hook, select the SSM document to run at the specified point of the operation:
  - Before installation
  - After installation
  - On exit
  - After scheduled reboot

Note
The default document, AWS-Noop, runs no operations.

10. Choose Patch now.

The Association execution summary page opens. (Patch now uses associations in State Manager, a capability of AWS Systems Manager, for its operations.) In the Operation summary area, you can monitor the status of scanning or patching on the managed nodes you specified.

Working with patch baselines

A patch baseline in Patch Manager, a capability of AWS Systems Manager, defines which patches are approved for installation on your managed nodes. You can specify approved or rejected patches one by one. You can also create auto-approval rules to specify that certain types of updates (for example, critical updates) should be automatically approved. The rejected list overrides both the rules and the approve list. To use a list of approved patches to install specific packages, you first remove all auto-approval rules. If you explicitly identify a patch as rejected, it won’t be approved or installed, even if it matches all of the criteria in an auto-approval rule. Also, a patch is installed on a
managed node only if it applies to the software on the node, even if the patch has otherwise been approved for the managed node.

**Topics**

- [Viewing AWS predefined patch baselines](#)
- [Working with custom patch baselines](#)
- [Setting an existing patch baseline as the default](#)

**More info**

- [About patch baselines](#)

**Viewing AWS predefined patch baselines**

Patch Manager, a capability of AWS Systems Manager, includes a predefined patch baseline for each operating system supported by Patch Manager. You can use these patch baselines (you can’t customize them), or you can create your own. The following procedure describes how to view a predefined patch baseline to see if it meets your needs. To learn more about patch baselines, see [About predefined and custom patch baselines](#).

**To view AWS predefined patch baselines**

2. In the navigation pane, choose **Patch Manager**.
3. In the patch baselines list, choose the baseline ID of one of the predefined patch baselines.

-or-

If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, choose the **Patch baselines** tab, and then choose the baseline ID of one of the predefined patch baselines.

**Note**

For Windows Server, three predefined patch baselines are provided. The patch baselines `AWS-DefaultPatchBaseline` and `AWS-WindowsPredefinedPatchBaseline-OS` support only operating system updates.
on the Windows operating system itself. AWS-DefaultPatchBaseline is used as the default patch baseline for Windows Server managed nodes unless you specify a different patch baseline. The configuration settings in these two patch baselines are the same. The newer of the two, AWS-WindowsPredefinedPatchBaseline-OS, was created to distinguish it from the third predefined patch baseline for Windows Server. That patch baseline, AWS-WindowsPredefinedPatchBaseline-OS-Applications, can be used to apply patches to both the Windows Server operating system and supported applications released by Microsoft. For more information, see Setting an existing patch baseline as the default.

4. In the Approval rules section, review the patch baseline configuration.

5. If the configuration is acceptable for your managed nodes, you can skip ahead to the procedure Working with patch groups.

-or-

To create your own default patch baseline, continue to the topic Working with custom patch baselines.

Working with custom patch baselines

Patch Manager, a capability of AWS Systems Manager, includes a predefined patch baseline for each operating system supported by Patch Manager. You can use these patch baselines (you can't customize them), or you can create your own.

The following procedures describe how to create, update, and delete your own custom patch baselines. To learn more about patch baselines, see About predefined and custom patch baselines.

Topics

- Creating a custom patch baseline (Linux)
- Creating a custom patch baseline (macOS)
- Creating a custom patch baseline (Windows)
- Updating or deleting a custom patch baseline
Creating a custom patch baseline (Linux)

Use the following procedure to create a custom patch baseline for Linux managed nodes in Patch Manager, a capability of AWS Systems Manager.

For information about creating a patch baseline for macOS managed nodes, see Creating a custom patch baseline (macOS). For information about creating a patch baseline for Windows managed nodes, see Creating a custom patch baseline (Windows).

To create a custom patch baseline for Linux managed nodes

2. In the navigation pane, choose Patch Manager.
3. Choose the Patch baselines tab, and then choose Create patch baseline.
4. For Name, enter a name for your new patch baseline, for example, MyRHELPatchBaseline.
5. (Optional) For Description, enter a description for this patch baseline.
6. For Operating system, choose an operating system, for example, Red Hat Enterprise Linux.
7. If you want to begin using this patch baseline as the default for the selected operating system as soon as you create it, check the box next to Set this patch baseline as the default patch baseline for operating system name instances.

Note

This option is available only if you first accessed Patch Manager before the patch policies release on December 22, 2022.
For information about setting an existing patch baseline as the default, see Setting an existing patch baseline as the default.

8. In the Approval rules for operating-systems section, use the fields to create one or more auto-approval rules.
- **Products**: The version of the operating systems the approval rule applies to, such as RedhatEnterpriseLinux7.4. The default selection is All.

- **Classification**: The type of patches the approval rule applies to, such as Security or Enhancement. The default selection is All.

**Tip**

You can configure a patch baseline to control whether minor version upgrades for Linux are installed, such as RHEL 7.8. Minor version upgrades can be installed automatically by Patch Manager provided that the update is available in the appropriate repository.

For Linux operating systems, minor version upgrades aren't classified consistently. They can be classified as bug fixes or security updates, or not classified, even within the same kernel version. Here are a few options for controlling whether a patch baseline installs them.

- **Option 1**: The broadest approval rule to ensure minor version upgrades are installed when available is to specify **Classification** as All (*) and choose the **Include nonsecurity updates** option.

- **Option 2**: To ensure patches for an operating system version are installed, you can use a wildcard (*) to specify its kernel format in the **Patch exceptions** section of the baseline. For example, the kernel format for RHEL 7.* is `kernel-3.10.*.el7.x86_64`.

  Enter `kernel-3.10.*.el7.x86_64` in the **Approved patches** list in your patch baseline to ensure all patches, including minor version upgrades, are applied to your RHEL 7.* managed nodes. (If you know the exact package name of a minor version patch, you can enter that instead.)

- **Option 3**: You can have the most control over which patches are applied to your managed nodes, including minor version upgrades, by using the **InstallOverrideList** parameter in the `AWS-RunPatchBaseline` document. For more information, see **About the AWS-RunPatchBaseline SSM document**.

- **Severity**: The severity value of patches the rule is to apply to, such as **Critical**. The default selection is All.

- **Auto-approval**: The method for selecting patches for automatic approval.
Note

Because it's not possible to reliably determine the release dates of update packages for Ubuntu Server, the auto-approval options aren't supported for this operating system.

• **Approve patches after a specified number of days**: The number of days for Patch Manager to wait after a patch is released or last updated before a patch is automatically approved. You can enter any integer from zero (0) to 360. For most scenarios, we recommend waiting no more than 100 days.

• **Approve patches released up to a specific date**: The patch release date for which Patch Manager automatically applies all patches released or updated on or before that date. For example, if you specify July 7, 2023, no patches released or last updated on or after July 8, 2023, are installed automatically.

• **(Optional) Compliance reporting**: The severity level you want to assign to patches approved by the baseline, such as Critical or High.

Note

If you specify a compliance reporting level and the patch state of any approved patch is reported as Missing, then the patch baseline's overall reported compliance severity is the severity level you specified.

• **Include non-security updates**: Select the check box to install nonsecurity Linux operating system patches made available in the source repository, in addition to the security-related patches.

Note

For SUSE Linux Enterprise Server, (SLES) it isn't necessary to select the check box because patches for security and nonsecurity issues are installed by default on SLES managed nodes. For more information, see the content for SLES in [How security patches are selected](#).
9. If you want to explicitly approve any patches in addition to those meeting your approval rules, do the following in the **Patch exceptions** section:

- For **Approved patches**, enter a comma-separated list of the patches you want to approve.

  **Note**
  For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

- (Optional) For **Approved patches compliance level**, assign a compliance level to the patches in the list.

- If any approved patches you specify aren't related to security, select the **Include non-security updates** check box for these patches to be installed on your Linux operating system as well.

10. If you want to explicitly reject any patches that otherwise meet your approval rules, do the following in the **Patch exceptions** section:

- For **Rejected patches**, enter a comma-separated list of the patches you want to reject.

  **Note**
  For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

- For **Rejected patches action**, select the action for Patch Manager to take on patches included in the **Rejected patches** list.
  
  - **Allow as dependency**: A package in the **Rejected patches** list is installed only if it's a dependency of another package. It's considered compliant with the patch baseline and its status is reported as `InstalledOther`. This is the default action if no option is specified.
  
  - **Block**: Packages in the **Rejected patches** list, and packages that include them as dependencies, aren't installed by Patch Manager under any circumstances. If a package was installed before it was added to the **Rejected patches** list, or is installed outside of...
Patch Manager afterward, it's considered noncompliant with the patch baseline and its status is reported as *InstalledRejected*.

11. (Optional) If you want to specify alternative patch repositories for different versions of an operating system, such as *AmazonLinux2016.03* and *AmazonLinux2017.09*, do the following for each product in the **Patch sources** section:

   - In **Name**, enter a name to help you identify the source configuration.
   - In **Product**, select the version of the operating systems the patch source repository is for, such as *RedhatEnterpriseLinux7.4*.
   - In **Configuration**, enter the value of the yum repository configuration to use in the following format:

     ```
     [main]
     name=MyCustomRepository
     baseurl=https://my-custom-repository
     enabled=1
     ```

     **Tip**
     For information about other options available for your yum repository configuration, see [dnf.conf(5)](https://docs.aws.amazon.com/systems-manager/latest/userguide/working-with-patch-manager-console.html).

     Choose **Add another source** to specify a source repository for each additional operating system version, up to a maximum of 20.

     For more information about alternative source patch repositories, see [How to specify an alternative patch source repository (Linux)](https://docs.aws.amazon.com/systems-manager/latest/userguide/working-with-patch-manager-console.html).

12. (Optional) For **Manage tags**, apply one or more tag key name/value pairs to the patch baseline.

    Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a patch baseline to identify the severity level of patches it specifies, the operating system family it applies to, and the environment type. In this case, you could specify tags similar to the following key name/value pairs:

    - **Key=PatchSeverity,Value=Critical**
• Key=OS, Value=RHEL
• Key=Environment, Value=Production

13. Choose **Create patch baseline**.

**Creating a custom patch baseline (macOS)**

Use the following procedure to create a custom patch baseline for macOS managed nodes in Patch Manager, a capability of AWS Systems Manager.

For information about creating a patch baseline for Windows Server managed nodes, see [Creating a custom patch baseline (Windows)](https://console.aws.amazon.com/systems-manager/). For information about creating a patch baseline for Linux managed nodes, see [Creating a custom patch baseline (Linux)](https://console.aws.amazon.com/systems-manager/).

**Note**

macOS is not supported in all AWS Regions. For more information about Amazon EC2 support for macOS, see [Amazon EC2 Mac instances](https://console.aws.amazon.com/systems-manager/) in the [Amazon EC2 User Guide](https://console.aws.amazon.com/systems-manager/).

**To create a custom patch baseline for macOS managed nodes**

2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Patch baselines** tab, and then choose **Create patch baseline**.
   - or -

   If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, choose the **Patch baselines** tab, and then choose **Create patch baseline**.
4. For **Name**, enter a name for your new patch baseline, for example, **MymacOSPatchBaseline**.
5. (Optional) For **Description**, enter a description for this patch baseline.
6. For **Operating system**, choose macOS.
7. If you want to begin using this patch baseline as the default for macOS as soon as you create it, check the box next to **Set this patch baseline as the default patch baseline for macOS instances**.
8. In the **Approval rules for operating-systems** section, use the fields to create one or more auto-approval rules.

- **Products**: The version of the operating systems the approval rule applies to, such as Mojave10.14.1 or Catalina10.15.1. The default selection is All.

  **Note**: The Homebrew open-source software package management system has discontinued support for macOS 10.14.x (Mojave) and 10.15.x (Catalina). As a result, patching operations on these versions are not currently supported.

- **Classification**: The package manager or package managers that you want to apply packages during the patching process. You can choose from the following:
  - softwareupdate
  - installer
  - brew
  - brew cask

  The default selection is All.

- **(Optional) Compliance reporting**: The severity level you want to assign to patches approved by the baseline, such as Critical or High.

  **Note**: If you specify a compliance reporting level and the patch state of any approved patch is reported as Missing, then the patch baseline's overall reported compliance severity is the severity level you specified.
• **Include non-security updates**: Select the check box to install nonsecurity operating system patches made available in the source repository, in addition to the security-related patches.

For more information about working with approval rules in a custom patch baseline, see [About custom baselines](#).

9. If you want to explicitly approve any patches in addition to those meeting your approval rules, do the following in the **Patch exceptions** section:

• For **Approved patches**, enter a comma-separated list of the patches you want to approve.

  **Note**

  For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

• (Optional) For **Approved patches compliance level**, assign a compliance level to the patches in the list.

• If any approved patches you specify aren't related to security, select the **Include non-security updates** check box for these patches to be installed on your macOS operating system as well.

10. If you want to explicitly reject any patches that otherwise meet your approval rules, do the following in the **Patch exceptions** section:

• For **Rejected patches**, enter a comma-separated list of the patches you want to reject.

  **Note**

  For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

• For **Rejected patches action**, select the action for Patch Manager to take on patches included in the **Rejected patches** list.

  • **Allow as dependency**: A package in the **Rejected patches** list is installed only if it's a dependency of another package. It's considered compliant with the patch baseline and its status is reported as *InstalledOther*. This is the default action if no option is specified.

  • **Block**: Packages in the **Rejected patches** list, and packages that include them as dependencies, aren't installed by Patch Manager under any circumstances. If a package
was installed before it was added to the **Rejected patches** list, or is installed outside of Patch Manager afterward, it's considered noncompliant with the patch baseline and its status is reported as **InstalledRejected**.

11. (Optional) For **Manage tags**, apply one or more tag key name/value pairs to the patch baseline.

   Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a patch baseline to identify the severity level of patches it specifies, the package manager it applies to, and the environment type. In this case, you could specify tags similar to the following key name/value pairs:

   - Key=PatchSeverity, Value=Critical
   - Key=PackageManager, Value=softwareupdate
   - Key=Environment, Value=Production

12. Choose **Create patch baseline**.

### Creating a custom patch baseline (Windows)

Use the following procedure to create a custom patch baseline for Windows managed nodes in Patch Manager, a capability of AWS Systems Manager.

For information about creating a patch baseline for Linux managed nodes, see [Creating a custom patch baseline (Linux)]( ). For information about creating a patch baseline for macOS managed nodes, see [Creating a custom patch baseline (macOS)]( ).

For an example of creating a patch baseline that is limited to installing Windows Service Packs only, see [Tutorial: Create a patch baseline for installing Windows Service Packs (console)]( ).

### To create a custom patch baseline (Windows)

2. In the navigation pane, choose **Patch Manager**.

3. Choose the **Patch baselines** tab, and then choose **Create patch baseline**.

   -or-
If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, choose the **Patch baselines** tab, and then choose **Create patch baseline**.

4. For **Name**, enter a name for your new patch baseline, for example, `MyWindowsPatchBaseline`.

5. (Optional) For **Description**, enter a description for this patch baseline.

6. For **Operating system**, choose Windows.

7. If you want to begin using this patch baseline as the default for Windows as soon as you create it, select **Set this patch baseline as the default patch baseline for Windows Server instances**.

   **Note**
   
   This option is available only if you first accessed Patch Manager before the patch policies release on December 22, 2022.
   
   For information about setting an existing patch baseline as the default, see **Setting an existing patch baseline as the default**.

8. In the **Approval rules for operating systems** section, use the fields to create one or more auto-approval rules.

   - **Products**: The version of the operating systems the approval rule applies to, such as `WindowsServer2012`. The default selection is **All**.

   - **Classification**: The type of patches the approval rule applies to, such as `CriticalUpdates`, `Drivers`, and `Tools`. The default selection is **All**.

   **Tip**
   
   You can include Windows Service Pack installations in your approval rules by including `ServicePacks` or by choosing **All** in your **Classification** list. For an example, see **Tutorial: Create a patch baseline for installing Windows Service Packs (console)**.

   - **Severity**: The severity value of patches the rule is to apply to, such as `Critical`. The default selection is **All**.

   - **Auto-approval**: The method for selecting patches for automatic approval.
• Approve patches after a specified number of days: The number of days for Patch Manager to wait after a patch is released or updated before a patch is automatically approved. You can enter any integer from zero (0) to 360. For most scenarios, we recommend waiting no more than 100 days.

• Approve patches released up to a specific date: The patch release date for which Patch Manager automatically applies all patches released or updated on or before that date. For example, if you specify July 7, 2023, no patches released or last updated on or after July 8, 2023, are installed automatically.

• (Optional) Compliance reporting: The severity level you want to assign to patches approved by the baseline, such as High.

Note
If you specify a compliance reporting level and the patch state of any approved patch is reported as Missing, then the patch baseline's overall reported compliance severity is the severity level you specified.

9. (Optional) In the Approval rules for applications section, use the fields to create one or more auto-approval rules.

Note
Instead of specifying approval rules, you can specify lists of approved and rejected patches as patch exceptions. See steps 10 and 11.

• Product family: The general Microsoft product family for which you want to specify a rule, such as Office or Exchange Server.

• Products: The version of the application the approval rule applies to, such as Office 2016 or Active Directory Rights Management Services Client 2.0 2016. The default selection is All.

• Classification: The type of patches the approval rule applies to, such as Critical Updates. The default selection is All.

• Severity: The severity value of patches the rule applies to, such as Critical. The default selection is All.

• Auto-approval: The method for selecting patches for automatic approval.
• **Approve patches after a specified number of days**: The number of days for Patch Manager to wait after a patch is released or updated before a patch is automatically approved. You can enter any integer from zero (0) to 360. For most scenarios, we recommend waiting no more than 100 days.

• **Approve patches released up to a specific date**: The patch release date for which Patch Manager automatically applies all patches released or updated on or before that date. For example, if you specify July 7, 2023, no patches released or last updated on or after July 8, 2023, are installed automatically.

• (Optional) **Compliance reporting**: The severity level you want to assign to patches approved by the baseline, such as Critical or High.

**Note**

If you specify a compliance reporting level and the patch state of any approved patch is reported as Missing, then the patch baseline's overall reported compliance severity is the severity level you specified.

10. (Optional) If you want to explicitly approve any patches instead of letting patches be selected according to approval rules, do the following in the **Patch exceptions** section:

• For **Approved patches**, enter a comma-separated list of the patches you want to approve.

**Note**

For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).

• (Optional) For **Approved patches compliance level**, assign a compliance level to the patches in the list.

11. If you want to explicitly reject any patches that otherwise meet your approval rules, do the following in the **Patch exceptions** section:

• For **Rejected patches**, enter a comma-separated list of the patches you want to reject.
For **Rejected patches action**, select the action for Patch Manager to take on patches included in the **Rejected patches** list.

- **Allow as dependency**: A package in the **Rejected patches** list is installed only if it's a dependency of another package. It's considered compliant with the patch baseline and its status is reported as `InstalledOther`. This is the default action if no option is specified.

- **Block**: Packages in the **Rejected patches** list, and packages that include them as dependencies, aren't installed by Patch Manager under any circumstances. If a package was installed before it was added to the **Rejected patches** list, or is installed outside of Patch Manager afterward, it's considered noncompliant with the patch baseline and its status is reported as `InstalledRejected`.

12. (Optional) For **Manage tags**, apply one or more tag key name/value pairs to the patch baseline.

Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a patch baseline to identify the severity level of patches it specifies, the operating system family it applies to, and the environment type. In this case, you could specify tags similar to the following key name/value pairs:

- Key=PatchSeverity,Value=Critical
- Key=OS,Value=RHEL
- Key=Environment,Value=Production

13. Choose **Create patch baseline**.

**Updating or deleting a custom patch baseline**

You can update or delete a custom patch baseline that you have created in Patch Manager, a capability of AWS Systems Manager. When you update a patch baseline, you can change its name or description, its approval rules, and its exceptions for approved and rejected patches. You can also update the tags that are applied to the patch baseline. You can't change the operating system
type that a patch baseline has been created for, and you can't make changes to a predefined patch baseline provided by AWS.

**Updating or deleting a patch baseline**

Follow these steps to update or delete a patch baseline.

⚠️ Important

Use caution when deleting a custom patch baseline that might be used by a patch policy configuration in Quick Setup.

If you are using a [patch policy configuration](#) in Quick Setup, updates you make to custom patch baselines are synchronized with Quick Setup once an hour.

If a custom patch baseline that was referenced in a patch policy is deleted, a banner displays on the Quick Setup **Configuration details** page for your patch policy. The banner informs you that the patch policy references a patch baseline that no longer exists, and that subsequent patching operations will fail. In this case, return to the Quick Setup **Configurations** page, select the Patch Manager configuration, and choose **Actions, Edit configuration**. The deleted patch baseline name is highlighted, and you must select a new patch baseline for the affected operating system.

**To update or delete a patch baseline**

2. In the navigation pane, choose **Patch Manager**.
3. Choose the patch baseline that you want to update or delete, and then do one of the following:

   - To remove the patch baseline from your AWS account, choose **Delete**. The system prompts you to confirm your actions.
   - To make changes to the patch baseline name or description, approval rules, or patch exceptions, choose **Edit**. On the **Edit patch baseline** page, change the values and options that you want, and then choose **Save changes**.
   - To add, change, or delete tags applied to the patch baseline, choose the **Tags** tab, and then choose **Edit tags**. On the **Edit patch baseline tags** page, make updates to the patch baseline tags, and then choose **Save changes**.
For information about the configuration choices you can make, see Working with custom patch baselines.

Setting an existing patch baseline as the default

⚠️ Important

Any default patch baseline selections you make here do not apply to patching operations that are based on a patch policy. Patch policies use their own patch baseline specifications. For more information about patch policies, see Using Quick Setup patch policies.

When you create a custom patch baseline in Patch Manager, a capability of AWS Systems Manager, you can set the baseline as the default for the associated operating system type as soon as you create it. For information, see Working with custom patch baselines.

You can also set an existing patch baseline as the default for an operating system type.

ℹ️ Note

The steps you follow depend on whether you first accessed Patch Manager before or after the patch policies release on December 22, 2022. If you used Patch Manager before that date, you can use the console procedure. Otherwise, use the AWS CLI procedure. The Actions menu referenced in the console procedure is not displayed in Regions where Patch Manager wasn't used before the patch policies release.

To set a patch baseline as the default

2. In the navigation pane, choose Patch Manager.
3. Choose the Patch baselines tab.
4. In the patch baselines list, choose the button of a patch baseline that isn't currently set as the default for an operating system type.
The **Default baseline** column indicates which baselines are currently set as the defaults.

5. In the **Actions** menu, choose **Set default patch baseline**.

⚠️ **Important**

The **Actions** menu is not available if you didn't work with Patch Manager in the current AWS account and Region before December 22, 2022. See the **Note** earlier in this topic for more information.

6. In the confirmation dialog box, choose **Set default**.

**To set a patch baseline as the default (AWS CLI)**

1. Run the `describe-patch-baselines` command to view a list of available patch baselines and their IDs and Amazon Resource Names (ARNs).

   ```bash
   aws ssm describe-patch-baselines
   ```

2. Run the `register-default-patch-baseline` command to set a baseline as the default for the operating system it's associated with. Replace `baseline-id-or-ARN` with the ID of the custom patch baseline or predefined baseline to use.

   **Linux & macOS**

   ```bash
   aws ssm register-default-patch-baseline \
   --baseline-id baseline-id-or-ARN
   ```

   The following is an example of a setting a custom baseline as the default.

   ```bash
   aws ssm register-default-patch-baseline \
   --baseline-id pb-abc123cf9bEXAMPLE
   ```

   The following is an example of a setting a predefined baseline managed by AWS as the default.

   ```bash
   aws ssm register-default-patch-baseline \
   --baseline-id baseline-id-or-ARN
   ```
Windows Server

```bash
aws ssm register-default-patch-baseline ^
   --baseline-id baseline-id-or-ARN
```

The following is an example of a setting a custom baseline as the default.

```bash
aws ssm register-default-patch-baseline ^
   --baseline-id pb-abc123cf9bEXAMPLE
```

The following is an example of a setting a predefined baseline managed by AWS as the default.

```bash
aws ssm register-default-patch-baseline ^
   pb-071da192df1226b63
```

### Viewing available patches

With Patch Manager, a capability of AWS Systems Manager, you can view all available patches for a specified operating system and, optionally, a specific operating system version.

**Tip**

To generate a list of available patches and save them to a file, you can use the `describe-available-patches` command and specify your preferred output.

**To view available patches**

2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Patches** tab.
-or-

If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, and then choose the **Patches** tab.

**Note**
For Windows Server, the **Patches** tab displays updates that are available from Windows Server Update Service (WSUS).

4. For **Operating system**, choose the operating system for which you want to view available patches, such as Windows or Amazon Linux.

5. (Optional) For **Product**, choose an OS version, such as WindowsServer2019 or AmazonLinux2018.03.

6. (Optional) To add or remove information columns for your results, choose the configure button

   at the top right of the **Patches** list. (By default, the **Patches** tab displays columns for only some of the available patch metadata.)

   For information about the types of metadata you can add to your view, see **Patch** in the **AWS Systems Manager API Reference**.

### Working with patch groups

If you are **not** using patch policies in your operations, you can organize your patching efforts by adding managed nodes to patch groups by using tags.

**Important**
Patch groups are not used in patching operations that are based on **patch policies**. For more information about working with patch policies, see **Using Quick Setup patch policies**.

To use tags in patching operations, you must apply the tag key **Patch** **Group** or **PatchGroup** to your managed nodes. You must also specify the name that you want to give the patch group
as the value of the tag. You can specify any tag value, but the tag key must be Patch Group or PatchGroup.

PatchGroup (without a space) is required if you have allowed tags in EC2 instance metadata.

After you group your managed nodes using tags, you add the patch group value to a patch baseline. By registering the patch group with a patch baseline, you ensure that the correct patches are installed during the patching operation. For more information about patch groups, see About patch groups.

Complete the tasks in this topic to prepare your managed nodes for patching using tags with your nodes and patch baseline. Task 1 is required only if you are patching Amazon EC2 instances. Task 2 is required only if you are patching non-EC2 instances in a hybrid and multicloud environment. Task 3 is required for all managed nodes.

Tip

You can also add tags to managed nodes using the AWS CLI command add-tags-to-resource or the Systems Manager API operation AddTagsToResource.

Tasks

- Task 1: Add EC2 instances to a patch group using tags
- Task 2: Add managed nodes to a patch group using tags
- Task 3: Add a patch group to a patch baseline

Task 1: Add EC2 instances to a patch group using tags

You can add tags to EC2 instances using the Systems Manager console or the Amazon EC2 console. This task is required only if you are patching Amazon EC2 instances.

Important

You can't apply the Patch Group tag (with a space) to an Amazon EC2 instance if the Allow tags in instance metadata option is enabled on the instance. Allowing tags in instance metadata prevents tag key names from containing spaces. If you have allowed tags in EC2 instance metadata, you must use the tag key PatchGroup (without a space).
Option 1: To add EC2 instances to a patch group (Systems Manager console)

2. In the navigation pane, choose Fleet Manager.
3. In the Managed nodes list, choose the ID of a managed EC2 instance that you want to configure for patching. Node IDs for EC2 instances begin with i-.

   **Note**
   When using the Amazon EC2 console and AWS CLI, it's possible to apply Key = Patch Group or Key = PatchGroup tags to instances that aren't yet configured for use with Systems Manager.
   If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

4. Choose the Tags tab, then choose Edit.
5. In the left column, enter Patch Group or PatchGroup. If you have allowed tags in EC2 instance metadata, you must use PatchGroup (without a space).
6. In the right column, enter a tag value to serve as the name for the patch group.
7. Choose Save.
8. Repeat this procedure to add other EC2 instances to the same patch group.

Option 2: To add EC2 instances to a patch group (Amazon EC2 console)

1. Open the Amazon EC2 console, and then choose Instances in the navigation pane.
2. In the list of instances, choose an instance that you want to configure for patching.
3. In the Actions menu, choose Instance settings, Manage tags.
5. For Key, enter Patch Group or PatchGroup. If you have allowed tags in EC2 instance metadata, you must use PatchGroup (without a space).
6. For Value, enter a value to serve as the name for the patch group.
7. Choose Save.
8. Repeat this procedure to add other instances to the same patch group.
Task 2: Add managed nodes to a patch group using tags

Follow the steps in this topic to add tags to AWS IoT Greengrass core devices and non-EC2 hybrid-activated managed nodes (mi-*). This task is required only if you are patching non-EC2 instances in a hybrid and multicloud environment.

Note
You can't add tags for non-EC2 managed nodes using the Amazon EC2 console.

To add non-EC2 managed nodes to a patch group (Systems Manager console)

2. In the navigation pane, choose Fleet Manager.
3. In the Managed nodes list, choose the name of the managed node that you want to configure for patching.

Note
If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

4. Choose the Tags tab, then choose Edit.
5. In the left column, enter Patch Group or PatchGroup. If you have allowed tags in EC2 instance metadata, you must use PatchGroup (without a space).
6. In the right column, enter a tag value to serve as the name for the patch group.
7. Choose Save.
8. Repeat this procedure to add other managed nodes to the same patch group.

Task 3: Add a patch group to a patch baseline

To associate a specific patch baseline with your managed nodes, you must add the patch group value to the patch baseline. By registering the patch group with a patch baseline, you can ensure that the correct patches are installed during a patching operation. This task is required whether you are patching EC2 instances, non-EC2 managed nodes, or both.
For more information about patch groups, see About patch groups.

**Note**

The steps you follow depend on whether you first accessed Patch Manager before or after the patch policies release on December 22, 2022.

To add a patch group to a patch baseline (Systems Manager console)

2. In the navigation pane, choose Patch Manager.
3. If you're accessing Patch Manager for the first time in the current AWS Region and the Patch Manager start page opens, choose Start with an overview.
4. Choose the Patch baselines tab, and then in the Patch baselines list, choose the name of the patch baseline that you want to configure for your patch group.
   
   If you didn't first access Patch Manager until after the patch policies release, you must choose a custom baseline that you have created.
5. If the Baseline ID details page includes an Actions menu, do the following:
   
   - Choose Actions, then Modify patch groups.
   - Enter the tag value you added to your managed nodes in Task 2: Add managed nodes to a patch group using tags, then choose Add.

   If the Baseline ID details page does *not* include an Actions menu, patch groups can't be configured in the console. Instead, you can do either of the following:

   - (Recommended) Set up a patch policy in Quick Setup, a capability of AWS Systems Manager, to map a patch baseline to one or more EC2 instances.
   
     For more information, see Using Quick Setup patch policies and Automate organization-wide patching using a Quick Setup patch policy.

   - Use the register-patch-baseline-for-patch-group command in the AWS Command Line Interface (AWS CLI) to configure a patch group.
Working with Patch Manager settings

Topics

• Integrating Patch Manager with AWS Security Hub

Integrating Patch Manager with AWS Security Hub

AWS Security Hub provides you with a comprehensive view of your security state in AWS. Security Hub collects security data from across AWS accounts, AWS services, and supported third-party partner products. With Security Hub, you can check your environment against security industry standards and best practices. Security Hub helps you to analyze your security trends and identify the highest priority security issues.

By using the integration between Patch Manager, a capability of AWS Systems Manager, and Security Hub, you can send findings about noncompliant nodes from Patch Manager to Security Hub. A finding is the observable record of a security check or security-related detection. Security Hub can then include those patch-related findings in its analysis of your security posture.

The information in the following topics applies no matter which method or type of configuration you are using for your patching operations:

• A patch policy configured in Quick Setup
• A Host Management option configured in Quick Setup
• A maintenance window to run a patch Scan or Install task
• An on-demand Patch now operation

• How to stop sending findings
How Patch Manager sends findings to Security Hub

In Security Hub, security issues are tracked as findings. Some findings come from issues that are detected by other AWS services or by third-party partners. Security Hub also has a set of rules that it uses to detect security issues and generate findings.

Patch Manager is one of the Systems Manager capabilities that sends findings to Security Hub. After you perform a patching operation by running a SSM document (AWS-RunPatchBaseline, AWS-RunPatchBaselineAssociation, or AWS-RunPatchBaselineWithHooks), the patching information is sent to Inventory or Compliance, capabilities of AWS Systems Manager, or both. After Inventory, Compliance, or both receive the data, Patch Manager receives a notification. Then, Patch Manager evaluates the data for accuracy, formatting, and compliance. If all conditions are met, Patch Manager forwards the data to Security Hub.

Security Hub provides tools to manage findings from across all of these sources. You can view and filter lists of findings and view details for a finding. For more information, see Viewing findings in the AWS Security Hub User Guide. You can also track the status of an investigation into a finding. For more information, see Taking action on findings in the AWS Security Hub User Guide.

All findings in Security Hub use a standard JSON format called the AWS Security Finding Format (ASFF). The ASFF includes details about the source of the issue, the affected resources, and the current status of the finding. For more information, see AWS Security Finding Format (ASFF) in the AWS Security Hub User Guide.

Types of findings that Patch Manager sends

Patch Manager sends the findings to Security Hub using the AWS Security Finding Format (ASFF). In ASFF, the Types field provides the finding type. Findings from Patch Manager have the following value for Types:

- Software and Configuration Checks/Patch Management

Patch Manager sends one finding per noncompliant managed node. The finding is reported with the resource type AwsEc2Instance so that findings can be correlated with other Security Hub integrations that report AwsEc2Instance resource types. Patch Manager only forwards a finding to Security Hub if the operation discovered the managed node to be noncompliant. The finding includes the Patch Summary results.

**Note**

After reporting a noncompliant node to Security Hub. Patch Manager doesn't send an update to Security Hub after the node is made compliant. You can manually resolve findings in Security Hub after the required patches have been applied to the managed node.

For more information about compliance definitions, see [Understanding patch compliance state values](#). For more information about PatchSummary, see [PatchSummary](#) in the [AWS Security Hub API Reference](#).

**Latency for sending findings**

When Patch Manager creates a new finding, it's usually sent to Security Hub within a few seconds to 2 hours. The speed depends on the traffic in the AWS Region being processed at that time.

**Retrying when Security Hub isn't available**

If there is a service outage, an AWS Lambda function is run to put the messages back into the main queue after the service is running again. After the messages are in the main queue, the retry is automatic.

If Security Hub isn't available, Patch Manager retries sending the findings until they're received.

**Viewing findings in Security Hub**

This procedure describes how to view findings in Security Hub about managed nodes in your fleet that are out of patch compliance.

**To review Security Hub findings for patch compliance**

2. In the navigation pane, choose **Findings**.
3. Choose the **Add filters**
   - box.
4. In the menu, under **Filters**, choose **Product name**.
5. In the dialog box that opens, choose **is** in the first field and then enter **Systems Manager Patch Manager** in the second field.

6. Choose **Apply**.

7. Add any additional filters you want to help narrow down your results.

8. In the list of results, choose the title of a finding you want more information about.

   A pane opens on the right side of the screen with more details about the resource, the issue discovered, and a recommended remediation.

   ! **Important**
   
   At this time, Security Hub reports the resource type of all managed nodes as EC2 Instance. This includes on-premises servers and virtual machines (VMs) that you have registered for use with Systems Manager.

### Severity classifications

The list of findings for **Systems Manager Patch Manager** includes a report of the severity of the finding. **Severity** levels include the following, from lowest to highest:

- **INFORMATIONAL** – No issue was found.
- **LOW** – The issue does not require remediation.
- **MEDIUM** – The issue must be addressed but is not urgent.
- **HIGH** – The issue must be addressed as a priority.
- **CRITICAL** – The issue must be remediated immediately to avoid escalation.

Severity is determined by the most severe noncompliant package on an instance. Because you can have multiple patch baselines with multiple severity levels, the highest severity is reported out of all the noncompliant packages. For example, suppose you have two noncompliant packages where the severity of package A is "Critical" and the severity of package B is "Low". "Critical" will be reported as the severity.

Note that the severity field correlates directly with the Patch Manager Compliance field. This is a field that you set assign to individual patches that match the rule. Because this Compliance field is assigned to individual patches, it is not reflected at the Patch Summary level.
Typical finding from Patch Manager

Here is an example of a typical finding from Patch Manager.

```json
{
   "SchemaVersion": "2018-10-08",
   "Id": "arn:aws:patchmanager:us-east-2:111122223333:instance/i-02573cafcfEXAMPLE/document/AWS-RunPatchBaseline/run-command/d710f5bd-04e3-47b4-82f6-df4e0EXAMPLE",
   "ProductArn": "arn:aws:securityhub:us-east-1::product/aws/ssm-patch-manager",
   "GeneratorId": "d710f5bd-04e3-47b4-82f6-df4e0EXAMPLE",
   "AwsAccountId": "111122223333",
   "Types": [
      "Software & Configuration Checks/Patch Management/Compliance"
   ],
   "CreatedAt": "2021-11-11T22:05:25Z",
   "UpdatedAt": "2021-11-11T22:05:25Z",
   "Severity": {
      "Label": "INFORMATIONAL",
      "Normalized": 0
   },
   "Title": "Systems Manager Patch Summary - Managed Instance Non-Compliant",
   "Description": "This AWS control checks whether each instance that is managed by AWS Systems Manager is in compliance with the rules of the patch baseline that applies to that instance when a compliance Scan runs."
   "Remediation": {
      "Recommendation": {
         "Text": "For information about bringing instances into patch compliance, see 'Remediating out-of-compliance instances (Patch Manager)'.",
         "Url": "https://docs.aws.amazon.com/systems-manager/latest/userguide/patch-compliance-remediation.html"
      }
   },
}```
Turning on and configuring the integration

To use the Patch Manager integration with Security Hub, you must turn on Security Hub. For information about how to turn on Security Hub, see Setting up Security Hub in the AWS Security Hub User Guide.
The following procedure describes how to integrate Patch Manager and Security Hub when Security Hub is already active but Patch Manager integration is turned off. You only need to complete this procedure if integration was manually turned off.

**To add Patch Manager to Security Hub integration**

1. In the navigation pane, choose **Patch Manager**.
2. Choose the **Settings** tab.
   - or -
   If you are accessing Patch Manager for the first time in the current AWS Region, choose **Start with an overview**, and then choose the **Settings** tab.
3. Under the **Export to Security Hub** section, to the right of **Patch compliance findings aren't being exported to Security Hub**, choose **Enable**.

**How to stop sending findings**

To stop sending findings to Security Hub, you can use either the Security Hub console or the API.

For more information, see the following topics in the *AWS Security Hub User Guide*:

- [Disabling and enabling the flow of findings from an integration (console)](security_hub_userguide.html#disabling-and-enabling-the-flow-of-findings-from-an-integration)
- [Disabling the flow of findings from an integration (Security Hub API, AWS CLI)](security_hub_userguide.html#disabling-the-flow-of-findings-from-an-integration)

**Working with Patch Manager (AWS CLI)**

The section includes examples of AWS Command Line Interface (AWS CLI) commands that you can use to perform configuration tasks for Patch Manager, a capability of AWS Systems Manager.

For an illustration of using the AWS CLI to patch a server environment by using a custom patch baseline, see [Tutorial: Patch a server environment (AWS CLI)](cli_userguide.html#tutorial-patch-a-server-environment).

For more information about using the AWS CLI for AWS Systems Manager tasks, see the [AWS Systems Manager section of the AWS CLI Command Reference](cli_userguide.html#aws-systems-manager).

- [AWS CLI commands for patch groups](cli_userguide.html#aws-cli-commands-for-patch-groups)
AWS CLI commands for viewing patch summaries and details
AWS CLI commands for scanning and patching managed nodes

AWS CLI commands for patch baselines

Sample commands for patch baselines

• Create a patch baseline
• Create a patch baseline with custom repositories for different OS versions
• Update a patch baseline
• Rename a patch baseline
• Delete a patch baseline
• List all patch baselines
• List all AWS-provided patch baselines
• List my patch baselines
• Display a patch baseline
• Get the default patch baseline
• Set a custom patch baseline as the default
• Reset an AWS patch baseline as the default
• Tag a patch baseline
• List the tags for a patch baseline
• Remove a tag from a patch baseline

Create a patch baseline

The following command creates a patch baseline that approves all critical and important security updates for Windows Server 2012 R2 5 days after they're released. Patches have also been specified for the Approved and Rejected patch lists. In addition, the patch baseline has been tagged to indicate that it's for a production environment.

Linux & macOS

```
aws ssm create-patch-baseline \
   --name "Windows-Server-2012R2" \
   --tags "Key=Environment,Value=Production"
```
Windows Server

```bash
aws ssm create-patch-baseline
  --name "Windows-Server-2012R2"
  --tags "Key=Environment,Value=Production"
  --description "Windows Server 2012 R2, Important and Critical security updates"
  --approved-patches "KB2032276,MS10-048"
  --rejected-patches "KB2124261"
  --rejected-patches-action "ALLOW_ASDEPENDENCY"
  --approval-rules
"PatchRules=[{PatchFilterGroup={PatchFilters=[{Key=MSRC_SEVERITY,Values=[Important,Critical]},
  {Key=CLASSIFICATION,Values=SecurityUpdates},
  {Key=PRODUCT,Values=WindowsServer2012R2}],ApproveAfterDays=5}]"
```

The system returns information like the following.

```json
{
  "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

Create a patch baseline with custom repositories for different OS versions

Applies to Linux managed nodes only. The following command shows how to specify the patch repository to use for a particular version of the Amazon Linux operating system. This sample uses a source repository allowed by default on Amazon Linux 2017.09, but it could be adapted to a different source repository that you have configured for a managed node.
To better demonstrate this more complex command, we're using the `--cli-input-json` option with additional options stored in an external JSON file.

1. Create a JSON file with a name like `my-patch-repository.json` and add the following content to it.

```json
{
    "Description": "My patch repository for Amazon Linux 2017.09",
    "Name": "Amazon-Linux-2017.09",
    "OperatingSystem": "AMAZON_LINUX",
    "ApprovalRules": {
        "PatchRules": [
            {
                "ApproveAfterDays": 7,
                "EnableNonSecurity": true,
                "PatchFilterGroup": {
                    "PatchFilters": [
                        {
                            "Key": "SEVERITY",
                            "Values": [
                                "Important",
                                "Critical"
                            ]
                        },
                        {
                            "Key": "CLASSIFICATION",
                            "Values": [
                                "Security",
                                "Bugfix"
                            ]
                        },
                        {
                            "Key": "PRODUCT",
                            "Values": [
                                "AmazonLinux2017.09"
                            ]
                        }
                    ]
                }
            }
        ]
    }
}
```
AWS Systems Manager

"Sources": [
{
"Name": "My-AL2017.09",
"Products": [
"AmazonLinux2017.09"
],
"Configuration": "[amzn-main] 
name=amzn-main-Base

\nmirrorlist=http://repo./$awsregion./$awsdomain//$releasever/main/ 
mirrorlist_expire=300
\nmirrorlist_expire=300
\nmetadata_expire=300
\npriority=10
\nfailovermethod=priority \nfastestmirror_enabled=0 \ngpgcheck=1
\ngpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-amazon-ga \nenabled=1 \nretries=3
\n\ntimeout=5
\nreport_instanceid=yes"
}
]

2. In the directory where you saved the file, run the following command.

```bash
aws ssm create-patch-baseline --cli-input-json file://my-patch-repository.json
```

The system returns information like the following.

```
{
  "BaselineId": "pb-0c10e65780EXAMPLE"
}
```

**Update a patch baseline**

The following command adds two patches as rejected and one patch as approved to an existing patch baseline.

**Note**

For information about accepted formats for lists of approved patches and rejected patches, see [About package name formats for approved and rejected patch lists](#).
Linux & macOS

```
aws ssm update-patch-baseline \
   --baseline-id pb-0c10e65780EXAMPLE \
   --rejected-patches "KB2032276" "MS10-048" \
   --approved-patches "KB2124261"
```

Windows Server

```
aws ssm update-patch-baseline ^
   --baseline-id pb-0c10e65780EXAMPLE ^
   --rejected-patches "KB2032276" "MS10-048" ^
   --approved-patches "KB2124261"
```

The system returns information like the following.

```
{
   "BaselineId":"pb-0c10e65780EXAMPLE",
   "Name":"Windows-Server-2012R2",
   "RejectedPatches":[
      "KB2032276",
      "MS10-048"
   ],
   "GlobalFilters":{
      "PatchFilters":[]
   },
   "ApprovalRules":{
      "PatchRules":[
      {
         "PatchFilterGroup":{
            "PatchFilters":[
            {
               "Values": [
                  "Important",
                  "Critical"
               ],
               "Key":"MSRC_SEVERITY"
            },
            {
               "Values": ["KB2032276", "MS10-048"
```

```
   ]
   },
   "GlobalFilters":{
      "PatchFilters":[]
   }
}
"SecurityUpdates"
],
"Key":"CLASSIFICATION"
},
{
 "Values": [
 "WindowsServer2012R2"
 ],
 "Key": "PRODUCT"
 }
],
"ApproveAfterDays": 5
}

"ModifiedDate": 1481001494.035,
"CreatedDate": 1480997823.81,
"ApprovedPatches": [
 "KB2124261"
 ],
"Description": "Windows Server 2012 R2, Important and Critical security updates"
}

## Rename a patch baseline

### Linux & macOS

```bash
aws ssm update-patch-baseline \
  --baseline-id pb-0c10e65780EXAMPLE \
  --name "Windows-Server-2012-R2-Important-and-Critical-Security-Updates"
```

### Windows Server

```bash
aws ssm update-patch-baseline ^
  --baseline-id pb-0c10e65780EXAMPLE ^
  --name "Windows-Server-2012-R2-Important-and-Critical-Security-Updates"
```

The system returns information like the following.

```json
{
 "BaselineId": "pb-0c10e65780EXAMPLE",
```
"Name": "Windows-Server-2012-R2-Important-and-Critical-Security-Updates",
"RejectedPatches": [
    "KB2032276",
    "MS10-048"
],
"GlobalFilters": {
    "PatchFilters": [
    ]
},
"ApprovalRules": {
    "PatchRules": [
        {
            "PatchFilterGroup": {
                "PatchFilters": [
                    {
                        "Values": [
                            "Important",
                            "Critical"
                        ],
                        "Key": "MSRC_SEVERITY"
                    },
                    {
                        "Values": [
                            "SecurityUpdates"
                        ],
                        "Key": "CLASSIFICATION"
                    },
                    {
                        "Values": [
                            "WindowsServer2012R2"
                        ],
                        "Key": "PRODUCT"
                    }
                ]
            },
            "ApproveAfterDays": 5
        }
    ],
    "ModifiedDate": 1481001795.287,
    "CreatedDate": 1480997823.81,
    "ApprovedPatches": [
        "KB2124261"
    ]
}
Delete a patch baseline

aws ssm delete-patch-baseline --baseline-id "pb-0c10e65780EXAMPLE"

The system returns information like the following.

```
{
  "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

List all patch baselines

aws ssm describe-patch-baselines

The system returns information like the following.

```
{
  "BaselineIdentities": [
    {
      "BaselineName":"AWS-DefaultPatchBaseline",
      "DefaultBaseline":true,
      "BaselineDescription":"Default Patch Baseline Provided by AWS.",
      "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
    },
    {
      "BaselineName":"Windows-Server-2012R2",
      "DefaultBaseline":false,
      "BaselineDescription":"Windows Server 2012 R2, Important and Critical security updates",
      "BaselineId":"pb-0c10e65780EXAMPLE"
    }
  ]
}
```

Here is another command that lists all patch baselines in an AWS Region.
Linux & macOS

```
aws ssm describe-patch-baselines \
  --region us-east-2 \
  --filters "Key=OWNER,Values=[All]"
```

Windows Server

```
aws ssm describe-patch-baselines ^
  --region us-east-2 ^
  --filters "Key=OWNER,Values=[All]"
```

The system returns information like the following.

```
{
  "BaselineIdentities": ["BaselineName": "AWS-DefaultPatchBaseline", 
                         "DefaultBaseline": true, 
                         "BaselineDescription": "Default Patch Baseline Provided by AWS.", 
                         "BaselineId": "arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"],
  "BaselineName": "Windows-Server-2012R2", 
  "DefaultBaseline": false, 
  "BaselineDescription": "Windows Server 2012 R2, Important and Critical security updates", 
  "BaselineId": "pb-0c10e65780EXAMPLE"
}
```

List all AWS-provided patch baselines

Linux & macOS

```
aws ssm describe-patch-baselines \
  --region us-east-2 \
  --filters "Key=OWNER,Values=[AWS]"
```
Windows Server

```bash
aws ssm describe-patch-baselines ^
  --region us-east-2 ^
  --filters "Key=OWNER,Values=[AWS]"
```

The system returns information like the following.

```
{
  "BaselineIdentities": [
    {
      "BaselineName": "AWS-DefaultPatchBaseline",
      "DefaultBaseline": true,
      "BaselineDescription": "Default Patch Baseline Provided by AWS.",
      "BaselineId": "arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
    }
  ]
}
```

List my patch baselines

Linux & macOS

```bash
aws ssm describe-patch-baselines \
  --region us-east-2 \
  --filters "Key=OWNER,Values=[Self]"
```

Windows Server

```bash
aws ssm describe-patch-baselines ^
  --region us-east-2 ^
  --filters "Key=OWNER,Values=[Self]"
```

The system returns information like the following.

```
{
  "BaselineIdentities": [
    {
      "BaselineName": "Windows-Server-2012R2",
      "BaselineId": "arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
    }
  ]
}
```
Display a patch baseline

```
aws ssm get-patch-baseline --baseline-id pb-0c10e65780EXAMPLE
```

⚠️ **Note**

For custom patch baselines, you can specify either the patch baseline ID or the full Amazon Resource Name (ARN). For an AWS-provided patch baseline, you must specify the full ARN. For example, `arn:aws:ssm:us-east-2:075727635805:patchbaseline/pb-0c10e65780EXAMPLE`.

The system returns information like the following.

```
{
  "BaselineId":"pb-0c10e65780EXAMPLE",
  "Name":"Windows-Server-2012R2",
  "PatchGroups": ["Web Servers"],
  "RejectedPatches": [ ],
  "GlobalFilters": { "PatchFilters": [ ] },
  "ApprovalRules": { "PatchRules": [ ] }
}
```
Get the default patch baseline

```bash
aws ssm get-default-patch-baseline --region us-east-2
```

The system returns information like the following.

```json
{
   "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
}
```
Set a custom patch baseline as the default

Linux & macOS

```
aws ssm register-default-patch-baseline \
    --region us-east-2 \
    --baseline-id "pb-0c10e65780EXAMPLE"
```

Windows Server

```
aws ssm register-default-patch-baseline ^
    --region us-east-2 ^
    --baseline-id "pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```
{
    "BaselineId": "pb-0c10e65780EXAMPLE"
}
```

Reset an AWS patch baseline as the default

Linux & macOS

```
aws ssm register-default-patch-baseline \
    --region us-east-2 \
    --baseline-id "arn:aws:ssm:us-east-2:123456789012:patchbaseline/pb-0c10e65780EXAMPLE"
```

Windows Server

```
aws ssm register-default-patch-baseline ^
    --region us-east-2 ^
    --baseline-id "arn:aws:ssm:us-east-2:123456789012:patchbaseline/pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```
{
}
```
Tag a patch baseline

**Linux & macOS**

```bash
aws ssm add-tags-to-resource
  --resource-type "PatchBaseline"
  --resource-id "pb-0c10e65780EXAMPLE"
  --tags "Key=Project,Value=Testing"
```

**Windows Server**

```bash
aws ssm add-tags-to-resource
  --resource-type "PatchBaseline"
  --resource-id "pb-0c10e65780EXAMPLE"
  --tags "Key=Project,Value=Testing"
```

List the tags for a patch baseline

**Linux & macOS**

```bash
aws ssm list-tags-for-resource
  --resource-type "PatchBaseline"
  --resource-id "pb-0c10e65780EXAMPLE"
```

**Windows Server**

```bash
aws ssm list-tags-for-resource
  --resource-type "PatchBaseline"
  --resource-id "pb-0c10e65780EXAMPLE"
```

Remove a tag from a patch baseline

**Linux & macOS**

```bash
aws ssm remove-tags-from-resource
  --resource-type "PatchBaseline"
  --resource-id "pb-0c10e65780EXAMPLE"
```
AWS Systems Manager

--tag-keys "Project"

Windows Server

aws ssm remove-tags-from-resource ^
   --resource-type "PatchBaseline" ^
   --resource-id "pb-0c10e65780EXAMPLE" ^
   --tag-keys "Project"

AWS CLI commands for patch groups

Sample commands for patch groups

- Create a patch group
- Register a patch group "web servers" with a patch baseline
- Register a patch group "Backend" with the AWS-provided patch baseline
- Display patch group registrations
- Deregister a patch group from a patch baseline

Create a patch group

To help you organize your patching efforts, we recommend that you add managed nodes to patch groups by using tags. Patch groups require use of the tag key `Patch Group` or `PatchGroup`. If you have allowed tags in EC2 instance metadata, you must use `PatchGroup` (without a space). You can specify any tag value, but the tag key must be `Patch Group` or `PatchGroup`. For more information about patch groups, see About patch groups.

After you group your managed nodes using tags, you add the patch group value to a patch baseline. By registering the patch group with a patch baseline, you ensure that the correct patches are installed during the patching operation.

Task 1: Add EC2 instances to a patch group using tags

Note

When using the Amazon Elastic Compute Cloud (Amazon EC2) console and AWS CLI, it's possible to apply `Key = Patch Group` or `Key = PatchGroup` tags to instances that aren't yet configured for use with Systems Manager. If an EC2 instance you expect to see in
Patch Manager isn't listed after applying the Patch Group or Key = PatchGroup tag, see Troubleshooting managed node availability for troubleshooting tips.

Run the following command to add the PatchGroup tag to an EC2 instance.

```bash
aws ec2 create-tags --resources "i-1234567890abcdef0" --tags "Key=PatchGroup,Value=GroupValue"
```

**Task 2: Add managed nodes to a patch group using tags**

Run the following command to add the PatchGroup tag to a managed node.

**Linux & macOS**

```bash
aws ssm add-tags-to-resource \
  --resource-type "ManagedInstance" \
  --resource-id "mi-0123456789abcdefg" \
  --tags "Key=PatchGroup,Value=GroupValue"
```

**Windows Server**

```bash
aws ssm add-tags-to-resource ^
  --resource-type "ManagedInstance" ^
  --resource-id "mi-0123456789abcdefg" ^
  --tags "Key=PatchGroup,Value=GroupValue"
```

**Task 3: Add a patch group to a patch baseline**

Run the following command to associate a PatchGroup tag value to the specified patch baseline.

**Linux & macOS**

```bash
aws ssm register-patch-baseline-for-patch-group \
  --baseline-id "pb-0c10e65780EXAMPLE" \
  --patch-group "Development"
```

**Windows Server**

```bash
aws ssm register-patch-baseline-for-patch-group ^
```
The system returns information like the following.

```json
{
  "PatchGroup": "Development",
  "BaselineId": "pb-0c10e65780EXAMPLE"
}
```

**Register a patch group "web servers" with a patch baseline**

**Linux & macOS**

```bash
aws ssm register-patch-baseline-for-patch-group
  --baseline-id "pb-0c10e65780EXAMPLE" \
  --patch-group "Web Servers"
```

**Windows Server**

```bash
aws ssm register-patch-baseline-for-patch-group ^
  --baseline-id "pb-0c10e65780EXAMPLE" ^
  --patch-group "Web Servers"
```

The system returns information like the following.

```json
{
  "PatchGroup": "Web Servers",
  "BaselineId": "pb-0c10e65780EXAMPLE"
}
```

**Register a patch group "Backend" with the AWS-provided patch baseline**

**Linux & macOS**

```bash
aws ssm register-patch-baseline-for-patch-group \
  --region us-east-2 \
  --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
```

Working with Patch Manager (AWS CLI)
aws ssm register-patch-baseline-for-patch-group
   --region us-east-2
   --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
   --patch-group "Backend"

Windows Server

aws ssm register-patch-baseline-for-patch-group
   --region us-east-2
   --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
   --patch-group "Backend"

The system returns information like the following.

{
   "PatchGroup":"Backend",
   "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
}

Display patch group registrations

aws ssm describe-patch-groups --region us-east-2

The system returns information like the following.

{
   "PatchGroupPatchBaselineMappings"[:
      {
         "PatchGroup":"Backend",
         "BaselineIdentity":{
            "BaselineName":"AWS-DefaultPatchBaseline",
            "DefaultBaseline":false,
            "BaselineDescription":"Default Patch Baseline Provided by AWS.",
            "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
         }
      },
      {
         "PatchGroup":"Web Servers",
         "BaselineIdentity":{
            "BaselineName":"Windows-Server-2012R2",
            "DefaultBaseline":true,
Deregister a patch group from a patch baseline

Linux & macOS

```
aws ssm deregister-patch-baseline-for-patch-group \
   --region us-east-2 \
   --patch-group "Production" \
   --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
```

Windows Server

```
aws ssm deregister-patch-baseline-for-patch-group ^
   --region us-east-2 ^
   --patch-group "Production" ^
   --baseline-id "arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```
{
   "PatchGroup":"Production",
   "BaselineId":"arn:aws:ssm:us-east-2:111122223333:patchbaseline/pb-0c10e65780EXAMPLE"
}
```

AWS CLI commands for viewing patch summaries and details

Sample commands for viewing patch summaries and details

- [Get all patches defined by a patch baseline](#)
- [Get all patches for AmazonLinux2018.03 that have a Classification SECURITY and Severity of Critical](#)
- Get all patches for Windows Server 2012 that have a MSRC severity of Critical
- Get all available patches
- Get patch summary states per-managed node
- Get patch compliance details for a managed node
- View patching compliance results (AWS CLI)

Get all patches defined by a patch baseline

ℹ️ Note
This command is supported for Windows Server patch baselines only.

Linux & macOS

```bash
aws ssm describe-effective-patches-for-patch-baseline --region us-east-2 --baseline-id "pb-0c10e65780EXAMPLE"
```

Windows Server

```bash
aws ssm describe-effective-patches-for-patch-baseline --region us-east-2 --baseline-id "pb-0c10e65780EXAMPLE"
```

The system returns information like the following.

```json
{
   "NextToken": "--token string truncated--",
   "EffectivePatches": [
      {
         "PatchStatus": {
            "ApprovalDate": 1384711200.0,
            "DeploymentStatus": "APPROVED"
         },
         "Patch": {
            "ContentUrl": "https://support.microsoft.com/en-us/kb/2876331",
            "ProductFamily": "Windows",
            "Product": "WindowsServer2012R2"
         }
      }
   ]
}
```
A security issue has been identified in a Microsoft software product that could affect your system. You can help protect your system by installing this update from Microsoft. For a complete listing of the issues that are included in this update, see the associated Microsoft Knowledge Base article. After you install this update, you may have to restart your system.

Windows Server 2012 R2 Update is a cumulative set of security updates, critical updates and updates. You must install Windows Server 2012 R2 Update to ensure that your computer can continue to receive future Windows Updates, including security updates. For a complete listing of the issues that are included in this update, see the associated Microsoft Knowledge Base article for more information. After you install this item, you may have to restart your computer.
Get all patches for AmazonLinux2018.03 that have a Classification SECURITY and Severity of Critical

Linux & macOS

```bash
aws ssm describe-available-patches 
  --region us-east-2 
  --filters Key=PRODUCT,Values=AmazonLinux2018.03 Key=SEVERITY,Values=Critical
```

Windows Server

```bash
aws ssm describe-available-patches ^
  --region us-east-2 ^
  --filters Key=PRODUCT,Values=AmazonLinux2018.03 Key=SEVERITY,Values=Critical
```

The system returns information like the following.

```json
{
  "Patches": [
    {
      "AdvisoryIds": ["ALAS-2011-1"],
      "BugzillaIds": [ "1234567" ],
      "Classification": "SECURITY",
      "CVEIds": [ "CVE-2011-3192"],
      "Name": "zziplib",
      "Epoch": "0",
      "Version": "2.71",
      "Release": "1.3.amzn1",

      }
   ]
}
Get patch summary states per-managed node

The per-managed node summary gives you the number of patches in the following states per node: "NotApplicable", "Missing", "Failed", "InstalledOther" and "Installed".

**Linux & macOS**

```
aws ssm describe-instance-patch-states \
  --instance-ids i-08ee91c0b17045407 i-09a618aec652973a9
```

**Windows Server**

```
aws ssm describe-instance-patch-states ^
  --instance-ids i-08ee91c0b17045407 i-09a618aec652973a9
```

The system returns information like the following.

```
{
  
}---output truncated---
```
Get patch compliance details for a managed node

aws ssm describe-instance-patches --instance-id i-08ee91c0b17045407
View patching compliance results (AWS CLI)

To view patch compliance results for a single managed node

Run the following command in the AWS Command Line Interface (AWS CLI) to view patch compliance results for a single managed node.

```
aws ssm describe-instance-patch-states --instance-id instance-id
```

Replace `instance-id` with the ID of the managed node for which you want to view results, in the format i-02573cafcfEXAMPLE or mi-0282f7c436EXAMPLE.
The systems returns information like the following.

```json
{
    "InstancePatchStates": [
        {
            "InstanceId": "i-02573cafcfEXAMPLE",
            "PatchGroup": "mypatchgroup",
            "BaselineId": "pb-0c10e65780EXAMPLE",
            "SnapshotId": "a3f5ff34-9bc4-4d2c-a665-4d1c1EXAMPLE",
            "CriticalNonCompliantCount": 2,
            "SecurityNonCompliantCount": 2,
            "OtherNonCompliantCount": 1,
            "InstalledCount": 123,
            "InstalledOtherCount": 334,
            "InstalledPendingRebootCount": 0,
            "InstalledRejectedCount": 0,
            "MissingCount": 1,
            "FailedCount": 2,
            "UnreportedNotApplicableCount": 11,
            "NotApplicableCount": 2063,
            "OperationStartTime": "2021-05-03T11:00:56-07:00",
            "OperationEndTime": "2021-05-03T11:01:09-07:00",
            "Operation": "Scan",
            "LastNoRebootInstallOperationTime": "2020-06-14T12:17:41-07:00",
            "RebootOption": "RebootIfNeeded"
        }
    ]
}
```

To view a patch count summary for all EC2 instances in a Region

The `describe-instance-patch-states` supports retrieving results for just one managed instance at a time. However, using a custom script with the `describe-instance-patch-states` command, you can generate a more granular report.

For example, if the `jq` filter tool is installed on your local machine, you could run the following command to identify which of your EC2 instances in a particular AWS Region have a status of `InstalledPendingReboot`.

```bash
aws ssm describe-instance-patch-states
    --instance-ids $(aws ec2 describe-instances --region region | jq '.Reservations[].Instances[] | .InstanceId' | tr '
|'' ' ')
```
region represents the identifier for an AWS Region supported by AWS Systems Manager, such as us-east-2 for the US East (Ohio) Region. For a list of supported region values, see the Region column in Systems Manager service endpoints in the Amazon Web Services General Reference.

For example:

```bash
aws ssm describe-instance-patch-states \
   --instance-ids $(aws ec2 describe-instances --region us-east-2 | jq \
   '.Reservations[].Instances[] | .InstanceId' | tr \n   | '' ) \
   --output text --query 'InstancePatchStates[*].{Instance:InstanceId, \
   InstalledPendingRebootCount:InstalledPendingRebootCount}'
```

The system returns information like the following.

```
1       i-02573cafcfEXAMPLE
0       i-0471e04240EXAMPLE
3       i-07782c72faEXAMPLE
6       i-083b678d37EXAMPLE
0       i-03a530a2d4EXAMPLE
1       i-01f68df0d0EXAMPLE
0       i-0a39c0f214EXAMPLE
7       i-0903a5101eEXAMPLE
7       i-03823c2fedEXAMPLE
```

In addition to InstalledPendingRebootCount, the list of count types you can search for include the following:

- CriticalNonCompliantCount
- SecurityNonCompliantCount
- OtherNonCompliantCount
- UnreportedNotApplicableCount
- InstalledPendingRebootCount
- FailedCount
- NotApplicableCount
- InstalledRejectedCount
• InstalledOtherCount
• MissingCount
• InstalledCount

**AWS CLI commands for scanning and patching managed nodes**

After running the following commands to scan for patch compliance or install patches, you can use commands in the [AWS CLI commands for viewing patch summaries and details](#) section to view information about patch status and compliance.

**Sample commands**

- [Scan managed nodes for patch compliance (AWS CLI)](#)
- [Install patches on managed nodes (AWS CLI)](#)

**Scan managed nodes for patch compliance (AWS CLI)**

**To scan specific managed nodes for patch compliance**

Run the following command.

**Linux & macOS**

```bash
aws ssm send-command \
   --document-name 'AWS-RunPatchBaseline' \
   --targets Key=InstanceIds,Values='i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE' \
   --parameters 'Operation=Scan' \
   --timeout-seconds 600
```

**Windows Server**

```bash
aws ssm send-command ^
   --document-name "AWS-RunPatchBaseline" ^
   --targets Key=InstanceIds,Values="i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE" ^
   --parameters "Operation=Scan" ^
   --timeout-seconds 600
```

The system returns information like the following.
To scan managed nodes for patch compliance by patch group tag

Run the following command.

**Linux & macOS**

```bash
aws ssm send-command \
  --document-name 'AWS-RunPatchBaseline' \
  --targets Key='tag:PatchGroup',Values='Web servers' \
  --parameters 'Operation=Scan'
```
--timeout-seconds 600

Windows Server

```bash
aws ssm send-command ^
   --document-name "AWS-RunPatchBaseline" ^
   --targets Key="tag:PatchGroup",Values="Web servers" ^
   --parameters "Operation=Scan" ^
   --timeout-seconds 600
```

The system returns information like the following.

```json
{
   "Command": {
      "CommandId": "87a448ee-8adc-44e0-b4d1-6b429EXAMPLE",
      "DocumentName": "AWS-RunPatchBaseline",
      "DocumentVersion": "$DEFAULT",
      "Comment": "",
      "ExpiresAfter": 1621974983.128,
      "Parameters": {
         "Operation": [
            "Scan"
         ],
      },
      "InstanceIds": [],
      "Targets": [
         {
            "Key": "tag:PatchGroup",
            "Values": [
               "Web servers"
            ]
         }
      ],
      "RequestedDateTime": 1621974983.128,
      "Status": "Pending",
      "StatusDetails": "Pending",
      "TimeoutSeconds": 600,
      --output truncated--
   }
}
```
Install patches on managed nodes (AWS CLI)

To install patches on specific managed nodes

Run the following command.

**Note**

The target managed nodes reboot as needed to complete patch installation. For more information, see [About the AWS-RunPatchBaseline SSM document](#).

---

**Linux & macOS**

```bash
aws ssm send-command \
  --document-name 'AWS-RunPatchBaseline' \
  --targets Key=InstanceIds,Values='i-02573cafcaEXAMPLE,i-0471e04240EXAMPLE' \
  --parameters 'Operation=Install' \
  --timeout-seconds 600
```

**Windows Server**

```bash
aws ssm send-command ^
  --document-name "AWS-RunPatchBaseline" ^
  --targets Key=InstanceIds,Values="i-02573cafcaEXAMPLE,i-0471e04240EXAMPLE" ^
  --parameters "Operation=Install" ^
  --timeout-seconds 600
```

The system returns information like the following.

```json
{
  "Command": {
    "CommandId": "5f403234-38c4-439f-a570-93623EXAMPLE",
    "DocumentName": "AWS-RunPatchBaseline",
    "DocumentVersion": "$DEFAULT",
    "Comment": "",
    "ExpiresAfter": 1621975301.791,
    "Parameters": {
      "Operation": ["Install"]
    }
  }
}```
To install patches on managed nodes in a specific patch group

Run the following command.

Linux & macOS

```
aws ssm send-command \
  --document-name 'AWS-RunPatchBaseline' \
  --targets Key='tag:PatchGroup',Values='Web servers' \
  --parameters 'Operation=Install' \
  --timeout-seconds 600
```

Windows Server

```
aws ssm send-command ^
  --document-name "AWS-RunPatchBaseline" ^
  --targets Key="tag:PatchGroup",Values="Web servers" ^
  --parameters "Operation=Install" ^
  --timeout-seconds 600
```

The system returns information like the following.
AWS Systems Manager Patch Manager tutorials

The tutorials in this section demonstrate how to use Patch Manager, a capability of AWS Systems Manager, for several patching scenarios.

Topics

- Tutorial: Create a patch baseline for installing Windows Service Packs (console)
- Tutorial: Update application dependencies, patch a managed node, and perform an application-specific health check
- Tutorial: Patch a server environment (AWS CLI)
Tutorial: Create a patch baseline for installing Windows Service Packs (console)

When you create a custom patch baseline, you can specify that all, some, or only one type of supported patch is installed.

In patch baselines for Windows, you can select Service Packs as the only **Classification** option in order to limit patching updates to Service Packs only. Service Packs can be installed automatically by Patch Manager, a capability of AWS Systems Manager, provided that the update is available in Windows Update or Windows Server Update Services (WSUS).

You can configure a patch baseline to control whether Service Packs for all Windows versions are installed, or just those for specific versions, such as Windows 7 or Windows Server 2016.

Use the following procedure to create a custom patch baseline to be used exclusively for installing all Service Packs on your Windows managed nodes.

**To create a patch baseline for installing Windows Service Packs (console)**

2. In the navigation pane, choose **Patch Manager**.
3. Choose the **Patch baselines** tab, and then choose **Create patch baseline**.
4. For **Name**, enter a name for your new patch baseline, for example, MyWindowsServicePackPatchBaseline.
5. (Optional) For **Description**, enter a description for this patch baseline.
6. For **Operating system**, choose Windows.
7. If you want to begin using this patch baseline as the default for Windows as soon as you create it, select **Set this patch baseline as the default patch baseline for Windows Server instances**.

---

**Note**

This option is available only if you first accessed Patch Manager before the [patch policies](https://aws.amazon.com/about-aws/services/patching/) release on December 22, 2022. For information about setting an existing patch baseline as the default, see [Setting an existing patch baseline as the default](https://aws.amazon.com/about-aws/services/patching/).
8. In the **Approval rules for operating systems** section, use the fields to create one or more auto-approval rules.

   - **Products**: The operating system versions that the approval rule applies to, such as Windows Server 2012. You can choose one, more than one, or all supported versions of Windows. The default selection is All.
   
   - **Classification**: Choose Service Packs.
   
   - **Severity**: The severity value of patches the rule is to apply to. To ensure that all Service Packs are included by the rule, choose All.
   
   - **Auto-approval**: The method for selecting patches for automatic approval.
      
      - **Approve patches after a specified number of days**: The number of days for Patch Manager to wait after a patch is released or updated before a patch is automatically approved. You can enter any integer from zero (0) to 360. For most scenarios, we recommend waiting no more than 100 days.
      
      - **Approve patches released up to a specific date**: The patch release date for which Patch Manager automatically applies all patches released or updated on or before that date. For example, if you specify July 7, 2023, no patches released or last updated on or after July 8, 2023, are installed automatically.
      
     - (Optional) **Compliance reporting**: The severity level you want to assign to Service Packs approved by the baseline, such as High.

   ![Note]

   If you specify a compliance reporting level and the patch state of any approved Service Pack is reported as Missing, then the patch baseline's overall reported compliance severity is the severity level you specified.

9. (Optional) For **Manage tags**, apply one or more tag key name/value pairs to the patch baseline.

   Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For this patch baseline dedicated to updating Service Packs, you could specify key-value pairs such as the following:
      
      - Key=OS, Value=Windows
      - Key=Classification, Value=ServicePacks
10. Choose **Create patch baseline**.

**Tutorial: Update application dependencies, patch a managed node, and perform an application-specific health check**

In many cases, a managed node must be rebooted after it has been patched with the latest software update. However, rebooting a node in production without safeguards in place can cause several problems, such as invoking alarms, recording incorrect metric data, and interrupting data synchronizations.

This tutorial demonstrates how to avoid problems like these by using the AWS Systems Manager document (SSM document) `AWS-RunPatchBaselineWithHooks` to achieve a complex, multi-step patching operation that accomplishes the following:

1. Prevent new connections to the application
2. Install operating system updates
3. Update the package dependencies of the application
4. Restart the system
5. Perform an application-specific health check

For this example, we have set up our infrastructure this way:

- The virtual machines targeted are registered as managed nodes with Systems Manager.
- `Iptables` is used as a local firewall.
- The application hosted on the managed nodes is running on port 443.
- The application hosted on the managed nodes is a `nodeJS` application.
- The application hosted on the managed nodes is managed by the `pm2` process manager.
- The application already has a specified health check endpoint.
- The application's health check endpoint requires no end user authentication. The endpoint allows for a health check that meets the organization's requirements in establishing availability. (In your environments, it might be enough to simply ascertain that the `nodeJS` application is running and able to listen for requests. In other cases, you might want to also verify that a connection to the caching layer or database layer has already been established.)
The examples in this tutorial are for demonstration purposes only and not meant to be implemented as-is into production environments. Also, keep in mind that the lifecycle hooks feature of Patch Manager, a capability of Systems Manager, with the AWS-RunPatchBaselineWithHooks document can support numerous other scenarios. Here are several examples.

- Stop a metrics reporting agent before patching and restarting it after the managed node reboots.
- Detach the managed node from a CRM or PCS cluster before patching and reattach after the node reboots.
- Update third-party software (for example, Java, Tomcat, Adobe applications, and so on) on Windows Server machines after operating system (OS) updates are applied, but before the managed node reboots.

To update application dependencies, patch a managed node, and perform an application-specific health check

1. Create an SSM document for your preinstallation script with the following contents and name it NodeJSAppPrePatch. Replace `your_application` with the name of your application.

   ```bash
   # exit on error
   set -e
   # set up rule to block incoming traffic
   iptables -I INPUT -j DROP -p tcp --syn --destination-port 443 || exit 1
   # wait for current connections to end. Set timeout appropriate to your application's latency
   sleep 5
   # Stop your application
   pm2 stop your_application
   ```

   For information about creating SSM documents, see [Creating SSM document content](#).

2. Create another SSM document with the following content for your postinstall script to update your application dependencies and name it NodeJSAppPostPatch. Replace `/your/application/path` with the path to your application.
cd /your/application/path
npm update
# you can use npm-check-updates if you want to upgrade major versions

3. Create another SSM document with the following content for your onExit script to bring your application back up and perform a health check. Name this SSM document NodeJSAppOnExitPatch. Replace your_application with the name of your application.

```bash
# exit on error
set -e
# restart nodeJs application
pm2 start your_application
# sleep while your application starts and to allow for a crash
sleep 10
# check with pm2 to see if your application is running
pm2 pid your_application
# re-enable incoming connections
iptables -D INPUT -j DROP -p tcp --syn --destination-port
# perform health check
/usr/bin/curl -m 10 -vk -A "" http://localhost:443/health-check || exit 1
```

4. Create an association in State Manager, a capability of AWS Systems Manager, to issue the operation by performing the following steps:

2. In the navigation pane, choose State Manager, and then choose Create association.
3. For Name, provide a name to help identify the purpose of the association.
4. In the Document list, choose AWS-RunPatchBaselineWithHooks.
5. For Operation, choose Install.
6. (Optional) For Snapshot Id, provide a GUID that you generate to help speed up the operation and ensure consistency. The GUID value can be as simple as 00000000-0000-0000-0000-111122223333.
7. For Pre Install Hook Doc Name, enter NodeJSAppPrePatch.
8. For Post Install Hook Doc Name, enter NodeJSAppPostPatch.
5. For **Targets**, identify your managed nodes by specifying tags, choosing nodes manually, choosing a resource group, or choosing all managed nodes.

6. For **Specify schedule**, specify how often to run the association. For managed node patching, once per week is a common cadence.

7. In the **Rate control** section, choose options to control how the association runs on multiple managed nodes. Ensure that only a portion of managed nodes are updated at a time. Otherwise, all or most of your fleet could be taken offline at once. For more information about using rate controls, see [About targets and rate controls in State Manager associations](#).

8. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

   ![Note]
   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#).

   In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

9. Choose **Create Association**.

**Tutorial: Patch a server environment (AWS CLI)**

The following procedure describes how to patch a server environment by using a custom patch baseline, patch groups, and a maintenance window.

**Before you begin**

- Install or update the SSM Agent on your managed nodes. To patch Linux managed nodes, your nodes must be running SSM Agent version 2.0.834.0 or later. For more information, see [Updating the SSM Agent using Run Command](#).

- Configure roles and permissions for Maintenance Windows, a capability of AWS Systems Manager. For more information, see [Setting up Maintenance Windows](#).

- Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.
For information, see [Installing or updating the latest version of the AWS CLI](#).

**To configure Patch Manager and patch managed nodes (command line)**

1. Run the following command to create a patch baseline for Windows named `Production-Baseline`. This patch baseline approves patches for a production environment 7 days after they're released or last updated. That is, we have tagged the patch baseline to indicate that it's for a production environment.

   ```bash
   aws ssm create-patch-baseline
   --name "Production-Baseline"
   --operating-system "WINDOWS"
   --tags "Key=Environment,Value=Production"
   --approval-rules
   "PatchRules=[[PatchFilterGroup={PatchFilters=[[Key=MSRC_SEVERITY,Values=[Critical,Important]],
   {Key=CLASSIFICATION,Values=[SecurityUpdates,Updates,ServicePacks,UpdateRollups,CriticalUpdates]]}],ApproveAfterDays=7}]
   --description "Baseline containing all updates approved for production systems"
   ```

   **Note**

   The `OperatingSystem` parameter and `PatchFilters` vary depending on the operating system of the target managed nodes the patch baseline applies to. For more information, see `OperatingSystem` and `PatchFilter`.

   ```bash
   Linux & macOS
   ```

   ```bash
   aws ssm create-patch-baseline \
   --name "Production-Baseline" \
   --operating-system "WINDOWS" \
   --tags "Key=Environment,Value=Production" \
   --approval-rules
   "PatchRules=[[PatchFilterGroup={PatchFilters=[[Key=MSRC_SEVERITY,Values=[Critical,Important]],
   {Key=CLASSIFICATION,Values=[SecurityUpdates,Updates,ServicePacks,UpdateRollups,CriticalUpdates]]}],ApproveAfterDays=7}]
   --description "Baseline containing all updates approved for production systems"
   ```

   ```bash
   Windows Server
   ```

   ```bash
   aws ssm create-patch-baseline ^
   --name "Production-Baseline" ^
   --operating-system "WINDOWS" ^
   --tags "Key=Environment,Value=Production" ^
   --approval-rules
   "PatchRules=[[PatchFilterGroup={PatchFilters=[[Key=MSRC_SEVERITY,Values=[Critical,Important]],
   {Key=CLASSIFICATION,Values=[SecurityUpdates,Updates,ServicePacks,UpdateRollups,CriticalUpdates]]}],ApproveAfterDays=7}]
   ```
2. Run the following commands to register the "Production-Baseline" patch baseline for two patch groups. The groups are named "Database Servers" and "Front-End Servers".

**Linux & macOS**

```bash
aws ssm register-patch-baseline-for-patch-group
   --baseline-id pb-0c10e65780EXAMPLE
   --patch-group "Database Servers"
```

**Windows Server**

```bash
aws ssm register-patch-baseline-for-patch-group ^
   --baseline-id pb-0c10e65780EXAMPLE ^
   --patch-group "Database Servers"
```

The system returns information like the following.

```json
{
   "PatchGroup":"Database Servers",
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

**Linux & macOS**

```bash
aws ssm register-patch-baseline-for-patch-group \
   --baseline-id pb-0c10e65780EXAMPLE \
   --patch-group "Front-End Servers"
```
Windows Server

```bash
aws ssm register-patch-baseline-for-patch-group
   --baseline-id pb-0c10e65780EXAMPLE
   --patch-group "Front-End Servers"
```

The system returns information like the following.

```
{
   "PatchGroup":"Front-End Servers",
   "BaselineId":"pb-0c10e65780EXAMPLE"
}
```

3. Run the following commands to create two maintenance windows for the production servers. The first window runs every Tuesday at 10 PM. The second window runs every Saturday at 10 PM. In addition, the maintenance window is tagged to indicate that it's for a production environment.

Linux & macOS

```bash
aws ssm create-maintenance-window \
   --name "Production-Tuesdays" \
   --tags "Key=Environment,Value=Production" \
   --schedule "cron(0 0 22 ? * TUE *)" \
   --duration 1 \
   --cutoff 0 \
   --no-allow-unassociated-targets
```

Windows Server

```bash
aws ssm create-maintenance-window \
   --name "Production-Tuesdays" \
   --tags "Key=Environment,Value=Production" \
   --schedule "cron(0 0 22 ? * TUE *)" \
   --duration 1 \
   --cutoff 0 \
   --no-allow-unassociated-targets
```
The system returns information like the following.

```
{
  "WindowId":"mw-0c50858d01EXAMPLE"
}
```

**Linux & macOS**

```
aws ssm create-maintenance-window \
  --name "Production-Saturdays" \
  --tags "Key=Environment,Value=Production" \
  --schedule "cron(0 0 22 ? * SAT ")" \
  --duration 2 \
  --cutoff 0 \
  --no-allow-unassociated-targets
```

**Windows Server**

```
aws ssm create-maintenance-window ^
  --name "Production-Saturdays" ^
  --tags "Key=Environment,Value=Production" ^
  --schedule "cron(0 0 22 ? * SAT ")" ^
  --duration 2 ^
  --cutoff 0 ^
  --no-allow-unassociated-targets
```

The system returns information like the following.

```
{
  "WindowId":"mw-9a8b7c6d5eEXAMPLE"
}
```

4. Run the following commands to register the Database and Front-End servers patch groups with their respective maintenance windows.

**Linux & macOS**

```
aws ssm register-target-with-maintenance-window \
```

Patch Manager tutorials 2010
--window-id mw-0c50858d01EXAMPLE \
--targets "Key=tag:PatchGroup,Values=Database Servers" \
--owner-information "Database Servers" \
--resource-type "INSTANCE"

Windows Server

aws ssm register-target-with-maintenance-window ^
--window-id mw-0c50858d01EXAMPLE ^
--targets "Key=tag:PatchGroup,Values=Database Servers" ^
--owner-information "Database Servers" ^
--resource-type "INSTANCE"

The system returns information like the following.

```
{
  "WindowTargetId":"e32eeccb2-646c-4f4b-8ed1-205fbEXAMPLE"
}
```

Linux & macOS

aws ssm register-target-with-maintenance-window \
--window-id mw-9a8b7c6d5eEXAMPLE \
--targets "Key=tag:PatchGroup,Values=Front-End Servers" \
--owner-information "Front-End Servers" \
--resource-type "INSTANCE"

Windows Server

aws ssm register-target-with-maintenance-window ^
--window-id mw-9a8b7c6d5eEXAMPLE ^
--targets "Key=tag:PatchGroup,Values=Front-End Servers" ^
--owner-information "Front-End Servers" ^
--resource-type "INSTANCE"

The system returns information like the following.

```
{
  "WindowTargetId":"faa01c41-1d57-496c-ba77-ff9caEXAMPLE"
}
5. Run the following commands to register a patch task that installs missing updates on the Database and Front-End servers during their respective maintenance windows.

**Linux & macOS**

```
aws ssm register-task-with-maintenance-window
   --window-id mw-0c50858d01EXAMPLE
   --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
   --task-arn "AWS-RunPatchBaseline"
   --service-role-arn "arn:aws:iam::123456789012:role/MW-Role"
   --task-type "RUN_COMMAND"
   --max-concurrency 2
   --max-errors 1
   --priority 1
   --task-invocation-parameters "RunCommand={Parameters={Operation=Install}}"
```

**Windows Server**

```
aws ssm register-task-with-maintenance-window
   --window-id mw-0c50858d01EXAMPLE
   --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
   --task-arn "AWS-RunPatchBaseline"
   --service-role-arn "arn:aws:iam::123456789012:role/MW-Role"
   --task-type "RUN_COMMAND"
   --max-concurrency 2
   --max-errors 1
   --priority 1
   --task-invocation-parameters "RunCommand={Parameters={Operation=Install}}"
```

The system returns information like the following.

```
{
   "WindowTaskId":"4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```
**Linux & macOS**

```bash
aws ssm register-task-with-maintenance-window \
   --window-id mw-9a8b7c6d5eEXAMPLE \ 
   --targets "Key=WindowTargetIds,Values=faa01c41-1d57-496c-ba77-ff9caEXAMPLE" \ 
   --task-arn "AWS-RunPatchBaseline" \ 
   --service-role-arn "arn:aws:iam::123456789012:role/MW-Role" \ 
   --task-type "RUN_COMMAND" \ 
   --max-concurrency 2 \ 
   --max-errors 1 \ 
   --priority 1 \ 
   --task-invocation-parameters "RunCommand={Parameters={Operation=Install}}"
```

**Windows Server**

```bash
aws ssm register-task-with-maintenance-window ^
   --window-id mw-9a8b7c6d5eEXAMPLE ^
   --targets "Key=WindowTargetIds,Values=faa01c41-1d57-496c-ba77-ff9caEXAMPLE" ^
   --task-arn "AWS-RunPatchBaseline" ^
   --service-role-arn "arn:aws:iam::123456789012:role/MW-Role" ^
   --task-type "RUN_COMMAND" ^
   --max-concurrency 2 ^
   --max-errors 1 ^
   --priority 1 ^
   --task-invocation-parameters "RunCommand={Parameters={Operation=Install}}"
```

The system returns information like the following.

```json
{
   "WindowTaskId":"8a5c4629-31b0-4edd-8aea-33698EXAMPLE"
}
```

6. Run the following command to get the high-level patch compliance summary for a patch group. The high-level patch compliance summary includes the number of managed nodes with patches in the respective patch states.
Note

It’s expected to see zeroes for the number of managed nodes in the summary until the patch task runs during the first maintenance window.

Linux & macOS

```bash
aws ssm describe-patch-group-state \
   --patch-group "Database Servers"
```

Windows Server

```bash
aws ssm describe-patch-group-state ^ \
   --patch-group "Database Servers"
```

The system returns information like the following.

```json
{
   "Instances": number,
   "InstancesWithFailedPatches": number,
   "InstancesWithInstalledOtherPatches": number,
   "InstancesWithInstalledPatches": number,
   "InstancesWithInstalledPendingRebootPatches": number,
   "InstancesWithInstalledRejectedPatches": number,
   "InstancesWithMissingPatches": number,
   "InstancesWithNotApplicablePatches": number,
   "InstancesWithUnreportedNotApplicablePatches": number
}
```

7. Run the following command to get patch summary states per-managed node for a patch group. The per-managed node summary includes a number of patches in the respective patch states per managed node for a patch group.

Linux & macOS

```bash
aws ssm describe-instance-patch-states-for-patch-group \
   --patch-group "Database Servers"
```
Windows Server

```
aws ssm describe-instance-patch-states-for-patch-group ^
   --patch-group "Database Servers"
```

The system returns information like the following.

```
{
   "InstancePatchStates": [
      {
         "BaselineId": "string",
         "FailedCount": number,
         "InstalledCount": number,
         "InstalledOtherCount": number,
         "InstalledPendingRebootCount": number,
         "InstalledRejectedCount": number,
         "InstallOverrideList": "string",
         "InstanceId": "string",
         "LastNoRebootInstallOperationTime": number,
         "MissingCount": number,
         "NotApplicableCount": number,
         "Operation": "string",
         "OperationEndTime": number,
         "OperationStartTime": number,
         "OwnerInformation": "string",
         "PatchGroup": "string",
         "RebootOption": "string",
         "SnapshotId": "string",
         "UnreportedNotApplicableCount": number
      }
   ]
}
```

For examples of other AWS CLI commands you can use for your Patch Manager configuration tasks, see Working with Patch Manager (AWS CLI).
Troubleshooting Patch Manager

Use the following information to help you troubleshoot problems with Patch Manager, a capability of AWS Systems Manager.

Topics

- **Issue: "Invoke-PatchBaselineOperation : Access Denied" error or "Unable to download file from S3" error for baseline_overrides.json**
- **Issue: Patching fails without an apparent cause or error message**
- **Issue: Unexpected patch compliance results**
- **Errors when running AWS-RunPatchBaseline on Linux**
- **Errors when running AWS-RunPatchBaseline on Windows Server**
- **Contacting AWS Support**

**Issue: "Invoke-PatchBaselineOperation : Access Denied" error or "Unable to download file from S3" error for baseline_overrides.json**

**Problem:** When the patching operations specified by your patch policy run, you receive an error similar to the following example.

**Example error on Windows Server**

```
----------ERROR----------
Invoke-PatchBaselineOperation : Access Denied
At C:\ProgramData\Amazon\SSM\InstanceData\i-02573cafcfEXAMPLE\document\orchestration\792dd5bd-2ad3-4f1e-931d-abEXAMPLE\PatchWindows\_script.ps1:219 char:13
+ $response = Invoke-PatchBaselineOperation -Operation Install -Snapshot ...
+ ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
+ CategoryInfo : OperationStopped: (Amazon.Patch.Ba...UpdateOpe
+ tion:InstallWindowsUpdateOperation) [Invoke-PatchBaselineOperation], Amazo
+ nS3Exception
+ erations.PowerShellCmdlets.InvokePatchBaselineOperation
failed to run commands: exit status 0xffffffff
```
Example error on Linux

```
[INFO]: Downloading Baseline Override from s3://aws-quicksetup-patchpolicy-123456789012-abcde/baseline_overrides.json
[ERROR]: Unable to download file from S3: s3://aws-quicksetup-patchpolicy-123456789012-abcde/baseline_overrides.json.
[ERROR]: Error loading entrance module.
```

**Cause:** You created a patch policy in Quick Setup, and some of your managed nodes already had an instance profile attached (for EC2 instances) or a service role attached (for non-EC2 machines). However, you didn't select the **Add required IAM policies to existing instance profiles attached to your instances** check box, as shown in the following image.

When you create a patch policy, an Amazon S3 bucket is also created to store the policy's configuration `baseline_overrides.json` file. If you don't select the **Add required IAM policies to existing instance profiles attached to your instances** check box when creating the policy, the IAM policies and resource tags that are needed to access `baseline_overrides.json` in the S3 bucket are not automatically added to your existing IAM instance profiles and service roles.

**Solution 1:** Delete the existing patch policy configuration, then create a replacement, making sure to select the **Add required IAM policies to existing instance profiles attached to your instances** check box. This selection applies the IAM policies created by this Quick Setup configuration to nodes that already have an instance profile or service role attached. (By default, Quick Setup adds the required policies to instances and nodes that do not already have instance profiles or service roles.) For more information, see [Automate organization-wide patching using a Quick Setup patch policy](#).
**Solution 2:** Manually add the required permissions and tags to each IAM instance profile and IAM service role that you use with Quick Setup. For instructions, see [Permissions for the patch policy S3 bucket](#).

**Issue: Patching fails without an apparent cause or error message**

**Problem:** A patching operation fails without returning an error message.

**Possible cause:** If more than one invocation of AWS-RunPatchBaseline occurs at a time, they can conflict with one another, causing patching tasks to fail. This might not be indicated in patching logs.

To check whether concurrent patching operations might have interrupted each other, review the command history in Run Command, a capability of AWS Systems Manager. For a managed node with a patching failure, check to see if multiple operations attempted to patch the machine within 2 minutes of one another. This scenario can sometimes cause a failure.

You can also use the AWS Command Line Interface (AWS CLI) to check for concurrent patching attempts by using the following command. Replace the value for `node-id` with the ID for your managed node.

```
aws ssm list-commands \
    --filter "key=DocumentName,value=AWS-RunPatchBaseline" \ 
    --query 'Commands[*].\n        {CommandId:CommandId,RequestedDateTime:RequestedDateTime,Status:Status}' \ 
    --instance-id node-id \ 
    --output table
```

**Solution:** If you determine that patching failed because of competing patching operations on the same managed node, adjust your patching configurations to avoid this occurring again. For example, if two maintenance windows specify overlapping patching times, remove or revise one of them. If a maintenance windows specifies one patching operation, but a patch policy specifies a different one for the same time, consider removing the task from the maintenance window.

If you determine that conflicting patching operations weren't the cause of the failure in this scenario, we recommend contacting AWS Support.

**Issue: Unexpected patch compliance results**

**Problem:** When reviewing the patching compliance details generated after a Scan operation, the results include information that don't reflect the rules set up in your patch baseline. For example,
an exception you added to the **Rejected patches** list in a patch baseline is listed as Missing. Or patches classified as **Important** are listed as missing even though your patch baseline specifies **Critical** patches only.

**Cause:** Patch Manager currently supports multiple methods of running **Scan** operations:

- A patch policy configured in Quick Setup
- A Host Management option configured in Quick Setup
- A maintenance window to run a patch **Scan** or **Install** task
- An on-demand **Patch now** operation

When a **Scan** operation runs, it overwrites the compliance details from the most recent scan. If you have more than one method set up to run a **Scan** operation, and they use different patch baselines with different rules, they will result in differing patch compliance results.

**Solution:** To avoid unexpected patch compliance results, we recommend using only one method at a time for running the Patch Manager **Scan** operation. For more information, see [Avoiding unintentional patch compliance data overwrites](#).

**Errors when running AWS-RunPatchBaseline on Linux**

**Topics**

- **Issue:** 'No such file or directory' error
- **Issue:** 'another process has acquired yum lock' error
- **Issue:** 'Permission denied / failed to run commands' error
- **Issue:** 'Unable to download payload' error
- **Issue:** 'unsupported package manager and python version combination' error
- **Issue:** Patch Manager isn't applying rules specified to exclude certain packages
- **Issue:** Patching fails and Patch Manager reports that the Server Name Indication extension to TLS is not available
- **Issue:** Patch Manager reports 'No more mirrors to try'
- **Issue:** Patching fails with 'Error code returned from curl is 23'
- **Issue:** Patching fails with 'Error unpacking rpm package...' message
- **Issue:** Patching fails with 'Errors were encountered while downloading packages’ message
- Issue: Patching fails with a message that 'The following signatures couldn't be verified because the public key is not available'
- Issue: Patching fails with a 'NoMoreMirrorsRepoError' message
- Issue: Patching fails with an 'Unable to download payload' message
- Issue: Patching fails with a message 'install errors: dpkg: error: dpkg frontend is locked by another process'
- Issue: Patching on Ubuntu Server fails with a 'dpkg was interrupted' error
- Issue: The package manager utility can't resolve a package dependency

Issue: 'No such file or directory' error

Problem: When you run AWS-RunPatchBaseline, patching fails with one of the following errors.

IOError: [Errno 2] No such file or directory: 'patch-baseline-operations-X.XX.tar.gz'

Unable to extract tar file: /var/log/amazon/ssm/patch-baseline-operations/patch-baseline-operations-1.75.tar.gz.failed to run commands: exit status 155

Unable to load and extract the content of payload, abort.failed to run commands: exit status 152

Cause 1: Two commands to run AWS-RunPatchBaseline were running at the same time on the same managed node. This creates a race condition that results in the temporary file patch-baseline-operations* not being created or accessed properly.

Cause 2: Insufficient storage space remains under the /var directory.

Solution 1: Ensure that no maintenance window has two or more Run Command tasks that run AWS-RunPatchBaseline with the same Priority level and that run on the same target IDs. If this is the case, reorder the priority. Run Command is a capability of AWS Systems Manager.

Solution 2: Ensure that only one maintenance window at a time is running Run Command tasks that use AWS-RunPatchBaseline on the same targets and on the same schedule. If this is the case, change the schedule.

Solution 3: Ensure that only one State Manager association is running AWS-RunPatchBaseline on the same schedule and targeting the same managed nodes. State Manager is a capability of AWS Systems Manager.
Solution 4: Free up sufficient storage space under the /var directory for the update packages.

Issue: 'another process has acquired yum lock' error

Problem: When you run AWS-RunPatchBaseline, patching fails with the following error.

12/20/2019 21:41:48 root [INFO]: another process has acquired yum lock, waiting 2 s and retry.

Cause: The AWS-RunPatchBaseline document has started running on a managed node where it's already running in another operation and has acquired the package manager yum process.

Solution: Ensure that no State Manager association, maintenance window tasks, or other configurations that run AWS-RunPatchBaseline on a schedule are targeting the same managed node around the same time.

Issue: 'Permission denied / failed to run commands' error

Problem: When you run AWS-RunPatchBaseline, patching fails with the following error.

Cause: /var/lib/amazon/ might be mounted with noexec permissions. This is an issue because SSM Agent downloads payload scripts to /var/lib/amazon/ssm and runs them from that location.

Solution: Ensure that you have configured exclusive partitions to /var/log/amazon and /var/lib/amazon, and that they're mounted with exec permissions.

Issue: 'Unable to download payload' error

Problem: When you run AWS-RunPatchBaseline, patching fails with the following error.

Unable to download payload: https://s3.DOC-EXAMPLE-BUCKET.region.amazonaws.com/aws-ssm-region/patchbaselineoperations/linux/payloads/patch-baseline-operations-X.XX.tar.gz.failed to run commands: exit status 156
**Cause:** The managed node doesn't have the required permissions to access the specified Amazon Simple Storage Service (Amazon S3) bucket.

**Solution:** Update your network configuration so that S3 endpoints are reachable. For more details, see information about required access to S3 buckets for Patch Manager in [SSM Agent communications with AWS managed S3 buckets](#).

**Issue: 'unsupported package manager and python version combination' error**

**Problem:** When you run `AWS-RunPatchBaseline`, patching fails with the following error.

```
An unsupported package manager and python version combination was found. Apt requires Python3 to be installed.
failed to run commands: exit status 1
```

**Cause:** A supported version of python3 isn't installed on the Debian Server, Raspberry Pi OS, or Ubuntu Server instance.

**Solution:** Install a supported version of python3 (3.0 - 3.10) on the server, which is required for Debian Server, Raspberry Pi OS, and Ubuntu Server managed nodes.

**Issue: Patch Manager isn't applying rules specified to exclude certain packages**

**Problem:** You have attempted to exclude certain packages by specifying them in the `/etc/yum.conf` file, in the format `exclude=`package-name`, but they aren't excluded during the Patch Manager Install operation.

**Cause:** Patch Manager doesn't incorporate exclusions specified in the `/etc/yum.conf` file.

**Solution:** To exclude specific packages, create a custom patch baseline and create a rule to exclude the packages you don't want installed.

**Issue: Patching fails and Patch Manager reports that the Server Name Indication extension to TLS is not available**

**Problem:** The patching operation issues the following message.

```
/var/log/amazon/ssm/patch-baseline-operations/urllib3/util/ssl_.py:369:
SNIMissingWarning: An HTTPS request has been made, but the SNI (Server Name Indication) extension
```
to TLS is not available on this platform. This might cause the server to present an
incorrect TLS
certificate, which can cause validation failures. You can upgrade to a newer version of
Python
to solve this.
For more information, see https://urllib3.readthedocs.io/en/latest/advanced-
usage.html#ssl-warnings

**Cause:** This message doesn't indicate an error. Instead, it's a warning that the older version of
Python distributed with the operating system doesn't support TLS Server Name Indication. The
Systems Manager patch payload script issues this warning when connecting to AWS APIs that
support SNI.

**Solution:** To troubleshoot any patching failures when this message is reported, review the contents
of the stdout and stderr files. If you haven't configured the patch baseline to store these files in
an S3 bucket or in Amazon CloudWatch Logs, you can locate the files in the following location on
your Linux managed node.

/var/lib/amazon/ssm/instance-id/document/orchestration/Run-Command-
execution-id/awsrunShellScript/PatchLinux

**Issue: Patch Manager reports 'No more mirrors to try'**

**Problem:** The patching operation issues the following message.

```
[Errno 256] No more mirrors to try.
```

**Cause:** The repositories configured on the managed node are not working correctly. Possible causes
for this include:

- The yum cache is corrupted.
- A repository URL can't be reached due to network-related issues.

**Solution:** Patch Manager uses the managed node's default package manager to perform patching
operation. Double-check that repositories are configured and operating correctly.

**Issue: Patching fails with 'Error code returned from curl is 23'**

**Problem:** A patching operating that uses AWS-RunPatchBaseline fails with an error similar to the
following:
**Cause**: The curl tool in use on your systems lacks the permissions needed to write to the filesystem. This can occur when if the package manager's default curl tool was replaced by a different version, such as one installed with snap.

**Solution**: If the curl version provided by the package manager was uninstalled when a different version was installed, reinstall it.

If you need to keep multiple curl versions installed, ensure that the version associated with the package manager is in the first directory listed in the PATH variable. You can check this by running the command `echo $PATH` to see the current order of directories that are checked for executable files on your system.

**Issue**: Patching fails with ‘Error unpacking rpm package...’ message

**Problem**: A patching operation fails with an error similar to the following:

```
Error : Error unpacking rpm package python-urllib3-1.25.9-1.amzn2.0.2.noarch
python-urllib3-1.25.9-1.amzn2.0.1.noarch was supposed to be removed but is not!
failed to run commands: exit status 1
```

**Cause 1**: When a particular package is present in multiple package installers, such as both pip and yum or dnf, conflicts can occur when using the default package manager.

A common example occurs with the urllib3 package, which is found in pip, yum, and dnf.

**Cause 2**: The python-urllib3 package is corrupted. This can happen if the package files were installed or updated by pip after the rpm was package was previously installed by yum or dnf.

**Solution**: Remove the python-urllib3 package from pip by running the command `sudo pip uninstall urllib3`, keeping the package only in the default package manager (yum or dnf).

**Issue**: Patching fails with ‘Errors were encountered while downloading packages’ message

**Problem**: During patching, you receive an error similar to the following:

```
YumDownloadError: [u'Errors were encountered while downloading packages.', u'libxml2-2.9.1-6.el7_9.x86_64: [Errno 5] [Errno 12]
Cannot allocate memory', u'libxslt-1.1.28-6.el7.x86_64: [Errno 5]
```
[Errno 12] Cannot allocate memory', u'libcroco-0.6.12-6.el7_9.x86_64:
[Errno 5] [Errno 12] Cannot allocate memory', u'openldap-2.4.44-25.el7_9.x86_64:
[Errno 5] [Errno 12] Cannot allocate memory',

**Cause:** This error can occur when insufficient memory is available on a managed node.

**Solution:** Configure the swap memory, or upgrade the instance to a different type to increase the memory support. Then start a new patching operation.

**Issue:** Patching fails with a message that 'The following signatures couldn't be verified because the public key is not available'

**Problem:** Patching fails on Ubuntu Server with an error similar to the following:

```
02/17/2022 21:08:43 root [ERROR]: W:GPG error:
http://repo.mysql.com/apt/ubuntu bionic InRelease: The following signatures couldn't be verified because the public key is not available:
NO_PUBKEY 467B942D3A79BD29, E:The repository ' http://repo.mysql.com/apt/ubuntu bionic
```

**Cause:** The GNU Privacy Guard (GPG) key has expired or is missing.

**Solution:** Refresh the GPG key, or add the key again.

For example, using the error shown previously, we see that the 467B942D3A79BD29 key is missing and must be added. To do so, run either of the following commands:

```
sudo apt-key adv --keyserver hkps://keyserver.ubuntu.com --recv-keys 467B942D3A79BD29
```

```
sudo apt-key adv --keyserver hkp://keyserver.ubuntu.com:80 --recv-keys 467B942D3A79BD29
```

Or, to refresh all keys, run the following command:

```
sudo apt-key adv --keyserver hkps://keyserver.ubuntu.com --refresh-keys
```

If the error recurs after this, we recommend reporting the issue to the organization that maintains the repository. Until a fix is available, you can edit the `/etc/apt/sources.list` file to omit the repository during the patching process.

To do so, open the `sources.list` file for editing, locate the line for the repository, and insert a `#` character at the beginning of the line to comment it out. Then save and close the file.
**Issue: Patching fails with a 'NoMoreMirrorsRepoError' message**

**Problem:** You receive an error similar to the following:

```markdown
NoMoreMirrorsRepoError: failure: repodata/repomd.xml from pgdg94: [Errno 256] No more mirrors to try.
```

**Cause:** There is an error in the source repository.

**Solution:** We recommend reporting the issue to the organization that maintains the repository. Until the error is fixed, you can disable the repository at the operating system level. To do so, run the following command, replacing the value for `repo-name` with your repository name:

```bash
yum-config-manager --disable repo-name
```

Following is an example.

```bash
yum-config-manager --disable pgdg94
```

After you run this command, run another patching operation.

**Issue: Patching fails with an 'Unable to download payload' message**

**Problem:** You receive an error similar to the following:

```markdown
Unable to download payload:
https://s3.dualstack.eu-west-1.amazonaws.com/aws-ssm-eu-west-1/patchbaselineoperations/
linux/payloads/patch-baseline-operations-1.83.tar.gz.
failed to run commands: exit status 156
```

**Cause:** The managed node configuration contains errors or is incomplete.

**Solution:** Make sure that the managed node is configured with the following:

- Outbound TCP 443 rule in security group.
- Egress TCP 443 rule in NACL.
- Ingress TCP 1024-65535 rule in NACL.
- NAT/IGW in route table to provide connectivity to an S3 endpoint. If the instance doesn't have internet access, provide it connectivity with the S3 endpoint. To do that, add an S3 gateway endpoint in the VPC and integrate it with the route table of the managed node.
Issue: Patching fails with a message 'install errors: dpkg: error: dpkg frontend is locked by another process'

Problem: Patching fails with an error similar to the following:

```
install errors: dpkg: error: dpkg frontend is locked by another process
failed to run commands: exit status 2
Failed to install package; install status Failed
```

Cause: The package manager is already running another process on a managed node at the operating system level. If that other process takes a long time to complete, the Patch Manager patching operation can time out and fail.

Solution: After the other process that’s using the package manager completes, run a new patching operation.

Issue: Patching on Ubuntu Server fails with a 'dpkg was interrupted' error

Problem: On Ubuntu Server, patching fails with an error similar to the following:

```
E: dpkg was interrupted, you must manually run 'dpkg --configure -a' to correct the problem.
```

Cause: One or more packages is misconfigured.

Solution: Perform the following steps:

1. Check to see which packages are affected, and what the issues are with each package by running the following commands, one at a time:

   ```
   sudo apt-get check
   sudo dpkg -C
   dpkg-query -W -f='${db:Status-Abbrev} ${binary:Package}\n' | grep -E ^[nci]
   ```

2. Correct the packages with issues by running the following command:

   ```
   sudo dpkg --configure -a
   ```
3. If the previous command didn't fully resolve the issue, run the following command:

```
sudo apt --fix-broken install
```

**Issue: The package manager utility can't resolve a package dependency**

**Problem:** The native package manager on the managed node is unable to resolve a package dependency and patching fails. The following error message example indicates this type of failure on an operating system that uses `yum` as the package manager.

```
09/22/2020 08:56:09 root [ERROR]: yum update failed with result code: 1, message: [u'rpm-python-4.11.3-25.amzn2.0.3.x86_64 requires rpm = 4.11.3-25.amzn2.0.3', u'awscli-1.18.107-1.amzn2.0.1.noarch requires python2-botocore = 1.17.31']
```

**Cause:** On Linux operating systems, Patch Manager uses the native package manager on the machine to run patching operations, such as `yum`, `dnf`, `apt`, and `zypper`. The applications automatically detect, install, update, or remove dependent packages as required. However, some conditions can result in the package manager being unable to complete a dependency operation, such as:

- Multiple conflicting repositories are configured on the operating system.
- A remote repository URL is inaccessible due to network-related issues.
- A package for the wrong architecture is found in the repository.

**Solution:** Patching might fail because of a dependency issue for a wide variety of reasons. Therefore, we recommend that you contact AWS Support to assist with troubleshooting.

**Errors when running AWS-RunPatchBaseline on Windows Server**

**Topics**

- **Issue: mismatched product family/product pairs**
- **Issue: AWS-RunPatchBaseline output returns an HRESULT (Windows Server)**
- **Issue: managed node doesn't have access to Windows Update Catalog or WSUS**
- **Issue: PatchBaselineOperations PowerShell module is not downloadable**
- **Issue: missing patches**
**Issue: mismatched product family/product pairs**

**Problem:** When you create a patch baseline in the Systems Manager console, you specify a product family and a product. For example, you might choose:

- **Product family:** Office
  - **Product:** Office 2016

**Cause:** If you attempt to create a patch baseline with a mismatched product family/product pair, an error message is displayed. The following are reasons this can occur:

- You selected a valid product family and product pair but then removed the product family selection.
- You chose a product from the **Obsolete or mismatched options** sublist instead of the **Available and matching options** sublist.

Items in the product **Obsolete or mismatched options** sublist might have been entered in error through an SDK or AWS Command Line Interface (AWS CLI) `create-patch-baseline` command. This could mean a typo was introduced or a product was assigned to the wrong product family. A product is also included in the **Obsolete or mismatched options** sublist if it was specified for a previous patch baseline but has no patches available from Microsoft.

**Solution:** To avoid this issue in the console, always choose options from the **Currently available options** sublists.

You can also view the products that have available patches by using the `describe-patch-properties` command in the AWS CLI or the `DescribePatchProperties` API command.

**Issue: AWS-RunPatchBaseline output returns an HRESULT (Windows Server)**

**Problem:** You received an error like the following.

```
--------ERROR--------
Invoke-PatchBaselineOperation : Exception Details: An error occurred when attempting to search Windows Update.
Exception Level 1:
  Error Message: Exception from HRESULT: 0x80240437
  Stack Trace: at WUApiLib.IUpdateSearcher.Search(String criteria)..
(Windows updates)
```
Cause: This output indicates that the native Windows Update APIs were unable to run the patching operations.

Solution: Check the HRESULT code in the following microsoft.com topics to identify troubleshooting steps for resolving the error:

- Windows Update error codes by component
- Windows Update common errors and mitigation

Issue: managed node doesn't have access to Windows Update Catalog or WSUS

Problem: You received an error like the following.

Extracting PatchBaselineOperations zip file contents to temporary folder.

Verifying SHA 256 of the PatchBaselineOperations PowerShell module files.

Successfully downloaded and installed the PatchBaselineOperations PowerShell module.

EC2AMAZ-VL3099P - PatchBaselineOperations Assessment Results - 2020-12-30T20:59:46.169

----------ERROR-------

Invoke-PatchBaselineOperation : Exception Details: An error occurred when attempting to search Windows Update.

Exception Level 1:

Error Message: Exception from HRESULT: 0x80072EE2

Stack Trace: at WUApiLib.IUpdateSearcher.Search(String criteria)

At C:\ProgramData\Amazon\SSM\InstanceData\i-02573cafcafEXAMPLE\document\orchestration\3d2d4864-04b7-4316-84fe-eafff1ea58\e3\PatchWindows\_script.ps1:230 char:13
$response = Invoke-PatchBaselineOperation -Operation Install -Snapshot ...

---Error truncated----

**Cause:** This error could be related to the Windows Update components, or to a lack of connectivity to the Windows Update Catalog or Windows Server Update Services (WSUS).

**Solution:** Confirm that the managed node has connectivity to the [Microsoft Update Catalog](https://go.microsoft.com/fwlink/?linkid=930551) through an internet gateway, NAT gateway, or NAT instance. If you're using WSUS, confirm that the managed node has connectivity to the WSUS server in your environment. If connectivity is available to the intended destination, check the Microsoft documentation for other potential causes of HRESULT 0x80072EE2. This might indicate an operating system level issue.

**Issue:** PatchBaselineOperations PowerShell module is not downloadable

**Problem:** You received an error like the following.

Preparing to download PatchBaselineOperations PowerShell module from S3.
Solution: Check the managed node connectivity and permissions to Amazon Simple Storage Service (Amazon S3). The managed node's AWS Identity and Access Management (IAM) role must use the minimum permissions cited in SSM Agent communications with AWS managed S3 buckets. The node must communicate with the Amazon S3 endpoint through the Amazon S3 gateway endpoint, NAT gateway, or internet gateway. For more information about the VPC Endpoint requirements for AWS Systems Manager SSM Agent (SSM Agent), see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

Issue: missing patches

Problem: AWS-RunPatchbaseline completed successfully, but there are some missing patches.

The following are some common causes and their solutions.

Cause 1: The baseline isn't effective.

Solution 1: To check if this is the cause, use the following procedure.

2. In the navigation pane, choose Run Command.
3. Select the Command history tab and then select the command whose baseline you want to check.
4. Select the managed node that has missing patches.
5. Select **Step 1 - Output** and find the BaselineId value.

6. Check the assigned **patch baseline configuration**, that is, the operating system, product name, classification, and severity for the patch baseline.

7. Go to the [Microsoft Update Catalog](#).

8. Search the Microsoft Knowledge Base (KB) article IDs (for example, KB3216916).

9. Verify that the value under **Product** matches that of your managed node and select the corresponding **Title**. A new **Update Details** window will open.

10. In the **Overview** tab, the **classification** and **MSRC severity** must match the patch baseline configuration you found earlier.

**Cause 2**: The patch was replaced.

**Solution 2**: To check if this is true, use the following procedure.

1. Go to the [Microsoft Update Catalog](#).

2. Search the Microsoft Knowledge Base (KB) article IDs (for example, KB3216916).

3. Verify that the value under **Product** matches that of your managed node and select the corresponding **Title**. A new **Update Details** window will open.

4. Go to the **Package Details** tab. Look for an entry under the **This update has been replaced by the following updates**: header.

**Cause 3**: The same patch might have different KB numbers because the WSUS and Window online updates are handled as independent Release Channels by Microsoft.

**Solution 3**: Check the patch eligibility. If the package isn't available under WSUS, install **OS Build 14393.3115**. If the package is available for all operating system builds, install **OS Builds 18362.1256 and 18363.1256**.

**Contacting AWS Support**

If you can't find troubleshooting solutions in this section or in the Systems Manager issues in [AWS re:Post](#), and you have a [Developer, Business, or Enterprise AWS Support plan](#), you can create a technical support case at [AWS Support](#).

Before you contact AWS Support, collect the following items:
- **SSM agent logs**
- Run Command command ID, maintenance window ID, or Automation execution ID
- For Windows Server managed nodes, also collect the following:
  - `%PROGRAMDATA%\Amazon\PatchBaselineOperations\Logs` as described on the **Windows** tab of [How patches are installed](#)
- For Linux managed nodes, also collect the following:
  - The contents of the directory `/var/lib/amazon/ssm/instance-id/document/orchestration/Run-Command-execution-id/awsrunShellScript/PatchLinux`

**AWS Systems Manager Distributor**

Distributor, a capability of AWS Systems Manager, helps you package and publish software to AWS Systems Manager managed nodes. You can package and publish your own software or use Distributor to find and publish AWS-provided agent software packages, such as `AmazonCloudWatchAgent`, or third-party packages such as `Trend Micro`. Publishing a package advertises specific versions of the package's document to managed nodes that you identify using node IDs, AWS account IDs, tags, or an AWS Region. To get started with Distributor, open the [Systems Manager console](#). In the navigation pane, choose Distributor.

After you create a package in Distributor, you can install the package in one of the following ways:

- One time by using [AWS Systems Manager Run Command](#)
- On a schedule by using [AWS Systems Manager State Manager](#)

---

**Important**

Packages distributed by third-party sellers are not managed by AWS and are published by the vendor of the package. We encourage you to conduct additional due diligence to ensure compliance with your internal security controls. Security is a shared responsibility between AWS and you. This is described as the shared responsibility model. To learn more, see the [shared responsibility model](#).
How can Distributor benefit my organization?

Distributor offers these benefits:

- **One package, many platforms**

  When you create a package in Distributor, the system creates an AWS Systems Manager document (SSM document). You can attach .zip files to this document. When you run Distributor, the system processes the instructions in the SSM document and installs the software package in the .zip file on the specified targets. Distributor supports multiple operating systems, including Windows, Ubuntu Server, Debian Server, and Red Hat Enterprise Linux. For more information about supported platforms, see [Supported package platforms and architectures](#).

- **Control package access across groups of managed instances**

  You can use Run Command or State Manager to control which of your managed nodes get a package and which version of that package. Run Command and State Manager are capabilities of AWS Systems Manager. Managed nodes can be grouped by instance or device IDs, AWS account numbers, tags, or AWS Regions. You can use State Manager associations to deliver different versions of a package to different groups of instances.

- **Many AWS agent packages included and ready to use**

  Distributor includes many AWS agent packages that are ready for you to deploy to managed nodes. Look for packages in the Distributor Packages list page that are published by Amazon. Examples include AmazonCloudWatchAgent and AWSPVDriver.

- **Automate deployment**

  To keep your environment current, use State Manager to schedule packages for automatic deployment on target managed nodes when those machines are first launched.

Who should use Distributor?

- Any AWS customer who wants to create new or deploy existing software packages, including AWS published packages, to multiple Systems Manager managed nodes at one time.

- Software developers who create software packages.

- Administrators who are responsible for keeping Systems Manager managed nodes current with the most up-to-date software packages.
What are the features of Distributor?

- **Deployment of packages to both Windows and Linux instances**

  With Distributor, you can deploy software packages to Amazon Elastic Compute Cloud (Amazon EC2) instances and AWS IoT Greengrass core devices for Linux and Windows Server. For a list of supported instance operating system types, see the section called “Supported package platforms and architectures”.

  **Note**
  
  Distributor isn't supported on the macOS operating system.

- **Deploy packages one time, or on an automated schedule**

  You can choose to deploy packages one time, on a regular schedule, or whenever the default package version is changed to a different version.

- **Completely reinstall packages, or perform in-place updates**

  To install a new package version, you can completely uninstall the current version and install a new one in its place, or only update the current version with new and updated components, according to an *update script* that you provide. Your package application is unavailable during a reinstallation, but can remain available during an in-place update. In-place updates are especially useful for security monitoring applications or other scenarios where you need to avoid application downtime.

- **Console, CLI, PowerShell, and SDK access to Distributor capabilities**

  You can work with Distributor by using the Systems Manager console, AWS Command Line Interface (AWS CLI), AWS Tools for PowerShell, or the AWS SDK of your choice.

- **IAM access control**

  By using AWS Identity and Access Management (IAM) policies, you can control which members of your organization can create, update, deploy, or delete packages or package versions. For example, you might want to give an administrator permissions to deploy packages, but not to change packages or create new package versions.

- **Logging and auditing capability support**
You can audit and log Distributor user actions in your AWS account through integration with other AWS services. For more information, see Auditing and logging Distributor activity.

What is a package?

A package is a collection of installable software or assets that includes the following.

- A .zip file of software per target operating system platform. Each .zip file must include the following.
  - An install and an uninstall script. Windows Server-based managed nodes require PowerShell scripts (scripts named install.ps1 and uninstall.ps1). Linux-based managed nodes require shell scripts (scripts named install.sh and uninstall.sh). AWS Systems Manager SSM Agent reads and carries out the instructions in the install and uninstall scripts.
  - An executable file. SSM Agent must find this executable to install the package on target managed nodes.
  - A JSON-formatted manifest file that describes the package contents. The manifest isn't included in the .zip file, but it's stored in the same Amazon Simple Storage Service (Amazon S3) bucket as the .zip files that form the package. The manifest identifies the package version and maps the .zip files in the package to target managed node attributes, such as operating system version or architecture. For information about how to create the manifest, see Step 2: Create the JSON package manifest.

When you choose Simple package creation in the Distributor console, Distributor generates the installation and uninstallation scripts, file hashes, and the JSON package manifest for you, based on the software executable file name and target platforms and architectures.

Supported package platforms and architectures

You can use Distributor to publish packages to the following Systems Manager managed node platforms. A version value must match the exact release version of the operating system Amazon Machine Image (AMI) that you're targeting. For more information about determining this version, see step 4 of Step 2: Create the JSON package manifest.
**Note**

Systems Manager doesn't support all of the following operating systems for AWS IoT Greengrass core devices. For more information, see [Setting up AWS IoT Greengrass core devices](#) in the *AWS IoT Greengrass Version 2 Developer Guide*.

Setting up Distributor

Before you use Distributor, a capability of AWS Systems Manager, to create, manage, and deploy software packages, follow these steps.

Topics

- Step 1: Complete Distributor prerequisites
- Step 2: Verify or create an IAM instance profile with Distributor permissions
- Step 3: Control user access to packages
- Step 4: Create or choose an Amazon S3 bucket

Step 1: Complete Distributor prerequisites

Before you use Distributor, a capability of AWS Systems Manager, be sure your environment meets the following requirements.

Distributor prerequisites

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSM Agent</td>
<td>AWS Systems Manager SSM Agent version 2.3.274.0 or later must be installed on the managed nodes on which you want to deploy or from which you want to remove packages. To install or update SSM Agent, see Working with SSM Agent.</td>
</tr>
<tr>
<td>AWS CLI</td>
<td>(Optional) To use the AWS Command Line Interface (AWS CLI) instead of the Systems</td>
</tr>
</tbody>
</table>
### AWS Systems Manager User Guide

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manager console to create and manage packages, install the newest release of the AWS CLI on your local computer.</td>
<td>For more information about how to install or upgrade the CLI, see <a href="#">Installing the AWS Command Line Interface</a> in the AWS Command Line Interface User Guide.</td>
</tr>
<tr>
<td>AWS Tools for PowerShell</td>
<td>(Optional) To use the Tools for PowerShell instead of the Systems Manager console to create and manage packages, install the newest release of Tools for PowerShell on your local computer.</td>
</tr>
<tr>
<td></td>
<td>For more information about how to install or upgrade the Tools for PowerShell, see <a href="#">Setting up the AWS Tools for Windows PowerShell or AWS Tools for PowerShell Core</a> in the AWS Tools for Windows PowerShell User Guide.</td>
</tr>
</tbody>
</table>

**Note**

Systems Manager doesn't support distributing packages to Oracle Linux managed nodes by using Distributor.

---

**Step 2: Verify or create an IAM instance profile with Distributor permissions**

By default, AWS Systems Manager doesn't have permission to perform actions on your instances. You must grant access by using an AWS Identity and Access Management (IAM) instance profile. An instance profile is a container that passes IAM role information to an Amazon Elastic Compute Cloud (Amazon EC2) instance at launch. This requirement applies to permissions for all Systems Manager capabilities, not just Distributor, which is a capability of AWS Systems Manager.
When you configure your edge devices to run AWS IoT Greengrass Core software and SSM Agent, you specify an IAM service role that enables Systems Manager to perform actions on it. You don't need to configure managed edge devices with an instance profile.

If you already use other Systems Manager capabilities, such as Run Command and State Manager, an instance profile with the required permissions for Distributor is already attached to your instances. The simplest way to ensure that you have permissions to perform Distributor tasks is to attach the `AmazonSSMManagedInstanceCore` policy to your instance profile. For more information, see [Configure instance permissions required for Systems Manager](#).

**Step 3: Control user access to packages**

Using AWS Identity and Access Management (IAM) policies, you can control who can create, deploy, and manage packages. You also control which Run Command and State Manager API operations they can perform on managed nodes. Like Distributor, both Run Command and State Manager, are capabilities of AWS Systems Manager.

**ARN Format**

User-defined packages are associated with document Amazon Resource Names (ARNs) and have the following format.

```
```

The following is an example.

```
```

You can use a pair of AWS supplied default IAM policies, one for end users and one for administrators, to grant permissions for Distributor activities. Or you can create custom IAM policies appropriate for your permissions requirements.

For more information about using variables in IAM policies, see [IAM Policy Elements: Variables](#).

For information about how to create policies and attach them to users or groups, see [Creating IAM Policies](#) and [Adding and Removing IAM Policies](#) in the *IAM User Guide*. 

---

**Note**

When you configure your edge devices to run AWS IoT Greengrass Core software and SSM Agent, you specify an IAM service role that enables Systems Manager to perform actions on it. You don't need to configure managed edge devices with an instance profile.
Step 4: Create or choose an Amazon S3 bucket

When you create a package by using the Simple workflow in the AWS Systems Manager console, you choose an existing Amazon Simple Storage Service (Amazon S3) bucket to which Distributor uploads your software. Distributor is a capability of AWS Systems Manager. In the Advanced workflow, you must upload .zip files of your software or assets to an Amazon S3 bucket before you begin. Whether you create a package by using the Simple or Advanced workflows in the console, or by using the API, you must have an Amazon S3 bucket before you start creating your package. As part of the package creation process, Distributor copies your installable software and assets from this bucket to an internal Systems Manager store. Because the assets are copied to an internal store, you can delete or repurpose your Amazon S3 bucket when package creation is finished.

For more information about how to create a bucket, see Create a Bucket in the Amazon Simple Storage Service Getting Started Guide. For more information about how to run an AWS CLI command to create a bucket, see mb in the AWS CLI Command Reference.

Working with Distributor

You can use the AWS Systems Manager console, AWS command line tools (AWS CLI and AWS Tools for PowerShell), and AWS SDKs to add, manage, or deploy packages in Distributor. Distributor is a capability of AWS Systems Manager. Before you add a package to Distributor:

- Create and zip installable assets.
- (Optional) Create a JSON manifest file for the package. This isn't required to use the Simple package creation process in the Distributor console. Simple package creation generates a JSON manifest file for you.

  You can use the AWS Systems Manager console or a text or JSON editor to create the manifest file.

- Have an Amazon Simple Storage Service (Amazon S3) bucket ready to store your installable assets or software. If you're using the Advanced package creation process, upload your assets to the Amazon S3 bucket before you begin.

Note

You can delete or repurpose this bucket after you finish creating your package because Distributor moves the package contents to an internal Systems Manager bucket as part of the package creation process.
AWS published packages are already packaged and ready for deployment. To deploy an AWS-published package to managed nodes, see Install or update packages.

You can share Distributor packages between AWS accounts. When using a package shared from another account in AWS CLI commands use the package Amazon Resource Name (ARN) instead of the package name.

Topics

- View packages
- Create a package
- Edit package permissions (console)
- Edit package tags (console)
- Add a package version to Distributor
- Install or update packages
- Uninstall a package
- Delete a package

View packages

To view packages that are available for installation, you can use the AWS Systems Manager console or your preferred AWS command line tool. Distributor is a capability of AWS Systems Manager. To access Distributor, open the AWS Systems Manager console and choose Distributor in the left navigation pane. You will see all of the packages available to you.

The following section describes how you can view Distributor packages using your preferred command line tool.

View packages (command line)

This section contains information about how you can use your preferred command line tool to view Distributor packages using the provided commands.

Linux & macOS

To view packages using the AWS CLI on Linux

- To view all packages, excluding shared packages, run the following command.
aws ssm list-documents \
  --filters Key=DocumentType,Values=Package

- To view all packages owned by Amazon, run the following command.

aws ssm list-documents \
  --filters Key=DocumentType,Values=Package Key=Owner,Values=Amazon

- To view all packages owned by third parties, run the following command.

aws ssm list-documents \
  --filters Key=DocumentType,Values=Package Key=Owner,Values=ThirdParty

Windows

To view packages using the AWS CLI on Windows

- To view all packages, excluding shared packages, run the following command.

aws ssm list-documents ^
  --filters Key=DocumentType,Values=Package

- To view all packages owned by Amazon, run the following command.

aws ssm list-documents ^
  --filters Key=DocumentType,Values=Package Key=Owner,Values=Amazon

- To view all packages owned by third parties, run the following command.

aws ssm list-documents ^
  --filters Key=DocumentType,Values=Package Key=Owner,Values=ThirdParty

PowerShell

To view packages using the Tools for PowerShell

- To view all packages, excluding shared packages, run the following command.

$filter.Key = "DocumentType"
$filter.Values = "Package"

Get-SSMDocumentList
   -Filters @{$filter}

• To view all packages owned by Amazon, run the following command.

$typeFilter = New-Object
   Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$typeFilter.Key = "DocumentType"
$typeFilter.Values = "Package"

$ownerFilter = New-Object
   Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$ownerFilter.Key = "Owner"
$ownerFilter.Values = "Amazon"

Get-SSMDocumentList
   -Filters @{$typeFilter,$ownerFilter}

• To view all packages owned by third parties, run the following command.

$typeFilter = New-Object
   Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$typeFilter.Key = "DocumentType"
$typeFilter.Values = "Package"

$ownerFilter = New-Object
   Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$ownerFilter.Key = "Owner"
$ownerFilter.Values = "ThirdParty"

Get-SSMDocumentList
   -Filters @{$typeFilter,$ownerFilter}

Create a package

To create a package, prepare your installable software or assets, one file per operating system platform. At least one file is required to create a package.
Different platforms might sometimes use the same file, but all files that you attach to your package must be listed in the Files section of the manifest. If you're creating a package by using the simple workflow in the console, the manifest is generated for you. The maximum number of files that you can attach to a single document is 20. The maximum size of each file is 1 GB. For more information about supported platforms, see Supported package platforms and architectures.

When you create a package, the system creates a new SSM document. This document allows you to deploy the package to managed nodes.

For demonstration purposes only, an example package, ExamplePackage.zip, is available for you to download from our website. The example package includes a completed JSON manifest and three .zip files containing installers for PowerShell v7.0.0. The installation and uninstallation scripts don't contain valid commands. Although you must zip each software installable and scripts into a .zip file to create a package in the Advanced workflow, you don't zip installable assets in the Simple workflow.

Topics

- Create a package (simple)
- Create a package (advanced)

Create a package (simple)

This section describes how to create a package in Distributor by choosing the Simple package creation workflow in the Distributor console. Distributor is a capability of AWS Systems Manager. To create a package, prepare your installable assets, one file per operating system platform. At least one file is required to create a package. The Simple package creation process generates installation and uninstallation scripts, file hashes, and a JSON-formatted manifest for you. The Simple workflow handles the process of uploading and zipping your installable files, and creating a new package and associated SSM document. For more information about supported platforms, see Supported package platforms and architectures.

When you use the Simple method to create a package, Distributor creates install and uninstall scripts for you. However, when you create a package for an in-place update, you must provide your own update script content on the Update script tab. When you add input commands for an update script, Distributor includes this script in the .zip package it creates for you, along with the install and uninstall scripts.
Note
Use the In-place update option to add new or updated files to an existing package installation without taking the associated application offline.

To create a package (simple)

2. In the navigation pane, choose Distributor.
3. On the Distributor home page, choose Create package, and then choose Simple.
4. On the Create package page, enter a name for your package. Package names can contain letters, numbers, periods, dashes, and underscores. The name should be generic enough to apply to all versions of the package attachments, but specific enough to identify the purpose of the package.
5. (Optional) For Version name, enter a version name. Version names can be a maximum of 512 characters, and can't contain special characters.
6. For Location, choose a bucket by using the bucket name and prefix or by using the bucket URL.
7. For Upload software, choose Add software, and then navigate to installable software files with .rpm, .msi, or .deb extensions. If the file name contains spaces, the upload fails. You can upload more than one software file in a single action.
8. For Target platform, verify that the target operating system platform shown for each installable file is correct. If the operating system shown isn't correct, choose the correct operating system from the dropdown list.

For the Simple package creation workflow, because you upload each installable file only once, extra steps are required to instruct Distributor to target a single file at multiple operating systems. For example, if you upload an installable software file named Logtool_v1.1.1.rpm, you must change some defaults in the Simple workflow to target the same software at both Amazon Linux and Ubuntu operating systems. When targeting multiple platforms, do one of the following.

- Use the Advanced workflow instead, zip each installable file into a .zip file before you begin, and manually author the manifest so that one installable file can be targeted at multiple
operating system platforms or versions. For more information, see Create a package (advanced).

- Manually edit the manifest file in the Simple workflow so that your .zip file is targeted at multiple operating system platforms or versions. For more information about how to do this, see the end of step 4 in Step 2: Create the JSON package manifest.

9. For Platform version, verify that the operating system platform version shown is either _any_, a major release version followed by a wildcard (7.*), or the exact operating system release version to which you want your software to apply. For more information about specifying an operating system platform version, see step 4 in Step 2: Create the JSON package manifest.

10. For Architecture, choose the correct processor architecture for each installable file from the dropdown list. For more information about supported processor architectures, see Supported package platforms and architectures.

11. (Optional) Expand Scripts, and review the scripts that Distributor generates for your installable software.

12. (Optional) To provide an update script for use with in-place updates, expand Scripts, choose the Update script tab, and enter your update script commands.

   Systems Manager doesn't generate update scripts on your behalf.

13. To add more installable software files, choose Add software. Otherwise, go to the next step.

14. (Optional) Expand Manifest, and review the JSON package manifest that Distributor generates for your installable software. If you changed any information about your software since you began this procedure, such as platform version or target platform, choose Generate manifest to show the updated package manifest.

   You can edit the manifest manually if you want to target a software installable at more than one operating system, as described in step 8. For more information about editing the manifest, see Step 2: Create the JSON package manifest.

15. Choose Create package.

Wait for Distributor to finish uploading your software and creating your package. Distributor shows upload status for each installable file. Depending on the number and size of packages you're adding, this can take a few minutes. Distributor automatically redirects you to the Package details page for the new package, but you can choose to open this page yourself after the software is uploaded. The Package details page doesn't show all information about your package until
Distributor finishes the package creation process. To stop the upload and package creation process, choose **Cancel**.

If Distributor can't upload any of the software installable files, it displays an **Upload failed** message. To retry the upload, choose **Retry upload**. For more information about how to troubleshoot package creation failures, see [Troubleshooting AWS Systems Manager Distributor](#).

### Create a package (advanced)

In this section, learn about how advanced users can create a package in Distributor after uploading installable assets zipped with installation and uninstallation scripts, and a JSON manifest file, to an Amazon S3 bucket.

To create a package, prepare your .zip files of installable assets, one .zip file per operating system platform. At least one .zip file is required to create a package. Next, create a JSON manifest. The manifest includes pointers to your package code files. When you have your required code files added to a folder or directory, and the manifest is populated with correct values, upload your package to an S3 bucket.

An example package, **ExamplePackage.zip**, is available for you to download from our website. The example package includes a completed JSON manifest and three .zip files.

### Topics

- **Step 1: Create the ZIP files**
- **Step 2: Create the JSON package manifest**
- **Step 3: Upload the package and manifest to an Amazon S3 bucket**
- **Step 4: Add a package to Distributor**

#### Step 1: Create the ZIP files

The foundation of your package is at least one .zip file of software or installable assets. A package includes one .zip file per operating system that you want to support, unless one .zip file can be installed on multiple operating systems. For example, Red Hat Enterprise Linux and Amazon Linux instances can typically run the same .RPM executable files, so you need to attach only one .zip file to your package to support both operating systems.

### Required files

The following items are required in each .zip file:
• An install and an uninstall script. Windows Server-based managed nodes require PowerShell scripts (scripts named install.ps1 and uninstall.ps1). Linux-based managed nodes require shell scripts (scripts named install.sh and uninstall.sh). SSM Agent runs the instructions in the install and uninstall scripts.

For example, your installation scripts might run an installer (such as .rpm or .msi), they might copy files, or they might set configurations.

• An executable file, installer packages (.rpm, .deb, .msi, etc.), other scripts, or configuration files.

Optional files

The following item is optional in each .zip file:

• An update script. Providing an update script makes it possible for you to use the In-place update option to install a package. When you want to add new or updated files to an existing package installation, the In-place update option doesn't take the package application offline while the update is performed. Windows Server-based managed nodes require a PowerShell script (script named update.ps1). Linux-based managed nodes require a shell script (script named update.sh). SSM Agent runs the instructions in the update script.

For more information about installing or updating packages, see Install or update packages.

For examples of .zip files, including sample install and uninstall scripts, download the example package, ExamplePackage.zip.

Step 2: Create the JSON package manifest

After you prepare and zip your installable files, create a JSON manifest. The following is a template. The parts of the manifest template are described in the procedure in this section. You can use a JSON editor to create this manifest in a separate file. Alternatively, you can author the manifest in the AWS Systems Manager console when you create a package.

```json
{
  "schemaVersion": "2.0",
  "version": "your-version",
  "publisher": "optional-publisher-name",
  "packages": {
    "platform": {
      "platform-version": {
      "platform-version": {
```
To create a JSON package manifest

1. Add the schema version to your manifest. In this release, the schema version is always 2.0.

   ```json
   { "schemaVersion": "2.0",
   
   2. Add a user-defined package version to your manifest. This is also the value of Version name
   that you specify when you add your package to Distributor. It becomes part of the AWS Systems Manager document that Distributor creates when you add your package. You also
provide this value as an input in the AWS-ConfigureAWSPackage document to install a version of the package other than the latest. A version value can contain letters, numbers, underscores, hyphens, and periods, and be a maximum of 128 characters in length. We recommend that you use a human-readable package version to make it easier for you and other administrators to specify exact package versions when you deploy. The following is an example.

```
"version": "1.0.1",
```

3. (Optional) Add a publisher name. The following is an example.

```
"publisher": "MyOrganization",
```

4. Add packages. The "packages" section describes the platforms, release versions, and architectures supported by the .zip files in your package. For more information, see Supported package platforms and architectures.

The platform-version can be the wildcard value, _any. Use it to indicate that a .zip file supports any release of the platform. You can also specify a major release version followed by a wildcard so all minor versions are supported, for example 7.*. If you choose to specify a platform-version value for a specific operating system version, be sure that it matches the exact release version of the operating system AMI that you're targeting. The following are suggested resources for getting the correct value of the operating system.

- On a Windows Server-based managed nodes, the release version is available as Windows Management Instrumentation (WMI) data. You can run the following command from a command prompt to get version information, then parse the results for version. This command doesn't show the version for Windows Server Nano; the version value for Windows Server Nano is nano.

  ```
  wmic OS get /format:list
  ```

- On a Linux-based managed node, get the version by first scanning for operating system release (the following command). Look for the value of VERSION_ID.

  ```
  cat /etc/os-release
  ```
If that doesn't return the results that you need, run the following command to get LSB release information from the `/etc/lsb-release` file, and look for the value of `DISTRIBUT_RELEASE`.

```
lsb_release -a
```

If these methods fail, you can usually find the release based on the distribution. For example, on Debian Server, you can scan the `/etc/debian_version` file, or on Red Hat Enterprise Linux, the `/etc/redhat-release` file.

```
hostnamectl
```

```json
"packages": {
  "platform": {
    "platform-version": {
      "architecture": {
        "file": "zip-file-name-1.zip"
      }
    },
  },
  "another-platform": {
    "platform-version": {
      "architecture": {
        "file": "zip-file-name-2.zip"
      }
    },
  },
  "another-platform": {
    "platform-version": {
      "architecture": {
        "file": "zip-file-name-3.zip"
      }
    }
  }
}
```
The following is an example. In this example, the operating system platform is `amazon`, the supported release version is `2016.09`, the architecture is `x86_64`, and the `.zip` file that supports this platform is `test.zip`.

```json
{
    "amazon": {
        "2016.09": {
            "x86_64": {
                "file": "test.zip"
            }
        }
    },
}
```

You can add the `_any` wildcard value to indicate that the package supports all versions of the parent element. For example, to indicate that the package is supported on any release version of Amazon Linux, your package statement should be similar to the following. You can use the `_any` wildcard at the version or architecture levels to support all versions of a platform, or all architectures in a version, or all versions and all architectures of a platform.

```json
{
    "amazon": {
        "_any": {
            "x86_64": {
                "file": "test.zip"
            }
        }
    },
}
```

The following example adds `_any` to show that the first package, `data1.zip`, is supported for all architectures of Amazon Linux 2016.09. The second package, `data2.zip`, is supported for all releases of Amazon Linux, but only for managed nodes with `x86_64` architecture. Both the `2016.09` and `_any` versions are entries under `amazon`. There is one platform (Amazon Linux), but different supported versions, architectures, and associated `.zip` files.

```json
{
    "amazon": {
        "2016.09": {
```
You can refer to a .zip file more than once in the "packages" section of the manifest, if the .zip file supports more than one platform. For example, if you have a .zip file that supports both Red Hat Enterprise Linux 7.x versions and Amazon Linux, you have two entries in the "packages" section that point to the same .zip file, as shown in the following example.

```
{
   "amazon": {
      "2018.03": {
         "x86_64": {
            "file": "test.zip"
         }
      }
   },
   "redhat": {
      "7.*": {
         "x86_64": {
            "file": "test.zip"
         }
      }
   }
}
```

5. Add the list of .zip files that are part of this package from step 4. Each file entry requires the file name and sha256 hash value checksum. Checksum values in the manifest must match the sha256 hash value in the zipped assets to prevent the package installation from failing.

To get the exact checksum from your installables, you can run the following commands. On Linux, run `shasum -a 256 file-name.zip` or `openssl dgst -sha256 file-`
name.zip. On Windows, run the Get-FileHash -Path path-to-.zip-file cmdlet in PowerShell.

The "files" section of the manifest includes one reference to each of the .zip files in your package.

```
"files": {
  "test-agent-x86.deb.zip": {
    "checksums": {
      "sha256": "EXAMPLE2706223c7616ca9fb28863a233b38e5a23a8c326bb4ae241dcEXAMPLE"
    }
  },
  "test-agent-x86_64.deb.zip": {
    "checksums": {
      "sha256": "EXAMPLE572a745844618c491045f25ee6aee8a66307ea9bff0e9d1052EXAMPLE"
    }
  },
  "test-agent-x86_64.nano.zip": {
    "checksums": {
      "sha256": "EXAMPLE63ccb86e830b63dfef46995af6b32b3c52ce72241b5e80c995EXAMPLE"
    }
  },
  "test-agent-rhel5-x86.nano.zip": {
    "checksums": {
      "sha256": "EXAMPLE13df60aa3219bf117638167e5bae0a55467e947a363fff0a51EXAMPLE"
    }
  },
  "test-agent-x86.msi.zip": {
    "checksums": {
      "sha256": "EXAMPLE12a4abb10315aa6b8a7384cc9b5ca8ad8e9ced8ef1bf0e5478EXAMPLE"
    }
  },
  "test-agent-x86_64.msi.zip": {
    "checksums": {
      "sha256": "EXAMPLE63ccb86e830b63dfef46995af6b32b3c52ce72241b5e80c995EXAMPLE"
    }
  }
}```
6. After you add your package information, save and close the manifest file.

The following is an example of a completed manifest. In this example, you have a .zip file, NewPackage_LINUX.zip, that supports more than one platform, but is referenced in the "files" section only once.

```json
{
    "schemaVersion": "2.0",
    "version": "1.7.1",
    "publisher": "Amazon Web Services",
    "packages": {
        "windows": {
            "_any": {
                "x86_64": {
                    "file": "NewPackage_WINDOWS.zip"
                }
            }
        },
        "amazon": {
            "_any": {
                "x86_64": {
                    "file": "NewPackage_LINUX.zip"
                }
            }
        },
        "ubuntu": {
            "_any": {
                "x86_64": {
                    "file": "NewPackage_LINUX.zip"
                }
            }
        }
    }
}
```
Package example

An example package, ExamplePackage.zip, is available for you to download from our website. The example package includes a completed JSON manifest and three .zip files.

Step 3: Upload the package and manifest to an Amazon S3 bucket

Prepare your package by copying or moving all .zip files into a folder or directory. A valid package requires the manifest that you created in Step 2: Create the JSON package manifest and all .zip files identified in the manifest file list.

To upload the package and manifest to Amazon S3

1. Copy or move all .zip archive files that you specified in the manifest to a folder or directory. Don't zip the folder or directory you move your .zip archive files and manifest file to.

2. Create a bucket or choose an existing bucket. For more information, see Create a Bucket in the Amazon Simple Storage Service Getting Started Guide. For more information about how to run an AWS CLI command to create a bucket, see mb in the AWS CLI Command Reference.

3. Upload the folder or directory to the bucket. For more information, see Add an Object to a Bucket in the Amazon Simple Storage Service Getting Started Guide. If you plan to paste your JSON manifest into the AWS Systems Manager console, don't upload the manifest. For more
information about how to run an AWS CLI command to upload files to a bucket, see `mv` in the
AWS CLI Command Reference.

4. On the bucket's home page, choose the folder or directory that you uploaded. If you uploaded
your files to a subfolder in a bucket, be sure to note the subfolder (also known as a prefix). You
need the prefix to add your package to Distributor.

**Step 4: Add a package to Distributor**

You can use the AWS Systems Manager console, AWS command line tools (AWS CLI and AWS Tools
for PowerShell), or AWS SDKs to add a new package to Distributor. When you add a package, you're
adding a new SSM document. The document allows you to deploy the package to managed nodes.

**Topics**
- Adding a package (console)
- Adding a package (AWS CLI)

**Adding a package (console)**

You can use the AWS Systems Manager console to create a package. Have ready the name of the
bucket to which you uploaded your package in Step 3: Upload the package and manifest to an
Amazon S3 bucket.

**To add a package to Distributor (console)**

2. In the navigation pane, choose Distributor.
3. On the Distributor home page, choose Create package, and then choose Advanced.
4. On the Create package page, enter a name for your package. Package names can contain
letters, numbers, periods, dashes, and underscores. The name should be generic enough to
apply to all versions of the package attachments, but specific enough to identify the purpose
of the package.
5. For Version name, enter the exact value of the version entry in your manifest file.
6. For S3 bucket name, choose the name of the bucket to which you uploaded your .zip files and
manifest in the section called “Step 3: Upload the package and manifest to an Amazon S3
bucket”.
7. For **S3 key prefix**, enter the subfolder of the bucket where your .zip files and manifest are stored.

8. For **Manifest**, choose **Extract from package** to use a manifest that you have uploaded to the Amazon S3 bucket with your .zip files.

   (Optional) If you didn't upload your JSON manifest to the S3 bucket where you stored your .zip files, choose **New manifest**. You can author or paste the entire manifest in the JSON editor field. For more information about how to create the JSON manifest, see [Step 2: Create the JSON package manifest](#).

9. When you're finished with the manifest, choose **Create package**.

10. Wait for Distributor to create your package from your .zip files and manifest. Depending on the number and size of packages you are adding, this can take a few minutes. Distributor automatically redirects you to the **Package details** page for the new package, but you can choose to open this page yourself after the software is uploaded. The **Package details** page doesn't show all information about your package until Distributor finishes the package creation process. To stop the upload and package creation process, choose **Cancel**.

### Adding a package (AWS CLI)

You can use the AWS CLI to create a package. Have the URL ready from the bucket to which you uploaded your package in [Step 3: Upload the package and manifest to an Amazon S3 bucket](#).

#### To add a package to Amazon S3 (AWS CLI)

1. To use the AWS CLI to create a package, run the following command, replacing **package-name** with the name of your package and **path-to-manifest-file** with the file path for your JSON manifest file. DOC-EXAMPLE-BUCKET is the URL of the Amazon S3 bucket where the entire package is stored. When you run the **create-document** command in Distributor, you specify the Package value for **--document-type**.

   ```bash
   aws ssm create-document \\
   --name "package-name" \\
   --content file:///path-to-manifest-file \\
   --attachments Key="SourceUrl",Values="DOC-EXAMPLE-BUCKET" \\
   --version-name version-value-from-manifest \\
   ```
The following is an example.

```bash
aws ssm create-document \
  --name "ExamplePackage" \
  --content file://path-to-manifest-file \
  --attachments Key="SourceUrl",Values="https://s3.amazonaws.com/DOC-EXAMPLE-BUCKET/ExamplePackage" \
  --version-name 1.0.1 \
  --document-type Package
```

2. Verify that your package was added and show the package manifest by running the following command, replacing `package-name` with the name of your package. To get a specific version of the document (not the same as the version of a package), you can add the `--document-version` parameter.

```bash
aws ssm get-document \
  --name "package-name"
```

For information about other options you can use with the `create-document` command, see `create-document` in the AWS Systems Manager section of the `AWS CLI Command Reference`. For information about other options you can use with the `get-document` command, see `get-document`.

**Edit package permissions (console)**

After you add a package to Distributor, a capability of AWS Systems Manager, you can edit the package's permissions in the Systems Manager console. You can add other AWS accounts to a package's permissions. Packages can be shared with other accounts in the same AWS Region only. Cross-Region sharing isn't supported. By default, packages are set to `Private`, meaning only those with access to the package creator's AWS account can view package information and update or delete the package. If `Private` permissions are acceptable, you can skip this procedure.

ℹ️ **Note**

You can update the permissions of packages that are shared with 20 or fewer accounts.
To edit package permissions (console)

2. In the navigation pane, choose Distributor.
3. On the Packages page, choose the package for which you want to edit permissions.
4. On the Package details tab, choose Edit permissions to change permissions.
5. For Edit permissions, choose Shared with specific accounts.
6. Under Shared with specific accounts, add AWS account numbers, one at a time. When you're finished, choose Save.

Edit package tags (console)

After you have added a package to Distributor, a capability of AWS Systems Manager, you can edit the package's tags in the Systems Manager console. These tags are applied to the package, and aren't connected to tags on the managed node on which you want to deploy the package. Tags are case sensitive key and value pairs that can help you group and filter your packages by criteria that are relevant to your organization. If you don't want to add tags, you're ready to install your package or add a new version.

To edit package tags (console)

2. In the navigation pane, choose Distributor.
3. On the Packages page, choose the package for which you want to edit tags.
5. For Add tags, enter a tag key, or a tag key and value pair, and then choose Add. Repeat if you want to add more tags. To delete tags, choose X on the tag at the bottom of the window.
6. When you're finished adding tags to your package, choose Save.

Add a package version to Distributor

To add a package version, create a package, and then use Distributor to add a package version by adding an entry to the AWS Systems Manager (SSM) document that already exists for older
versions. Distributor is a capability of AWS Systems Manager. To save time, update the manifest for an older version of the package, change the value of the version entry in the manifest (for example, from Test_1.0 to Test_2.0) and save it as the manifest for the new version. The simple Add version workflow in the Distributor console updates the manifest file for you.

A new package version can:

- Replace at least one of the installable files attached to the current version.
- Add new installable files to support additional platforms.
- Delete files to discontinue support for specific platforms.

A newer version can use the same Amazon Simple Storage Service (Amazon S3) bucket, but must have a URL with a different file name shown at the end. You can use the Systems Manager console or the AWS Command Line Interface (AWS CLI) to add the new version. Uploading an installable file with the exact name as an existing installable file in the Amazon S3 bucket overwrites the existing file. No installable files are copied over from the older version to the new version; you must upload installable files from the older version to have them be part of a new version. After Distributor is finished creating your new package version, you can delete or repurpose the Amazon S3 bucket, because Distributor copies your software to an internal Systems Manager bucket as part of the versioning process.

⚠️ Note

Each package is held to a maximum of 25 versions. You can delete versions that are no longer required.

Topics

- Adding a package version (console)
- Adding a package version (AWS CLI)

Adding a package version (console)

Before you perform these steps, follow the instructions in Create a package to create a new package for the version. Then, use the Systems Manager console to add a new package version to Distributor.
Adding a package version (simple)

To add a package version by using the **Simple** workflow, prepare updated installable files or add installable files to support more platforms and architectures. Then, use Distributor to upload new and updated installable files and add a package version. The simplified **Add version** workflow in the Distributor console updates the manifest file and associated SSM document for you.

**To add a package version (simple)**

2. In the navigation pane, choose **Distributor**.
3. On the Distributor home page, choose the package to which you want to add another version.
4. On the **Add version** page, choose **Simple**.
5. For **Version name**, enter a version name. The version name for the new version must be different from older version names. Version names can be a maximum of 512 characters, and can't contain special characters.
6. For **S3 bucket name**, choose an existing S3 bucket from the list. This can be the same bucket that you used to store installable files for older versions, but the installable file names must be different to avoid overwriting existing installable files in the bucket.
7. For **S3 key prefix**, enter the subfolder of the bucket where your installable assets are stored.
8. For **Upload software**, navigate to the installable software files that you want to attach to the new version. Installable files from existing versions aren't automatically copied over to a new version; you must upload any installable files from older versions of the package if you want any of the same installable files to be part of the new version. You can upload more than one software file in a single action.
9. For **Target platform**, verify that the target operating system platform shown for each installable file is correct. If the operating system shown isn't correct, choose the correct operating system from the dropdown list.

In the **Simple** versioning workflow, because you upload each installable file only once, extra steps are required to target a single file at multiple operating systems. For example, if you upload an installable software file named `Logtool_v1.1.1.rpm`, you must change some defaults in the **Simple** workflow to instruct Distributor to target the same software at both Amazon Linux and Ubuntu operating systems. You can do one of the following to work around this limitation.
- Use the **Advanced** versioning workflow instead, zip each installable file into a .zip file before you begin, and manually author the manifest so that one installable file can be targeted at multiple operating system platforms or versions. For more information, see [Adding a package version (advanced)].

- Manually edit the manifest file in the **Simple** workflow so that your .zip file is targeted at multiple operating system platforms or versions. For more information about how to do this, see the end of step 4 in [Step 2: Create the JSON package manifest].

10. For **Platform version**, verify that the operating system platform version shown is either `_any`, a major release version followed by a wildcard (7.*), or the exact operating system release version to which you want your software to apply. For more information about specifying a platform version, see step 4 in [Step 2: Create the JSON package manifest].

11. For **Architecture**, choose the correct processor architecture for each installable file from the drop-down list. For more information about supported architectures, see [Supported package platforms and architectures].

12. (Optional) Expand **Scripts**, and review the installation and uninstallation scripts that Distributor generates for your installable software.

13. To add more installable software files to the new version, choose **Add software**. Otherwise, go to the next step.

14. (Optional) Expand **Manifest**, and review the JSON package manifest that Distributor generates for your installable software. If you changed any information about your installable software since you began this procedure, such as platform version or target platform, choose **Generate manifest** to show the updated package manifest.

   You can edit the manifest manually if you want to target a software installable at more than one operating system, as described in step 9. For more information about editing the manifest, see [Step 2: Create the JSON package manifest].

15. When you finish adding software and reviewing the target platform, version, and architecture data, choose **Add version**.

16. Wait for Distributor to finish uploading your software and creating the new package version. Distributor shows upload status for each installable file. Depending on the number and size of packages you are adding, this can take a few minutes. Distributor automatically redirects you to the **Package details** page for the package, but you can choose to open this page yourself after the software is uploaded. The **Package details** page doesn't show all information about your package until Distributor finishes creating the new package version. To stop the upload and package version creation, choose **Stop upload**.
17. If Distributor can't upload any of the software installable files, it displays an **Upload failed** message. To retry the upload, choose **Retry upload**. For more information about how to troubleshoot package version creation failures, see [Troubleshooting AWS Systems Manager Distributor](#).

18. When Distributor is finished creating the new package version, on the package's **Details** page, on the **Versions** tab, view the new version in the list of available package versions. Set a default version of the package by choosing a version, and then choosing **Set default version**.

   If you don't set a default version, the newest package version is the default version.

### Adding a package version (advanced)

To add a package version, [create a package](#), and then use Distributor to add a package version by adding an entry to the SSM document that exists for older versions. To save time, update the manifest for an older version of the package, change the value of the version entry in the manifest (for example, from `Test_1.0` to `Test_2.0`) and save it as the manifest for the new version. You must have an updated manifest to add a new package version by using the **Advanced** workflow.

#### To add a package version (advanced)

2. In the navigation pane, choose **Distributor**.

3. On the Distributor home page, choose the package to which you want to add another version, and then choose **Add version**.

4. For **Version name**, enter the exact value that is in the version entry of your manifest file.

5. For **S3 bucket name**, choose an existing S3 bucket from the list. This can be the same bucket that you used to store installable files for older versions, but the installable file names must be different to avoid overwriting existing installable files in the bucket.

6. For **S3 key prefix**, enter the subfolder of the bucket where your installable assets are stored.

7. For **Manifest**, choose **Extract from package** to use a manifest that you uploaded to the S3 bucket with your .zip files.

   (Optional) If you didn't upload your revised JSON manifest to the Amazon S3 bucket where you stored your .zip files, choose **New manifest**. You can author or paste the entire manifest in
the JSON editor field. For more information about how to create the JSON manifest, see Step 2: Create the JSON package manifest.

8. When you're finished with the manifest, choose Add package version.

9. On the package's Details page, on the Versions tab, view the new version in the list of available package versions. Set a default version of the package by choosing a version, and then choosing Set default version.

If you don't set a default version, the newest package version is the default version.

Adding a package version (AWS CLI)

You can use the AWS CLI to add a new package version to Distributor. Before you run these commands, you must create a new package version and upload it to S3, as described at the start of this topic.

To add a package version (AWS CLI)

1. Run the following command to edit the AWS Systems Manager document with an entry for a new package version. Replace document-name with the name of your document. Replace DOC-EXAMPLE-BUCKET with the URL of the JSON manifest that you copied in Step 3: Upload the package and manifest to an Amazon S3 bucket. S3-bucket-URL-of-package is the URL of the Amazon S3 bucket where the entire package is stored. Replace version-name-from-updated-manifest with the value of version in the manifest. Set the --document-version parameter to $LATEST to make the document associated with this package version the latest version of the document.

```bash
aws ssm update-document \
  --name "document-name" \
  --content "S3-bucket-URL-to-manifest-file" \
  --attachments Key="SourceUrl",Values="DOC-EXAMPLE-BUCKET" \
  --version-name version-name-from-updated-manifest \
  --document-version $LATEST
```

The following is an example.

```bash
aws ssm update-document \
  --name ExamplePackage \
  --content "https://s3.amazonaws.com/DOC-EXAMPLE-BUCKET/ExamplePackage/manifest.json"
```
2. Run the following command to verify that your package was updated and show the package manifest. Replace `package-name` with the name of your package, and optionally, `document-version` with the version number of the document (not the same as the package version) that you updated. If this package version is associated with the latest version of the document, you can specify `$LATEST` for the value of the optional `--document-version` parameter.

```
aws ssm get-document \
  --name "package-name" \
  --document-version "document-version"
```

For information about other options you can use with the `update-document` command, see `update-document` in the AWS Systems Manager section of the AWS CLI Command Reference.

Install or update packages

You can deploy packages to your AWS Systems Manager managed nodes by using Distributor, a capability of AWS Systems Manager. To deploy the packages, use either the AWS Management Console or AWS Command Line Interface (AWS CLI). You can deploy one version of one package per command. You can install new packages or update existing installations in place. You can choose to deploy a specific version or choose to always deploy the latest version of a package for deployment. We recommend using State Manager, a capability of AWS Systems Manager, to install packages. Using State Manager helps ensure that your managed nodes are always running the most up-to-date version of your package.

Installing or updating a package one time (console)

You can use the AWS Systems Manager console to install or update a package one time. When you configure a one-time installation, Distributor uses AWS Systems Manager Run Command, a capability of AWS Systems Manager, to perform the installation.

To install or update a package one time (console)

2. In the navigation pane, choose Distributor.
3. On the Distributor home page, choose the package that you want to install.
4. Choose Install one time.
   
   This command opens Run Command with the command document AWS-ConfigureAWSPackage and your Distributor package already selected.
5. For Document version, select the version of the AWS-ConfigureAWSPackage document that you want to run.
6. For Action, choose Install.
7. For Installation type, choose one of the following:
   
   - Uninstall and reinstall: The package is completely uninstalled, and then reinstalled. The application is unavailable until the reinstallation is complete.
   - In-place update: Only new or changed files are added to the existing installation according to instructions you provide in an update script. The application remains available throughout the update process. This option isn't supported for AWS published packages except the AWSEC2Launch-Agent package.
8. For Name, verify that the name of the package you selected is entered.
9. (Optional) For Version, enter the version name value of the package. If you leave this field blank, Run Command installs the default version that you selected in Distributor.
10. In the Targets section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or devices manually, or by specifying a resource group.
Note

If you don't see a managed node in the list, see Troubleshooting managed node availability.

11. For Other parameters:

- For Comment, enter information about this command.
- For Timeout (seconds), specify the number of seconds for the system to wait before failing the overall command execution.

12. For Rate Control:

- For Concurrency, specify either a number or a percentage of targets on which to run the command at the same time.

Note

If you selected targets by specifying tags or resource groups and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For Error threshold, specify when to stop running the command on other targets after it fails on either a number or a percentage of managed nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

13. (Optional) For Output options, to save the command output to a file, select the Write command output to an S3 bucket box. Enter the bucket and prefix (folder) names in the boxes.

Note

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service
role associated with the managed node has the necessary permissions to write to that bucket.

14. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](https://docs.aws.amazon.com/systems-manager/latest/userguide/monitor-sns-notifications.html).

15. When you're ready to install the package, choose **Run**.

16. The **Command status** area reports the progress of the execution. If the command is still in progress, choose the refresh icon in the top-left corner of the console until the **Overall status** or **Detailed status** column shows **Success** or **Failed**.

17. In the **Targets and outputs** area, choose the button next to a managed node name, and then choose **View output**.

The command output page shows the results of your command execution.

18. (Optional) If you chose to write command output to an Amazon S3 bucket, choose **Amazon S3** to view the output log data.

### Scheduling a package installation or update (console)

You can use the AWS Systems Manager console to schedule the installation or update of a package. When you schedule package installation or update, Distributor uses [AWS Systems Manager State Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/monitor-sns-notifications.html) to install or update.

#### To schedule a package installation (console)

2. In the navigation pane, choose **Distributor**.

3. On the Distributor home page, choose the package that you want to install or update.

4. For **Package**, choose **Install on a schedule**.

   This command opens State Manager to a new association that is created for you.

5. For **Name**, enter a name (for example, **Deploy-test-agent-package**). This is optional, but recommended. Spaces aren't allowed in the name.
6. In the **Document** list, the document name AWS-ConfigureAWSPackage is already selected.

7. For **Action**, verify that **Install** is selected.

8. For **Installation type**, choose one of the following:

   - **Uninstall and reinstall**: The package is completely uninstalled, and then reinstalled. The application is unavailable until the reinstallation is complete.

   - **In-place update**: Only new or changed files are added to the existing installation according to instructions you provide in an update script. The application remains available throughout the update process.

9. For **Name**, verify that the name of your package is entered.

10. For **Version**, if you want to install a package version other than the latest published version, enter the version identifier.

11. For **Targets**, choose **Selecting all managed instances in this account**, **Specifying tags**, or **Manually Selecting Instance**. If you target resources by using tags, enter a tag key and a tag value in the fields provided.

   **Note**
   You can choose managed AWS IoT Greengrass core devices by choosing either **Selecting all managed instances in this account** or **Manually Selecting Instance**.

12. For **Specify schedule**, choose **On Schedule** to run the association on a regular schedule, or **No Schedule** to run the association once. For more information about these options, see [Working with associations in Systems Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/working-with-association.html). Use the controls to create a cron or rate schedule for the association.

13. Choose **Create Association**.

14. On the **Association** page, choose the button next to the association you created, and then choose **Apply association now**.

   State Manager creates and immediately runs the association on the specified targets. For more information about the results of running associations, see [Working with associations in Systems Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/working-with-association.html) in this guide.

For more information about working with the options in **Advanced options**, **Rate control**, and **Output options**, see [Working with associations in Systems Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/working-with-association.html).
Installing a package one time (AWS CLI)

You can run `send-command` in the AWS CLI to install a Distributor package one time. If the package is already installed, the application will be taken offline while the package is uninstalled and the new version installed in its place.

To install a package one time (AWS CLI)

- Run the following command in the AWS CLI.

```bash
aws ssm send-command
   --document-name "AWS-ConfigureAWSPackage"
   --instance-ids "instance-IDs"
   --parameters '{"action": ["Install"], "installationType": ["Uninstall and reinstall"], "name": ["package-name (in same account) or package-ARN (shared from different account)"]}'
```

**Note**

The default behavior for `installationType` is Uninstall and reinstall. You can omit "installationType": ["Uninstall and reinstall"] from this command when you're installing a complete package.

The following is an example.

```bash
aws ssm send-command
   --document-name "AWS-ConfigureAWSPackage"
   --instance-ids "i-00000000000000"
   --parameters '{"action": ["Install"], "installationType": ["Uninstall and reinstall"], "name": ["ExamplePackage"]}'
```

For information about other options you can use with the `send-command` command, see `send-command` in the AWS Systems Manager section of the AWS CLI Command Reference.

Updating a package one time (AWS CLI)

You can run `send-command` in the AWS CLI to update a Distributor package without taking the associated application offline. Only new or updated files in the package are replaced.
To update a package one time (AWS CLI)

- Run the following command in the AWS CLI.

```bash
aws ssm send-command \
    --document-name "AWS-ConfigureAWSPackage" \ 
    --instance-ids "instance-IDs" \ 
    --parameters '{"action":"Install","installationType":"In-place update","name":["package-name (in same account) or package-ARN (shared from different account)"]}'
```

**Note**

When you add new or changed files, you must include "installationType":"In-place update" in the command.

The following is an example.

```bash
aws ssm send-command \
    --document-name "AWS-ConfigureAWSPackage" \
    --instance-ids "i-02573cafcfEXAMPLE" \
    --parameters '{"action":"Install","installationType":"In-place update","name":["ExamplePackage"]}'
```

For information about other options you can use with the `send-command` command, see `send-command` in the AWS Systems Manager section of the AWS CLI Command Reference.

**Scheduling a package installation (AWS CLI)**

You can run `create-association` in the AWS CLI to install a Distributor package on a schedule. The value of `--name`, the document name, is always AWS-ConfigureAWSPackage. The following command uses the key `InstanceIds` to specify target managed nodes. If the package is already installed, the application will be taken offline while the package is uninstalled and the new version installed in its place.

```bash
aws ssm create-association \
    --name "AWS-ConfigureAWSPackage"
```
--parameters '{"action": ["Install"], "installationType": ["Uninstall and reinstall"], "name": ["package-name (in same account) or package-ARN (shared from different account)"]}' \ 
--targets ["InstanceIds": ["instance-ID1", "instance-ID2"]]

**Note**

The default behavior for installationType is Uninstall and reinstall. You can omit "installationType": ["Uninstall and reinstall"] from this command when you're installing a complete package.

The following is an example.

```bash
aws ssm create-association
   --name "AWS-ConfigureAWSPackage"
   --parameters '{"action": ["Install"], "installationType": ["Uninstall and reinstall"], "name": ["Test-ConfigureAWSPackage"]}' \ 
   --targets ["InstanceIds": ["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]]
```

For information about other options you can use with the **create-association** command, see [create-association](#) in the AWS Systems Manager section of the [*AWS CLI Command Reference*](#).

**Scheduling a package update (AWS CLI)**

You can run **create-association** in the AWS CLI to update a Distributor package on a schedule without taking the associated application offline. Only new or updated files in the package are replaced. The value of --name, the document name, is always **AWS-ConfigureAWSPackage**. The following command uses the key InstanceIds to specify target instances.

```bash
aws ssm create-association
   --name "AWS-ConfigureAWSPackage"
   --parameters '{"action": ["Install"], "installationType": ["In-place update"], "name": ["package-name (in same account) or package-ARN (shared from different account)"]}' \ 
   --targets ["InstanceIds": ["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]]
```
Note

When you add new or changed files, you must include "installationType" : ["In-place update"] in the command.

The following is an example.

```
aws ssm create-association \
   --name "AWS-ConfigureAWSPackage" \ 
   --parameters '{"action" : ["Install"], "installationType" : ["In-place update"], "name" : ["Test-ConfigureAWSPackage"]}' \ 
   --targets [{"Key" : "InstanceIds", "Values" : ["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]}]
```

For information about other options you can use with the `create-association` command, see `create-association` in the AWS Systems Manager section of the AWS CLI Command Reference.

Uninstall a package

You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to uninstall Distributor packages from your AWS Systems Manager managed nodes by using Run Command. Distributor and Run Command are capabilities of AWS Systems Manager. In this release, you can uninstall one version of one package per command. You can uninstall a specific version or the default version.

Topics

- Uninstalling a package (console)
- Uninstalling a package (AWS CLI)

Uninstalling a package (console)

You can use Run Command in the Systems Manager console to uninstall a package one time. Distributor uses AWS Systems Manager Run Command to uninstall packages.

To uninstall a package (console)

2. In the navigation pane, choose **Run Command**.

3. On the Run Command home page, choose **Run command**.

5. From **Action**, choose **Uninstall**.

6. For **Name**, enter the name of the package that you want to uninstall.

7. For **Targets**, choose how you want to target your managed nodes. You can specify a tag key and values that are shared by the targets. You can also specify targets by choosing attributes, such as an ID, platform, and SSM Agent version.

8. You can use the advanced options to add comments about the operation, change **Concurrency** and **Error threshold** values in **Rate control**, specify output options, or configure Amazon Simple Notification Service (Amazon SNS) notifications. For more information, see **Running Commands from the Console** in this guide.

9. When you're ready to uninstall the package, choose **Run**, and then choose **View results**.

10. In the commands list, choose the AWS-ConfigureAWSPackage command that you ran. If the command is still in progress, choose the refresh icon in the top-right corner of the console.

11. When the **Status** column shows **Success** or **Failed**, choose the **Output** tab.

12. Choose **View output**. The command output page shows the results of your command execution.

**Uninstalling a package (AWS CLI)**

You can use the AWS CLI to uninstall a Distributor package from managed nodes by using Run Command.

**To uninstall a package (AWS CLI)**

- Run the following command in the AWS CLI.

```bash
aws ssm send-command \
  --document-name "AWS-ConfigureAWSPackage" \
  --instance-ids "instance-IDs" \
  --parameters '{"action":["Uninstall"],"name":["package-name (in same account) or package-ARN (shared from different account)"]}'
```

The following is an example.
aws ssm send-command \
  --document-name "AWS-ConfigureAWSPackage" \
  --instance-ids "i-02573cafcfEXAMPLE" \
  --parameters '{"action":['"Uninstall"'],"name":['"Test-ConfigureAWSPackage"]}''

For information about other options you can use with the `send-command` command, see `send-command` in the AWS Systems Manager section of the **AWS CLI Command Reference**.

### Delete a package

This section describes how to delete a package. You can't delete a version of a package, only the entire package.

#### Deleting a package (console)

You can use the AWS Systems Manager console to delete a package or a package version from Distributor, a capability of AWS Systems Manager. Deleting a package deletes all versions of a package from Distributor.

**To delete a package (console)**

2. In the navigation pane, choose **Distributor**.
3. On the **Distributor** home page, choose the package that you want to delete.
4. On the package's details page, choose **Delete package**.
5. When you're prompted to confirm the deletion, choose **Delete package**.

#### Deleting a package version (console)

You can use the Systems Manager console to delete a package version from Distributor.

**To delete a package version (console)**

2. In the navigation pane, choose **Distributor**.
3. On the **Distributor** home page, choose the package that you want to delete a version of.

4. On the versions page for the package, choose the version to delete and choose **Delete version**.

5. When you're prompted to confirm the deletion, choose **Delete package version**.

### Deleting a package (command line)

You can use your preferred command line tool to delete a package from Distributor.

**Linux & macOS**

**To delete a package (AWS CLI)**

1. Run the following command to list documents for specific packages. In the results of this command, look for the package that you want to delete.

   ```bash
   aws ssm list-documents --filters Key=Name,Values=package-name
   ```

2. Run the following command to delete a package. Replace `package-name` with the package name.

   ```bash
   aws ssm delete-document --name "package-name"
   ```

3. Run the **list-documents** command again to verify that the package was deleted. The package you deleted shouldn't be included in the list.

   ```bash
   aws ssm list-documents --filters Key=Name,Values=package-name
   ```

**Windows**

**To delete a package (AWS CLI)**

1. Run the following command to list documents for specific packages. In the results of this command, look for the package that you want to delete.

   ```bash
   aws ssm list-documents ^
   --filters Key=Name,Values=package-name
   ```
2. Run the following command to delete a package. Replace package-name with the package name.

```bash
aws ssm delete-document ^
   --name "package-name"
```

3. Run the list-documents command again to verify that the package was deleted. The package you deleted shouldn't be included in the list.

```bash
aws ssm list-documents ^
   --filters Key=Name,Values="package-name"
```

**PowerShell**

**To delete a package (Tools for PowerShell)**

1. Run the following command to list documents for specific packages. In the results of this command, look for the package that you want to delete.

```powershell
$filter = New-Object
   Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$filter.Key = "Name"
$filter.Values = "package-name"

Get-SSMDocumentList `
   -Filters @{$filter}
```

2. Run the following command to delete a package. Replace package-name with the package name.

```powershell
Remove-SSMDocument `
   -Name "package-name"
```

3. Run the Get-SSMDocumentList command again to verify that the package was deleted. The package you deleted shouldn't be included in the list.

```powershell
$filter = New-Object
   Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$filter.Key = "Name"
$filter.Values = "package-name"
```
Deleting a package version (command line)

You can use your preferred command line tool to delete a package version from Distributor.

Linux & macOS

To delete a package version (AWS CLI)

1. Run the following command to list the versions of your package. In the results of this command, look for the package version that you want to delete.

   ```
   aws ssm list-document-versions \
   --name "package-name"
   ```

2. Run the following command to delete a package version. Replace `package-name` with the package name and `version` with the version number.

   ```
   aws ssm delete-document \
   --name "package-name" \
   --document-version version
   ```

3. Run the `list-document-versions` command to verify that the version of the package was deleted. The package version that you deleted shouldn't be found.

   ```
   aws ssm list-document-versions \
   --name "package-name"
   ```

Windows

To delete a package version (AWS CLI)

1. Run the following command to list the versions of your package. In the results of this command, look for the package version that you want to delete.

   ```
   aws ssm list-document-versions ^
   ```
2. Run the following command to delete a package version. Replace `package-name` with the package name and `version` with the version number.

```
aws ssm delete-document
  --name "package-name"
  --document-version version
```

3. Run the `list-document-versions` command to verify that the version of the package was deleted. The package version that you deleted shouldn't be found.

```
aws ssm list-document-versions
  --name "package-name"
```

**PowerShell**

To delete a package version (Tools for PowerShell)

1. Run the following command to list the versions of your package. In the results of this command, look for the package version that you want to delete.

```
Get-SSMDocumentVersionList
  -Name "package-name"
```

2. Run the following command to delete a package version. Replace `package-name` with the package name and `version` with the version number.

```
Remove-SSMDocument
  -Name "package-name"
  -DocumentVersion version
```

3. Run the `Get-SSMDocumentVersionList` command to verify that the version of the package was deleted. The package version that you deleted shouldn't be found.

```
Get-SSMDocumentVersionList
  -Name "package-name"
```
For information about other options you can use with the `list-documents` command, see `list-documents` in the AWS Systems Manager section of the *AWS CLI Command Reference*. For information about other options you can use with the `delete-document` command, see `delete-document`.

**Auditing and logging Distributor activity**

You can use AWS CloudTrail to audit activity related to Distributor, a capability of AWS Systems Manager. For more information about auditing and logging options for Systems Manager, see [Monitoring AWS Systems Manager](#).

**Audit Distributor activity using CloudTrail**

CloudTrail captures API calls made in the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), and the Systems Manager SDK. The information can be viewed in the CloudTrail console or stored in an Amazon Simple Storage Service (Amazon S3) bucket. One bucket is used for all CloudTrail logs for your account.

Logs of Run Command and State Manager actions show document creation, package installation, and package uninstallation activity. Run Command and State Manager are capabilities of AWS Systems Manager. For more information about viewing and using CloudTrail logs of Systems Manager activity, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#).

**Troubleshooting AWS Systems Manager Distributor**

The following information can help you troubleshoot problems that might occur when you use Distributor, a capability of AWS Systems Manager.

**Topics**

- **Wrong package with the same name is installed**
- **Error: Failed to retrieve manifest: Could not find latest version of package**
- **Error: Failed to retrieve manifest: Validation exception**
- **Package isn't supported (package is missing install action)**
- **Error: Failed to download manifest : Document with name does not exist**
- **Upload failed.**
Wrong package with the same name is installed

**Problem:** You've installed a package, but Distributor installed a different package instead.

**Cause:** During installation, Systems Manager finds AWS published packages as results before user-defined external packages. If your user-defined package name is the same as an AWS published package name, the AWS package is installed instead of your package.

**Solution:** To avoid this problem, name your package something different from the name for an AWS published package.

Error: Failed to retrieve manifest: Could not find latest version of package

**Problem:** You received an error like the following.

```
Failed to retrieve manifest: ResourceNotFoundException: Could not find the latest version of package
arn:aws:ssm::package/package-name status code: 400, request id: guid
```

**Cause:** You're using a version of SSM Agent with Distributor that is earlier than version 2.3.274.0.

**Solution:** Update the version of SSM Agent to version 2.3.274.0 or later. For more information, see [Updating the SSM Agent using Run Command](#) or [Walkthrough: Automatically update SSM Agent (CLI)](#).

Error: Failed to retrieve manifest: Validation exception

**Problem:** You received an error like the following.

```
Failed to retrieve manifest: ValidationException: 1 validation error detected: Value 'documentArn'
at 'packageName' failed to satisfy constraint: Member must satisfy regular expression pattern:
arn:aws:ssm:region-id:account-id:package/package-name
```

**Cause:** You're using a version of SSM Agent with Distributor that is earlier than version 2.3.274.0.

**Solution:** Update the version of SSM Agent to version 2.3.274.0 or later. For more information, see [Updating the SSM Agent using Run Command](#) or [Walkthrough: Automatically update SSM Agent (CLI)](#).
Package isn't supported (package is missing install action)

**Problem:** You received an error like the following.

```
Package is not supported (package is missing install action)
```

**Cause:** The package directory structure is incorrect.

**Solution:** Don't zip a parent directory containing the software and required scripts. Instead, create a .zip file of all the required contents directly in the absolute path. To verify the .zip file was created correctly, unzip the target platform directory and review the directory structure. For example, the install script absolute path should be `/ExamplePackage_targetPlatform/install.sh`.

Error: Failed to download manifest : Document with name does not exist

**Problem:** You received an error like the following.

```
```

**Cause:** Distributor can't find the package by the package name when sharing a Distributor package from another account.

**Solution:** When sharing a package from another account, use the full Amazon Resource Name (ARN) for the package and not just its name.

Upload failed.

**Problem:** You received an error like the following.

```
Upload failed. At least one of your files was not successfully uploaded to your S3 bucket.
```

**Cause:** The name of your software package includes a space. For example, `Hello World.msi` would fail to upload.
AWS Systems Manager Shared Resources

Systems Manager uses the following shared resources for managing and configuring your AWS resources.

Topics
- AWS Systems Manager Documents

AWS Systems Manager Documents

An AWS Systems Manager document (SSM document) defines the actions that Systems Manager performs on your managed instances. Systems Manager includes more than 100 pre-configured documents that you can use by specifying parameters at runtime. You can find pre-configured documents in the Systems Manager Documents console by choosing the Owned by Amazon tab, or by specifying Amazon for the Owner filter when calling the ListDocuments API operation. Documents use JavaScript Object Notation (JSON) or YAML, and they include steps and parameters that you specify. To get started with SSM documents, open the Systems Manager console. In the navigation pane, choose Documents.

How can the Documents capability benefit my organization?

Documents, a capability of AWS Systems Manager, offers these benefits:

- **Document categories**
  
  To help you find the documents you need, choose a category depending on the type of document you're searching for. To broaden your search, you can choose multiple categories of the same document type. Choosing categories of different document types is not supported. Categories are only supported for documents owned by Amazon.

- **Document versions**
  
  You can create and save different versions of documents. You can then specify a default version for each document. The default version of a document can be updated to a newer version or reverted to an older version of the document. When you change the content of a document, Systems Manager automatically increments the version of the document. You can retrieve or use any version of a document by specifying the document version in the console, AWS Command Line Interface (AWS CLI) commands, or API calls.
• **Customize documents for your needs**

If you want to customize the steps and actions in a document, you can create your own. The system stores the document with your AWS account in the AWS Region you create it in. For more information about how to create an SSM document, see [Creating SSM document content](#).

• **Tag documents**

You can tag your documents to help you quickly identify one or more documents based on the tags you’ve assigned to them. For example, you can tag documents for specific environments, departments, users, groups, or periods. You can also restrict access to documents by creating an AWS Identity and Access Management (IAM) policy that specifies the tags that a user or group can access. For more information, see [Tagging Systems Manager documents](#).

• **Share documents**

You can make your documents public or share them with specific AWS accounts in the same AWS Region. Sharing documents between accounts can be useful if, for example, you want all of the Amazon Elastic Compute Cloud (Amazon EC2) instances that you supply to customers or employees to have the same configuration. In addition to keeping applications or patches on the instances up to date, you might want to restrict customer instances from certain activities. Or you might want to ensure that the instances used by employee accounts throughout your organization are granted access to specific internal resources. For more information, see [Sharing SSM documents](#).

### Who should use Documents?

- Any AWS customer who wants to use Systems Manager capabilities to improve their operational efficiency at scale, reduce errors associated with manual intervention, and reduce time to resolution of common issues.
- Infrastructure experts who want to automate deployment and configuration tasks.
- Administrators who want to reliably resolve common issues, improve troubleshooting efficiency, and reduce repetitive operations.
- Users who want to automate a task they normally perform manually.

### What are the types of SSM documents?

The following table describes the different types of SSM documents and their uses.
<table>
<thead>
<tr>
<th>Type</th>
<th>Use with</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApplicationConfiguration</td>
<td>AWS AppConfig</td>
<td>AWS AppConfig, a capability of AWS Systems Manager, enables you to create, manage, and quickly deploy application configurations. You can store configuration data in an SSM document by creating a document that uses the ApplicationConfiguration document type. For more information, see <a href="https://docs.aws.amazon.com/appconfig/latest/userguide/configurations-freeform.html">Freeform configurations</a> in the AWS AppConfig User Guide. If you create a configuration in an SSM document, then you must specify a corresponding JSON Schema. The schema uses the ApplicationConfigurationSchema document type and, like a set of rules, defines the allowable properties for each application configuration setting. For more information, see <a href="https://docs.aws.amazon.com/appconfig/latest/userguide/validators.html">About validators</a> in the AWS AppConfig User Guide.</td>
</tr>
<tr>
<td>ApplicationConfigurationSchema</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Automation runbook</td>
<td>Automation</td>
<td>Use Automation runbooks when performing common maintenance and deployment tasks such as creating or updating an Amazon Machine Image (AMI). State Manager</td>
</tr>
<tr>
<td></td>
<td>State Manager</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Maintenance Windows</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Use with</td>
<td>Details</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Change Calendar document</td>
<td>Change Calendar</td>
<td>Change Calendar, a capability of AWS Systems Manager, uses the ChangeCalendar document type. A Change Calendar document stores a calendar entry and associated events that can allow or prevent Automation actions from changing your environment. In Change Calendar, a document stores iCalendar 2.0 data in plaintext format. Change Calendar isn't supported on EC2 instances for macOS.</td>
</tr>
</tbody>
</table>
### What are the types of SSM documents?

<table>
<thead>
<tr>
<th>Type</th>
<th>Use with</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS CloudFormation template</td>
<td><strong>AWS CloudFormation</strong></td>
<td><strong>AWS CloudFormation templates describe the resources that you want to provision in your CloudFormation stacks. By storing CloudFormation templates as Systems Manager documents, you can benefit from Systems Manager document features. These include creating and comparing multiple versions of your template, and sharing your template with other accounts in the same AWS Region.</strong> You can create and edit CloudFormation templates and stacks by using Application Manager, a capability of Systems Manager. For more information, see <a href="https://aws.amazon.com/solutions/">Working with AWS CloudFormation templates and stacks in Application Manager</a>.</td>
</tr>
</tbody>
</table>
Command document

**Use with**
- Run Command
- State Manager
- Maintenance Windows

Details:
Run Command, a capability of AWS Systems Manager, uses Command documents to run commands. State Manager, a capability of AWS Systems Manager, uses command documents to apply a configuration. These actions can be run on one or more targets at any point during the lifecycle of an instance. Maintenance Windows, a capability of AWS Systems Manager, uses Command documents to apply a configuration based on the specified schedule.

Most Command documents are supported on all Linux and Windows Server operating systems supported by Systems Manager. The following Command documents are supported on EC2 instances for macOS:

- AWS-ConfigureAWSPackage
- AWS-RunPatchBaseline
- AWS-RunPatchBaselineAssociation
- AWS-RunShellScript
### AWS Config conformance pack template

<table>
<thead>
<tr>
<th>Type</th>
<th>Use with</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Config conformance pack template</td>
<td>AWS Config</td>
<td>AWS Config conformance pack templates are YAML formatted documents used to create conformance packs that contain the list of AWS Config managed or custom rules and remediation actions. For more information, see <a href="#">Conformance Packs</a>.</td>
</tr>
</tbody>
</table>

### Package document

<table>
<thead>
<tr>
<th>Type</th>
<th>Use with</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Package document</td>
<td>Distributor</td>
<td>In Distributor, a capability of AWS Systems Manager, a package is represented by an SSM document. A package document includes attached ZIP archive files that contain software or assets to install on managed instances. Creating a package in Distributor creates the package document. Distributor isn't supported on Oracle Linux and macOS managed instances.</td>
</tr>
</tbody>
</table>
### What are the types of SSM documents?

<table>
<thead>
<tr>
<th>Type</th>
<th>Use with</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy document</td>
<td>State Manager</td>
<td>Inventory, a capability of AWS Systems Manager, uses the AWS-GatherSoftwareInventory Policy document with a State Manager association to collect inventory data from managed instances. When creating your own SSM documents, Automation runbooks and Command documents are the preferred method for enforcing a policy on a managed instance. Systems Manager Inventory and the AWS-GatherSoftwareInventory Policy document are supported on all operating systems supported by Systems Manager.</td>
</tr>
<tr>
<td>Post-incident analysis template</td>
<td>Incident Manager post-incident analysis</td>
<td>Incident Manager uses the post-incident analysis template to create an analysis based on AWS operations management best practices. Use the template to create an analysis that your team can use to identify improvements to your incident response.</td>
</tr>
<tr>
<td>Type</td>
<td>Use with</td>
<td>Details</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Session document</td>
<td><strong>Session Manager</strong></td>
<td>Session Manager, a capability of AWS Systems Manager, uses Session documents to determine which type of session to start, such as a port forwarding session, a session to run an interactive command, or a session to create an SSH tunnel. Session documents are supported on all Linux and Windows Server operating systems supported by Systems Manager. The following Command documents are supported on EC2 instances for macOS:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AWS-PasswordReset</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AWS-StartInteractiveCommand</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AWS-StartPortForwardingSession</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AWS-StartPortForwardingSessionToSocket</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AWS-StartSSHSession</td>
</tr>
</tbody>
</table>

### SSM document quotas

For information about SSM document quotas, see [Systems Manager service quotas](https://docs.aws.amazon.com/systems-manager/latest/userguide/what-are-ssm-document-quotas.html) in the *Amazon Web Services General Reference*. 
Topics

- Document components
- Creating SSM document content
- Working with documents

Document components

This section includes information about the components that make up SSM documents.

Contents

- Schemas, features, and examples
- Data elements and parameters
- Command document plugin reference

Schemas, features, and examples

AWS Systems Manager (SSM) documents use the following schema versions.

- Documents of type Command can use schema version 1.2, 2.0, and 2.2. If you use schema 1.2 documents, we recommend that you create documents that use schema version 2.2.
- Documents of type Policy must use schema version 2.0 or later.
- Documents of type Automation must use schema version 0.3.
- You can create documents in JSON or YAML.

By using the latest schema version for Command and Policy documents, you can take advantage of the following features.

Schema version 2.2 document features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Document editing</td>
<td>Documents can now be updated. With version 1.2, any update to a document required that you save it with a different name.</td>
</tr>
<tr>
<td>Feature</td>
<td>Details</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Automatic versioning</td>
<td>Any update to a document creates a new version. This isn't a schema version, but a version of the document.</td>
</tr>
<tr>
<td>Default version</td>
<td>If you have multiple versions of a document, you can specify which version is the default document.</td>
</tr>
<tr>
<td>Sequencing</td>
<td>Plugins or steps in a document run in the order that you specified.</td>
</tr>
<tr>
<td>Cross-platform support</td>
<td>Cross-platform support allows you to specify different operating systems for different plugins within the same SSM document. Cross-platform support uses the precondition parameter within a step.</td>
</tr>
</tbody>
</table>

**Note**

You must keep AWS Systems Manager SSM Agent on your instances updated with the latest version to use new Systems Manager features and SSM document features. For more information, see [Updating the SSM Agent using Run Command](#).

The following table lists the differences between major schema versions.

<table>
<thead>
<tr>
<th>Version 1.2</th>
<th>Version 2.2 (latest version)</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>runtimeConfig</td>
<td>mainSteps</td>
<td>In version 2.2, the mainSteps section replaces runtimeConfig. The mainSteps section allows Systems Manager to run steps in sequence.</td>
</tr>
</tbody>
</table>
In version 2.2, the `inputs` section replaces the `properties` section. The `inputs` section accepts parameters for steps.

In version 2.2, the `runCommand` parameter instead of the `commands` parameter.

In version 2.2, Action replaces ID. This is just a name change.

In version 2.2, name is any user-defined name for a step.

### Using the precondition parameter

With schema version 2.2 or later, you can use the `precondition` parameter to specify the target operating system for each plugin or to validate input parameters you’ve defined in your SSM document. The `precondition` parameter supports referencing your SSM document’s input parameters, and `platformType` using values of Linux, MacOS, and Windows. Only the `StringEquals` operator is supported.

For documents that use schema version 2.2 or later, if `precondition` isn’t specified, each plugin is either run or skipped based on the plugin’s compatibility with the operating system. Plugin compatibility with the operating system is evaluated before the `precondition`. For documents that use schema 2.0 or earlier, incompatible plugins throw an error.

For example, in a schema version 2.2 document, if `precondition` isn’t specified and the `aws:runShellScript` plugin is listed, then the step runs on Linux instances, but the system skips it on Windows Server instances because the `aws:runShellScript` isn’t compatible with Windows Server instances. However, for a schema version 2.0 document, if you specify the `aws:runShellScript` plugin, and then run the document on a Windows Server instances, the
execution fails. You can see an example of the precondition parameter in an SSM document later in this section.

**Schema version 2.2**

**Top-level elements**

The following example shows the top-level elements of an SSM document using schema version 2.2.

**YAML**

```yaml
---
schemaVersion: "2.2"
description: A description of the document.
parameters:
  parameter 1:
    property 1: "value"
    property 2: "value"
  parameter 2:
    property 1: "value"
    property 2: "value"
mainSteps:
  - action: Plugin name
    name: A name for the step.
    inputs:
      input 1: "value"
      input 2: "value"
      input 3: "{{ parameter 1 }}"
```

**JSON**

```json
{
  "schemaVersion": "2.2",
  "description": "A description of the document.",
  "parameters": {
    "parameter 1": {
      "property 1": "value",
      "property 2": "value"
    },
    "parameter 2": {
      "property 1": "value",
      "property 2": "value"
    }
  }
}```
### Schema version 2.2 example

The following example uses the `aws:runPowerShellScript` plugin to run a PowerShell command on the target instances.

**YAML**

```yaml
---
schemaVersion: "2.2"
description: "Example document"
parameters:
  Message:
    type: "String"
    description: "Example parameter"
    default: "Hello World"
mainSteps:
- action: "aws:runPowerShellScript"
  name: "example"
  inputs:
    timeoutSeconds: '60'
    runCommand:
    - "Write-Output {{Message}}"
```

**JSON**

```json
{
  "schemaVersion": "2.2",
```
Schema version 2.2 precondition parameter examples

Schema version 2.2 provides cross-platform support. This means that within a single SSM document you can specify different operating systems for different plugins. Cross-platform support uses the precondition parameter within a step, as shown in the following example. You can also use the precondition parameter to validate input parameters you've defined in your SSM document. You can see this in the second of the following examples.

YAML

```yaml
---
schemaVersion: '2.2'
description: cross-platform sample
mainSteps:
- action: aws:runPowerShellScript
  name: PatchWindows
  precondition:
    StringEquals:
    - platformType
    - Windows
```
inputs:
  runCommand:
    - cmd
- action: aws:runShellScript
  name: PatchLinux
  precondition:
    StringEquals:
      - platformType
      - Linux
inputs:
  runCommand:
    - cmd

JSON

```json
{
  "schemaVersion": "2.2",
  "description": "cross-platform sample",
  "mainSteps": [
    {
      "action": "aws:runPowerShellScript",
      "name": "PatchWindows",
      "precondition": {
        "StringEquals": [
          "platformType",
          "Windows"
        ]
      },
      "inputs": {
        "runCommand": ["cmd"]
      }
    },
    {
      "action": "aws:runShellScript",
      "name": "PatchLinux",
      "precondition": {
        "StringEquals": [
          "platformType",
          "Linux"
        ]
      },
      "inputs": {
        "runCommand": ["cmd"]
      }
    }
  ]
}
```
```yaml
---
schemaVersion: '2.2'
parameters:
  action:
    type: String
    allowedValues:
    - Install
    - Uninstall
  confirmed:
    type: String
    allowedValues:
    - True
    - False
mainSteps:
- action: aws:runShellScript
  name: InstallAwsCLI
  precondition:
    StringEquals:
    - "{{ action }}"
    - "Install"
  inputs:
    runCommand:
    - sudo apt install aws-cli
- action: aws:runShellScript
  name: UninstallAwsCLI
  precondition:
    StringEquals:
    - "{{ action }} {{ confirmed }}"
    - "Uninstall True"
  inputs:
    runCommand:
```

YAML

```yaml
---
schemaVersion: '2.2'
parameters:
  action:
    type: String
    allowedValues:
    - Install
    - Uninstall
  confirmed:
    type: String
    allowedValues:
    - True
    - False
mainSteps:
- action: aws:runShellScript
  name: InstallAwsCLI
  precondition:
    StringEquals:
    - "{{ action }}"
    - "Install"
  inputs:
    runCommand:
    - sudo apt install aws-cli
- action: aws:runShellScript
  name: UninstallAwsCLI
  precondition:
    StringEquals:
    - "{{ action }} {{ confirmed }}"
    - "Uninstall True"
  inputs:
    runCommand:
```
- `sudo apt remove aws-cli`

### JSON

```json
{
    "schemaVersion": "2.2",
    "parameters": {
        "action": {
            "type": "String",
            "allowedValues": [
                "Install",
                "Uninstall"
            ]
        },
        "confirmed": {
            "type": "String",
            "allowedValues": [
                true,
                false
            ]
        }
    },
    "mainSteps": [
        {
            "action": "aws:runShellScript",
            "name": "InstallAwsCLI",
            "precondition": {
                "StringEquals": [
                    "{{ action }}",
                    "Install"
                ]
            },
            "inputs": {
                "runCommand": [
                    "sudo apt install aws-cli"
                ]
            }
        },
        {
            "action": "aws:runShellScript",
            "name": "UninstallAwsCLI",
            "precondition": {
                "StringEquals": [
                    "{{ action }}",
                    "Uninstall"
                ]
            }
        }
    ]
}
```
Schema version 2.2 State Manager example

You can use the following SSM document with State Manager, a capability of Systems Manager, to download and install the ClamAV antivirus software. State Manager enforces a specific configuration, which means that each time the State Manager association is run, the system checks to see if the ClamAV software is installed. If not, State Manager reruns this document.

YAML

```yaml
---
schemaVersion: '2.2'
description: State Manager Bootstrap Example
parameters: {}
mainSteps:
  - action: aws:runShellScript
    name: configureServer
    inputs:
      runCommand:
      - sudo yum install -y httpd24
      - sudo yum --enablerepo=epel install -y clamav
```

JSON

```json
{
  "schemaVersion": "2.2",
  "description": "State Manager Bootstrap Example",
  "parameters": {},
  "mainSteps": [ {
```
"action": "aws:runShellScript",
"name": "configureServer",
"inputs": {
  "runCommand": [
    "sudo yum install -y httpd24",
    "sudo yum --enablerepo=epel install -y clamav"
  ]
}

            "action": "{{ action }}",
            "version": "{{ version }}"
        }
    }
]

Schema version 1.2

The following example shows the top-level elements of a schema version 1.2 document.

```json
{
    "schemaVersion": "1.2",
    "description": "A description of the SSM document.",
    "parameters": {
```
Schema version 1.2 aws:runShellScript example

The following example shows the AWS-RunShellScript SSM document. The runtimeConfig section includes the aws:runShellScript plugin.

```json
{
    "schemaVersion":"1.2",
    "description":"Run a shell script or specify the commands to run.",
    "parameters":{
        "commands":{
            "type":"StringList",
            "description":"(Required) Specify a shell script or a command to run.",
            "minItems":1,
            "displayType":"textarea"
        },
        "workingDirectory":{
            "type":"String",
            "default":"
            "description":"(Optional) The path to the working directory on your instance.",
            "maxChars":4096
        }
    }
}
```
"executionTimeout":{
  "type":"String",
  "default":"3600",
  "description":"(Optional) The time in seconds for a command to complete before it is considered to have failed. Default is 3600 (1 hour). Maximum is 172800 (48 hours).",
  "allowedPattern": "([1-9][0-9]{0,3})|(1[0-9]{1,4})|(2[0-7][0-9]{1,3})|(28[0-7][0-9]{1,2})|(28800)"
}

}
}

YAML Automation runbook example
The following sample shows the contents of an Automation runbook, in YAML format. This working example of version 0.3 of the document schema also demonstrates the use of Markdown to format document descriptions.

```yaml
description: >-
   ##Title: LaunchInstanceAndCheckState
   
   **Purpose**: This Automation runbook first launches an EC2 instance using the AMI ID provided in the parameter `'imageId'`. The second step of this document continuously checks the instance status check value for the launched instance until the status `'ok'` is returned.

   ##Parameters:
   
   Name | Type | Description | Default Value
   ------------- | ------------- | ------------- | -------------
   assumeRole | String | (Optional) The ARN of the role that allows Automation to perform the actions on your behalf. | -
   imageId  | String | (Optional) The AMI ID to use for launching the instance. The default value uses the latest Amazon Linux AMI ID available. | {{ ssm:/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-gp2 }}
   schemaVersion: '0.3'
   assumeRole: 'arn:aws:iam::111122223333::role/AutomationServiceRole'
   parameters:
   imageId:
      type: String
      default: '{{ ssm:/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-gp2 }}'
      description: >-
         (Optional) The AMI ID to use for launching the instance. The default value uses the latest released Amazon Linux AMI ID.
   tagValue:
      type: String
      default: 'LaunchedBySsmAutomation'
      description: >-
         (Optional) The tag value to add to the instance. The default value is
LaunchedBySsmAutomation.

instanceType:
  type: String
  default: t2.micro
  description: >-
    (Optional) The instance type to use for the instance. The default value is t2.micro.

mainSteps:
- name: LaunchEc2Instance
  action: 'aws:executeScript'
  outputs:
    - Name: payload
      Selector: $.Payload
      Type: StringMap
  inputs:
    Runtime: python3.8
    Handler: launch_instance
    Script: ''
    InputPayload:
      image_id: '{{ imageId }}'
      tag_value: '{{ tagValue }}'
      instance_type: '{{ instanceType }}'
    Attachment: launch.py
  description: >-
    **About This Step**

This step first launches an EC2 instance using the `aws:executeScript` action and the provided python script.

- name: WaitForInstanceStatusOk
  action: 'aws:executeScript'
  inputs:
    Runtime: python3.8
    Handler: poll_instance
    Script: |-
      def poll_instance(events, context):
        import boto3
        import time

        ec2 = boto3.client('ec2')

        instance_id = events['InstanceId']

        print('INFO] Waiting for instance status check to report ok', instance_id)
instance_status = "null"

while True:
    res = ec2.describe_instance_status(InstanceIds=[instance_id])

    if len(res['InstanceStatuses']) == 0:
        print("Instance status information is not available yet")
        time.sleep(5)
        continue

    instance_status = res['InstanceStatuses'][0]['InstanceStatus']['Status']

    print('[[INFO] Polling to get status of the instance', instance_status)

    if instance_status == 'ok':
        break

    time.sleep(10)

return {'Status': instance_status, 'InstanceId': instance_id}

InputPayload: '{{ LaunchEc2Instance.payload }}'
description: >-
    **About This Step**

    The python script continuously polls the instance status check value for
the instance launched in Step 1 until the ```ok``` status is returned.

Data elements and parameters

This topic describes the data elements used in SSM documents. The schema version used to create
a document defines the syntax and data elements that the document accepts. We recommend
that you use schema version 2.2 or later for Command documents. Automation runbooks use
schema version 0.3. Additionally, Automation runbooks support the use of Markdown, a markup
language, which allows you to add wiki-style descriptions to documents and individual steps within
the document. For more information about using Markdown, see [Using Markdown in the Console](https://aws.amazon.com/getting-started/) in
the AWS Management Console Getting Started Guide.
The following section describes the data elements that you can include in a SSM document.

**Top-level data elements**

**schemaVersion**

The schema version to use.

Type: Version

Required: Yes

**description**

Information you provide to describe the purpose of the document. You can also use this field to specify whether a parameter requires a value for a document to run, or if providing a value for the parameter is optional. Required and optional parameters can be seen in the examples throughout this topic.

Type: String

Required: No

**parameters**

A structure that defines the parameters the document accepts.

For parameters that you use often, we recommend that you store those parameters in Parameter Store, a capability of AWS Systems Manager. Then, you can define parameters in your document that reference Parameter Store parameters as their default value. To reference a Parameter Store parameter, use the following syntax.

```
{{ssm:parameter-name}}
```

You can use a parameter that references a Parameter Store parameter the same way as any other document parameters. In the following example, the default value for the commands parameter is the Parameter Store parameter myShellCommands. By specifying the commands parameter as a `runCommand` string, the document runs the commands stored in the myShellCommands parameter.

YAML

```yaml
---
```
schemaVersion: '2.2'
description: runShellScript with command strings stored as Parameter Store parameter
parameters:
  commands:
    type: StringList
    description: "(Required) The commands to run on the instance."
    default: "[{{ ssm:myShellCommands }}]"
mainSteps:
- action: aws:runShellScript
  name: runShellScriptDefaultParams
  inputs:
    runCommand:
    - "{{ commands }}"
Note
You can reference String and StringList Parameter Store parameters in the parameters section of your document. You can't reference SecureString Parameter Store parameters.

For more information about Parameter Store, see [AWS Systems Manager Parameter Store](https://docs.aws.amazon.com/systems-manager/latest/userguide/parameter-store.html).

Type: Structure

The parameters structure accepts the following fields and values:

- **type**: (Required) Allowed values include the following: String, StringList, Integer, Boolean, MapList, and StringMap. To view examples of each type, see [SSM document parameter type examples](https://docs.aws.amazon.com/systems-manager/latest/userguide/parameter-store.html) in the next section.

Note
Command type documents only support the String and StringList parameter types.

- **description**: (Optional) A description of the parameter.

- **default**: (Optional) The default value of the parameter or a reference to a parameter in Parameter Store.

- **allowedValues**: (Optional) An array of values allowed for the parameter. Defining allowed values for the parameter validates the user input. If a user inputs a value that isn't allowed, the execution fails to start.

YAML

```yaml
DirectoryType:
  type: String
  description: "(Required) The directory type to launch."
  default: AwsMad
  allowedValues:
    - AdConnector
    - AwsMad
    - SimpleAd
```
**JSON**

```json
"DirectoryType": {
  "type": "String",
  "description": "(Required) The directory type to launch.",
  "default": "AwsMad",
  "allowedValues": [
    "AdConnector",
    "AwsMad",
    "SimpleAd"
  ]
}
```

- **allowedPattern**: (Optional) A regular expression that validates whether the user input matches the defined pattern for the parameter. If the user input doesn't match the allowed pattern, the execution fails to start.

**Note**

Systems Manager performs two validations for `allowedPattern`. The first validation is performed using the [Java regex library](https://docs.oracle.com/javase/9/docs/api/java/util/regex/Pattern.html) at the API level when you use a document. The second validation is performed on SSM Agent by using the [GO regexp library](https://golang.org/pkg/text/regexp/) before processing the document.

**YAML**

```yaml
InstanceId:
  type: String
  description: "(Required) The instance ID to target."
  allowedPattern: "^[a-z0-9]{8,17}$"
  default: ''
```

**JSON**

```json
"InstanceId": {
  "type": "String",
  "description": "(Required) The instance ID to target.",
  "allowedPattern": "^[a-z0-9]{8,17}$",
  "default": ""
}
```
• **displayType**: (Optional) Used to display either a `textfield` or a `textarea` in the AWS Management Console. `textfield` is a single-line text box. `textarea` is a multi-line text area.

- **minItems**: (Optional) The minimum number of items allowed.
- **maxItems**: (Optional) The maximum number of items allowed.
- **minChars**: (Optional) The minimum number of parameter characters allowed.
- **maxChars**: (Optional) The maximum number of parameter characters allowed.

Required: No

**variables**

(Schema version 0.3 only) Values you can reference or update throughout the steps in an Automation runbook. Variables are similar to parameters, but differ in a very important way. Parameter values are static in the context of a runbook, but the values of variables can be changed in the context of the runbook. When updating the value of a variable, the data type must match the defined data type. For information about updating variables values in an automation, see [aws:updateVariable – Updates a value for a runbook variable](#)

Type: Boolean | Integer | MapList | String | StringList | StringMap

Required: No

**YAML**

```yaml
variables:
  payload:
    type: StringMap
    default: "{}"
```

**JSON**

```json
{
  "variables": [
    {
      "payload": {
        "type": "StringMap",
        "default": "{}"
      }
    }
  ]
}
```
runtimeConfig

(Schema version 1.2 only) The configuration for the instance as applied by one or more Systems Manager plugins. Plugins aren't guaranteed to run in sequence.

Type: Dictionary<string,PluginConfiguration>

Required: No

mainSteps

(Schema version 0.3, 2.0, and 2.2 only) An object that can include multiple steps (plugins). Plugins are defined within steps. Steps run in sequential order as listed in the document.

Type: Dictionary<string,PluginConfiguration>

Required: Yes

outputs

(Schema version 0.3 only) Data generated by the execution of this document that can be used in other processes. For example, if your document creates a new AMI, you might specify "CreateImage.ImageId" as the output value, and then use this output to create new instances in a subsequent automation execution. For more information about outputs, see Using action outputs as inputs.

Type: Dictionary<string,OutputConfiguration>

Required: No

files

(Schema version 0.3 only) The script files (and their checksums) attached to the document and run during an automation execution. Applies only to documents that include the aws:executeScript action and for which attachments have been specified in one or more steps.

For script runtime support, Automation runbooks support scripts for Python 3.7, Python 3.8, PowerShell Core 6.0, and PowerShell 7.0. For more information about including scripts in Automation runbooks, see Using scripts in runbooks and Using Document Builder to create runbooks.
When creating an Automation runbook with attachments, you must also specify attachment files using the `--attachments` option (for AWS CLI) or Attachments (for API and SDK). You can specify the file location for both local files and files stored in Amazon Simple Storage Service (Amazon S3) buckets. For more information, see Attachments in the AWS Systems Manager API Reference.

**YAML**

```yaml
---
files:
  launch.py:
    checksums:
      sha256: 18871b1311b295c43d0f...
[truncated]...772da97b67e99d84d342ef4aEXAMPLE
```

**JSON**

```json
"files": {
  "launch.py": {
    "checksums": {
      "sha256": "18871b1311b295c43d0f...
[truncated]...772da97b67e99d84d342ef4aEXAMPLE"
    }
  }
}
```

Type: Dictionary<string,FilesConfiguration>

Required: No

**SSM document parameter type examples**

Parameter types in SSM documents are static. This means the parameter type can't be changed after it's defined. When using parameters with SSM document plugins, the type of a parameter can't be dynamically changed within a plugin's input. For example, you can't reference an Integer parameter within the `runCommand` input of the `aws:runShellScript` plugin because this input accepts a string or list of strings. To use a parameter for a plugin input, the parameter type must match the accepted type. For example, you must specify a Boolean type parameter for the `allowDowngrade` input of the `aws:updateSsmAgent` plugin. If your parameter type doesn't match the input type for a plugin, the SSM document fails to validate and the system doesn't
create the document. This is also true when using parameters downstream within inputs for
other plugins or AWS Systems Manager Automation actions. For example, you can't reference
a StringList parameter within the documentParameters input of the aws:runDocument
plugin. The documentParameters input accepts a map of strings even if the downstream
SSM document parameter type is a StringList parameter and matches the parameter you're
referencing.

When using parameters with Automation actions, parameter types aren't validated when you
create the SSM document in most cases. Only when you use the aws:runCommand action are
parameter types validated when you create the SSM document. In all other cases, the parameter
validation occurs during the automation execution when an action's input is verified before
running the action. For example, if your input parameter is a String and you reference it as the
value for the MaxInstanceCount input of the aws:runInstances action, the SSM document
is created. However, when running the document, the automation fails while validating the
aws:runInstances action because the MaxInstanceCount input requires an Integer.

The following are examples of each parameter type.

String

A sequence of zero or more Unicode characters wrapped in quotation marks. For example,
"i-1234567890abcdef0". Use backslashes to escape.

YAML

```yaml
---
InstanceId:
  type: String
  description: "(Optional) The target EC2 instance ID."
```

JSON

```json
"InstanceId":{
  "type":"String",
  "description":"(Optional) The target EC2 instance ID."
}
```

StringList

A list of String items separated by commas. For example, ["cd ~", "pwd"].
YAML

```yaml
---
commands:
  type: StringList
  description: "(Required) Specify a shell script or a command to run."
  default: ""
  minItems: 1
  displayType: textarea

JSON

```json```
"commands":{
  "type":"StringList",
  "description":"(Required) Specify a shell script or a command to run.",
  "minItems":1,
  "displayType":"textarea"
}

Boolean

Accepts only true or false. Doesn't accept "true" or 0.

YAML

```yaml
---
canRun:
  type: Boolean
  description: ''
  default: true

JSON

```json```
"canRun": {
  "type": "Boolean",
  "description": "",
  "default": true
}

Integer

Integral numbers. Doesn't accept decimal numbers, for example 3.14159, or numbers wrapped in quotation marks, for example "3".
YAML

```yaml
---
timeout:
  type: Integer
  description: The type of action to perform.
  default: 100
```

JSON

```json
"timeout": {
  "type": "Integer",
  "description": "The type of action to perform.",
  "default": 100
}
```

StringMap

A mapping of keys to values. Keys and values must be strings. For example, `{"Env": "Prod"}`.

YAML

```yaml
---
notificationConfig:
  type: StringMap
  description: The configuration for events to be notified about
  default:
    NotificationType: 'Command'
    NotificationEvents:
      - 'Failed'
    NotificationArn: "$dependency.topicArn"
  maxChars: 150
```

JSON

```json
"notificationConfig" : {
  "type" : "StringMap",
  "description" : "The configuration for events to be notified about",
  "default" : {
    "NotificationType" : "Command",
    "NotificationEvents" : ["Failed"],
    "NotificationArn" : "$dependency.topicArn"
```

Document components

2128
MapList

A list of StringMap objects.

YAML

```yaml
blockDeviceMappings:
  type: MapList
  description: The mappings for the create image inputs
  default:
    - DeviceName: "/dev/sda1"
      Ebs:
        VolumeSize: "50"
    - DeviceName: "/dev/sdm"
      Ebs:
        VolumeSize: "100"
  maxItems: 2
```

JSON

```json
"blockDeviceMappings":{
  "type":"MapList",
  "description":"The mappings for the create image inputs",
  "default":[
    {
      "DeviceName":"/dev/sda1",
      "Ebs":{
        "VolumeSize":"50"
      }
    },
    {
      "DeviceName":"/dev/sdm",
      "Ebs":{
        "VolumeSize":"100"
      }
    }
  ],
  "maxItems":2
}
```
Viewing SSM Command document content

To preview the required and optional parameters for an AWS Systems Manager (SSM) Command document, in addition to the actions the document runs, you can view the content of the document in the Systems Manager console.

To view SSM Command document content

2. In the navigation pane, choose Documents.
3. In the search box, select Document type, and then select Command.
4. Choose the name of a document, and then choose the Content tab.
5. In the content field, review the available parameters and action steps for the document.

For example, the following image shows that (1) version and (2) allowDowngrade are optional parameters for the AWS-UpdateSSMAgent document, and that the first action run by the document is (3) aws:updateSsmAgent.
Command document plugin reference

This reference describes the plugins that you can specify in an AWS Systems Manager (SSM) Command type document. These plugins can't be used in SSM Automation runbooks, which use Automation actions. For information about AWS Systems Manager Automation actions, see Systems Manager Automation actions reference.

Systems Manager determines the actions to perform on a managed instance by reading the contents of an SSM document. Each document includes a code-execution section. Depending on the schema version of your document, this code-execution section can include one or more plugins or steps. For the purpose of this Help topic, plugins and steps are called plugins. This section includes information about each of the Systems Manager plugins. For more information about documents, including information about creating documents and the differences between schema versions, see AWS Systems Manager Documents.

Note

Some of the plugins described here run only on either Windows Server instances or Linux instances. Platform dependencies are noted for each plugin. The following document plugins are supported on Amazon Elastic Compute Cloud (Amazon EC2) instances for macOS:

- aws:refreshAssociation
- aws:runShellScript
- aws:runPowerShellScript
- aws:softwareInventory
- aws:updateSsmAgent

Contents

- Shared inputs
- aws:applications
- aws:cloudWatch
- aws:configureDocker
- aws:configurePackage
- aws:domainJoin
• **aws:downloadContent**
• **aws:psModule**
• **aws:refreshAssociation**
• **aws:runDockerAction**
• **aws:runDocument**
• **aws:runPowerShellScript**
• **aws:runShellScript**
• **aws:softwareInventory**
• **aws:updateAgent**
• **aws:updateSsmAgent**

**Shared inputs**

With SSM Agent version 3.0.502 and later only, all plugins can use the following inputs:

**finallyStep**

The last step you want the document to run. If this input is defined for a step, it takes precedence over an exit value specified in the onFailure or onSuccess inputs. In order for a step with this input to run as expected, the step must be the last one defined in the mainSteps of your document.

Type: Boolean

Valid values: true | false

Required: No

**onFailure**

If you specify this input for a plugin with the exit value and the step fails, the step status reflects the failure and the document doesn't run any remaining steps unless a finallyStep has been defined. If you specify this input for a plugin with the successAndExit value and the step fails, the step status shows successful and the document doesn't run any remaining steps unless a finallyStep has been defined.

Type: String

Valid values: exit | successAndExit

**Document components**

2132
Required: No

**onSuccess**

If you specify this input for a plugin and the step runs successfully, the document doesn't run any remaining steps unless a `finallyStep` has been defined.

Type: String

Valid values: exit

Required: No

**YAML**

```yaml
---
schemaVersion: '2.2'
description: Shared inputs example
parameters:
  customDocumentParameter:
    type: String
    description: Example parameter for a custom Command-type document.
mainSteps:
- action: aws:runDocument
  name: runCustomConfiguration
  inputs:
    documentType: SSMDocument
documentPath: "yourCustomDocument"
documentParameters: ""documentParameter":{{customDocumentParameter}}"
onSuccess: exit
- action: aws:runDocument
  name: ifConfigurationFailure
  inputs:
    documentType: SSMDocument
documentPath: "yourCustomRepairDocument"
onFailure: exit
- action: aws:runDocument
  name: finalConfiguration
  inputs:
    documentType: SSMDocument
documentPath: "yourCustomFinalDocument"
finallyStep: true
```
```json
{
    "schemaVersion": "2.2",
    "description": "Shared inputs example",
    "parameters": {
        "customDocumentParameter": {
            "type": "String",
            "description": "Example parameter for a custom Command-type document."
        }
    },
    "mainSteps": [
        {
            "action": "aws:runDocument",
            "name": "runCustomConfiguration",
            "inputs": {
                "documentType": "SSMDocument",
                "documentPath": "yourCustomDocument",
                "documentParameters": "\"documentParameter\": {{customDocumentParameter}}",
                "onSuccess": "exit"
            }
        },
        {
            "action": "aws:runDocument",
            "name": "ifConfigurationFailure",
            "inputs": {
                "documentType": "SSMDocument",
                "documentPath": "yourCustomRepairDocument",
                "onFailure": "exit"
            }
        },
        {
            "action": "aws:runDocument",
            "name": "finalConfiguration",
            "inputs": {
                "documentType": "SSMDocument",
                "documentPath": "yourCustomFinalDocument",
                "finallyStep": true
            }
        }
    ]
}
```
**aws:applications**

Install, repair, or uninstall applications on an EC2 instance. This plugin only runs on Windows Server operating systems.

**Syntax**

**Schema 2.2**

**YAML**

```yaml
---
schemaVersion: '2.2'
description: aws:applications plugin
parameters:
  source:
    description: "(Required) Source of msi."
    type: String
mainSteps:
- action: aws:applications
  name: example
  inputs:
    action: Install
    source: "{{ source }}"
```

**JSON**

```json
{
  "schemaVersion": "2.2",
  "description": "aws:applications",
  "parameters":{
    "source":{
      "description": "(Required) Source of msi.",
      "type": "String"
    }
  },
  "mainSteps":[
    {
      "action": "aws:applications",
      "name": "example",
      "inputs":{
        "action": "Install",
        "source": "{{ source }}"
      }
    }
  ]
}
```
Schema 1.2

YAML

```yaml
---
runtimeConfig:
  aws:applications:
    properties:
      - id: 0.aws:applications
        action: "{{ action }}"
        parameters: "{{ parameters }}"
        source: "{{ source }}"
        sourceHash: "{{ sourceHash }}"
```

JSON

```json
{
  "runtimeConfig":{
    "aws:applications":{
      "properties":[
        {
          "id":"0.aws:applications",
          "action":"{{ action }}",
          "parameters":"{{ parameters }}",
          "source":"{{ source }}",
          "sourceHash":"{{ sourceHash }}"
        }
      ]
    }
  }
}
```
Properties

**action**

The action to take.

Type: Enum

Valid values: Install | Repair | Uninstall

Required: Yes

**parameters**

The parameters for the installer.

Type: String

Required: No

**source**

The URL of the .msi file for the application.

Type: String

Required: Yes

**sourceHash**

The SHA256 hash of the .msi file.

Type: String

Required: No

**aws:cloudWatch**

Export data from Windows Server to Amazon CloudWatch or Amazon CloudWatch Logs and monitor the data using CloudWatch metrics. This plugin only runs on Windows Server operating systems. For more information about configuring CloudWatch integration with Amazon Elastic Compute Cloud (Amazon EC2), see [Collecting metrics, logs, and traces with the CloudWatch agent](#) in the Amazon CloudWatch User Guide.
Important

The unified CloudWatch agent has replaced SSM Agent as the tool for sending log data to Amazon CloudWatch Logs. The SSM Agent aws:cloudWatch plugin is not supported. We recommend using only the unified CloudWatch agent for your log collection processes. For more information, see the following topics:

- Sending node logs to unified CloudWatch Logs (CloudWatch agent)
- Migrate Windows Server node log collection to the CloudWatch agent
- Collecting metrics, logs, and traces with the CloudWatch agent in the Amazon CloudWatch User Guide.

You can export and monitor the following data types:

**ApplicationEventLog**

Sends application event log data to CloudWatch Logs.

**CustomLogs**

Sends any text-based log file to Amazon CloudWatch Logs. The CloudWatch plugin creates a fingerprint for log files. The system then associates a data offset with each fingerprint. The plugin uploads files when there are changes, records the offset, and associates the offset with a fingerprint. This method is used to avoid a situation where a user turns on the plugin, associates the service with a directory that contains a large number of files, and the system uploads all of the files.

Warning

Be aware that if your application truncates or attempts to clean logs during polling, any logs specified for LogDirectoryPath can lose entries. If, for example, you want to limit log file size, create a new log file when that limit is reached, and then continue writing data to the new file.

**ETW**

Sends Event Tracing for Windows (ETW) data to CloudWatch Logs.
IIS

Sends IIS log data to CloudWatch Logs.

**PerformanceCounter**

Sends Windows performance counters to CloudWatch. You can select different categories to upload to CloudWatch as metrics. For each performance counter that you want to upload, create a `PerformanceCounter` section with a unique ID (for example, "PerformanceCounter2", "PerformanceCounter3", and so on) and configure its properties.

**Note**

If the AWS Systems Manager SSM Agent or the CloudWatch plugin is stopped, performance counter data isn't logged in CloudWatch. This behavior is different than custom logs or Windows Event logs. Custom logs and Windows Event logs preserve performance counter data and upload it to CloudWatch after SSM Agent or the CloudWatch plugin is available.

**SecurityEventLog**

Sends security event log data to CloudWatch Logs.

**SystemEventLog**

Sends system event log data to CloudWatch Logs.

You can define the following destinations for the data:

**CloudWatch**

The destination where your performance counter metric data is sent. You can add more sections with unique IDs (for example, "CloudWatch2", CloudWatch3", and so on), and specify a different Region for each new ID to send the same data to different locations.

**CloudWatchLogs**

The destination where your log data is sent. You can add more sections with unique IDs (for example, "CloudWatchLogs2", CloudWatchLogs3", and so on), and specify a different Region for each new ID to send the same data to different locations.
Syntax

```json
"runtimeConfig":{
  "aws:cloudWatch":{
    "settings":{
      "startType":"{{ status }}"
    },
    "properties":"{{ properties }}"
  }
}
```

Settings and properties

AccessKey

Your access key ID. This property is required unless you launched your instance using an IAM role. This property can't be used with SSM.

Type: String

Required: No

CategoryName

The performance counter category from Performance Monitor.

Type: String

Required: Yes

CounterName

The name of the performance counter from Performance Monitor.

Type: String

Required: Yes

CultureName

The locale where the timestamp is logged. If CultureName is blank, it defaults to the same locale used by your Windows Server instance.

Type: String
Valid values: For a list of supported values, see National Language Support (NLS) on the Microsoft website. The div, div-MV, hu, and hu-HU values aren't supported.

Required: No

**DimensionName**

A dimension for your Amazon CloudWatch metric. If you specify DimensionName, you must specify DimensionValue. These parameters provide another view when listing metrics. You can use the same dimension for multiple metrics so that you can view all metrics belonging to a specific dimension.

Type: String

Required: No

**DimensionValue**

A dimension value for your Amazon CloudWatch metric.

Type: String

Required: No

**Encoding**

The file encoding to use (for example, UTF-8). Use the encoding name, not the display name.

Type: String

Valid values: For a list of supported values, see Encoding Class in the Microsoft Learn Library.

Required: Yes

**Filter**

The prefix of log names. Leave this parameter blank to monitor all files.

Type: String

Valid values: For a list of supported values, see the FileSystemWatcherFilter Property in the MSDN Library.

Required: No
Each data type to upload, along with the destination for the data (CloudWatch or CloudWatch Logs). For example, to send a performance counter defined under "Id": "PerformanceCounter" to the CloudWatch destination defined under "Id": "CloudWatch", enter "PerformanceCounter,CloudWatch". Similarly, to send the custom log, ETW log, and system log to the CloudWatch Logs destination defined under "Id": "ETW", enter "(ETW),CloudWatchLogs". In addition, you can send the same performance counter or log file to more than one destination. For example, to send the application log to two different destinations that you defined under "Id": "CloudWatchLogs" and "Id": "CloudWatchLogs2", enter "ApplicationEventLog,(CloudWatchLogs, CloudWatchLogs2)". Type: String

Valid values (source): ApplicationEventLog | CustomLogs | ETW | PerformanceCounter | SystemEventLog | SecurityEventLog

Valid values (destination): CloudWatch | CloudWatchLogs | CloudWatchLogs | CloudWatchLogs2

Required: Yes

**FullName**

The full name of the component.

Type: String

Required: Yes

**Id**

Identifies the data source or destination. This identifier must be unique within the configuration file.

Type: String

Required: Yes

**InstanceName**

The name of the performance counter instance. Don't use an asterisk (*) to indicate all instances because each performance counter component only supports one metric. You can, however use _Total.
Type: String

Required: Yes

Levels

The types of messages to send to Amazon CloudWatch.

Type: String

Valid values:

- 1 - Only error messages uploaded.
- 2 - Only warning messages uploaded.
- 4 - Only information messages uploaded.

You can add values together to include more than one type of message. For example, 3 means that error messages (1) and warning messages (2) are included. A value of 7 means that error messages (1), warning messages (2), and informational messages (4) are included.

Required: Yes

Note

Windows Security Logs should set Levels to 7.

LineCount

The number of lines in the header to identify the log file. For example, IIS log files have virtually identical headers. You could enter 3, which would read the first three lines of the log file's header to identify it. In IIS log files, the third line is the date and time stamp, which is different between log files.

Type: Integer

Required: No

LogDirectoryPath

For CustomLogs, the path where logs are stored on your EC2 instance. For IIS logs, the folder where IIS logs are stored for an individual site (for example, C:\inetpub\logs\LogFiles)
For IIS logs, only W3C log format is supported. IIS, NCSA, and Custom formats aren't supported.

Type: String

Required: Yes

**LogGroup**

The name for your log group. This name is displayed on the Log Groups screen in the CloudWatch console.

Type: String

Required: Yes

**LogName**

The name of the log file.

1. To find the name of the log, in Event Viewer, in the navigation pane, select Applications and Services Logs.

2. In the list of logs, right-click the log you want to upload (for example, Microsoft>Windows>Backup>Operational), and then select Create Custom View.

3. In the Create Custom View dialog box, select the XML tab. The LogName is in the <Select Path=> tag (for example, Microsoft-Windows-Backup). Copy this text into the LogName parameter.

Type: String

Valid values: Application | Security | System | Microsoft-Windows-WinINet/Analytic

Required: Yes

**LogStream**

The destination log stream. If you use {instance_id}, the default, the instance ID of this instance is used as the log stream name.

Type: String

Valid values: {instance_id} | {hostname} | {ip_address} <log_stream_name>
If you enter a log stream name that doesn't already exist, CloudWatch Logs automatically creates it for you. You can use a literal string or predefined variables (\{instance_id\}, \{hostname\}, \{ip_address\}, or a combination of all three to define a log stream name.

The log stream name specified in this parameter is displayed on the Log Groups > Streams for \(<YourLogStream>\) screen in the CloudWatch console.

Required: Yes

**MetricName**

The CloudWatch metric that you want performance data to be included under.

![Note]

Don't use special characters in the name. If you do, the metric and associated alarms might not work.

Type: String

Required: Yes

**NameSpace**

The metric namespace where you want performance counter data to be written.

Type: String

Required: Yes

**PollInterval**

How many seconds must elapse before new performance counter and log data is uploaded.

Type: Integer

Valid values: Set this to 5 or more seconds. Fifteen seconds (00:00:15) is recommended.

Required: Yes

**Region**

The AWS Region where you want to send log data. Although you can send performance counters to a different Region from where you send your log data, we recommend that you set this parameter to the same Region where your instance is running.
Type: String

Valid values: Regions IDs of the AWS Regions supported by both Systems Manager and CloudWatch Logs, such as us-east-2, eu-west-1, and ap-southeast-1. For lists of AWS Regions supported by each service, see Amazon CloudWatch Logs Service Endpoints and Systems Manager service endpoints in the Amazon Web Services General Reference.

Required: Yes

SecretKey

Your secret access key. This property is required unless you launched your instance using an IAM role.

Type: String

Required: No

startType

Turn on or turn off CloudWatch on the instance.

Type: String

Valid values: Enabled | Disabled

Required: Yes

TimestampFormat

The timestamp format you want to use. For a list of supported values, see Custom Date and Time Format Strings in the MSDN Library.

Type: String

Required: Yes

TimeZoneKind

Provides time zone information when no time zone information is included in your log’s timestamp. If this parameter is left blank and if your timestamp doesn’t include time zone information, CloudWatch Logs defaults to the local time zone. This parameter is ignored if your timestamp already contains time zone information.
Type: String

Valid values: Local | UTC

Required: No

Unit

The appropriate unit of measure for the metric.

Type: String

Required: Yes

aws:configureDocker

(Schema version 2.0 or later) Configure an instance to work with containers and Docker. This plugin is supported on Linux and Windows Server operating systems.

Syntax

Schema 2.2

YAML

```yaml
---
schemaVersion: '2.2'
description: aws:configureDocker
parameters:
  action:
    description: "(Required) The type of action to perform."
    type: String
    default: Install
    allowedValues:
      - Install
      - Uninstall
mainSteps:
  - action: aws:configureDocker
```
name: configureDocker
inputs:
  action: "{{ action }}"

JSON

```json
{
  "schemaVersion": "2.2",
  "description": "aws:configureDocker plugin",
  "parameters": {
    "action": {
      "description": "(Required) The type of action to perform.",
      "type": "String",
      "default": "Install",
      "allowedValues": [
        "Install",
        "Uninstall"
      ]
    }
  },
  "mainSteps": [
    {
      "action": "aws:configureDocker",
      "name": "configureDocker",
      "inputs": {
        "action": "{{ action }}"
      }
    }
  ]
}
```

**Inputs**

**action**

The type of action to perform.

Type: Enum

Valid values: Install | Uninstall

Required: Yes
**aws:configurePackage**

(Schema version 2.0 or later) Install or uninstall an AWS Systems Manager Distributor package. You can install the latest version, default version, or a version of the package you specify. Packages provided by AWS are also supported. This plugin runs on Windows Server and Linux operating systems, but not all the available packages are supported on Linux operating systems.

Available AWS packages for Windows Server include the following: AWSPVDriver, AWSNVMe, AwsEnaNetworkDriver, AwsVssComponents, AmazonCloudWatchAgent, CodeDeployAgent, and AWSSupport-EC2Rescue.

Available AWS packages for Linux operating systems include the following: AmazonCloudWatchAgent, CodeDeployAgent, and AWSSupport-EC2Rescue.

**Syntax**

**Schema 2.2**

YAML

```yaml
---
schemaVersion: '2.2'
description: aws:configurePackage
parameters:
  name:
    description: "(Required) The name of the AWS package to install or uninstall."
    type: String
  action:
    description: "(Required) The type of action to perform."
    type: String
    default: Install
    allowedValues:
    - Install
    - Uninstall
  ssmParameter:
    description: "(Required) Argument stored in Parameter Store."
    type: String
    default: "{{ ssm:parameter_store_arg }}"

mainSteps:
- action: aws:configurePackage
  name: configurePackage
  inputs:
    name: "{{ name }}"
```
JSON

```json
{
    "schemaVersion": "2.2",
    "description": "aws:configurePackage",
    "parameters": {
        "name": {
            "description": "(Required) The name of the AWS package to install or uninstall.",
            "type": "String"
        },
        "action": {
            "description": "(Required) The type of action to perform.",
            "type": "String",
            "default": "Install",
            "allowedValues": [
                "Install",
                "Uninstall"
            ]
        },
        "ssmParameter": {
            "description": "(Required) Argument stored in Parameter Store.",
            "type": "String",
            "default": "{{ ssm:parameter_store_arg }}"
        }
    },
    "mainSteps": [
        {
            "action": "aws:configurePackage",
            "name": "configurePackage",
            "inputs": {
                "name": "{{ name }}",
                "action": "{{ action }}",
                "additionalArguments": "{{"SSM_parameter_store_arg": "{{ ssmParameter }}", "SSM_custom_arg": "myValue"}}"
            }
        }
    ]
}
```
**Inputs**

**name**

The name of the AWS package to install or uninstall. Available packages include the following: AWSPVDriver, AwsEnaNetworkDriver, AwsVssComponents, and AmazonCloudWatchAgent.

Type: String

Required: Yes

**action**

Install or uninstall a package.

Type: Enum

Valid values: Install | Uninstall

Required: Yes

**installationType**

The type of installation to perform. If you specify Uninstall and reinstall, the package is completely uninstalled, and then reinstalled. The application is unavailable until the reinstallation is complete. If you specify In-place update, only new or changed files are added to the existing installation according you instructions you provide in an update script. The application remains available throughout the update process. The In-place update option isn't supported for AWS-published packages. Uninstall and reinstall is the default value.

Type: Enum

Valid values: Uninstall and reinstall | In-place update

Required: No

**additionalArguments**

A JSON string of the additional parameters to provide to your install, uninstall, or update scripts. Each parameter must be prefixed with SSM_. You can reference a Parameter Store.
parameter in your additional arguments by using the convention \{ssm:parameter-name\}. To use the additional parameter in your install, uninstall, or update script, you must reference the parameter as an environment variable using the syntax appropriate for the operating system. For example, in PowerShell, you reference the SSM_arg argument as $Env:SSM_arg. There is no limit to the number of arguments you define, but the additional argument input has a 4096 character limit. This limit includes all of the keys and values you define.

Type: StringMap

Required: No

version

A specific version of the package to install or uninstall. If installing, the system installs the latest published version, by default. If uninstalling, the system uninstalls the currently installed version, by default. If no installed version is found, the latest published version is downloaded, and the uninstall action is run.

Type: String

Required: No

aws:domainJoin

Join an EC2 instance to a domain. This plugin runs on Linux and Windows Server operating systems. This plugin changes the hostname for Linux instances to the format EC2AMAZ-XXXXXXX. For more information about joining EC2 instances, see Join an EC2 Instance to Your AWS Managed Microsoft AD Directory in the AWS Directory Service Administration Guide.

Syntax

Schema 2.2

YAML

---
schemaVersion: '2.2'
description: aws:domainJoin
parameters:
directoryId:
  description: "(Required) The ID of the directory."
type: String
directoryName:
  description: "(Required) The name of the domain."
type: String
directoryOU:
  description: "(Optional) The organizational unit to assign the computer object to."
type: String
dnsIpAddresses:
  description: "(Required) The IP addresses of the DNS servers for your directory."
type: StringList

mainSteps:
- action: aws:domainJoin
  name: domainJoin
  inputs:
    directoryId: "{{ directoryId }}"
    directoryName: "{{ directoryName }}"
    directoryOU: "{{ directoryOU }}"
    dnsIpAddresses: "{{ dnsIpAddresses }}"

JSON

```json
{
  "schemaVersion": "2.2",
  "description": "aws:domainJoin",
  "parameters": {
    "directoryId": {
      "description": "(Required) The ID of the directory.",
      "type": "String"
    },
    "directoryName": {
      "description": "(Required) The name of the domain.",
      "type": "String"
    },
    "directoryOU": {
      "description": "(Optional) The organizational unit to assign the computer object to.",
      "type": "String"
    },
    "dnsIpAddresses": {
      "description": "(Required) The IP addresses of the DNS servers for your directory."
    }
  }
}```
"mainSteps": [
  {
    "action": "aws:domainJoin",
    "name": "domainJoin",
    "inputs": {
      "directoryId": "{{ directoryId }}",
      "directoryName": "{{ directoryName }}",
      "directoryOU": "{{ directoryOU }}",
      "dnsIpAddresses": "{{ dnsIpAddresses }}"
    }
  }
]

---

runtimeConfig:
  aws:domainJoin:
    properties:
      directoryId: "{{ directoryId }}"
      directoryName: "{{ directoryName }}"
      directoryOU: "{{ directoryOU }}"
      dnsIpAddresses: "{{ dnsIpAddresses }}"

Properties

directoryId

The ID of the directory.

Type: String

Required: Yes

Example: "directoryId": "d-1234567890"

directoryName

The name of the domain.

Type: String

Required: Yes

Example: "directoryName": "example.com"

directoryOU

The organizational unit (OU).

Type: String

Required: No

Example: "directoryOU": "OU=test,DC=example,DC=com"

dnsIpAddresses

The IP addresses of the DNS servers.

Type: StringList

Required: Yes
Example: "dnsIpAddresses": ["198.51.100.1","198.51.100.2"]

Examples

For examples, see Join an Amazon EC2 Instance to your AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

**aws:downloadContent**

(Schema version 2.0 or later) Download SSM documents and scripts from remote locations. GitHub Enterprise repositories are not supported. This plugin is supported on Linux and Windows Server operating systems.

**Syntax**

**Schema 2.2**

**YAML**

```yaml
---
schemaVersion: '2.2'
description: aws:downloadContent

parameters:
  sourceType:
    description: "(Required) The download source."
    type: String

sourceInfo:
  description: "(Required) The information required to retrieve the content from the required source."
  type: StringMap

mainSteps:
- action: aws:downloadContent
  name: downloadContent
  inputs:
    sourceType: "{{ sourceType }}"
    sourceInfo: "{{ sourceInfo }}"
```

**JSON**

```json
{
  "schemaVersion": "2.2",
  "description": "aws:downloadContent",
}
"parameters": {
  "sourceType": {
    "description": "(Required) The download source.",
    "type": "String"
  },
  "sourceInfo": {
    "description": "(Required) The information required to retrieve the content from the required source.",
    "type": "StringMap"
  }
},
"mainSteps": [
  {
    "action": "aws:downloadContent",
    "name": "downloadContent",
    "inputs": {
      "sourceType": "{{ sourceType }}",
      "sourceInfo": "{{ sourceInfo }}"
    }
  }
]

Inputs

sourceType

The download source. Systems Manager supports the following source types for downloading scripts and SSM documents: GitHub, Git, HTTP, S3, and SSMDocument.

Type: String

Required: Yes

sourceInfo

The information required to retrieve the content from the required source.

Type: StringMap

Required: Yes

For sourceType GitHub, specify the following:
• owner: The repository owner.
• repository: The name of the repository.
• path: The path to the file or directory you want to download.

• getOptions: Extra options to retrieve content from a branch other than master or from a specific commit in the repository. getOptions can be omitted if you're using the latest commit in the master branch. If your repository was created after October 1, 2020 the default branch might be named main instead of master. In this case, you will need to specify values for the getOptions parameter.

This parameter uses the following format:

• branch:refs/heads/branch_name

The default is master.

To specify a non-default branch use the following format:

branch:refs/heads/branch_name

• commitID:commitID

The default is head.

To use the version of your SSM document in a commit other than the latest, specify the full commit ID. For example:

"getOptions": "commitID:bbc1ddb94...b76d3bEXAMPLE",

• tokenInfo: The Systems Manager parameter (a SecureString parameter) where you store your GitHub access token information, in the format {{ssm-secure:secure-string-token-name}}.

ℹ️ Note

This tokenInfo field is the only SSM document plugin field that supports a SecureString parameter. SecureString parameters aren't supported for any other fields, nor for any other SSM document plugins.
For sourceType Git, you must specify the following:

- **repository**

  The Git repository URL to the file or directory you want to download.

  Type: String

  Additionally, you can specify the following optional parameters:

  - **getOptions**

    Extra options to retrieve content from a branch other than master or from a specific commit in the repository. getOptions can be omitted if you're using the latest commit in the master branch.

    Type: String

    This parameter uses the following format:

    - **branch:** *refs/heads/branch_name*

      The default is *master*.

      "branch" is required only if your SSM document is stored in a branch other than *master*. For example:

      "getOptions": "branch:refs/head/main"

    - **commitID:** *commitID*

      The default is head.

      To use the version of your SSM document in a commit other than the latest, specify the full commit ID. For example:

      "getOptions": "commitID:bbc1ddb94...b76d3bEXAMPLE"
• **privateSSHKey**

  The SSH key to use when connecting to the repository you specify. You can use the following format to reference a SecureString parameter for the value of your SSH key: `{{ssm-secure:your-secure-string-parameter}}`.

  Type: String

• **skipHostKeyChecking**

  Determines the value of the StrictHostKeyChecking option when connecting to the repository you specify. The default value is **false**.

  Type: Boolean

• **username**

  The username to use when connecting to the repository you specify using HTTP. You can use the following format to reference a SecureString parameter for the value of your username: `{{ssm-secure:your-secure-string-parameter}}`.

  Type: String

• **password**

  The password to use when connecting to the repository you specify using HTTP. You can use the following format to reference a SecureString parameter for the value of your password: `{{ssm-secure:your-secure-string-parameter}}`.

  Type: String

**For sourceType HTTP, you must specify the following:**

• **url**

  The URL to the file or directory you want to download.

  Type: String

Additionally, you can specify the following optional parameters:

• **allowInsecureDownload**

  Determines whether a download can be performed over a connection that isn't encrypted with Secure Socket Layer (SSL) or Transport Layer Security (TLS). The default value is **false**.
We don’t recommend performing downloads without encryption. If you choose to do so, you assume all associated risks. Security is a shared responsibility between AWS and you. This is described as the shared responsibility model. To learn more, see the shared responsibility model.

Type: Boolean

- authMethod

Determines whether a username and password are used for authentication when connecting to the url you specify. If you specify Basic or Digest, you must provide values for the username and password parameters. To use the Digest method, SSM Agent version 3.0.1181.0 or later must be installed on your instance. The Digest method supports MD5 and SHA256 encryption.

Type: String

Valid values: None | Basic | Digest

- username

The username to use when connecting to the url you specify using Basic authentication. You can use the following format to reference a SecureString parameter for the value of your username: {{ssm-secure:your-secure-string-parameter}}.

Type: String

- password

The password to use when connecting to the url you specify using Basic authentication. You can use the following format to reference a SecureString parameter for the value of your password: {{ssm-secure:your-secure-string-parameter}}.

Type: String

**For sourceType S3, specify the following:**

- path: The URL to the file or directory you want to download from Amazon S3.

```json
{
   "path": "https://s3.amazonaws.com/DOC-EXAMPLE-BUCKET/powershell/helloPowershell.ps1"
}
```
For sourceType SSMDocument, specify one of the following:

- **name**: The name and version of the document in the following format: `name:version`. Version is optional.

  ```json
  {
    "name": "Example-RunPowerShellScript:3"
  }
  ```

- **name**: The ARN for the document in the following format:

  ```json
  {
  }
  ```

destinationPath

An optional local path on the instance where you want to download the file. If you don't specify a path, the content is downloaded to a path relative to your command ID.

- **Type**: String
- **Required**: No

aws:psModule

Install PowerShell modules on an Amazon EC2 instance. This plugin only runs on Windows Server operating systems.

**Syntax**

**Schema 2.2**

**YAML**

```yaml
---
schemaVersion: '2.2'
description: aws:psModule
parameters:
  source:
    description: "(Required) The URL or local path on the instance to the application
```
.zip file."
   type: String
mainSteps:
- action: aws:psModule
  name: psModule
  inputs:
    source: "{{ source }}"

JSON

{
   "schemaVersion": "2.2",
   "description": "aws:psModule",
   "parameters": {
      "source": {
         "description": "(Required) The URL or local path on the instance to the application .zip file.",
         "type": "String"
      }
   },
   "mainSteps": [
      {
         "action": "aws:psModule",
         "name": "psModule",
         "inputs": {
            "source": "{{ source }}"
         }
      }
   ]
}

Schema 1.2

YAML

---
runtimeConfig:
  aws:psModule:
    properties:
      - runCommand: "{{ commands }}"
        source: "{{ source }}"
        sourceHash: "{{ sourceHash }}"
workingDirectory: "{{ workingDirectory }}"
timeoutSeconds: "{{ executionTimeout }}"

JSON

```
{
  "runtimeConfig":{
    "aws:psModule":{
      "properties":[
        {
          "runCommand":"{{ commands }}",
          "source":"{{ source }}",
          "sourceHash":"{{ sourceHash }}",
          "workingDirectory":"{{ workingDirectory }}",
          "timeoutSeconds":"{{ executionTimeout }}"
        }
      ]
    }
  }
}
```

Properties

runCommand

The PowerShell command to run after the module is installed.

Type: StringList

Required: No

source

The URL or local path on the instance to the application .zip file.

Type: String

Required: Yes

sourceHash

The SHA256 hash of the .zip file.

Type: String
**timeoutSeconds**

The time in seconds for a command to be completed before it's considered to have failed.

Type: String

Required: No

**workingDirectory**

The path to the working directory on your instance.

Type: String

Required: No

**aws:refreshAssociation**

(Schema version 2.0 or later) Refresh (force apply) an association on demand. This action will change the system state based on what is defined in the selected association or all associations bound to the targets. This plugin runs on Linux and Microsoft Windows Server operating systems.

**Syntax**

**Schema 2.2**

**YAML**

```yaml
---
schemaVersion: '2.2'
description: aws:refreshAssociation
parameters:
  associationIds:
    description: "(Optional) List of association IDs. If empty, all associations bound to the specified target are applied."
    type: StringList
mainSteps:
- action: aws:refreshAssociation
  name: refreshAssociation
  inputs:
    associationIds:
```
- "{{ associationIds }}"

### JSON

```json
{
  "schemaVersion": "2.2",
  "description": "aws:refreshAssociation",
  "parameters": {
    "associationIds": {
      "description": "(Optional) List of association IDs. If empty, all associations bound to the specified target are applied.",
      "type": "StringList"
    }
  },
  "mainSteps": [
    {
      "action": "aws:refreshAssociation",
      "name": "refreshAssociation",
      "inputs": {
        "associationIds": [
          "{{ associationIds }}"
        ]
      }
    }
  ]
}
```

### Inputs

**associationIds**

List of association IDs. If empty, all associations bound to the specified target are applied.

Type: StringList

Required: No

**aws:runDockerAction**

(Schema version 2.0 or later) Run Docker actions on containers. This plugin runs on Linux and Microsoft Windows Server operating systems.
Syntax

Schema 2.2

YAML

```yaml
---
mainSteps:
- action: aws:runDockerAction
  name: RunDockerAction
  inputs:
    action: "{{ action }}"
    container: "{{ container }}"
    image: "{{ image }}"
    memory: "{{ memory }}"
    cpuShares: "{{ cpuShares }}"
    volume: "{{ volume }}"
    cmd: "{{ cmd }}"
    env: "{{ env }}"
    user: "{{ user }}"
    publish: "{{ publish }}"
```

JSON

```json
{
  "mainSteps": [
    {
      "action": "aws:runDockerAction",
      "name": "RunDockerAction",
      "inputs": {
        "action": "{{ action }}",
        "container": "{{ container }}",
        "image": "{{ image }}",
        "memory": "{{ memory }}",
        "cpuShares": "{{ cpuShares }}",
        "volume": "{{ volume }}",
        "cmd": "{{ cmd }}",
        "env": "{{ env }}",
        "user": "{{ user }}",
        "publish": "{{ publish }}"
      }
    }
  ]
}
```
Inputs

action

The type of action to perform.

Type: String

Required: Yes

container

The Docker container ID.

Type: String

Required: No

image

The Docker image name.

Type: String

Required: No

cmd

The container command.

Type: String

Required: No

memory

The container memory limit.

Type: String

Required: No
**cpuShares**

The container CPU shares (relative weight).

Type: String

Required: No

**volume**

The container volume mounts.

Type: StringList

Required: No

**env**

The container environment variables.

Type: String

Required: No

**user**

The container user name.

Type: String

Required: No

**publish**

The container published ports.

Type: String

Required: No

**aws:runDocument**

(Schema version 2.0 or later) Runs SSM documents stored in Systems Manager or on a local share. You can use this plugin with the `aws:downloadContent` plugin to download an SSM
document from a remote location to a local share, and then run it. This plugin is supported on Linux and Windows Server operating systems. This plugin doesn't support running the AWS-UpdateSSMAgent document or any document that uses the aws:updateSsmAgent plugin.

**Syntax**

**Schema 2.2**

**YAML**

```yaml
---
schemaVersion: '2.2'
description: aws:runDocument
parameters:
documentType:
  description: "(Required) The document type to run."
  type: String
  allowedValues:
  - LocalPath
  - SSMDocument
mainSteps:
- action: aws:runDocument
  name: runDocument
  inputs:
    documentType: "{{ documentType }}"
```

**JSON**

```json
{
  "schemaVersion": "2.2",
  "description": "aws:runDocument",
  "parameters": {
    "documentType": {
      "description": "(Required) The document type to run."
    },
    "type": "String",
    "allowedValues": [
      "LocalPath",
      "SSMDocument"
    ]
  },
  "mainSteps": [ 
    
```
Inputs

documentType

The document type to run. You can run local documents (LocalPath) or documents stored in Systems Manager (SSMDocument).

Type: String

Required: Yes

documentPath

The path to the document. If documentType is LocalPath, then specify the path to the document on the local share. If documentType is SSMDocument, then specify the name of the document.

Type: String

Required: No

documentParameters

Parameters for the document.

Type: StringMap

Required: No

aws:runPowerShellScript

Run PowerShell scripts or specify the path to a script to run. This plugin runs on Microsoft Windows Server and Linux operating systems.
Syntax

Schema 2.2

YAML

```yaml
---
schemaVersion: '2.2'
description: aws:runPowerShellScript
parameters:
  commands:
    type: String
    description: "(Required) The commands to run or the path to an existing script on the instance."
    default: Write-Host "Hello World"

mainSteps:
- action: aws:runPowerShellScript
  name: runPowerShellScript
  inputs:
    timeoutSeconds: '60'
    runCommand:
    - "{{ commands }}"
```

JSON

```json
{
  "schemaVersion": "2.2",
  "description": "aws:runPowerShellScript",
  "parameters": {
    "commands": {
      "type": "String",
      "description": "(Required) The commands to run or the path to an existing script on the instance."
    },
    "default": "Write-Host \"Hello World\"
  }
},
"mainSteps": [
{
  "action": "aws:runPowerShellScript",
  "name": "runPowerShellScript",
  "inputs": {
    "timeoutSeconds": "60",
    "runCommand": [
```
Schema 1.2

YAML

```yaml
---
runtimeConfig:
  aws:runPowerShellScript:
    properties:
      - id: 0.aws:runPowerShellScript
        runCommand: "{{ commands }}"
        workingDirectory: "{{ workingDirectory }}"
        timeoutSeconds: "{{ executionTimeout }}"
```

JSON

```json
{
  "runtimeConfig":{
    "aws:runPowerShellScript":{
      "properties":[
        {
          "id":"0.aws:runPowerShellScript",
          "runCommand":"{{ commands }}",
          "workingDirectory":"{{ workingDirectory }}",
          "timeoutSeconds":"{{ executionTimeout }}"
        }
      ]
    }
  }
}
```
Properties

runCommand

Specify the commands to run or the path to an existing script on the instance.

Type: StringList

Required: Yes

timeoutSeconds

The time in seconds for a command to be completed before it's considered to have failed. When the timeout is reached, Systems Manager stops the command execution.

Type: String

Required: No

workingDirectory

The path to the working directory on your instance.

Type: String

Required: No

aws:runShellScript

Run Linux shell scripts or specify the path to a script to run. This plugin only runs on Linux operating systems.

Syntax

Schema 2.2

YAML

```yaml
---
schemaVersion: '2.2'
description: aws:runShellScript
parameters:
  commands:
    type: String
    description: "(Required) The commands to run or the path to an existing script"```
on the instance.
    default: echo Hello World
mainSteps:
- action: aws:runShellScript
  name: runShellScript
  inputs:
    timeoutSeconds: '60'
    runCommand:
    - "{{ commands }}"

```

JSON

{
  "schemaVersion": "2.2",
  "description": "aws:runShellScript",
  "parameters": {
    "commands": {
      "type": "String",
      "description": "(Required) The commands to run or the path to an existing
      script on the instance.",
      "default": "echo Hello World"
    }
  },
  "mainSteps": [
    {
      "action": "aws:runShellScript",
      "name": "runShellScript",
      "inputs": {
        "timeoutSeconds": "60",
        "runCommand": [
          "{{ commands }}"
        ]
      }
    }
  ]
}

Schema 1.2

YAML

---
runtimeConfig:
  aws:runShellScript:
    properties:
      - runCommand: "{{ commands }}"
      workingDirectory: "{{ workingDirectory }}"
      timeoutSeconds: "{{ executionTimeout }}"

JSON

```
{
  "runtimeConfig": {
    "aws:runShellScript": {
      "properties": [
        {
          "runCommand": "{{ commands }}",
          "workingDirectory": "{{ workingDirectory }}",
          "timeoutSeconds": "{{ executionTimeout }}"
        }
      ]
    }
  }
}
```

**Properties**

**runCommand**

Specify the commands to run or the path to an existing script on the instance.

Type: StringList

Required: Yes

**timeoutSeconds**

The time in seconds for a command to be completed before it's considered to have failed. When the timeout is reached, Systems Manager stops the command execution.

Type: String

Required: No
workingDirectory

The path to the working directory on your instance.

Type: String

Required: No

aws:softwareInventory

(Schema version 2.0 or later) Gather metadata about applications, files, and configurations on your managed instances. This plugin runs on Linux and Microsoft Windows Server operating systems. When you configure inventory collection, you start by creating an AWS Systems Manager State Manager association. Systems Manager collects the inventory data when the association is run. If you don't create the association first, and attempt to invoke the aws:softwareInventory plugin the system returns the following error:

The aws:softwareInventory plugin can only be invoked via ssm-associate.

An instance can have only one inventory association configured at a time. If you configure an instance with two or more associations, the inventory association doesn't run and no inventory data is collected. For more information about collecting inventory, see AWS Systems Manager Inventory.

Syntax

Schema 2.2

YAML

```yaml
---
mainSteps:
- action: aws:softwareInventory
  name: collectSoftwareInventoryItems
  inputs:
    applications: "{{ applications }}"
    awsComponents: "{{ awsComponents }}"
    networkConfig: "{{ networkConfig }}"
    files: "{{ files }}"
    services: "{{ services }}"
    windowsRoles: "{{ windowsRoles }}"
```
windowRegistry: "{{ windowsRegistry }}"
windowUpdates: "{{ windowUpdates }}"
instanceDetailedInformation: "{{ instanceDetailedInformation }}"
customInventory: "{{ customInventory }}"

**JSON**

```json
{
  "mainSteps": [
    {
      "action": "aws:softwareInventory",
      "name": "collectSoftwareInventoryItems",
      "inputs": {
        "applications": "{{ applications }}",
        "awsComponents": "{{ awsComponents }}",
        "networkConfig": "{{ networkConfig }}",
        "files": "{{ files }}",
        "services": "{{ services }}",
        "windowsRoles": "{{ windowsRoles }}",
        "windowsRegistry": "{{ windowsRegistry }}",
        "windowsUpdates": "{{ windowsUpdates }}",
        "instanceDetailedInformation": "{{ instanceDetailedInformation }}",
        "customInventory": "{{ customInventory }}"
      }
    }
  ]
}
```

**Inputs**

**applications**

(Optional) Collect metadata for installed applications.

Type: String

Required: No

**awsComponents**

(Optional) Collect metadata for AWS components like `amazon-ssm-agent`.

Type: String
files

(Optional, requires SSM Agent version 2.2.64.0 or later) Collect metadata for files, including file names, the time files were created, the time files were last modified and accessed, and file sizes, to name a few. For more information about collecting file inventory, see Working with file and Windows registry inventory.

Type: String
Required: No

networkConfig

(Optional) Collect metadata for network configurations.

Type: String
Required: No

windowsUpdates

(Optional) Collect metadata for all Windows updates.

Type: String
Required: No

instanceDetailedInformation

(Optional) Collect more instance information than is provided by the default inventory plugin (aws:instanceInformation), including CPU model, speed, and the number of cores, to name a few.

Type: String
Required: No

services

(Optional, Windows OS only, requires SSM Agent version 2.2.64.0 or later) Collect metadata for service configurations.

Type: String
Required: No
windowsRegistry

(Optional, Windows OS only, requires SSM Agent version 2.2.64.0 or later) Collect Windows Registry keys and values. You can choose a key path and collect all keys and values recursively. You can also collect a specific registry key and its value for a specific path. Inventory collects the key path, name, type, and the value. For more information about collecting Windows Registry inventory, see Working with file and Windows registry inventory.

Type: String
Required: No

windowsRoles

(Optional, Windows OS only, requires SSM Agent version 2.2.64.0 or later) Collect metadata for Microsoft Windows role configurations.

Type: String
Required: No

customInventory

(Optional) Collect custom inventory data. For more information about custom inventory, see Working with custom inventory

Type: String
Required: No

aws:updateAgent

Update the EC2Config service to the latest version or specify an older version. This plugin only runs on Microsoft Windows Server operating systems. For more information about the EC2Config service, see Configuring a Windows Instance using the EC2Config service (legacy) in the Amazon EC2 User Guide.

Syntax

Schema 2.2

YAML

---
JSON

```json
{
  "schemaVersion": "2.2",
  "description": "aws:updateAgent",
  "mainSteps": [
    {
      "action": "aws:updateAgent",
      "name": "updateAgent",
      "inputs": {
        "agentName": "Ec2Config",
        "source": "https://s3.{Region}.amazonaws.com/aws-ssm-{Region}/manifest.json"
      }
    }
  ]
}
```

YAML

```yaml
---
runtimeConfig:
  aws:updateAgent:
    properties:
      agentName: Ec2Config
      source: https://s3.{Region}.amazonaws.com/aws-ssm-{Region}/manifest.json
      allowDowngrade: "{{ allowDowngrade }}"
      targetVersion: "{{ version }}"
```

JSON

```json
{

```
"runtimeConfig":{
  "aws:updateAgent":{
    "properties":{
      "agentName":"Ec2Config",
      "source":"https://s3.{Region}.amazonaws.com/aws-ssm-{Region}/manifest.json",
      "allowDowngrade":"{{ allowDowngrade }}",
      "targetVersion":"{{ version }}"
    }
  }
}

Properties

agentName

EC2Config. This is the name of the agent that runs the EC2Config service.

Type: String

Required: Yes

allowDowngrade

Allow the EC2Config service to be downgraded to an earlier version. If set to false, the service can be upgraded to newer versions only (default). If set to true, specify the earlier version.

Type: Boolean

Required: No

source

The location where Systems Manager copies the version of EC2Config to install. You can't change this location.

Type: String

Required: Yes

targetVersion

A specific version of the EC2Config service to install. If not specified, the service will be updated to the latest version.
aws:updateSsmAgent

Update the SSM Agent to the latest version or specify an older version. This plugin runs on Linux and Windows Server operating systems. For more information, see Working with SSM Agent.

Syntax

Schema 2.2

YAML

```yaml
---
schemaVersion: '2.2'
description: aws:updateSsmAgent
parameters:
  allowDowngrade:
    default: 'false'
    description: "(Optional) Allow the Amazon SSM Agent service to be downgraded to an earlier version. If set to false, the service can be upgraded to newer versions only (default). If set to true, specify the earlier version."
    type: String
    allowedValues:
    - 'true'
    - 'false'
mainSteps:
- action: aws:updateSsmAgent
  name: updateSSMAgent
  inputs:
    agentName: amazon-ssm-agent
    source: https://s3.{Region}.amazonaws.com/amazon-ssm-{Region}/ssm-agent-manifest.json
    allowDowngrade: "{{ allowDowngrade }}"
```

JSON

```json
{
  "schemaVersion": "2.2",
  "description": "aws:updateSsmAgent",
}
"parameters": {
   "allowDowngrade": {
      "default": "false",
      "description": "(Required) Allow the Amazon SSM Agent service to be downgraded to an earlier version. If set to false, the service can be upgraded to newer versions only (default). If set to true, specify the earlier version.",
      "type": "String",
      "allowedValues": [
         "true",
         "false"
      ]
   }
},
"mainSteps": [
   {
      "action": "aws:updateSsmAgent",
      "name": "awsupdateSsmAgent",
      "inputs": {
         "agentName": "amazon-ssm-agent",
         "source": "https://s3.{Region}.amazonaws.com/amazon-ssm-{Region}/ssm-agent-manifest.json",
         "allowDowngrade": "{{ allowDowngrade }}"
      }
   }
]
}

---

runtimeConfig:
  aws:updateSsmAgent:
    properties:
      - agentName: amazon-ssm-agent
        source: https://s3.{Region}.amazonaws.com/aws-ssm-{Region}/manifest.json
        allowDowngrade: "{{ allowDowngrade }}"

JSON

```json
{
}
```
Properties

agentName

amazon-ssm-agent. This is the name of the Systems Manager agent that processes requests and runs commands on the instance.

Type: String

Required: Yes

allowDowngrade

Allow the SSM Agent to be downgraded to an earlier version. If set to false, the agent can be upgraded to newer versions only (default). If set to true, specify the earlier version.

Type: Boolean

Required: Yes

source

The location where Systems Manager copies the SSM Agent version to install. You can't change this location.

Type: String

Required: Yes
targetVersion

A specific version of SSM Agent to install. If not specified, the agent will be updated to the latest version.

Type: String

Required: No

Creating SSM document content

If the AWS Systems Manager public documents don’t perform all the actions you want to perform on your AWS resources, you can create your own SSM documents. You can also clone SSM documents using the console. Cloning documents copies content from an existing document to a new document that you can modify. When creating or cloning a document, the content of the document must not exceed 64KB. This quota also includes the content specified for input parameters at runtime. When you create a new Command or Policy document, we recommend that you use schema version 2.2 or later so you can take advantage of the latest features, such as document editing, automatic versioning, sequencing, and more.

Writing SSM document content

To create your own SSM document content, it’s important to understand the different schemas, features, plugins, and syntax available for SSM documents. We recommend becoming familiar with the following resources.

- Writing your own AWS Systems Manager documents
- Data elements and parameters
- Schemas, features, and examples
- Command document plugin reference
- Systems Manager Automation actions reference
- Automation system variables
- Additional runbook examples
- Working with Systems Manager Automation runbooks using the AWS Toolkit for Visual Studio Code
- Using Document Builder to create runbooks
- Using scripts in runbooks
AWS pre-defined SSM documents might perform some of the actions you require. You can call these documents by using the `aws:runDocument`, `aws:runCommand`, or `aws:executeAutomation` plugins within your custom SSM document, depending on the document type. You can also copy portions of those documents into a custom SSM document, and edit the content to meet your requirements.

**Tip**
When creating SSM document content, you might change the content and update your SSM document several times while testing. The following commands update the SSM document with your latest content, and update the document's default version to the latest version of the document.

**Note**
The Linux and Windows commands use the `jq` command line tool to filter the JSON response data.

**Linux & macOS**

```
latestDocVersion=$(aws ssm update-document \
    --content file://path/to/file/documentContent.json \
    --name "ExampleDocument" \
    --document-format JSON \
    --document-version '$LATEST' \
    | jq -r '.DocumentDescription.LatestVersion')

aws ssm update-document-default-version \
    --name "ExampleDocument" \
    --document-version $latestDocVersion
```

**Windows**

```
latestDocVersion=$(aws ssm update-document ^
    --content file://C:\path\to\file\documentContent.json ^
    --name "ExampleDocument" ^
    --document-format JSON ^
    --document-version "$LATEST" ^
    | jq -r '.DocumentDescription.LatestVersion')
```
## Cloning an SSM document

You can clone AWS Systems Manager documents using the Systems Manager Documents console to create SSM documents. Cloning SSM documents copies content from an existing document to a new document that you can modify. You can't clone a document larger than 64KB.

### To clone an SSM document

2. In the navigation pane, choose Documents.
3. In the search box, enter the name of the document you want to clone.
4. Choose the name of the document you want to clone, and then choose Clone document in the Actions dropdown.
5. Modify the document as you prefer, and then choose Create document to save the document.

### Creating SSM document content

After writing your SSM document content, you can use your content to create an SSM document using one of the following methods.
Create SSM documents
- Creating composite documents

Creating composite documents

A composite AWS Systems Manager (SSM) document is a custom document that performs a series of actions by running one or more secondary SSM documents. Composite documents promote *infrastructure as code* by allowing you to create a standard set of SSM documents for common tasks such as boot-strapping software or domain-joining instances. You can then share these documents across AWS accounts in the same AWS Region to reduce SSM document maintenance and ensure consistency.

For example, you can create a composite document that performs the following actions:

1. Installs all patches in the allow list.
2. Installs antivirus software.
3. Downloads scripts from GitHub and runs them.

In this example, your custom SSM document includes the following plugins to perform these actions:

1. The `aws:runDocument` plugin to run the `AWS-RunPatchBaseline` document, which installs all allow listed patches.
2. The `aws:runDocument` plugin to run the `AWS-InstallApplication` document, which installs the antivirus software.
3. The `aws:downloadContent` plugin to download scripts from GitHub and run them.

Composite and secondary documents can be stored in Systems Manager, GitHub (public and private repositories), or Amazon S3. Composite documents and secondary documents can be created in JSON or YAML.

**Note**

Composite documents can only run to a maximum depth of three documents. This means that a composite document can call a child document; and that child document can call one last document.
To create a composite document, add the `aws:runDocument` plugin in a custom SSM document and specify the required inputs. The following is an example of a composite document that performs the following actions:

1. Runs the `aws:downloadContent` plugin to download an SSM document from a GitHub public repository to a local directory called `bootstrap`. The SSM document is called `StateManagerBootstrap.yml` (a YAML document).

2. Runs the `aws:runDocument` plugin to run the `StateManagerBootstrap.yml` document. No parameters are specified.

3. Runs the `aws:runDocument` plugin to run the `AWS-ConfigureDocker` pre-defined SSM document. The specified parameters install Docker on the instance.

```json
{
    "schemaVersion": "2.2",
    "description": "My composite document for bootstrapping software and installing Docker."

    "parameters": {
    
    "mainSteps": [

    
    "action": "aws:downloadContent",
    "name": "downloadContent",
    "inputs": {
        "sourceType": "GitHub",
        "sourceInfo": "{\"owner\":"TestUser1"","repository\":"TestPublic","path\":"documents/bootstrap/StateManagerBootstrap.yml"}",
        "destinationPath": "bootstrap"
    
    
    "action": "aws:runDocument",
    "name": "runDocument",
    "inputs": {
        "documentType": "LocalPath",
        "documentPath": "bootstrap",
        "documentParameters": "{}"
    
    
    "action": "aws:runDocument",
```
More info

- For information about rebooting servers and instances when using Run Command to call scripts, see Handling reboots when running commands.

- For more information about the plugins you can add to a custom SSM document, see Command document plugin reference.

- If you simply want to run a document from a remote location (without creating a composite document), see Running documents from remote locations.

Working with documents

This section includes information about how to use and work with SSM documents.

Contents

- Using SSM documents in State Manager Associations
- Comparing SSM document versions
- Create an SSM document (console)
- Create an SSM document (command line)
- Create an SSM document (API)
- Deleting custom SSM documents
- Running documents from remote locations
- Sharing SSM documents
- Searching for SSM documents
Using SSM documents in State Manager Associations

If you create an SSM document for State Manager, a capability of AWS Systems Manager, you must associate the document with your managed instances after you add the document to the system. For more information, see Working with associations in Systems Manager.

Keep in mind the following details when using SSM documents in State Manager associations.

• You can assign multiple documents to a target by creating different State Manager associations that use different documents.

• If you create a document with conflicting plugins (for example, domain join and remove from domain), the last plugin run will be the final state. State Manager doesn't validate the logical sequence or rationality of the commands or plugins in your document.

• When processing documents, instance associations are applied first, and next tagged group associations are applied. If an instance is part of multiple tagged groups, then the documents that are part of the tagged group won't be run in any particular order. If an instance is directly targeted through multiple documents by its instance ID, there is no particular order of execution.

• If you change the default version of an SSM Policy document for State Manager, any association that uses the document will start using the new default version the next time Systems Manager applies the association to the instance.

• If you create an association using an SSM document that was shared with you, and then the owner stops sharing the document with you, your associations no longer have access to that document. However, if the owner shares the same SSM document with you again later, your associations automatically remap to it.

Comparing SSM document versions

You can compare the differences in content between versions of AWS Systems Manager (SSM) documents in the Systems Manager Documents console. When comparing versions of an SSM document, differences between the content of the versions are highlighted.

To compare SSM document content (console)

2. In the navigation pane, choose Documents.
3. In the documents list, choose the document whose content you want to compare.
4. On the **Content** tab, select **Compare versions**, and choose the version of the document you want to compare the content to.

---

**Create an SSM document (console)**

After you create the content for your custom SSM document, as described in [Writing SSM document content](#), you can use the Systems Manager console to create an SSM document using your content.

**To create an SSM document (console)**

2. In the navigation pane, choose **Documents**.
3. Choose **Create command or session**.
4. Enter a descriptive name for the document
5. (Optional) For **Target type**, specify the type of resources the document can run on.
6. In the **Document type** list, choose the type of document you want to create.
7. Delete the brackets in the **Content** field, and then paste the document content you created earlier.
8. (Optional) In the **Document tags** section, apply one or more tag key name/value pairs to the document.

    Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a document to identify the type of tasks it runs, the type of operating systems it targets, and the environment it runs in. In this case, you could specify the following key name/value pairs:

    - Key=TaskType, Value=MyConfigurationUpdate
    - Key=OS, Value=AMAZON_LINUX_2
    - Key=Environment, Value=Production

    For more information about tagging Systems Manager resources, see [Tagging Systems Manager resources](#).
9. Choose **Create document** to save the document.

### Create an SSM document (command line)

After you create the content for your custom AWS Systems Manager (SSM) document, as described in [Writing SSM document content](#), you can use the AWS Command Line Interface (AWS CLI) or AWS Tools for PowerShell to create an SSM document using your content. This is shown in the following command.

**Before you begin**

Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven’t already. For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

Run the following command. Replace each *example resource placeholder* with your own information.

**Linux & macOS**

```bash
aws ssm create-document \
--content file://path/to/file/documentContent.json \
--name "document-name" \
--document-type "Command" \
--tags "Key=tag-key,Value=tag-value"
```

**Windows**

```bash
aws ssm create-document ^
--content file://C:\path\to\file\documentContent.json ^
--name "document-name" ^
--document-type "Command" ^
--tags "Key=tag-key,Value=tag-value"
```

**PowerShell**

```powershell
$json = Get-Content -Path "C:\path\to\file\documentContent.json" | Out-String
New-SSMDocument `  
-Content $json `  
-Name "document-name" `  
```
If successful, the command returns a response similar to the following.

```json
{
    "DocumentDescription": {
        "CreatedDate": 1.585061751738E9,
        "DefaultVersion": "1",
        "Description": "MyCustomDocument",
        "DocumentFormat": "JSON",
        "DocumentType": "Command",
        "DocumentVersion": "1",
        "Hash": "0d3d879b3ca072e03c12638d0255ebd004d2c65bd318f8354fcde820dEXAMPLE",
        "HashType": "Sha256",
        "LatestVersion": "1",
        "Name": "Example",
        "Owner": "111122223333",
        "Parameters": [
            --truncated--
        ],
        "PlatformTypes": [
            "Windows",
            "Linux"
        ],
        "SchemaVersion": "0.3",
        "Status": "Creating",
        "Tags": [
            {
                "Key": "Purpose",
                "Value": "Test"
            }
        ]
    }
}
```

### Create an SSM document (API)

After you create the content for your custom AWS Systems Manager (SSM) document, as described in [Writing SSM document content](Writing_SSM_document_content), you can use your preferred SDK to call the AWS Systems Manager [CreateDocument](CreateDocument) API operation to create an SSM document using your content. The JSON
or YAML string for the Content request parameter is generally read from a file. The following sample functions create an SSM document using the SDKs for Python, Go, and Java.

Python

```python
import boto3

ssm = boto3.client('ssm')
filepath = '/path/to/file/documentContent.yaml'

def createDocumentApiExample():
    with open(filepath) as openFile:
        documentContent = openFile.read()
        createDocRequest = ssm.create_document(
            Content = documentContent,
            Name = 'createDocumentApiExample',
            DocumentType = 'Automation',
            DocumentFormat = 'YAML'
        )
        print(createDocRequest)

createDocumentApiExample()
```

Go

```go
package main

import (
    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/ssm"
    "fmt"
    "io/ioutil"
    "log"
)

func main() {
    openFile, err := ioutil.ReadFile("/path/to/file/documentContent.yaml")
    if err != nil {
```
log.Fatal(err)
}
documentContent := string(openFile)
sesh := session.Must(session.NewSessionWithOptions(session.Options{
    SharedConfigState: session.SharedConfigEnable}))

ssmClient := ssm.New(sesh)
createDocRequest, err := ssmClient.CreateDocument(&ssm.CreateDocumentInput{
    Content: &documentContent,
    Name:  aws.String("createDocumentApiExample"),
    DocumentType: aws.String("Automation"),
    DocumentFormat: aws.String("YAML"),
})
result := *createDocRequest
fmt.Println(result)

Java

import java.io.IOException;
import java.nio.charset.Charset;
import java.nio.charset.StandardCharsets;
import java.nio.file.Files;

    byte[] encoded = Files.readAllBytes(Paths.get(filepath));
    String documentContent = new String(encoded, StandardCharsets.UTF_8);
    return documentContent;
}

public static void createDocumentMethod (final String documentContent) {
    AWSSimpleSystemsManagement ssm =
    AWSSimpleSystemsManagementClientBuilder.defaultClient();
    final CreateDocumentRequest createDocRequest = new CreateDocumentRequest()
        .withContent(documentContent)
        .withName("createDocumentApiExample")
        .withDocumentType("Automation")
        .withDocumentFormat("YAML");
    final CreateDocumentResult result = ssm.createDocument(createDocRequest);
}

For more information about creating custom document content, see Data elements and parameters.

Deleting custom SSM documents

If you no longer want to use a custom SSM document, you can delete it by using either the AWS Command Line Interface (AWS CLI) or the AWS Systems Manager console.

To delete an SSM document (AWS CLI)

1. Before you delete the document, we recommend that you disassociate all instances that are associated with the document.

   Run the following command to disassociate an instance from a document.

   
   ```
   aws ssm delete-association --instance-id "123456789012" --name "documentName"
   ```

   There is no output if the command succeeds.

2. Run the following command. Replace each example resource placeholder with your own information.
To delete an SSM document (console)

2. In the navigation pane, choose Documents.
3. Select the document you want to delete.
4. Select Delete. When prompted to delete the document, select Delete.
Running documents from remote locations

You can run AWS Systems Manager (SSM) documents from remote locations by using the AWS-RunDocument pre-defined SSM document. This document supports running SSM documents stored in the following locations:

- Public and private GitHub repositories (GitHub Enterprise is not supported)
- Amazon S3 buckets
- Systems Manager

While you can also run remote documents by using State Manager or Automation, capabilities of AWS Systems Manager, the following procedure describes only how to run remote SSM documents by using AWS Systems Manager Run Command in the Systems Manager console.

⚠️ Note
AWS-RunDocument can be used to run only command-type SSM documents, not other types such as Automation runbooks. The AWS-RunDocument uses the `aws:downloadContent` plugin. For more information about the `aws:downloadContent` plugin, see [aws:downloadContent](https://docs.aws.amazon.com/systems-manager/latest/userguide/systems-manager-runcommand-ref-aws-runcommand.html).

Before you begin

Before you run a remote document, you must complete the following tasks.

- Create an SSM Command document and save it in a remote location. For more information, see [Creating SSM document content](https://docs.aws.amazon.com/systems-manager/latest/userguide/systems-manager-runcommand-ref-create-ssm-document.html).

- If you plan to run a remote document that is stored in a private GitHub repository, then you must create a Systems Manager SecureString parameter for your GitHub security access token. You can't access a remote document in a private GitHub repository by manually passing your token over SSH. The access token must be passed as a Systems Manager SecureString parameter. For more information about creating a SecureString parameter, see [Creating Systems Manager parameters](https://docs.aws.amazon.com/systems-manager/latest/userguide/systems-manager-runcommand-ref-create-ssm-parameter.html).
Run a remote document (console)

To run a remote document

2. In the navigation pane, choose Run Command.
3. Choose Run command.
5. In Command parameters, for Source Type, choose an option.
   - If you choose GitHub, specify Source Info information in the following format:

   ```json
   {
   "owner": "owner_name",
   "repository": "repository_name",
   "path": "path_to_document",
   "getOptions": "branch:branch_name",
   "tokenInfo": "{{ssm-secure:secure-string-token}}"
   }
   
   For example:

   ```json
   {
   "owner": "TestUser",
   "repository": "GitHubTestExamples",
   "path": "scripts/python/test-script",
   "getOptions": "branch:exampleBranch",
   "tokenInfo": "{{ssm-secure:my-secure-string-token}}"
   }
   ```

   **Note**

   getOptions are extra options to retrieve content from a branch other than master, or from a specific commit in the repository. getOptions can be omitted if you are using the latest commit in the master branch. The branch parameter is required only if your SSM document is stored in a branch other than master. To use the version of your SSM document in a particular commit in your repository, use commitID with getOptions instead of branch. For example:
If you choose S3, specify Source Info information in the following format:

```json
{"path":"URL_to_document_in_S3"}
```

For example:

```json
{"path":"https://s3.amazonaws.com/DOC-EXAMPLE-BUCKET/scripts/ruby/mySSMdoc.json"}
```

If you choose SSMDocument, specify Source Info information in the following format:

```json
{"name": "document_name"}
```

For example:

```json
{"name": "mySSMdoc"}
```

6. In the Document Parameters field, enter parameters for the remote SSM document. For example, if you run the AWS-RunPowerShell document, you could specify:

```json
{"commands": ["date", "echo \"Hello World\"]}
```

If you run the AWS-ConfigureAWSPack document, you could specify:

```json
{
   "action":"Install",
   "name":"AWSPVDriver"
}
```

7. In the Targets section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

Tip

If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.
8. For **Other parameters**:

- For **Comment**, enter information about this command.
- For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

9. For **Rate control**:

- For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

**Note**

If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren’t certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

10. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

**Note**

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.
11. In the SNS notifications section, if you want notifications sent about the status of the command execution, select the Enable SNS notifications check box.

For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

**Note**

For information about rebooting servers and instances when using Run Command to call scripts, see Handling reboots when running commands.

---

**Sharing SSM documents**

You can share AWS Systems Manager (SSM) documents privately or publicly with accounts in the same AWS Region. To privately share a document, you modify the document permissions and allow specific individuals to access it according to their AWS account ID. To publicly share an SSM document, you modify the document permissions and specify All. Documents can't be simultaneously shared publicly and privately.

**Warning**

Use shared SSM documents only from trusted sources. When using any shared document, carefully review the contents of the document before using it so that you understand how it will change the configuration of your instance. For more information about shared document best practices, see Best practices for shared SSM documents.

---

**Limitations**

As you begin working with SSM documents, be aware of the following limitations.

- Only the owner can share a document.
- You must stop sharing a document before you can delete it. For more information, see Modify permissions for a shared SSM document.
You can share a document with a maximum of 1000 AWS accounts. You can request an increase to this limit in the AWS Support Center. For Limit type, choose EC2 Systems Manager and describe your reason for the request.

You can publicly share a maximum of five SSM documents. You can request an increase to this limit in the AWS Support Center. For Limit type, choose EC2 Systems Manager and describe your reason for the request.

Documents can be shared with other accounts in the same AWS Region only. Cross-Region sharing isn’t supported.

For more information about Systems Manager service quotas, see AWS Systems Manager Service Quotas.

Contents

- Best practices for shared SSM documents
- Block public sharing for SSM documents
- Share an SSM document
- Modify permissions for a shared SSM document
- Using shared SSM documents

Best practices for shared SSM documents

Review the following guidelines before you share or use a shared document.

Remove sensitive information

Review your AWS Systems Manager (SSM) document carefully and remove any sensitive information. For example, verify that the document doesn't include your AWS credentials. If you share a document with specific individuals, those users can view the information in the document. If you share a document publicly, anyone can view the information in the document.

Block public sharing for documents

Unless your use case requires public sharing to be turned on, we recommend turning on the block public sharing setting for your Systems Manager documents in the Preferences section of the Systems Manager Documents console.
Restrict Run Command actions using an IAM trust policy

Create a restrictive AWS Identity and Access Management (IAM) policy for users who will have access to the document. The IAM policy determines which SSM documents a user can see in either the Amazon Elastic Compute Cloud (Amazon EC2) console or by calling ListDocuments using the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell. The policy also restricts the actions the user can perform with SSM documents. You can create a restrictive policy so that a user can only use specific documents. For more information, see Customer managed policy examples.

Use caution when using shared SSM documents

Review the contents of every document that is shared with you, especially public documents, to understand the commands that will be run on your instances. A document could intentionally or unintentionally have negative repercussions after it's run. If the document references an external network, review the external source before you use the document.

Send commands using the document hash

When you share a document, the system creates a Sha-256 hash and assigns it to the document. The system also saves a snapshot of the document content. When you send a command using a shared document, you can specify the hash in your command to ensure that the following conditions are true:

- You're running a command from the correct Systems Manager document
- The content of the document hasn't changed since it was shared with you.

If the hash doesn't match the specified document or if the content of the shared document has changed, the command returns an InvalidDocument exception. The hash can't verify document content from external locations.

Block public sharing for SSM documents

Unless your use case requires public sharing to be turned on, we recommend turning on the block public sharing setting for your AWS Systems Manager (SSM) documents. Turning on this setting prevents unwanted access to your SSM documents. The block public sharing setting is an account level setting that can differ for each AWS Region. Complete the following tasks to block public sharing for your SSM documents.
Block public sharing (console)

To block public sharing of your SSM documents

2. In the navigation pane, choose Documents.
3. Choose Preferences, and then choose Edit in the Block public sharing section.
4. Select the Block public sharing check box, and then choose Save.

Block public sharing (command line)

Open the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell on your local computer and run the following command to block public sharing of your SSM documents.

Linux & macOS

```bash
aws ssm update-service-setting  \
   --setting-id /ssm/documents/console/public-sharing-permission \
   --setting-value Disable \
   --region 'The AWS Region you want to block public sharing in'
```

Windows

```bash
aws ssm update-service-setting ^
   --setting-id /ssm/documents/console/public-sharing-permission ^
   --setting-value Disable ^
   --region "The AWS Region you want to block public sharing in"
```

PowerShell

```powershell
Update-SSMServiceSetting `  
   -SettingId /ssm/documents/console/public-sharing-permission `  
   -SettingValue Disable `  
   -Region The AWS Region you want to block public sharing in
```

Confirm the setting value was updated using the following command.
Restricting access to block public sharing with IAM

You can create AWS Identity and Access Management (IAM) policies that restrict users from modifying the block public sharing setting. This prevents users from allowing unwanted access to your SSM documents.

The following is an example of an IAM policy that prevents users from updating the block public sharing setting. To use this example, you must replace the example Amazon Web Services account ID with your own account ID.

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Deny",
        "Action": "ssm:UpdateServiceSetting",
    }
    ]
}
```
Share an SSM document

You can share AWS Systems Manager (SSM) documents by using the Systems Manager console. When sharing documents from the console, only the default version of the document can be shared. You can also share SSM documents programmatically by calling the ModifyDocumentPermission API operation using the AWS Command Line Interface (AWS CLI), AWS Tools for Windows PowerShell, or the AWS SDK. Before you share a document, get the AWS account IDs of the people with whom you want to share. You will specify these account IDs when you share the document.

Share a document (console)

2. In the navigation pane, choose Documents.
3. In the documents list, choose the document you want to share, and then choose View details. On the Permissions tab, verify that you're the document owner. Only a document owner can share a document.
4. Choose Edit.
5. To share the command publicly, choose Public and then choose Save. To share the command privately, choose Private, enter the AWS account ID, choose Add permission, and then choose Save.

Share a document (command line)

The following procedure requires that you specify an AWS Region for your command line session.

1. Open the AWS CLI or AWS Tools for Windows PowerShell on your local computer and run the following command to specify your credentials.

   In the following command, replace region with your own information. For a list of supported region values, see the Region column in Systems Manager service endpoints in the Amazon Web Services General Reference.

   **Linux & macOS**

   ```bash
   aws config
   ```
AWS Access Key ID: [your key]
AWS Secret Access Key: [your key]
Default region name: region
Default output format [None]:

Windows

aws config

AWS Access Key ID: [your key]
AWS Secret Access Key: [your key]
Default region name: region
Default output format [None]:

PowerShell

Set-AWSCredentials -AccessKey your key -SecretKey your key
Set-DefaultAWSRegion -Region region

2. Use the following command to list all of the SSM documents that are available for you. The list includes documents that you created and documents that were shared with you.

Linux & macOS

aws ssm list-documents

Windows

aws ssm list-documents

PowerShell

Get-SSMDocumentList

3. Use the following command to get a specific document.

Linux & macOS

aws ssm get-document \  
   --name document name
4. Use the following command to get a description of the document.

**Linux & macOS**

```
aws ssm describe-document \
  --name document name
```

**Windows**

```
aws ssm describe-document ^
  --name document name
```

**PowerShell**

```
Get-SSMDocumentDescription `\n  -Name document name
```

5. Use the following command to view the permissions for the document.

**Linux & macOS**

```
aws ssm describe-document-permission \
  --name document name \
  --permission-type Share
```

**Windows**

```
aws ssm describe-document-permission ^
  --name document name ^
```

Working with documents
6. Use the following command to modify the permissions for the document and share it. You must be the owner of the document to edit the permissions. Optionally, you can specify a version of the document you want to share using the `--shared-document-version` parameter. If you don't specify a version, the system shares the Default version of the document. This example command privately shares the document with a specific individual, based on that person's AWS account ID.

**Linux & macOS**

```bash
aws ssm modify-document-permission \
   --name document name \
   --permission-type Share \
   --account-ids-to-add AWS account ID
```

**Windows**

```bash
aws ssm modify-document-permission ^
   --name document name ^
   --permission-type Share ^
   --account-ids-to-add AWS account ID
```

**PowerShell**

```powershell
Edit-SSMDocumentPermission ` 
   -Name document name ` 
   -PermissionType Share ` 
   -AccountIdsToAdd AWS account ID
```

7. Use the following command to share a document publicly.

**Linux & macOS**

```bash
aws ssm modify-document-permission \
```

**PowerShell**

```powershell
Get-SSMDocumentPermission ` 
   -Name document name ` 
   -PermissionType Share
```
Modify permissions for a shared SSM document

If you share a command, users can view and use that command until you either remove access to the AWS Systems Manager (SSM) document or delete the SSM document. However, you can't delete a document as long as it's shared. You must stop sharing it first and then delete it.

Stop sharing a document (console)

Stop sharing a document

2. In the navigation pane, choose Documents.
3. In the documents list, choose the document you want to stop sharing, and then choose the Details. In the Permissions section, verify that you're the document owner. Only a document owner can stop sharing a document.
4. Choose Edit.
5. Choose X to delete the AWS account ID that should no longer have access to the command, and then choose Save.
Stop sharing a document (command line)

Open the AWS CLI or AWS Tools for Windows PowerShell on your local computer and run the following command to stop sharing a command.

Linux & macOS

```bash
aws ssm modify-document-permission
   --name document name
   --permission-type Share
   --account-ids-to-remove 'AWS account ID'
```

Windows

```bash
aws ssm modify-document-permission ^
   --name document name ^
   --permission-type Share ^
   --account-ids-to-remove "AWS account ID"
```

PowerShell

```bash
Edit-SSMDocumentPermission `
   -Name document name `
   -PermissionType Share `
   -AccountIdsToRemove AWS account ID
```

Using shared SSM documents

When you share an AWS Systems Manager (SSM) document, the system generates an Amazon Resource Name (ARN) and assigns it to the command. If you select and run a shared document from the Systems Manager console, you don't see the ARN. However, if you want to run a shared SSM document using a method other than the Systems Manager console, you must specify the full ARN of the document for the DocumentName request parameter. You're shown the full ARN for an SSM document when you run the command to list documents.

⚠️ Note

You aren't required to specify ARNs for AWS public documents (documents that begin with AWS-*) or documents that you own.
Use a shared SSM document (command line)

To list all public SSM documents

Linux & macOS

```bash
aws ssm list-documents \
   --filters Key=Owner,Values=Public
```

Windows

```bash
aws ssm list-documents ^
   --filters Key=Owner,Values=Public
```

PowerShell

```powershell
$filter.Key = "Owner"
$filter.Values = "Public"

Get-SSMDocumentList `  
   -Filters @{$filter}
```

To list private SSM documents that have been shared with you

Linux & macOS

```bash
aws ssm list-documents \
   --filters Key=Owner,Values=Private
```

Windows

```bash
aws ssm list-documents ^
   --filters Key=Owner,Values=Private
```

PowerShell

```powershell
$filter.Key = "Owner"
```
To list all SSM documents available to you

Linux & macOS

aws ssm list-documents

Windows

aws ssm list-documents

PowerShell

Get-SSMDocumentList

To get information about an SSM document that has been shared with you

Linux & macOS

aws ssm describe-document

Windows

aws ssm describe-document

PowerShell

Get-SSMDocumentDescription

To run a shared SSM document
Linux & macOS

```
aws ssm send-command \
  --instance-ids ID
```

Windows

```
aws ssm send-command ^
  --instance-ids ID
```

PowerShell

```
Send-SSMCommand `  
  -InstanceIds ID
```

Searching for SSM documents

You can search the AWS Systems Manager (SSM) document store for SSM documents by using either free text search or a filter-based search. You can also favorite documents to help you find frequently used SSM documents. The following sections describes how to use these features.

**Using free text search**

The search box on the Systems Manager Documents page supports free text search. Free text search compares the search term or terms that you enter against the document name in each SSM document. If you enter a single search term, for example `ansible`, then Systems Manager returns all SSM documents where this term was discovered. If you enter multiple search terms, then Systems Manager searches by using an OR statement. For example, if you specify `ansible` and `linux`, then search returns all documents with either keyword in their name.

If you enter a free text search term and choose a search option, such as Platform type, then search uses an AND statement and returns all documents with the keyword in their name and the specified platform type.

**Note**

Note the following details about free text search.
Free text search is not case sensitive.

- Search terms require a minimum of three characters and have a maximum of 20 characters.
- Free text search accepts up to five search terms.
- If you enter a space between search terms, the system includes the space when searching.
- You can combine free text search with other search options such as Document type or Platform type.
- The Document Name Prefix filter and free text search can't be used together. They're mutually exclusive.

To search for an SSM document

2. In the navigation pane, choose Documents.
3. Enter your search terms in the search box, and press Enter.

Performing free text document search by using the AWS CLI

To perform a free text document search by using the CLI

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.
   For information, see Installing or updating the latest version of the AWS CLI.
2. To perform free text document search with a single term, run the following command. In this command, replace search_term with your own information.

   ```bash
   aws ssm list-documents --filters Key="SearchKeyword",Values="search_term"
   
   Here's an example.
   
   aws ssm list-documents --filters Key="SearchKeyword",Values="aws-asg" --region us-east-2
   ```
To search using multiple terms that create an AND statement, run the following command. In this command, replace `search_term_1` and `search_term_2` with your own information.

```
aws ssm list-documents --filters
  Key="SearchKeyword",Values="search_term_1","search_term_2","search_term_3" --region us-east-2
```

Here's an example.

```
aws ssm list-documents --filters Key="SearchKeyword",Values="aws-asg","aws-ec2","restart" --region us-east-2
```

**Using filters**

The Systems Manager **Documents** page automatically displays the following filters when you choose the search box.

- Document name prefix
- Platform types
- Document type
- Tag key
You can search for SSM documents by using a single filter. If you want to return a more specific set of SSM documents, you can apply multiple filters. Here is an example of a search that uses the **Platform types** and the **Document name prefix** filters.

If you apply multiple filters, Systems Manager creates different search statements based on the filters you choose:

- If you apply the *same* filter multiple times, for example **Document name prefix**, then Systems Manager searches by using an OR statement. For example, if you specify one filter of **Document name prefix=AWS** and a second filter of **Document name prefix=Lambda**, then search returns all documents with the prefix "AWS" and all documents with the prefix "Lambda".

- If you apply *different* filters, for example **Document name prefix** and **Platform types**, then Systems Manager searches by using an AND statement. For example, if you specify a **Document name prefix=AWS** filter and a **Platform types=Linux** filter, then search returns all documents with the prefix "AWS" that are specific to the Linux platform.

**Note**

Searches that use filters are case sensitive.

**Adding documents to your favorites**

To help you find frequently used SSM documents, add documents to your favorites. You can favorite up to 20 documents per document type, per AWS account and AWS Region. You can choose, modify, and view your favorites from the documents AWS Management Console. The following procedures describe how to choose, modify, and view your favorites.
To favorite an SSM document

2. In the navigation pane, choose Documents.
3. Select the star icon next to the document name you want to favorite.

To remove an SSM document from your favorites

2. In the navigation pane, choose Documents.
3. Deselect the star icon next to the document name you want to remove from your favorites.

To view your favorites from the documents AWS Management Console

2. In the navigation pane, choose Documents.
3. Select the Favorites tab.
Security in AWS Systems Manager

Cloud security at Amazon Web Services is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to AWS Systems Manager, see AWS services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You're also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using AWS Systems Manager. The following topics show you how to configure Systems Manager to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Systems Manager resources.

**Topics**

- Data protection in AWS Systems Manager
- Identity and access management for AWS Systems Manager
- Using service-linked roles for Systems Manager
- Logging and monitoring in AWS Systems Manager
- Compliance validation for AWS Systems Manager
- Resilience in AWS Systems Manager
- Infrastructure security in AWS Systems Manager
- Configuration and vulnerability analysis in AWS Systems Manager
- Security best practices for Systems Manager
Data protection in AWS Systems Manager

Data protection refers to protecting data while *in transit* (as it travels to and from Systems Manager) and *at rest* (while it's stored in AWS data centers).

The AWS **shared responsibility model** applies to data protection in AWS Systems Manager. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the [Data Privacy FAQ](#). For information about data protection in Europe, see the [AWS Shared Responsibility Model and GDPR](#) blog post on the [AWS Security Blog](#).

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard (FIPS) 140-2](#).

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Systems Manager or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.
Data encryption

Encryption at rest

Parameter Store parameters

The types of parameters you can create in Parameter Store, a capability of AWS Systems Manager, include String, StringList, and SecureString.

To encrypt SecureString parameter values, Parameter Store uses an AWS KMS key in AWS Key Management Service (AWS KMS). AWS KMS uses either a customer managed key or an AWS managed key to encrypt the parameter value in an AWS managed database.

⚠️ Important

Don't store sensitive data in a String or StringList parameter. For all sensitive data that must remain encrypted, use only the SecureString parameter type.

For more information, see What is a parameter? and Restricting access to Systems Manager parameters using IAM policies.

Content in S3 buckets

As part of your Systems Manager operations, you might choose to upload or store data in one or more Amazon Simple Storage Service (Amazon S3) buckets.

For information about S3 bucket encryption, see Protecting data using encryption and Data protection in Amazon S3 in the Amazon Simple Storage Service User Guide.

The following are types of data you can upload or have stored in S3 buckets as part of your Systems Manager activities:

- The output of commands in Run Command, a capability of AWS Systems Manager
- Packages in Distributor, a capability of AWS Systems Manager
- Patching operation logs in Patch Manager, a capability of AWS Systems Manager
- Patch Manager patch override lists
- Scripts or Ansible Playbooks to run in a runbook workflow in Automation, a capability of AWS Systems Manager
• Chef InSpec profiles for use with scans in Compliance, a capability of AWS Systems Manager
• AWS CloudTrail logs
• Session history logs in Session Manager, a capability of AWS Systems Manager
• Reports from Explorer, a capability of AWS Systems Manager
• OpsData from OpsCenter, a capability of AWS Systems Manager
• AWS CloudFormation templates for use with Automation workflows
• Compliance data from a resource data sync scan
• Output of requests to create or edit association in State Manager, a capability of AWS Systems Manager, on managed nodes
• Custom Systems Manager documents (SSM documents) that you can run using the AWS managed SSM document AWS-RunDocument

CloudWatch Logs log groups

As part of your Systems Manager operations, you might choose to stream data to one or more Amazon CloudWatch Logs log groups.

For information about CloudWatch Logs log group encryption, see Encrypt log data in CloudWatch Logs using AWS Key Management Service in the Amazon CloudWatch Logs User Guide.

The following are types of data you might have streamed to a CloudWatch Logs log group as part of your Systems Manager activities:

• The output of Run Command commands
• The output of scripts run using the aws:executeScript action in an Automation runbook
• Session Manager session history logs
• Logs from SSM Agent on your managed nodes

Encryption in transit

We recommend that you use an encryption protocol such as Transport Layer Security (TLS) to encrypt sensitive data in transit between clients and your nodes.

Systems Manager provides the following support for encryption of your data in transit.
Connections to Systems Manager API endpoints

Systems Manager API endpoints only support secure connections over HTTPS. When you manage Systems Manager resources with the AWS Management Console, AWS SDK, or the Systems Manager API, all communication is encrypted with Transport Layer Security (TLS). For a full list of API endpoints, see AWS service endpoints in the Amazon Web Services General Reference.

Managed instances

AWS provides secure and private connectivity between Amazon Elastic Compute Cloud (Amazon EC2) instances. In addition, we automatically encrypt in-transit traffic between supported instances in the same virtual private cloud (VPC) or in peered VPCs, using AEAD algorithms with 256-bit encryption. This encryption feature uses the offload capabilities of the underlying hardware, and there is no impact on network performance. The supported instances are: C5n, G4, I3en, M5dn, M5n, P3dn, R5dn, and R5n.

Session Manager sessions

By default, Session Manager uses TLS 1.2 to encrypt session data transmitted between the local machines of users in your account and your EC2 instances. You can also choose to further encrypt the data in transit using an AWS KMS key that has been created in AWS KMS. AWS KMS encryption is available for Standard Steam, InteractiveCommands, and NonInteractiveCommands session types.

Run Command access

By default, remote access to your nodes using Run Command is encrypted using TLS 1.2, and requests to create a connection are signed using SigV4.

Internetwork traffic privacy

You can use Amazon Virtual Private Cloud (Amazon VPC) to create boundaries between resources in your managed nodes and control traffic between them, your on-premises network, and the internet. For details, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

For more information about Amazon Virtual Private Cloud security, see Internetwork traffic privacy in Amazon VPC in the Amazon VPC User Guide.
Identity and access management for AWS Systems Manager

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Systems Manager resources. IAM is an AWS service that you can use with no additional charge.

**Topics**

- Audience
- Authenticating with identities
- Managing access using policies
- How AWS Systems Manager works with IAM
- AWS Systems Manager identity-based policy examples
- AWS managed policies for AWS Systems Manager
- Troubleshooting AWS Systems Manager identity and access

**Audience**

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in Systems Manager.

**Service user** – If you use the Systems Manager service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Systems Manager features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Systems Manager, see [Troubleshooting AWS Systems Manager identity and access](#).

**Service administrator** – If you're in charge of Systems Manager resources at your company, you probably have full access to Systems Manager. It's your job to determine which Systems Manager features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Systems Manager, see [How AWS Systems Manager works with IAM](#).

**IAM administrator** – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to Systems Manager. To view example Systems Manager...
identity-based policies that you can use in IAM, see AWS Systems Manager identity-based policy examples.

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the AWS Sign-In User Guide.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the IAM User Guide.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the AWS IAM Identity Center User Guide and Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the IAM User Guide.
IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can’t sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center User Guide.

- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.
• **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](https://docs.aws.amazon.com/IAM/latest/UserGuide) in the IAM User Guide.

• **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

• **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](https://docs.aws.amazon.com/IAM/latest/UserGuide).

• **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](https://docs.aws.amazon.com/IAM/latest/UserGuide) in the IAM User Guide.

• **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](https://docs.aws.amazon.com/IAM/latest/UserGuide) in the IAM User Guide.
To learn whether to use IAM roles or IAM users, see When to create an IAM role (instead of a user) in the IAM User Guide.

**Managing access using policies**

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the iam:GetRole action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

**Identity-based policies**

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

For information about AWS managed policies for Systems Manager, see AWS Systems Manager managed policies.
Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can’t use AWS managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the Amazon Simple Storage Service Developer Guide.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- Permissions boundaries – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- Service control policies (SCPs) – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If
you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](https://docs.aws.amazon.com/organizations/latest/userguide/orgs_user_guide.html) in the *AWS Organizations User Guide*.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](https://docs.aws.amazon.com/IAM/latest/UserGuide/id-policies-session-profiling.html) in the *IAM User Guide*.

### Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](https://docs.aws.amazon.com/IAM/latest/UserGuide/id-policies-logical-statement-eval.html) in the *IAM User Guide*.

### How AWS Systems Manager works with IAM

Before you use AWS Identity and Access Management (IAM) to manage access to AWS Systems Manager, you should understand what IAM features are available to use with Systems Manager. To get a high-level view of how Systems Manager and other AWS services work with IAM, see [AWS services that work with IAM](https://docs.aws.amazon.com/IAM/latest/UserGuide/list_aws-services.html) in the *IAM User Guide*.

#### Topics

- **Authorization based on Systems Manager tags**
- **Systems Manager IAM roles**

### Systems Manager identity-based policies

With IAM identity-based policies, you can specify allowed or denied actions and resources and the conditions under which actions are allowed or denied. Systems Manager supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see [IAM JSON policy elements reference](https://docs.aws.amazon.com/IAM/latest/UserGuide/reference_iam-policies-elements.html) in the *IAM User Guide*.
Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Systems Manager use the following prefix before the action: ssm:. For example, to grant someone permission to create a Systems Manager parameter (SSM parameter) with the Systems Manager PutParameter API operation, you include the ssm:PutParameter action in their policy. Policy statements must include either an Action or NotAction element. Systems Manager defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": [
  "ssm:action1",
  "ssm:action2"
]
```

⚠️ Note

The following capabilities of AWS Systems Manager use different prefixes before actions.

- AWS AppConfig uses the prefix appconfig: before actions.
- Incident Manager uses the prefix ssm-incidents: or ssm-contacts: before actions.
- Systems Manager GUI Connect uses the prefix ssm-guiconnect before actions.

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "ssm:Describe***"
```
To see a list of Systems Manager actions, see Actions Defined by AWS Systems Manager in the Service Authorization Reference.

Resources

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

"Resource": "*"

For example, the Systems Manager maintenance window resource has the following ARN format.

```
arn:aws:ssm:region:account-id:maintenancewindow/window-id
```

To specify the mw-0c50858d01EXAMPLE maintenance windows in your statement in the US East (Ohio) Region, you would use an ARN similar to the following.

"Resource": "arn:aws:ssm:us-east-2:123456789012:maintenancewindow/mw-0c50858d01EXAMPLE"

To specify all maintenance windows that belong to a specific account, use the wildcard (*).

For Parameter Store API operations, you can provide or restrict access to all parameters in one level of a hierarchy by using hierarchical names and AWS Identity and Access Management (IAM) policies as follows.

Some Systems Manager actions, such as those for creating resources, can't be performed on a specific resource. In those cases, you must use the wildcard (*).

"Resource": "*"

Some Systems Manager API operations accept multiple resources. To specify multiple resources in a single statement, separate their ARNs with commas as follows.

"Resource": [
  "resource1",
  "resource2"
]

**Note**

Most AWS services treat a colon (:) or a forward slash (/) as the same character in ARNs. However, Systems Manager requires an exact match in resource patterns and rules. When creating event patterns, be sure to use the correct ARN characters so that they match the resource's ARN.

The table below describes the ARN formats for the resource types supported by Systems Manager.

**Note**

Note the following exceptions to ARN formats.

- The following capabilities of AWS Systems Manager use different prefixes before actions.
  - AWS AppConfig uses the prefix `appconfig:` before actions.
  - Incident Manager uses the prefix `ssm-incidents:` or `ssm-contacts:` before actions.
  - Systems Manager GUI Connect uses the prefix `ssm-guiconnect` before actions.
- Documents and automation definition resources that are owned by Amazon, as well as public parameters that are provided by both Amazon and third-party sources, do not include account IDs in their ARN formats. For example:
  - The SSM document `AWS-RunPatchBaseline`:
    
    arn:aws:ssm:us-east-2:::document/AWS-RunPatchBaseline
The automation runbook `AWS-ConfigureMaintenanceWindows`:

```
```

The public parameter `/aws/service/bottlerocket/aws-ecs-1-nvidia/x86_64/1.13.4/image_version`:

```
arn:aws:ssm:us-east-2:::parameter/aws/service/bottlerocket/aws-ecs-1-nvidia/x86_64/1.13.4/image_version
```

For more information about these three resource types, see the following topics:

- [Working with documents](#)
- [Running automations](#)
- [Working with public parameters](#)

### Resource type | ARN format
<p>|:----------------|-------------------------------------------------------|
| Application (AWS AppConfig) | <code>arn:aws:appconfig:region:account-id :application/application-id</code> |
| Association | <code>arn:aws:ssm:region:account-id :association/association-id</code> |
| Contact (Incident Manager) | <code>arn:aws:ssm-contacts:region:account-id :contact/contact-alias</code> |</p>
<table>

</tbody>
</table>

1. For automation definitions, Systems Manager supports a second-level resource, *version ID*. In AWS, these second-level resources are known as *subresources*. Specifying a version subresource for an automation definition resource allows you to provide access to certain versions of an automation definition. For example, you might want to ensure that only the latest version of an automation definition is used in your node management.

2. To organize and manage parameters, you can create names for parameters with a hierarchical construction. With hierarchical construction, a parameter name can include a path that you define by using forward slashes. You can name a parameter resource with a maximum of fifteen levels. We suggest that you create hierarchies that reflect an existing hierarchical structure in your environment. For more information, see [Creating Systems Manager parameters](#).

3. In most cases, the session ID is constructed using the ID of the account user who started the session, plus an alphanumeric suffix. For example:

   `arn:aws:us-east-2:111122223333:session/JohnDoe-1a2b3c4sEXAMPLE`
However, if the user ID isn't available, the ARN is constructed this way instead:

```
arn:aws:us-east-2:111122223333:session/session-1a2b3c4sEXAMPLE
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) in the Amazon Web Services General Reference.

For a list of Systems Manager resource types and their ARNs, see Resources Defined by AWS Systems Manager in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by AWS Systems Manager.

### Condition keys for Systems Manager

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

To see a list of Systems Manager condition keys, see Condition Keys for AWS Systems Manager in the Service Authorization Reference. To learn with which actions and resources you can use a condition key, see Actions Defined by AWS Systems Manager.

For information about using the `ssm:resourceTag/*` condition key, see the following topics:

- Restricting access to root-level commands through SSM Agent
Restricting Run Command access based on tags

Restrict session access based on instance tags

For information about using the `ssm:Recursive` and `ssm:Overwrite` condition keys, see Working with parameter hierarchies.

Examples

To view examples of Systems Manager identity-based policies, see AWS Systems Manager identity-based policy examples.

Systems Manager resource-based policies

Other AWS services, such as Amazon Simple Storage Service (Amazon S3), support resource-based permissions policies. For example, you can attach a permissions policy to an S3 bucket to manage access permissions to that bucket.

Systems Manager doesn’t support resource-based policies.

Authorization based on Systems Manager tags

You can attach tags to Systems Manager resources or pass tags in a request to Systems Manager. To control access based on tags, you provide tag information in the condition element of a policy using the `ssm:resourceTag/key-name`, `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys. You can add tags to the following resource types when you create or update them:

- Document
- Managed node
- Maintenance window
- Parameter
- Patch baseline
- OpsItem

For information about tagging Systems Manager resources, see Tagging Systems Manager resources.
To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see [Viewing Systems Manager documents based on tags](#).

**Systems Manager IAM roles**

An [IAM role](#) is an entity within your AWS account that has specific permissions.

**Using temporary credentials with Systems Manager**

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS Security Token Service (AWS STS) API operations such as [AssumeRole](#) or [GetFederationToken](#).

Systems Manager supports using temporary credentials.

**Service-linked roles**

[Service-linked roles](#) allow AWS services to access resources in other services to complete an action on your behalf. Service-linked roles are listed in your IAM account and are owned by the service. An administrator can view but not edit the permissions for service-linked roles.

Systems Manager supports service-linked roles. For details about creating or managing Systems Manager service-linked roles, see [Using service-linked roles for Systems Manager](#).

**Service roles**

This feature allows a service to assume a [service role](#) on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles are displayed in your IAM account and are owned by the account. This means that an administrator can change the permissions for this role. However, doing so might break the functionality of the service.

Systems Manager supports service roles.

**Choosing an IAM role in Systems Manager**

For Systems Manager to interact with your managed nodes, you must choose a role to allow Systems Manager to access nodes on your behalf. If you have previously created a service role or service-linked role, then Systems Manager provides you with a list of roles to choose from. It's important to choose a role that allows access to start and stop managed nodes.

To access EC2 instances, you must configure instance permissions. For information, see [Configure instance permissions required for Systems Manager](#).
To access non-EC2 nodes in a **hybrid and multicloud**, the role your AWS account needs is an IAM service role. For information, see [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#).

An Automation workflow can be initiated under the context of a service role (or assume role). This allows the service to perform actions on your behalf. If you don't specify an assume role, Automation uses the context of the user who invoked the execution. However, certain situations require that you specify a service role for Automation. For more information, see [Configuring a service role (assume role) access for automations](#).

**AWS Systems Manager managed policies**

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS *managed policies* grant necessary permissions for common use cases so you can avoid having to investigate which permissions are needed. (You can also create your own custom IAM policies to allow permissions for Systems Manager actions and resources.)

For more information about managed policies for Systems Manager, see [AWS managed policies for AWS Systems Manager](#)

For general information about managed policies, see [AWS managed policies](#) in the *IAM User Guide*.

**AWS Systems Manager identity-based policy examples**

By default, AWS Identity and Access Management (IAM) entities (users and roles) don't have permission to create or modify AWS Systems Manager resources. They also can't perform tasks using the Systems Manager console, AWS Command Line Interface (AWS CLI), or AWS API. An administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the users or groups that require those permissions.

The following is an example of a permissions policy that allows a user to delete documents with names that begin with *MyDocument* in the US East (Ohio) (us-east-2) AWS Region.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```
To learn how to create an IAM identity-based policy using these example JSON Policy documents, see Creating IAM policies in the IAM User Guide.

- Viewing Systems Manager documents based on tags

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Systems Manager resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- Get started with AWS managed policies and move toward least-privilege permissions – To get started granting permissions to your users and workloads, use the AWS managed policies that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the IAM User Guide.

- Apply least-privilege permissions – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the IAM User Guide.
Use conditions in IAM policies to further restrict access – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the IAM User Guide.

Require multi-factor authentication (MFA) – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the IAM User Guide.

For more information about best practices in IAM, see Security best practices in IAM in the IAM User Guide.

Using the Systems Manager console

To access the Systems Manager console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Systems Manager resources and other resources in your AWS account.

To fully use Systems Manager in the Systems Manager console, you must have permissions from the following services:

- AWS Systems Manager
- Amazon Elastic Compute Cloud (Amazon EC2)
- AWS Identity and Access Management (IAM)

You can grant the required permissions with the following policy statement.

```json
{
    "Version": "2012-10-17",
    "Statement": [
```
If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for IAM entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

**Allow users to view their own permissions**

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.
Cross-service confused deputy prevention

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies to limit the permissions that AWS Systems Manager gives another service to the resource. If the `aws:SourceArn` value does not contain the account ID, such as an Amazon Resource Name (ARN) for an S3 bucket, you must use both global
condition context keys to limit permissions. If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

The following sections provide example policies for AWS Systems Manager capabilities.

**Hybrid activation policy example**

For service roles used in a [hybrid activation](https://aws.amazon.com/about-aws/whats-new/), the value of `aws:SourceArn` must be the ARN of the AWS account. Be sure to specify the AWS Region in the ARN where you created your hybrid activation. If you don't know the full ARN of the resource or if you're specifying multiple resources, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. For example, `arn:aws:ssm::*:region:123456789012::*`.

The following example demonstrates using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys for Automation to prevent the confused deputy problem in the US East (Ohio) Region (us-east-2).

```json
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"
            "Effect":"Allow",
            "Principal":{
                "Service":"ssm.amazonaws.com"
            },
            "Action":"sts:AssumeRole",
            "Condition":{
                "StringEquals":{
                    "aws:SourceAccount":"123456789012"
                },
                "ArnEquals":{
                }
            }
        }
    ]
}
```
Resource data sync policy example

Systems Manager Inventory, Explorer, and Compliance enable you to create a resource data sync to centralize storage of your operations data (OpsData) in a central Amazon Simple Storage Service bucket. If you want to encrypt a resource data sync by using AWS Key Management Service (AWS KMS), then you must either create a new key that includes the following policy, or you must update an existing key and add this policy to it. The `aws:SourceArn` and `aws:SourceAccount` condition keys in this policy prevent the confused deputy problem. Here is an example policy.

```
{
  "Version": "2012-10-17",
  "Id": "ssm-access-policy",
  "Statement": [
    {
      "Sid": "ssm-access-policy-statement",
      "Action": [
        "kms:GenerateDataKey"
      ],
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Condition": {
        "StringLike": {
          "aws:SourceAccount": "123456789012"
        },
        "ArnLike": {
          "aws:SourceArn": "arn:aws:ssm:*:123456789012:role/aws-service-role/ssm.amazonaws.com/AWSServiceRoleForAmazonSSM"
        }
      }
    }
  ]
}
```

**Note**

The ARN in the policy example enables the system to encrypt OpsData from all sources except AWS Security Hub. If you need to encrypt Security Hub data, for example if you
use Explorer to collect Security Hub data, then you must attach an additional policy that specifies the following ARN:

"aws:SourceArn": "arn:aws:ssm:*:account-id:role/aws-service-role/opsdatasync.ssm.amazonaws.com/AWSServiceRoleForSystemsManagerOpsDataSync"

Customer managed policy examples

You can create standalone policies that you administer in your own AWS account. We refer to these as customer managed policies. You can attach these policies to multiple principal entities in your AWS account. When you attach a policy to a principal entity, you give the entity the permissions that are defined in the policy. For more information, see Customer managed policy examples in the IAM User Guide.

The following examples of user policies grant permissions for various Systems Manager actions. Use them to limit the Systems Manager access for your IAM entities (users and roles). These policies work when performing actions in the Systems Manager API, AWS SDKs, or the AWS CLI. For users who use the console, you need to grant additional permissions specific to the console. For more information, see Using the Systems Manager console.

Note

All examples use the US West (Oregon) Region (us-west-2) and contain fictitious account IDs. The account ID shouldn't be specified in the Amazon Resource Name (ARN) for AWS public documents (documents that begin with AWS-*).

Examples

- Example 1: Allow a user to perform Systems Manager operations in a single Region
- Example 2: Allow a user to list documents for a single Region

Example 1: Allow a user to perform Systems Manager operations in a single Region

The following example grants permissions to perform Systems Manager operations only in the US East (Ohio) Region (us-east-2).
Example 2: Allow a user to list documents for a single Region

The following example grants permissions to list all document names that begin with Update in the US East (Ohio) Region (us-east-2).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:*"
            ],
            "Resource": [
            ]
        }
    ]
}
```

Example 3: Allow a user to use a specific SSM document to run commands on specific nodes

The following example IAM policy allows a user to do the following in the US East (Ohio) Region (us-east-2):

- List Systems Manager documents (SSM documents) and document versions.
- View details about documents.
AWS Systems Manager User Guide

• Send a command using the document specified in the policy. The name of the document is determined by the following entry.

```
```

• Send a command to three nodes. The nodes are determined by the following entries in the second Resource section.

```
"arn:aws:ec2:us-east-2:aws-account-ID:instance/i-07782c72faEXAMPLE"
```

• View details about a command after it has been sent.

• Start and stop workflows in Automation, a capability of AWS Systems Manager.

• Get information about Automation workflows.

If you want to give a user permission to use this document to send commands on any node for which the user has access, you could specify an entry similar to the following in the Resource section and remove the other node entries. The following example uses the US East (Ohio) Region (us-east-2).

```
"arn:aws:ec2:us-east-2:*:instance/*"
```

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "ssm:ListDocuments",
            "ssm:ListDocumentVersions",
            "ssm:DescribeDocument",
            "ssm:GetDocument",
            "ssm:DescribeInstanceInformation",
            "ssm:DescribeDocumentParameters",
            "ssm:DescribeInstanceProperties"
         ],
         "Effect": "Allow",
         "Resource": "*
      },
   
      // Other rules...
   
      {
```
"Action": "ssm:SendCommand",
"Effect": "Allow",
"Resource": [
  "arn:aws:ec2:us-east-2:aws-account-ID:instance/i-07782c72faEXAMPLE",
],
]
[
  {
    "Action": [  
      "ssm:CancelCommand",
      "ssm:ListCommands",
      "ssm:ListCommandInvocations"
    ],
    "Effect": "Allow",
    "Resource": "*"
  },
  {
    "Action": "ec2:DescribeInstanceStatus",
    "Effect": "Allow",
    "Resource": "*"
  },
  {
    "Action": "ssm:StartAutomationExecution",
    "Effect": "Allow",
    "Resource": [
    ]
  },
  {
    "Action": "ssm:DescribeAutomationExecutions",
    "Effect": "Allow",
    "Resource": [  
      "*"
    ]
  },
  {
    "Action": [  
      "ssm:StopAutomationExecution",
      "ssm:GetAutomationExecution"
    ]
  },
]
Viewing Systems Manager documents based on tags

You can use conditions in your identity-based policy to control access to Systems Manager resources based on tags. This example shows how you might create a policy that allows viewing an SSM document. However, permission is granted only if the document tag `Owner` has the value of that user's user name. This policy also grants the permissions necessary to complete this action on the console.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ListDocumentsInConsole",
            "Effect": "Allow",
            "Action": "ssm:ListDocuments",
            "Resource": "*"
        },
        {
            "Sid": "ViewDocumentIfOwner",
            "Effect": "Allow",
            "Action": "ssm:GetDocument",
            "Resource": "arn:aws:ssm:*:*:document/*",
            "Condition": {
                "StringEquals": {"ssm:ResourceTag/Owner": "${aws:username}"}
            }
        }
    ]
}
```

You can attach this policy to the users in your account. If a user named `richard-roe` attempts to view an Systems Manager document, the document must be tagged `Owner=richard-roe` or `owner=richard-roe`. Otherwise they're denied access. The condition tag key `Owner` matches
both Owner and owner because condition key names aren't case-sensitive. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

**AWS managed policies for AWS Systems Manager**

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the IAM User Guide.

**AWS managed policy: AmazonSSMServiceRolePolicy**

You can't attach AmazonSSMServiceRolePolicy to your AWS Identity and Access Management (IAM) entities. This policy is attached to a service-linked role that allows AWS Systems Manager to perform actions on your behalf. For more information, see Using roles to collect inventory and view OpsData.

AmazonSSMServiceRolePolicy allows Systems Manager to complete the following actions on all related resources ("Resource": "*"), except where indicated:

- ssm:CancelCommand
- ssm:GetCommand Invocation
- `ssm:ListCommandInvocations`
- `ssm:ListCommands`
- `ssm:SendCommand`
- `ssm:GetAutomationExecution`
- `ssm:GetParameters`
- `ssm:StartAutomationExecution`
- `ssm:StopAutomationExecution`
- `ssm:ListTagsForResource`
- `ssm:GetCalendarState`
- `ssm:UpdateServiceSetting` [1]
- `ssm:GetServiceSetting` [1]
- `ec2:DescribeInstanceAttribute`
- `ec2:DescribeInstanceStatus`
- `ec2:DescribeInstances`
- `lambda:InvokeFunction` [2]
- `states:DescribeExecution` [3]
- `states:StartExecution` [3]
- `resource-groups:ListGroupResources`
- `resource-groups:ListGroupGroups`
- `resource-groups:GetGroupQuery`
- `tag:GetResources`
- `config:SelectResourceConfig`
- `config:DescribeComplianceByConfigRule`
- `config:DescribeComplianceByResource`
- `config:DescribeRemediationConfigurations`
- `config:DescribeConfigurationRecorders`
- `cloudwatch:DescribeAlarms`
- `compute-optimizer:GetEC2InstanceRecommendations`
- `compute-optimizer:GetEnrollmentStatus`
• support:DescribeTrustedAdvisorChecks
• support:DescribeTrustedAdvisorCheckSummaries
• support:DescribeTrustedAdvisorCheckResult
• support:DescribeCases
• iam:PassRole [4]
• cloudformation:DescribeStacks
• cloudformation:ListStackResources
• cloudformation:ListStackInstances [5]
• cloudformation:DescribeStackSetOperation [5]
• cloudformation:DeleteStackSet [5]
• cloudformation:DeleteStackInstances [6]
• events:PutRule [7]
• events:PutTargets [7]
• events:RemoveTargets [8]
• events:DeleteRule [8]
• events:DescribeRule
• securityhub:DescribeHub

[1] The ssm:UpdateServiceSetting and ssm:GetServiceSetting actions are allowed permissions for the following resources only.

    arn:aws:ssm:*:*:servicesetting/ssm/opsitem/*
    arn:aws:ssm:*:*:servicesetting/ssm/opsdata/*

[2] The lambda:InvokeFunction action is allowed permissions for the following resources only.

    arn:aws:lambda:*:*:function:SSM*
    arn:aws:lambda:*:*:function:*:SSM*

[3] The states: actions are allowed permissions on the following resources only.

    arn:aws:states:*:*:stateMachine:SSM*
    arn:aws:states:*:*:execution:SSM*
[4] The `iam:PassRole` action is allowed permissions by the following condition for the Systems Manager service only.

```json
"Condition": {
    "StringEquals": {
        "iam:PassedToService": ["ssm.amazonaws.com"]
    }
}
```

[5] The `cloudformation:ListStackInstances`, `cloudformation:DescribeStackSetOperation`, and `cloudformation:DeleteStackSet` actions are allowed permissions on the following resource only.

```text
arn:aws:cloudformation::*::*:stackset/AWS-QuickSetup-SSM::*
```

[6] The `cloudformation:DeleteStackInstances` action is allowed permissions on the following resources only.

```text
arn:aws:cloudformation::*::*:stackset/AWS-QuickSetup-SSM::*
arn:aws:cloudformation::*::*:stackset-target/AWS-QuickSetup-SSM::*
arn:aws:cloudformation::*::*:type/resource/*
```

[7] The `events:PutRule` and `events:PutTargets` actions are allowed permissions by the following condition for the Systems Manager service only.

```json
"Condition": {
    "StringEquals": {
        "events:ManagedBy": "ssm.amazonaws.com"
    }
}
```

[8] The `events:RemoveTargets` and `events:DeleteRule` actions are allowed permissions on the following resource only.

```text
arn:aws:events::*::*:rule/SSMExplorerManagedRule
```

To view more details about the policy, including the latest version of the JSON policy document, see [AmazonSSMServiceRolePolicy](https://docs.aws.amazon.com/AWSManagedPolicies/latest/reference/AmazonSSMServiceRolePolicy.html) in the *AWS Managed Policy Reference Guide*. 

AWS managed policies

2258
AWS managed policy: AmazonSSMReadOnlyAccess

You can attach the AmazonSSMReadOnlyAccess policy to your IAM identities. This policy grants read-only access to AWS Systems Manager API operations including Describe*, Get*, and List*.

To view more details about the policy, including the latest version of the JSON policy document, see AmazonSSMReadOnlyAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AWSSystemsManagerOpsDataSyncServiceRolePolicy

You can't attach AWSSystemsManagerOpsDataSyncServiceRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows Systems Manager to perform actions on your behalf. For more information, see Using roles to create OpsData and OpsItems for Explorer.

AWSSystemsManagerOpsDataSyncServiceRolePolicy allows the AWSServiceRoleForSystemsManagerOpsDataSync service-linked role to create and update OpsItems and OpsData from AWS Security Hub findings.

The policy allows Systems Manager to complete the following actions on all related resources ("Resource": "*"), except where indicated:

- ssm:GetOpsItem[1]
- ssm:UpdateOpsItem[1]
- ssm:CreateOpsItem
- ssm:AddTagsToResource[2]
- ssm:UpdateServiceSetting[3]
- ssm:GetServiceSetting[3]
- securityhub:GetFindings
- securityhub:GetFindings
- securityhub:BatchUpdateFindings[4]

[1] The ssm:GetOpsItem and ssm:UpdateOpsItem actions are allowed permissions by the following condition for the Systems Manager service only.

```
"Condition": {
   "StringEquals": {
      "aws:ResourceTag/ExplorerSecurityHubOpsItem": "true"
   }
}```
[2] The `ssm:AddTagsToResource` action is allowed permissions for the following resource only.

```
arn:aws:ssm:*:*:opsitem/*
```

[3] The `ssm:UpdateServiceSetting` and `ssm:GetServiceSetting` actions are allowed permissions for the following resources only.

```
arn:aws:ssm:*:*:servicesetting/ssm/opsitem/*
arn:aws:ssm:*:*:servicesetting/ssm/opsdata/*
```

[4] The `securityhub:BatchUpdateFindings` are denied permissions by the following condition for the Systems Manager service only.

```
{
    "Effect": "Deny",
    "Action": "securityhub:BatchUpdateFindings",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "securityhub:ASFFSyntaxPath/Workflow.Status": "SUPPRESSED"
        }
    },
},
{
    "Effect": "Deny",
    "Action": "securityhub:BatchUpdateFindings",
    "Resource": "*",
    "Condition": {
        "Null": {
            "securityhub:ASFFSyntaxPath/Confidence": false
        }
    },
},
{
    "Effect": "Deny",
    "Action": "securityhub:BatchUpdateFindings",
    "Resource": "*",
    "Condition": {
        "Null": {
            "securityhub:ASFFSyntaxPath/Criticality": false
        }
    },
}
```

```json
{
  
  
  
  },

  
  
  
  },

  
  
  
  },

  
  
  
  },

  
  
  
  },

  
  
  
  },

  
  
  
  },

  
  
  
  },

  
  
  
  }

```
"Effect": "Deny",
"Action": "securityhub:BatchUpdateFindings",
"Resource": "*",
"Condition": {
  "Null": {
    "securityhub:ASFFSyntaxPath/UserDefinedFields.key": false
  }
}
},
{
  "Effect": "Deny",
  "Action": "securityhub:BatchUpdateFindings",
  "Resource": "*",
  "Condition": {
    "Null": {
      "securityhub:ASFFSyntaxPath/UserDefinedFields.value": false
    }
  }
},
{
  "Effect": "Deny",
  "Action": "securityhub:BatchUpdateFindings",
  "Resource": "*",
  "Condition": {
    "Null": {
      "securityhub:ASFFSyntaxPath/VerificationState": false
    }
  }
}

**AWS managed policy: AmazonSSMManagedEC2InstanceDefaultPolicy**

You should only attach AmazonSSMManagedEC2InstanceDefaultPolicy to IAM roles for Amazon EC2 instances that you want to have permission to use Systems Manager functionality. You shouldn’t attach this role to other IAM entities, such as IAM users and IAM groups, or to IAM roles that serve other purposes. For more information, see [Using the Default Host Management Configuration setting](https://docs.aws.amazon.com/systems-manager/latest/userguide/using-control-access-iam.html).
This policy grants permissions that allow the SSM Agent on your Amazon EC2 instance to retrieve Documents, execute commands using Run Command, establish sessions using Session Manager, collect an inventory of the instance, and scan for patches and patch compliance using Patch Manager.

Systems Manager uses a personalized authorization token for each instance to ensure that SSM Agent performs the API operations on the correct instance. Systems Manager validates the personalized authorization token against the Amazon Resource Name (ARN) of the instance, provided in the API operation.

The AmazonSSMManagedEC2InstanceDefaultPolicy role permissions policy allows Systems Manager to complete the following actions on all related resources:

- `ssm:DescribeAssociation`
- `ssm:GetDeployablePatchSnapshotForInstance`
- `ssm:GetDocument`
- `ssm:DescribeDocument`
- `ssm:GetManifest`
- `ssm:ListAssociations`
- `ssm:ListInstanceAssociations`
- `ssm:PutInventory`
- `ssm:PutComplianceItems`
- `ssm:PutConfigurePackageResult`
- `ssm:UpdateAssociationStatus`
- `ssm:UpdateInstanceAssociationStatus`
- `ssm:UpdateInstanceInformation`
- `ssmmessages:CreateControlChannel`
- `ssmmessages:CreateDataChannel`
- `ssmmessages:OpenControlChannel`
- `ssmmessages:OpenDataChannel`
- `ec2messages:AcknowledgeMessage`
- `ec2messages:DeleteMessage`
• ec2messages:FailMessage
• ec2messages:GetEndpoint
• ec2messages:GetMessages
• ec2messages:SendReply

To view more details about the policy, including the latest version of the JSON policy document, see AmazonSSMManagedEC2InstanceDefaultPolicy in the AWS Managed Policy Reference Guide.

Systems Manager updates to AWS managed policies

In the following table, view details about updates to AWS managed policies for Systems Manager since this service began tracking these changes on March 12, 2021. For information about other managed policies for the Systems Manager service, see Additional managed policies for Systems Manager later in this topic. For automatic alerts about changes to this page, subscribe to the RSS feed on the Systems Manager Document history page.

### Additional managed policies for Systems Manager

In addition to the managed policies described earlier in this topic, the following policies are also supported by Systems Manager.

- **AmazonSSMAutomationApproverAccess** – AWS managed policy that allows access to view automation executions and send approval decisions to automation that is waiting for approval.
- **AmazonSSMAutomationRole** – AWS managed policy that provides permissions for the Systems Manager Automation service to run activities defined within Automation runbooks. Assign this policy to administrators and trusted power users.

- **AmazonSSMDirectoryServiceAccess** – AWS managed policy that allows SSM Agent to access AWS Directory Service on behalf of the user for requests to join the domain by the managed node.

- **AmazonSSMFullAccess** – AWS managed policy that grants full access to the Systems Manager API and documents.

- **AmazonSSMMaintenanceWindowRole** – AWS managed policy that provides maintenance windows with permissions to the Systems Manager API.

- **AmazonSSMManagedInstanceCore** – AWS managed policy that allows a node to use Systems Manager service core functionality.

- **AmazonSSMPatchAssociation** – AWS managed policy that provides access to child instances for patch association operations.

- **AmazonSSMReadOnlyAccess** – AWS managed policy that grants access to Systems Manager read-only API operations, such as Get* and List*.

- **AWSSSMOpsInsightsServiceRolePolicy** – AWS managed policy that provides permissions for creating and updating operational insight OpsItems in Systems Manager. Used to provide permissions through the service-linked role AWSServiceRoleForAmazonSSM_OpsInsights.

- **AWSSystemsManagerAccountDiscoveryServicePolicy** – AWS managed policy that grants Systems Manager permission to discover AWS account information.

- **AWSSystemsManagerChangeManagementServicePolicy** – AWS managed policy that provides access to AWS resources managed or used by the Systems Manager change management framework and used by the service-linked role AWSServiceRoleForSystemsManagerChangeManagement.

- **AmazonEC2RoleforSSM** – This policy is no longer supported and should not be used. In its place, use the AmazonSSMManagedInstanceCore policy to allow Systems Manager service core functionality on EC2 instances. For information, see Configure instance permissions required for Systems Manager.
Troubleshooting AWS Systems Manager identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with AWS Systems Manager and AWS Identity and Access Management (IAM).

Topics

- I am not authorized to perform an action in Systems Manager
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my Systems Manager resources

I am not authorized to perform an action in Systems Manager

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the mateojackson user tries to use the console to view details about a document but doesn't have ssm:GetDocument permissions.

In this case, Mateo asks his administrator to update his policies to allow him to access the MyExampleDocument resource using the ssm:GetDocument action.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, your policies must be updated to allow you to pass a role to Systems Manager.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Systems Manager. However, the action requires the service to have
permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

**I want to allow people outside of my AWS account to access my Systems Manager resources**

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Systems Manager supports these features, see [How AWS Systems Manager works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users (identity federation)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

**Using service-linked roles for Systems Manager**

AWS Systems Manager uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Systems Manager. Service-
linked roles are predefined by Systems Manager and include all the permissions that the service requires to call other AWS services on your behalf.

**Note**

A *service role* role differs from a service-linked role. A service role is a type of AWS Identity and Access Management (IAM) role that grants permissions to an AWS service so that the service can access AWS resources. Only a few Systems Manager scenarios require a service role. When you create a service role for Systems Manager, you choose the permissions to grant so that it can access or interact with other AWS resources.

A service-linked role makes setting up Systems Manager easier because you don’t have to manually add the necessary permissions. Systems Manager defines the permissions of its service-linked roles, and unless defined otherwise, only Systems Manager can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Systems Manager resources because you can't inadvertently remove permission to access the resources.

**Note**

For non-EC2 nodes in a [hybrid and multicloud](#) environment, you need an additional IAM role that allows those machines to communicate with the Systems Manager service. This is the IAM service role for Systems Manager. This role grants AWS Security Token Service (AWS STS) *AssumeRole* trust to the Systems Manager service. The *AssumeRole* action returns a set of temporary security credentials (consisting of an access key ID, a secret access key, and a security token). You use these temporary credentials to access AWS resources that you might not normally have access to. For more information, see [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#) and *AssumeRole* in the [AWS Security Token Service API Reference](#).

For information about other services that support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have *Yes* in the *Service-linked roles* column. Choose a *Yes* with a link to view the service-linked role documentation for that service.
Using roles to collect inventory and view OpsData

Systems Manager uses the service-linked role named **AWSServiceRoleForAmazonSSM**. AWS Systems Manager uses this IAM service role to manage AWS resources on your behalf.

**Service-linked role permissions for inventory, OpsData, and OpsItems**

The **AWSServiceRoleForAmazonSSM** service-linked role trusts only *ssm.amazonaws.com* to assume this role.

You can use the Systems Manager service-linked role **AWSServiceRoleForAmazonSSM** for the following:

- The Systems Manager Inventory capability uses the service-linked role **AWSServiceRoleForAmazonSSM** to collect inventory metadata from tags and resource groups.
- The Explorer capability uses the service-linked role **AWSServiceRoleForAmazonSSM** to enable viewing OpsData and OpsItems from multiple accounts. This service-linked role also allows Explorer to create a managed rule when you enable Security Hub as a data source from Explorer or OpsCenter.

⚠️ **Important**

Previously, the Systems Manager console provided you with the ability to choose the AWS managed IAM service-linked role **AWSServiceRoleForAmazonSSM** to use as the maintenance role for your tasks. Using this role and its associated policy, **AmazonSSMSMSserviceRolePolicy**, for maintenance window tasks is no longer recommended. If you're using this role for maintenance window tasks now, we encourage you to stop using it. Instead, create your own IAM role that enables communication...
The managed policy that is used to provide permissions for the AWSServiceRoleForAmazonSSM role is AmazonSSMServiceRolePolicy. For details about the permissions it grants, see AWS managed policy: AmazonSSMServiceRolePolicy.

Creating the AWSServiceRoleForAmazonSSM service-linked role for Systems Manager

You can use the IAM console to create a service-linked role with the EC2 use case. Using commands for IAM in the AWS Command Line Interface (AWS CLI) or using the IAM API, create a service-linked role with the ssm.amazonaws.com service name. For more information, see Creating a service-linked role in the IAM User Guide.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account.

Editing the AWSServiceRoleForAmazonSSM service-linked role for Systems Manager

Systems Manager doesn't allow you to edit the AWSServiceRoleForAmazonSSM service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting the AWSServiceRoleForAmazonSSM service-linked role for Systems Manager

If you no longer need to use any feature or service that requires a service-linked role, then we recommend that you delete that role. That way you don't have an unused entity that isn't actively monitored or maintained. You can use the IAM console, the AWS CLI, or the IAM API to manually delete the service-linked role. To do this, you must first manually clean up the resources for your service-linked role, and then you can manually delete it.

Because the AWSServiceRoleForAmazonSSM service-linked role can be used by multiple capabilities, ensure that none are using the role before attempting to delete it.
• **Inventory:** If you delete the service-linked role used by the Inventory capability, then the Inventory data for tags and resource groups will no longer be synchronized. You must clean up the resources for your service-linked role before you can manually delete it.

• **Explorer:** If you delete the service-linked role used by the Explorer capability, then the cross-account and cross-Region OpsData and OpsItems are no longer viewable.

---

**Note**

If the Systems Manager service is using the role when you try to delete tags or resource groups, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

---

**To delete Systems Manager resources used by the AWSServiceRoleForAmazonSSM**

1. To delete tags, see [Add and delete tags on an individual resource](#).
2. To delete resource groups, see [Delete groups from AWS Resource Groups](#).

**To manually delete the AWSServiceRoleForAmazonSSM service-linked role using IAM**

Use the IAM console, the AWS CLI, or the IAM API to delete the AWSServiceRoleForAmazonSSM service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

**Supported Regions for the Systems Manager AWSServiceRoleForAmazonSSM service-linked role**

Systems Manager supports using the AWSServiceRoleForAmazonSSM service-linked role in all of the AWS Regions where the service is available. For more information, see [AWS Systems Manager endpoints and quotas](#).

**Using roles to collect AWS account information for OpsCenter and Explorer**

Systems Manager uses the service-linked role named AWSServiceRoleForAmazonSSM_AccountDiscovery. AWS Systems Manager uses this IAM service role to call other AWS services to discover AWS account information.
Service-linked role permissions for Systems Manager account discovery

The AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role trusts the following services to assume the role:

- accountdiscovery.ssm.amazonaws.com

The role permissions policy allows Systems Manager to complete the following actions on the specified resources:

- organizations:DescribeAccount
- organizations:DescribeOrganizationalUnit
- organizations:DescribeOrganization
- organizations:ListAccounts
- organizations:ListAWSServiceAccessForOrganization
- organizations:ListChildren
- organizations:ListParents
- organizations:ListDelegatedServicesForAccount
- organizations:ListDelegatedAdministrators
- organizations:ListRoots

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

Creating the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role for Systems Manager

You must create a service-linked role if you want to use Explorer and OpsCenter, capabilities of Systems Manager, across multiple AWS accounts. For OpsCenter, you must manually create the service-linked role. For more information, see (Optional) Setting up OpsCenter to centrally manage OpsItems across accounts.

For Explorer, if you create a resource data sync by using Systems Manager in the AWS Management Console, you can create the service-linked role by choosing the Create role button. If you want to
create a resource data sync programmatically, then you must create the role before you create the resource data sync. You can create the role by using the `CreateServiceLinkedRole` API operation.

**Editing the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role for Systems Manager**

Systems Manager doesn’t allow you to edit the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role. After you create a service-linked role, you can’t change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

**Deleting the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role for Systems Manager**

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don’t have an unused entity that isn’t actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

**Cleaning up the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role**

Before you can use IAM to delete the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role, you must first delete all Explorer resource data syncs. For more information, see [Deleting a Systems Manager Explorer resource data sync](#).

---

**Note**

If the Systems Manager service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

---

**Manually delete the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role**

Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*. 
Supported Regions for the Systems Manager

**AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role**

Systems Manager supports using service-linked roles in all of the regions where the service is available. For more information, see [AWS Systems Manager endpoints and quotas](#).

**Updates to the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role**

View details about updates to the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Systems Manager Document history page.

Using roles to create OpsData and OpsItems for Explorer

Systems Manager uses the service-linked role named `AWSServiceRoleForSystemsManagerOpsDataSync`. AWS Systems Manager uses this IAM service role for Explorer to create OpsData and OpsItems.

**Service-linked role permissions for Systems Manager OpsData sync**

The `AWSServiceRoleForSystemsManagerOpsDataSync` service-linked role trusts the following services to assume the role:

- opssdataasync.ssm.amazonaws.com

The role permissions policy allows Systems Manager to complete the following actions on the specified resources:

- Systems Manager Explorer requires that a service-linked role grant permission to update a security finding when an OpsItem is updated, create and update an OpsItem, and turn off the Security Hub data source when an SSM managed rule is deleted by customers.

The managed policy that is used to provide permissions for the `AWSServiceRoleForSystemsManagerOpsDataSync` role is `AWSSystemsManagerOpsDataSyncServiceRolePolicy`. For details about the permissions it grants, see [AWS managed policy: AWSSystemsManagerOpsDataSyncServiceRolePolicy](#).

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-linked role permissions](#) in the [IAM User Guide](#).

**Creating the AWSServiceRoleForSystemsManagerOpsDataSync service-linked role for Systems Manager**

You don't need to manually create a service-linked role. When you enable Explorer in the AWS Management Console, Systems Manager creates the service-linked role for you.

⚠️ **Important**

This service-linked role can be displayed in your account if you completed an action in another service that uses the features supported by this role. Also,
If you were using the Systems Manager service before January 1, 2017, when it began supporting service-linked roles, then Systems Manager created the AWSServiceRoleForSystemsManagerOpsDataSync role in your account. To learn more, see A new role appeared in my IAM account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable Explorer in the AWS Management Console, Systems Manager creates the service-linked role for you again.

You can also use the IAM console to create a service-linked role with the AWS service role that allows Explorer to create OpsData and OpsItems use case. In the AWS CLI or the AWS API, create a service-linked role with the opsdatasync.ssm.amazonaws.com service name. For more information, see Creating a service-linked role in the IAM User Guide. If you delete this service-linked role, you can use this same process to create the role again.

Editing the AWSServiceRoleForSystemsManagerOpsDataSync service-linked role for Systems Manager

Systems Manager doesn't allow you to edit the AWSServiceRoleForSystemsManagerOpsDataSync service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting the AWSServiceRoleForSystemsManagerOpsDataSync service-linked role for Systems Manager

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don’t have an unused entity that isn't actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

⚠️ Note

If the Systems Manager service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.
The procedure for deleting Systems Manager resources used by the AWSServiceRoleForSystemsManagerOpsDataSync role depends on if you've configured Explorer or OpsCenter to integrate with Security Hub.

**To delete Systems Manager resources used by the AWSServiceRoleForSystemsManagerOpsDataSync role**

- To stop Explorer from creating new OpsItems for Security Hub findings, see [How to stop receiving findings](#).
- To stop OpsCenter from creating new OpsItems for Security Hub findings, see [Deleting a service-linked role](#) in the IAM User Guide.

**Supported Regions for the Systems Manager AWSServiceRoleForSystemsManagerOpsDataSync service-linked role**

Systems Manager supports using service-linked roles in all of the Regions where the service is available. For more information, see [AWS Systems Manager endpoints and quotas](#).

Systems Manager doesn't support using service-linked roles in every Region where the service is available. You can use the AWSServiceRoleForSystemsManagerOpsDataSync role in the following Regions.

<table>
<thead>
<tr>
<th>AWS Region name</th>
<th>Region identity</th>
<th>Support in Systems Manager</th>
</tr>
</thead>

</table>

**Using roles to create operational insight OpsItems in Systems Manager OpsCenter**

Systems Manager uses the service-linked role named **AWSServiceRoleForAmazonSSM_OpsInsights**. AWS Systems Manager uses this IAM service role to create and update operational insight OpsItems in Systems Manager OpsCenter.
AWSServiceRoleForAmazonSSM_OpsInsights service-linked role permissions for Systems Manager operational insight OpsItems

The AWSServiceRoleForAmazonSSM_OpsInsights service-linked role trusts the following services to assume the role:

- opsinsights.ssm.amazonaws.com

The role permissions policy allows Systems Manager to complete the following actions on the specified resources:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCreateOpsItem",
      "Effect": "Allow",
      "Action": [
        "ssm:CreateOpsItem",
        "ssm:AddTagsToResource"
      ],
      "Resource": "*"
    },
    {
      "Sid": "AllowAccessOpsItem",
      "Effect": "Allow",
      "Action": [
        "ssm:UpdateOpsItem",
        "ssm:GetOpsItem"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/SsmOperationalInsight": "true"
        }
      }
    }
  ]
}
```
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

**Creating the AWSServiceRoleForAmazonSSM_OpsInsights service-linked role for Systems Manager**

You must create a service-linked role. If you enable operational insights by using Systems Manager in the AWS Management Console, you can create the service-linked role by choosing the Enable button.

**Editing the AWSServiceRoleForAmazonSSM_OpsInsights service-linked role for Systems Manager**

Systems Manager does not allow you to edit the AWSServiceRoleForAmazonSSM_OpsInsights service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

**Deleting the AWSServiceRoleForAmazonSSM_OpsInsights service-linked role for Systems Manager**

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

**Cleaning up the AWSServiceRoleForAmazonSSM_OpsInsights service-linked role**

Before you can use IAM to delete the AWSServiceRoleForAmazonSSM_OpsInsights service-linked role, you must first deactivate operational insights in Systems Manager OpsCenter. For more information, see Analyzing operational insights to reduce OpsItems.

**Manually delete the AWSServiceRoleForAmazonSSM_OpsInsights service-linked role**

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonSSM_OpsInsights service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.
**Supported Regions for the Systems Manager**

**AWSServiceRoleForAmazonSSM_OpsInsights service-linked role**

Systems Manager does not support using service-linked roles in every Region where the service is available. You can use the AWSServiceRoleForAmazonSSM_OpsInsights role in the following Regions.

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region identity</th>
<th>Support in Systems Manager</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>

**Using roles to export Explorer OpsData**

AWS Systems Manager Explorer uses the `AmazonSSMExplorerExportRole` service role to export operations data (OpsData) using the `AWS-ExportOpsDataToS3` automation runbook.

**Service-linked role permissions for Explorer**

The `AmazonSSMExplorerExportRole` service-linked role trusts only `ssm.amazonaws.com` to assume this role.

You can use the `AmazonSSMExplorerExportRole` service-linked role to export operations data (OpsData) using the `AWS-ExportOpsDataToS3` automation runbook. You can export 5,000 OpsData items from Explorer as a comma separated value (.csv) file to an Amazon Simple Storage Service (Amazon S3) bucket.

The role permissions policy allows Systems Manager to complete the following actions on the specified resources:

- `s3:PutObject`
- `s3:GetBucketAcl`
- `s3:GetBucketLocation`
- `sns:Publish`
- `logs:DescribeLogGroups`
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

Creating the AmazonSSMExplorerExportRole service-linked role for Systems Manager

Systems Manager creates the AmazonSSMExplorerExportRole service-linked role when you export OpsData using Explorer in the Systems Manager console. For more information, see Exporting OpsData from Systems Manager Explorer.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account.

Editing the AmazonSSMExplorerExportRole service-linked role for Systems Manager

Systems Manager doesn't allow you to edit the AmazonSSMExplorerExportRole service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting the AmazonSSMExplorerExportRole service-linked role for Systems Manager

If you no longer need to use any feature or service that requires a service-linked role, then we recommend that you delete that role. That way you don't have an unused entity that isn't actively monitored or maintained. You can use the IAM console, the AWS CLI, or the IAM API to manually delete the service-linked role. To do this, you must first manually clean up the resources for your service-linked role, and then you can manually delete it.
**Note**

If the Systems Manager service is using the role when you try to delete tags or resource groups, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Systems Manager resources used by the AmazonSSMEexplorerExportRole

1. To delete tags, see [Add and delete tags on an individual resource](#).
2. To delete resource groups, see [Delete groups from AWS Resource Groups](#).

To manually delete the AmazonSSMEexplorerExportRole service-linked role using IAM

Use the IAM console, the AWS CLI, or the IAM API to delete the AmazonSSMEexplorerExportRole service-linked role. For more information, see [Deleting a service-linked role](#) in the [IAM User Guide](#).

**Supported Regions for the Systems Manager AmazonSSMEexplorerExportRole service-linked role**

Systems Manager supports using the AmazonSSMEexplorerExportRole service-linked role in all of the AWS Regions where the service is available. For more information, see [AWS Systems Manager endpoints and quotas](#).

**Logging and monitoring in AWS Systems Manager**

Monitoring is an important part of maintaining the reliability, availability, and performance of AWS Systems Manager and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Systems Manager and other resources and responding to potential incidents.

**AWS CloudTrail logs**

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Systems Manager. Using the information collected by CloudTrail, you can determine the request that was made to Systems Manager, the IP address from which the request was made, who made
the request, when it was made, and additional details. For more information, see *Logging AWS Systems Manager API calls with AWS CloudTrail*.

**Amazon CloudWatch alarms**

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify for your Amazon Elastic Compute Cloud (Amazon EC2) instances and other resources. If the metric exceeds a given threshold, a notification is sent to an Amazon Simple Notification Service (Amazon SNS) topic or AWS Auto Scaling policy. CloudWatch alarms don't invoke actions because they're in a particular state. Rather the state must have changed and been maintained for a specified number of periods. For more information, see *Using Amazon CloudWatch alarms* in the *Amazon CloudWatch User Guide*.

**Amazon CloudWatch dashboards**

CloudWatch dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view, even those resources that are spread across different AWS Regions. You can use CloudWatch dashboards to create customized views of the metrics and alarms for your AWS resources. For more information, see *Amazon CloudWatch dashboards hosted by Systems Manager*.

**Amazon EventBridge**

Using Amazon EventBridge, you can configure rules to alert you to changes in Systems Manager resources, and to direct EventBridge to take actions based on the content of those events. EventBridge provides support for a number of events that are emitted by various Systems Manager capabilities. For more information, see *Monitoring Systems Manager events with Amazon EventBridge*.

**Amazon CloudWatch Logs and SSM Agent logs**

SSM Agent writes information about executions, scheduled actions, errors, and health statuses to log files on each node. You can view log files by manually connecting to a node. We recommend automatically sending agent log data to a log group in CloudWatch Logs for analysis. For more information, see *Sending node logs to unified CloudWatch Logs (CloudWatch agent)* and *Viewing SSM Agent logs*.

**AWS Systems Manager Compliance**

You can use Compliance, a capability of AWS Systems Manager, to scan your fleet of managed nodes for patch compliance and configuration inconsistencies. You can collect and aggregate data from multiple AWS accounts and AWS Regions, and then drill down into specific resources that aren't compliant. By default, Compliance displays current compliance data about
patching in Patch Manager, a capability of AWS Systems Manager, and associations in State Manager, a capability of AWS Systems Manager. For more information, see AWS Systems Manager Compliance.

AWS Systems Manager Explorer

Explorer, a capability of AWS Systems Manager, is a customizable operations dashboard that reports information about your AWS resources. Explorer displays an aggregated view of operations data (OpsData) for your AWS accounts and across AWS Regions. In Explorer, OpsData includes metadata about your EC2 instances, patch compliance details, and operational work items (OpsItems). Explorer provides context about how OpsItems are distributed across your business units or applications, how they trend over time, and how they vary by category. You can group and filter information in Explorer to focus on items that are relevant to you and that require action. For more information, see AWS Systems Manager Explorer.

AWS Systems Manager OpsCenter

OpsCenter, a capability of AWS Systems Manager, provides a central location where operations engineers and IT professionals can view, investigate, and resolve operational work items (OpsItems) related to AWS resources. OpsCenter aggregates and standardizes OpsItems across services while providing contextual investigation data about each OpsItem, related OpsItems, and related resources. OpsCenter also provides runbooks in Automation, a capability of AWS Systems Manager, that you can use to quickly resolve issues. OpsCenter is integrated with Amazon EventBridge. This means you can create EventBridge rules that automatically create OpsItems for any AWS service that publishes events to EventBridge. For more information, see AWS Systems Manager OpsCenter.

Amazon Simple Notification Service

You can configure Amazon Simple Notification Service (Amazon SNS) to send notifications about the status of commands that you send using Run Command or Maintenance Windows, capabilities of AWS Systems Manager. Amazon SNS coordinates and manages sending and delivering notifications to clients or endpoints that are subscribed to Amazon SNS topics. You can receive a notification whenever a command changes to a new state or to a specific state, such as Failed or Timed Out. In cases where you send a command to multiple nodes, you can receive a notification for each copy of the command sent to a specific node. For more information, see Monitoring Systems Manager status changes using Amazon SNS notifications.

AWS Trusted Advisor and AWS Health Dashboard

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations
when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with either an AWS Support Business or Enterprise plan can view all Trusted Advisor checks. For more information, see AWS Trusted Advisor in the AWS Support User Guide and the AWS Health User Guide.

More info
• Monitoring AWS Systems Manager

Compliance validation for AWS Systems Manager

This topic addresses AWS Systems Manager compliance with third-party assurance programs. For information about viewing compliance data for your managed nodes, see AWS Systems Manager Compliance.

Third-party auditors assess the security and compliance of Systems Manager as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Systems Manager is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

• Security and Compliance Quick Start Guides – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.

• Architecting for HIPAA Security and Compliance Whitepaper – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.

• AWS Compliance Resources – This collection of workbooks and guides might apply to your industry and location.

• Evaluating Resources with Rules in the AWS Config Developer Guide – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
• **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

### Resilience in AWS Systems Manager

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](https://docs.aws.amazon.com/AmazonS3/latest/userguide/aws-global-infrastructure.html).

### Infrastructure security in AWS Systems Manager

As a managed service, AWS Systems Manager is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see [AWS Cloud Security](https://aws.amazon.com/security/). To design your AWS environment using the best practices for infrastructure security, see [Infrastructure Protection](https://docs.aws.amazon.com/wellarchitected/latest/framework/security-pillar.html) in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access Systems Manager through the network. Clients must support the following:

- **Transport Layer Security (TLS).** We require TLS 1.2 and recommend TLS 1.3.
- **Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman).** Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [AWS Security Token Service](https://docs.aws.amazon.com/AmazonS3/latest/userguide/security-token-service.html) (AWS STS) to generate temporary security credentials to sign requests.
Configuration and vulnerability analysis in AWS Systems Manager

AWS handles basic security tasks such as firewall configuration and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- Compliance validation for AWS Systems Manager
- Shared Responsibility Model

Security best practices for Systems Manager

AWS Systems Manager provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don’t represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

Topics

- Systems Manager preventative security best practices
- Systems Manager monitoring and auditing best practices

Systems Manager preventative security best practices

The following best practices for Systems Manager can help prevent security incidents.

Implement least privilege access

When granting permissions, you decide who is getting what permissions to which Systems Manager resources. You allow specific actions that you want to allow on those resources. Therefore you should grant only the permissions that are required to perform a task. Implementing least privilege access is fundamental in reducing security risk and the impact that could result from errors or malicious intent.

The following tools are available to implement least privilege access:

- IAM policies and Permissions boundaries for IAM entities
• **Service control policies**

**Use recommended settings for SSM Agent when configured to use a proxy**

If you configure SSM Agent to use a proxy, use the no_proxy variable with the IP address of the Systems Manager instance metadata service to ensure that calls to Systems Manager don't take on the identity of the proxy service.

For more information, see [Configuring SSM Agent to use a proxy on Linux nodes](#) and [Configure SSM Agent to use a proxy for Windows Server instances](#).

**Use SecureString parameters to encrypt and protect secret data**

In Parameter Store, a capability of AWS Systems Manager, a SecureString parameter is any sensitive data that needs to be stored and referenced in a secure manner. If you have data that you don't want users to alter or reference in plaintext, such as passwords or license keys, create those parameters using the SecureString data type. Parameter Store uses an AWS KMS key in AWS Key Management Service (AWS KMS) to encrypt the parameter value. AWS KMS uses either a customer managed key or an AWS managed key when encrypting the parameter value. For maximum security, we recommend using your own KMS key. If you use the AWS managed key, any user with permission to run the GetParameter and GetParameters actions in your account can view or retrieve the content of all SecureString parameters. If you're using customer managed keys to encrypt your secure SecureString values, you can use IAM policies and key policies to manage permissions for encrypting and decrypting parameters. It's more difficult to establish access control policies for these operations when you use the customer managed keys. For example, you if you use the AWS managed key to encrypt SecureString parameters and don't want users to work with SecureString parameters, their IAM policies must explicitly deny access to the default key.

For more information, see [Restricting access to Systems Manager parameters using IAM policies](#) and [How AWS Systems Manager Parameter Store Uses AWS KMS](#) in the [AWS Key Management Service Developer Guide](#).

**Define allowedValues and allowedPattern for document parameters**

You can validate user input for parameters in Systems Manager documents (SSM documents) by defining allowedValues and allowedPattern. For allowedValues, you define an array of values allowed for the parameter. If a user inputs a value that isn't allowed, the execution fails to start. For allowedPattern, you define a regular expression that validates whether the user input matches the defined pattern for the parameter. If the user input doesn't match the allowed pattern, the execution fails to start.
For more information about allowedValues and allowedPattern, see Data elements and parameters.

**Block public sharing for documents**

Unless your use case requires public sharing to be allowed, we recommend turning on the block public sharing setting for your SSM documents in the Preferences section of the Systems Manager Documents console.

**Use an Amazon Virtual Private Cloud (Amazon VPC) and VPC endpoints**

You can use Amazon VPC to launch AWS resources into a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

By implementing a VPC endpoint, you can privately connect your VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink without requiring an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don't require public IP addresses to communicate with resources in the service. Traffic between your VPC and the other service doesn't leave the Amazon network.

For more information about Amazon VPC security, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager and Internetwork traffic privacy in Amazon VPC in the Amazon VPC User Guide.

**Restrict Session Manager users to sessions using interactive commands and specific SSM session documents**

Session Manager, a capability of AWS Systems Manager, provides several methods for starting sessions to your managed nodes. For the most secure connections, you can require users to connect using the interactive commands method to limit user interaction to a specific command or command sequence. This helps you manage the interactive actions a user can take. For more information, see Starting a session (interactive and noninteractive commands).

For added security, you can limit Session Manager access to specific Amazon EC2 instances and specific Session Manager session documents. You grant or revoke Session Manager access in this way by using AWS Identity and Access Management (IAM) policies. For more information, see Step 3: Control session access to managed nodes.

**Provide temporary node permissions for Automation workflows**

During a workflow in Automation, a capability of AWS Systems Manager, your nodes might need permissions that are needed for that execution only but not for other Systems Manager
operations. For example, an Automation workflow might require a node to call a particular API operation or access an AWS resource specifically during the workflow. If these calls or resources are ones that you want to limit access to, you can provide temporary, supplemental permissions for your nodes within the Automation runbook itself instead of adding the permissions to your IAM instance profile. At the end of the Automation workflow, the temporary permissions are removed. For more information, see Providing temporary instance permissions with AWS Systems Manager Automations on the AWS Management and Governance Blog.

Keep AWS and Systems Manager tools up to date

AWS regularly releases updated versions of tools and plugins that you can use in your AWS and Systems Manager operations. Keeping these resources up to date ensures that users and nodes in your account have access to the latest functionality and security features in these tools.

- SSM Agent – AWS Systems Manager Agent (SSM Agent) is Amazon software that can be installed and configured on an Amazon Elastic Compute Cloud (Amazon EC2) instance, an on-premises server, or a virtual machine (VM). SSM Agent makes it possible for Systems Manager to update, manage, and configure these resources. We recommend checking for new versions, or automating updates to the agent, at least every two weeks. For information, see Automating updates to SSM Agent. We also recommend verifying the signature of SSM Agent as part of your update process. For information, see Verifying the signature of SSM Agent.

- AWS CLI – The AWS Command Line Interface (AWS CLI) is an open source tool that allows you to interact with AWS services using commands in your command-line shell. To update the AWS CLI, you run the same command used to install the AWS CLI. We recommend creating a scheduled task on your local machine to run the command appropriate to your operating system at least once every two weeks. For information about installation commands, see Installing the AWS CLI version 2 in the AWS Command Line Interface User Guide.

- AWS Tools for Windows PowerShell – The Tools for Windows PowerShell are a set of PowerShell modules that are built on the functionality exposed by the AWS SDK for .NET. The AWS Tools for Windows PowerShell allow you to script operations on your AWS resources from the PowerShell command line. Periodically, as updated versions of the Tools for Windows PowerShell are released, you should update the version that you're running locally. For information, see Updating the AWS Tools for Windows PowerShell on Windows or Updating the AWS Tools for Windows PowerShell on Linux or macOS in the IAM Policy Simulator User Guide.

- Session Manager plugin – If users in your organization with permissions to use Session Manager want to connect to a node using the AWS CLI, they must first install the Session Manager plugin on their local machines. To update the plugin, you run the same command
used to install the plugin. We recommend creating a scheduled task on your local machine to run the command appropriate to your operating system at least once every two weeks. For information, see Install the Session Manager plugin for the AWS CLI.

- CloudWatch agent – You can configure and use the CloudWatch agent to collect metrics and logs from your EC2 instances, on-premises instances, and virtual machines (VMs). These logs can be sent to Amazon CloudWatch Logs for monitoring and analysis. We recommend checking for new versions, or automating updates to the agent, at least every two weeks. For the simplest updates, use AWS Systems Manager Quick Setup. For information, see AWS Systems Manager Quick Setup.

**Systems Manager monitoring and auditing best practices**

The following best practices for Systems Manager can help detect potential security weaknesses and incidents.

**Identify and audit all your Systems Manager resources**

Identification of your IT assets is a crucial aspect of governance and security. You need to identify all of your Systems Manager resources to assess their security posture and take action on potential areas of weakness.

Use Tag Editor to identify security-sensitive or audit-sensitive resources, then use those tags when you need to search for these resources. For more information, see Find resources to tag in the AWS Resource Groups User Guide.

Create resource groups for your Systems Manager resources. For more information, see What are resource groups?

**Implement monitoring using Amazon CloudWatch monitoring tools**

Monitoring is an important part of maintaining the reliability, security, availability, and performance of Systems Manager and your AWS solutions. Amazon CloudWatch provides several tools and services to help you monitor Systems Manager and your other AWS services. For more information, see Sending node logs to unified CloudWatch Logs (CloudWatch agent) and Monitoring Systems Manager events with Amazon EventBridge.

**Use CloudTrail**

AWS CloudTrail provides a record of actions taken by a user, role, or an AWS service in Systems Manager. Using the information collected by CloudTrail, you can determine the request that
was made to Systems Manager, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging AWS Systems Manager API calls with AWS CloudTrail.

Turn on AWS Config

AWS Config allows you to assess, audit, and evaluate the configurations of your AWS resources. AWS Config monitors resource configurations, allowing you to evaluate the recorded configurations against the required secure configurations. Using AWS Config, you can review changes in configurations and relationships between AWS resources, investigate detailed resource configuration histories, and determine your overall compliance against the configurations specified in your internal guidelines. This can help you simplify compliance auditing, security analysis, change management, and operational troubleshooting. For more information, see Setting Up AWS Config with the Console in the AWS Config Developer Guide. When specifying the resource types to record, ensure that you include Systems Manager resources.

Monitor AWS security advisories

You should regularly check security advisories posted in Trusted Advisor for your AWS account. You can do this programmatically using describe-trusted-advisor-checks.

Further, actively monitor the primary email address registered to each of your AWS accounts. AWS will contact you, using this email address, about emerging security issues that might affect you.

AWS operational issues with broad impact are posted on the AWS Service Health Dashboard. Operational issues are also posted to individual accounts through the Personal Health Dashboard. For more information, see the AWS Health Documentation.

Code examples for Systems Manager using AWS SDKs

The following code examples show how to use Systems Manager with an AWS software development kit (SDK).

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello Systems Manager

The following code example shows how to get started using Systems Manager.

Java

**SDK for Java 2.x**

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ssm.SsmClient;
import software.amazon.awssdk.services.ssm.model.DocumentFilter;
import software.amazon.awssdk.services.ssm.model.ListDocumentsRequest;
import software.amazon.awssdk.services.ssm.model.ListDocumentsResponse;

public class HelloSSM {
    public static void main(String[] args) {
```
final String usage = ""
    Usage:
        <awsAccount>
    Where:
        awsAccount - Your AWS Account number.
    ""

if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

String awsAccount = args[0] ;
Region region = Region.US_EAST_1;
SsmClient ssmClient = SsmClient.builder()
    .region(region)
    .build();

listDocuments(ssmClient, awsAccount);
}

/*
This code automatically fetches the next set of results using the `nextToken`
and stops once the desired maxResults (20 in this case) have been reached.
*/
public static void listDocuments(SsmClient ssmClient, String awsAccount) {
    String nextToken = null;
    int totalDocumentsReturned = 0;
    int maxResults = 20;
    do {
        ListDocumentsRequest request = ListDocumentsRequest.builder()
            .documentFilterList(
                DocumentFilter.builder()
                    .key("Owner")
                    .value(awsAccount)
                    .build()
                )
            .maxResults(maxResults)
            .nextToken(nextToken)
            .build();

    } while (nextToken != null && totalDocumentsReturned < maxResults);
ListDocumentsResponse response = ssmClient.listDocuments(request);
response.documentIdentifiers().forEach(identifier ->
System.out.println("Document Name: " + identifier.name()));
nextToken = response.nextToken();
totalDocumentsReturned += response.documentIdentifiers().size();
} while (nextToken != null && totalDocumentsReturned < maxResults);

• For API details, see listThings in AWS SDK for Java 2.x API Reference.

- Use RegisterDefaultPatchBaseline with an AWS SDK or CLI
- Use RegisterPatchBaselineForPatchGroup with an AWS SDK or CLI
- Use RegisterTargetWithMaintenanceWindow with an AWS SDK or CLI
- Use RegisterTaskWithMaintenanceWindow with an AWS SDK or CLI
• Use RemoveTagsFromResource with an AWS SDK or CLI
• Use SendCommand with an AWS SDK or CLI
• Use StartAutomationExecution with an AWS SDK or CLI
• Use StopAutomationExecution with an AWS SDK or CLI
• Use UpdateAssociation with an AWS SDK or CLI
• Use UpdateAssociationStatus with an AWS SDK or CLI
• Use UpdateDocument with an AWS SDK or CLI
• Use UpdateDocumentDefaultVersion with an AWS SDK or CLI
• Use UpdateMaintenanceWindow with an AWS SDK or CLI
• Use UpdateManagedInstanceRole with an AWS SDK or CLI
• Use UpdateOpsItem with an AWS SDK or CLI
• Use UpdatePatchBaseline with an AWS SDK or CLI

Scenarios for Systems Manager using AWS SDKs

Actions for Systems Manager using AWS SDKs

The following code examples demonstrate how to perform individual Systems Manager actions with AWS SDKs. These excerpts call the Systems Manager API and are code excerpts from larger programs that must be run in context. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

The following examples include only the most commonly used actions. For a complete list, see the AWS Systems Manager API Reference.

Examples
• Use AddTagsToResource with an AWS SDK or CLI
• Use CancelCommand with an AWS SDK or CLI
• Use CreateActivation with an AWS SDK or CLI
• Use CreateAssociation with an AWS SDK or CLI
• Use CreateAssociationBatch with an AWS SDK or CLI
• Use CreateDocument with an AWS SDK or CLI
• Use CreateDocument with an AWS SDK or CLI
• Use CreateMaintenanceWindow with an AWS SDK or CLI
• Use CreateOpsItem with an AWS SDK or CLI
• Use CreatePatchBaseline with an AWS SDK or CLI
• Use DeleteActivation with an AWS SDK or CLI
• Use DeleteAssociation with an AWS SDK or CLI
• Use DeleteDocument with an AWS SDK or CLI
• Use DeleteMaintenanceWindow with an AWS SDK or CLI
• Use DeleteParameter with an AWS SDK or CLI
• Use DeletePatchBaseline with an AWS SDK or CLI
• Use DeregisterManagedInstance with an AWS SDK or CLI
• Use DeregisterPatchBaselineForPatchGroup with an AWS SDK or CLI
• Use DeregisterTargetFromMaintenanceWindow with an AWS SDK or CLI
• Use DeregisterTaskFromMaintenanceWindow with an AWS SDK or CLI
• Use DescribeActivations with an AWS SDK or CLI
• Use DescribeAssociation with an AWS SDK or CLI
• Use DescribeAssociationExecutionTargets with an AWS SDK or CLI
• Use DescribeAssociationExecutions with an AWS SDK or CLI
• Use DescribeAutomationExecutions with an AWS SDK or CLI
• Use DescribeAutomationStepExecutions with an AWS SDK or CLI
• Use DescribeAvailablePatches with an AWS SDK or CLI
• Use DescribeDocument with an AWS SDK or CLI
• Use DescribeDocumentPermission with an AWS SDK or CLI
• Use DescribeEffectiveInstanceAssociations with an AWS SDK or CLI
• Use DescribeEffectivePatchesForPatchBaseline with an AWS SDK or CLI
• Use DescribeInstanceAssociationsStatus with an AWS SDK or CLI
• Use DescribeInstanceInformation with an AWS SDK or CLI
• Use DescribeInstancePatchStates with an AWS SDK or CLI
• Use DescribeInstancePatchStatesForPatchGroup with an AWS SDK or CLI
• Use DescribeInstancePatches with an AWS SDK or CLI
• Use DescribeMaintenanceWindowExecutionTaskInvocations with an AWS SDK or CLI
• Use DescribeMaintenanceWindowExecutionTasks with an AWS SDK or CLI
• Use DescribeMaintenanceWindowExecutions with an AWS SDK or CLI
• Use DescribeMaintenanceWindowTargets with an AWS SDK or CLI
• Use DescribeMaintenanceWindowTasks with an AWS SDK or CLI
• Use DescribeMaintenanceWindows with an AWS SDK or CLI
• Use DescribeOpsItems with an AWS SDK or CLI
• Use DescribeParameters with an AWS SDK or CLI
• Use DescribePatchBaselines with an AWS SDK or CLI
• Use DescribePatchGroupState with an AWS SDK or CLI
• Use DescribePatchGroups with an AWS SDK or CLI
• Use GetAutomationExecution with an AWS SDK or CLI
• Use GetCommandInvocation with an AWS SDK or CLI
• Use GetConnectionStatus with an AWS SDK or CLI
• Use GetDefaultPatchBaseline with an AWS SDK or CLI
• Use GetDeployablePatchSnapshotForInstance with an AWS SDK or CLI
• Use GetDocument with an AWS SDK or CLI
• Use GetInventory with an AWS SDK or CLI
• Use GetInventorySchema with an AWS SDK or CLI
• Use GetMaintenanceWindow with an AWS SDK or CLI
• Use GetMaintenanceWindowExecution with an AWS SDK or CLI
• Use GetMaintenanceWindowExecutionTask with an AWS SDK or CLI
• Use GetParameterHistory with an AWS SDK or CLI
• Use GetParameters with an AWS SDK or CLI
• Use GetPatchBaseline with an AWS SDK or CLI
• Use GetPatchBaselineForPatchGroup with an AWS SDK or CLI
• Use ListAssociationVersions with an AWS SDK or CLI
• Use ListAssociations with an AWS SDK or CLI
• Use ListCommandInvocations with an AWS SDK or CLI
• Use ListCommands with an AWS SDK or CLI
• Use ListComplianceItems with an AWS SDK or CLI
• Use ListComplianceSummaries with an AWS SDK or CLI
• Use ListDocumentVersions with an AWS SDK or CLI
• Use ListDocuments with an AWS SDK or CLI
• Use ListInventoryEntries with an AWS SDK or CLI
• Use ListResourceComplianceSummaries with an AWS SDK or CLI
• Use ListTagsForResource with an AWS SDK or CLI
• Use ModifyDocumentPermission with an AWS SDK or CLI
• Use PutComplianceItems with an AWS SDK or CLI
• Use PutInventory with an AWS SDK or CLI
• Use PutParameter with an AWS SDK or CLI
• Use RegisterDefaultPatchBaseline with an AWS SDK or CLI
• Use RegisterPatchBaselineForPatchGroup with an AWS SDK or CLI
• Use RegisterTargetWithMaintenanceWindow with an AWS SDK or CLI
• Use RegisterTaskWithMaintenanceWindow with an AWS SDK or CLI
• Use RemoveTagsFromResource with an AWS SDK or CLI
• Use SendCommand with an AWS SDK or CLI
• Use StartAutomationExecution with an AWS SDK or CLI
• Use StopAutomationExecution with an AWS SDK or CLI
• Use UpdateAssociation with an AWS SDK or CLI
• Use UpdateAssociationStatus with an AWS SDK or CLI
• Use UpdateDocument with an AWS SDK or CLI
• Use UpdateDocumentDefaultVersion with an AWS SDK or CLI
• Use UpdateMaintenanceWindow with an AWS SDK or CLI
• Use UpdateManagedInstanceRole with an AWS SDK or CLI
Use AddTagsToResource with an AWS SDK or CLI

The following code examples show how to use AddTagsToResource.

CLI

AWS CLI

**Example 1: To add tags to a maintenance window**

The following add-tags-to-resource example adds a tag to the specified maintenance window.

```bash
aws ssm add-tags-to-resource \
   --resource-type "MaintenanceWindow" \
   --resource-id "mw-03eb9db428EXAMPLE" \
   --tags "Key=Stack,Value=Production"
```

This command produces no output.

**Example 2: To add tags to a parameter**

The following add-tags-to-resource example adds two tags to the specified parameter.

```bash
aws ssm add-tags-to-resource \
   --resource-type "Parameter" \
   --resource-id "My-Parameter" \
   --tags '[["Key":"Region","Value":"East"],"Key":"Environment","Value":"Production"]'
```

This command produces no output.

**Example 3: To add tags to an SSM document**

The following add-tags-to-resource example adds a tag to the specified document.
aws ssm add-tags-to-resource \
    --resource-type "Document" \ 
    --resource-id "My-Document" \ 
    --tags "Key=Quarter,Value=Q322"

This command produces no output.

For more information, see [Tagging Systems Manager resources](#) in the *AWS Systems Manager User Guide*.

- For API details, see [AddTagsToResource](#) in *AWS CLI Command Reference*.

### PowerShell

**Tools for PowerShell**

**Example 1:** This example updates a maintenance window with new tags. There is no output if the command succeeds. The syntax used by this example requires PowerShell version 3 or later.

```powershell
$option1 = @([Key]="Stack";[Value]="Production")
Add-SSMResourceTag -ResourceId "mw-03eb9db42890fb82d" -ResourceType "MaintenanceWindow" -Tag $option1
```

**Example 2:** With PowerShell version 2, you must use New-Object to create each tag. There is no output if the command succeeds.

```powershell
$tag1 = New-Object Amazon.SimpleSystemsManagement.Model.Tag
$tag1.Key = "Stack"
$tag1.Value = "Production"

Add-SSMResourceTag -ResourceId "mw-03eb9db42890fb82d" -ResourceType "MaintenanceWindow" -Tag $tag1
```

- For API details, see [AddTagsToResource](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.
Use CancelCommand with an AWS SDK or CLI

The following code examples show how to use CancelCommand.

CLI

AWS CLI

Example 1: To cancel a command for all instances

The following cancel-command example attempts to cancel the specified command that is already running for all instances.

```
aws ssm cancel-command \\
    --command-id "662add3d-5831-4a10-b64a-f2ff3EXAMPLE"
```

This command produces no output.

Example 2: To cancel a command for specific instances

The following cancel-command example attempts to cancel a command for the specified instance only.

```
aws ssm cancel-command \\
    --command-id "662add3d-5831-4a10-b64a-f2ff3EXAMPLE" \\
    --instance-ids "i-02573cafcfEXAMPLE"
```

This command produces no output.

For more information, see Tagging Systems Manager Parameters in the AWS Systems Manager User Guide.

- For API details, see CancelCommand in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example attempts to cancel a command. There is no output if the operation succeeds.

```
Stop-SSMCommand -CommandId "9ded293e-e792-4440-8e3e-7b8ec5feaa38"
```
For API details, see CancelCommand in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use CreateActivation with an AWS SDK or CLI**

The following code examples show how to use CreateActivation.

**CLI**

**AWS CLI**

**To create a managed instance activation**

The following create-activation example creates a managed instance activation.

```bash
aws ssm create-activation 
  --default-instance-name "HybridWebServers" 
  --iam-role "HybridWebServersRole" 
  --registration-limit 5
```

Output:

```
{
  "ActivationId": "5743558d-563b-4457-8682-d16c3EXAMPLE",
  "ActivationCode": "dRmgnyAfV567vEXAMPLE"
}
```

For more information, see Step 4: Create a Managed-Instance Activation for a Hybrid Environment in the AWS Systems Manager User Guide.

- For API details, see CreateActivation in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example creates a managed instance.**
New-SSMAActivation -DefaultInstanceName "MyWebServers" -IamRole "SSMAutomationRole" -RegistrationLimit 10

### Output:

<table>
<thead>
<tr>
<th>ActivationCode</th>
<th>ActivationId</th>
</tr>
</thead>
<tbody>
<tr>
<td>KWChh0xBTiwDcKE9B1KC</td>
<td>08e51e79-1e36-446c-8e63-9458569c1363</td>
</tr>
</tbody>
</table>

- For API details, see [CreateActivation](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

### Use CreateAssociation with an AWS SDK or CLI

The following code examples show how to use CreateAssociation.

**CLI**

#### AWS CLI

**Example 1: To associate a document using instance IDs**

This example associates a configuration document with an instance, using instance IDs.

```bash
aws ssm create-association \
  --instance-id "i-0cb2b964d3e14fd9f" \
  --name "AWS-UpdateSSMAgent"
```

**Output:**

```json
{
   "AssociationDescription": {
      "Status": {
         "Date": 1487875500.33,
         "Message": "Associated with AWS-UpdateSSMAgent",
         "Name": "Associated"
      }
   }
}
```
For more information, see [CreateAssociation](https://docs.aws.amazon.com/systems-manager/latest/userguide/associations.html) in the AWS Systems Manager API Reference.

**Example 2: To associate a document using targets**

This example associates a configuration document with an instance, using targets.

```bash
aws ssm create-association \
--name "AWS-UpdateSSMAgent" \
--targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f"
```

Output:

```json
{
  "AssociationDescription": {
    "Status": {
      "Date": 1487875500.33,
      "Message": "Associated with AWS-UpdateSSMAgent",
      "Name": "Associated"
    },
    "Name": "AWS-UpdateSSMAgent",
    "InstanceId": "i-0cb2b964d3e14fd9f",
    "Overview": {
```

CreateAssociation

2310
For more information, see [CreateAssociation](https://docs.aws.amazon.com/ssmservicedocumentation/latest/api-reference/api-create-association.html) in the *AWS Systems Manager API Reference*.

**Example 3: To create an association that runs only once**

This example creates a new association that only runs once on the specified date and time. Associations created with a date in the past or present (by the time it is processed the date is in the past) run immediately.

```bash
aws ssm create-association \
  --name "AWS-UpdateSSMAgent" \ 
  --targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f" \ 
  --schedule-expression "at(2020-05-14T15:55:00)" \ 
  --apply-only-at-cron-interval
```

Output:

```json
{
    "AssociationDescription": {
        "Status": {
            "Date": 1487875500.33,
            "Message": "Associated with AWS-UpdateSSMAgent",
            "Name": "Associated"
        },
        "Name": "AWS-UpdateSSMAgent",
        "InstanceId": "i-0cb2b964d3e14fd9f",
    }
}
```
For more information, see CreateAssociation in the AWS Systems Manager API Reference or Reference: Cron and rate expressions for Systems Manager in the AWS Systems Manager User Guide.

- For API details, see CreateAssociation in AWS CLI Command Reference.

PowerShell

**Tools for PowerShell**

**Example 1: This example associates a configuration document with an instance, using instance IDs.**

```powershell
New-SSMAssociation -InstanceId "i-0cb2b964d3e14fd9f" -Name "AWS-UpdateSSMAgent"
```

**Output:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>AWS-UpdateSSMAgent</td>
</tr>
<tr>
<td>InstanceId</td>
<td>i-0000293ff8c57862</td>
</tr>
<tr>
<td>Date</td>
<td>2/23/2017 6:55:22 PM</td>
</tr>
<tr>
<td>Status.Name</td>
<td>Associated</td>
</tr>
<tr>
<td>Status.Message</td>
<td>Associated with AWS-UpdateSSMAgent</td>
</tr>
</tbody>
</table>
**Example 2: This example associates a configuration document with an instance, using targets.**

```
$target = @{Key="instanceids";Values=(@("i-0cb2b964d3e14fd9f"))}
New-SSMAssociation -Name "AWS-UpdateSSMAgent" -Target $target
```

Output:

```
Name                  : AWS-UpdateSSMAgent
InstanceId            :
Date                  : 3/1/2017 6:22:21 PM
Status.Name           :
Status.Date           :
Status.Message        :
Status.AdditionalInfo :
```

**Example 3: This example associates a configuration document with an instance, using targets and parameters.**

```
$target = @{Key="instanceids";Values=(@("i-0cb2b964d3e14fd9f"))}
$params = @{
  "action"="configure"
  "mode"="ec2"
  "optionalConfigurationSource"="ssm"
  "optionalConfigurationLocation"=""
  "optionalRestart"="yes"
}
New-SSMAssociation -Name "Configure-CloudWatch" -AssociationName "CWConfiguration" -Target $target -Parameter $params
```

Output:

```
Name                  : Configure-CloudWatch
InstanceId            :
Date                  : 5/17/2018 3:17:44 PM
Status.Name           :
Status.Date           :
Status.Message        :
Status.AdditionalInfo :
```
Example 4: This example creates an association with all instances in the region, with \n\texttt{AWS-GatherSoftwareInventory}. It also provides custom files and registry locations in \nthe parameters to collect

\begin{verbatim}
$params =
$params["windowsRegistry"] = @"{"Path":"HKEY_LOCAL_MACHINE\SOFTWARE\Amazon \nMachineImage","Recursive":false,"ValueNames":["AMIName"]}";
$params["files"] = @"{"Path":"C:\Program Files","Pattern":
["*.exe"],"Recursive":true}, {"Path":"C:\ProgramData","Pattern":
["*.log"],"Recursive":true}"
New-SSMAssociation -AssociationName new-in-mum -Name AWS-GatherSoftwareInventory 
-Target @{Key="instanceids";Values="*"} -Parameter $params -region ap-south-1 -ScheduleExpression "rate(720 minutes)"
\end{verbatim}

\textbf{Output:}

\begin{verbatim}
Name                  : AWS-GatherSoftwareInventory
InstanceId            :
Date                  : 6/9/2019 8:57:56 AM
Status.Name           :
Status.Date           :
Status.Message        :
Status.AdditionalInfo :
\end{verbatim}

- For API details, see \url{CreateAssociation} in \textit{AWS Tools for PowerShell Cmdlet Reference}.

For a complete list of AWS SDK developer guides and code examples, see \url{Using Systems Manager with an AWS SDK}. This topic also includes information about getting started and details about previous SDK versions.

**Use CreateAssociationBatch with an AWS SDK or CLI**

The following code examples show how to use CreateAssociationBatch.

**CLI**

**AWS CLI**

To create multiple associations
This example associates a configuration document with multiple instances. The output returns a list of successful and failed operations, if applicable.

Command:

```bash
aws ssm create-association-batch --entries "Name=AWS-UpdateSSMAgent,InstanceId=i-1234567890abcdef0" "Name=AWS-UpdateSSMAgent,InstanceId=i-9876543210abcdef0"
```

Output:

```json
{
  "Successful": [
    {
      "Name": "AWS-UpdateSSMAgent",
      "InstanceId": "i-1234567890abcdef0",
      "AssociationVersion": "1",
      "Date": 1550504725.007,
      "LastUpdateAssociationDate": 1550504725.007,
      "Status": {
        "Date": 1550504725.007,
        "Name": "Associated",
        "Message": "Associated with AWS-UpdateSSMAgent"
      },
      "Overview": {
        "Status": "Pending",
        "DetailedStatus": "Creating"
      },
      "DocumentVersion": "$DEFAULT",
      "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
      "Targets": [
        {
          "Key": "InstanceIds",
          "Values": [
            "i-1234567890abcdef0"
          ]
        }
      ]
    },
    {
      "Name": "AWS-UpdateSSMAgent",
      "InstanceId": "i-9876543210abcdef0",
      "AssociationVersion": "1",
      "Date": 1550504725.007,
      "LastUpdateAssociationDate": 1550504725.007,
      "Status": {
        "Date": 1550504725.007,
        "Name": "Associated",
        "Message": "Associated with AWS-UpdateSSMAgent"
      },
      "Overview": {
        "Status": "Pending",
        "DetailedStatus": "Creating"
      },
      "DocumentVersion": "$DEFAULT",
      "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
      "Targets": [
        {
          "Key": "InstanceIds",
          "Values": [
            "i-9876543210abcdef0"
          ]
        }
      ]
    }
  ]
}
```
For API details, see [CreateAssociationBatch](https://docs.aws.amazon.com/cli/latest/reference/ssm/create-association-batch.html) in *AWS CLI Command Reference*.

### PowerShell

**Tools for PowerShell**

**Example 1:** This example associates a configuration document with multiple instances. The output returns a list of successful and failed operations, if applicable.

```powershell
$options1 = @{InstanceId='i-0cb2b964d3e14fd9f'; Name='AWS-UpdateSSMAgent'}
$options2 = @{InstanceId='i-0000293fffd8c57862'; Name='AWS-UpdateSSMAgent'}
New-SSMAssociationFromBatch -Entry $options1,$options2
```

**Output:**

```
Failed  Successful
```
Example 2: This example will show the full details of a successful operation.

```powershell
$option1 = @{InstanceId="i-0cb2b964d3e14fd9f";Name="AWS-UpdateSSMAgent"}
$option2 = @{InstanceId="i-0000293fffd8c57862";Name="AWS-UpdateSSMAgent"}
(New-SSMAssociationFromBatch -Entry $option1,$option2).Successful
```

- For API details, see [CreateAssociationBatch](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

### Use CreateDocument with an AWS SDK or CLI

The following code examples show how to use CreateDocument.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with Systems Manager](#)

#### CLI

**AWS CLI**

**To create a document**

The following `create-document` example creates a Systems Manager document.

```bash
aws ssm create-document \
    --content file://exampleDocument.yml \
    --name "Example" \
    --document-type "Automation" \
    --document-format YAML
```

Output:
For more information, see [Creating Systems Manager Documents](https://docs.aws.amazon.com/systems-manager/latest/userguide/creating-systems-manager-documents.html) in the *AWS Systems Manager User Guide*. 
For API details, see CreateDocument in AWS CLI Command Reference.

Java

SDK for Java 2.x

```java
// Create an AWS SSM document to use in this scenario.
public static void createSSMDoc(SsmClient ssmClient, String docName) {
    // Create JSON for the content
    String jsonData = ""
    {
        "schemaVersion": "2.2",
        "description": "Run a simple shell command",
        "mainSteps": [
            { 
                "action": "aws:runShellScript",
                "name": "runEchoCommand",
                "inputs": { 
                    "runCommand": [
                        "echo 'Hello, world!'"
                    ]
                }
            }
        ]
    }"
    
    try {
        CreateDocumentRequest request = CreateDocumentRequest.builder()
            .content(jsonData)
            .name(docName)
            .documentType(DocumentType.COMMAND)
            .build();

        // Create the document.
        CreateDocumentResponse response = ssmClient.createDocument(request);
    }
```
System.out.println("The status of the document is " +
response.documentDescription().status());

} catch (DocumentAlreadyExistsException e) {
    System.err.println("The document already exists. Moving on."");
} catch (SsmException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see CreateDocument in AWS SDK for Java 2.x API Reference.

PowerShell

Tools for PowerShell

Example 1: This example creates a document in your account. The document must be in JSON format. For more information about writing a configuration document, see Configuration Document in the SSM API Reference.

New-SSMDocument -Content (Get-Content -Raw "c:\temp\RunShellScript.json") -Name "RunShellScript" -DocumentType "Command"

Output:

CreatedDate : 3/1/2017 1:21:33 AM
DefaultVersion : 1
Description : Run an updated script
DocumentType : Command
DocumentVersion : 1
Hash :
    1d5ce820e999ff051eb4841ed887593daf77120fd76cae0d18a53cc42e4e22c1
HashType : Sha256
LatestVersion : 1
Name : RunShellScript
Owner : 809632081692
Parameters : {commands}
PlatformTypes : {Linux}
SchemaVersion : 2.0
Sha1 :
For API details, see CreateDocument in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use CreateMaintenanceWindow with an AWS SDK or CLI**

The following code examples show how to use CreateMaintenanceWindow.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with Systems Manager

**CLI**

**AWS CLI**

**Example 1: To create a maintenance window**

The following create-maintenance-window example creates a new maintenance window that every five minutes for up to two hours (as needed), prevents new tasks from starting within one hour of the end of the maintenance window execution, allows unassociated targets (instances that you haven't registered with the maintenance window), and indicates through the use of custom tags that its creator intends to use it in a tutorial.

```
aws ssm create-maintenance-window \
    --name "My-Tutorial-Maintenance-Window" \
    --schedule "rate(5 minutes)" \
    --duration 2 --cutoff 1 \
    --allow-unassociated-targets \
    --tags "Key=Purpose,Value=Tutorial"
```

**Output:**

```
{
    "WindowId": "mw-0c50858d01EXAMPLE"
}
```
Example 2: To create a maintenance window that runs only once

The following create-maintenance-window example creates a new maintenance window that only runs one time on the specified date and time.

```bash
aws ssm create-maintenance-window \
   --name My-One-Time-Maintenance-Window \
   --schedule "at(2020-05-14T15:55:00)" \
   --duration 5 \ 
   --cutoff 2 \ 
   --allow-unassociated-targets \ 
   --tags "Key=Environment,Value=Production"
```

Output:

```json
{
   "WindowId": "mw-01234567890abcdef"
}
```

For more information, see Maintenance Windows in the AWS Systems Manager User Guide.

- For API details, see CreateMaintenanceWindow in AWS CLI Command Reference.

Java

SDK for Java 2.x

```
public static String createMaintenanceWindow(SsmClient ssmClient, String winName) {
    CreateMaintenanceWindowRequest request = 
        CreateMaintenanceWindowRequest.builder() 
            .name(winName) 
            .description("This is my maintenance window")
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
.allowUnassociatedTargets(true)
.duration(2)
.cutoff(1)
.schedule("cron(0 10 ? * MON-FRI *)")
.build();

try {
    CreateMaintenanceWindowResponse response =
        ssmClient.createMaintenanceWindow(request);
    String maintenanceWindowId = response.windowId();
    System.out.println("The maintenance window id is " +
        maintenanceWindowId);
    return maintenanceWindowId;
}

catch (DocumentAlreadyExistsException e) {
    System.err.println("The maintenance window already exists. Moving
    on.");
}

catch (SsmException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

MaintenanceWindowFilter filter = MaintenanceWindowFilter.builder()
    .key("name")
    .values(winName)
    .build();

DescribeMaintenanceWindowsRequest winRequest =
    DescribeMaintenanceWindowsRequest.builder()
    .filters(filter)
    .build();

String windowId = "";
DescribeMaintenanceWindowsResponse response =
    ssmClient.describeMaintenanceWindows(winRequest);
List<MaintenanceWindowIdentity> windows = response.windowIdentities();
if (!windows.isEmpty()) {
    windowId = windows.get(0).windowId();
    System.out.println("Window ID: " + windowId);
} else {
    System.out.println("Window not found.");
}
return windowId;
• For API details, see CreateMaintenanceWindow in AWS SDK for Java 2.x API Reference.

PowerShell

Tools for PowerShell

Example 1: This example creates a new maintenance window with the specified name that runs at 4 PM on every Tuesday for 4 hours, with a 1 hour cutoff, and that allows unassociated targets.

New-SSMMaintenanceWindow -Name "MyMaintenanceWindow" -Duration 4 -Cutoff 1 - AllowUnassociatedTarget $true -Schedule "cron(0 16 ? * TUE *)"

Output:

mw-03eb53e1ea7383998

• For API details, see CreateMaintenanceWindow in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use CreateOpsItem with an AWS SDK or CLI

The following code examples show how to use CreateOpsItem.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

• Get started with Systems Manager

CLI

AWS CLI

To create an OpsItems
The following create-ops-item example uses the /aws/resources key in OperationalData to create an OpsItem with an Amazon DynamoDB related resource.

```
aws ssm create-ops-item \
  --title "EC2 instance disk full" \
  --description "Log clean up may have failed which caused the disk to be full" \
  --priority 2 \
  --source ec2 \
  --operational-data '{"/aws/resources":{"Value": ["{ "arn": "arn:aws:dynamodb:us-west-2:12345678:table/OpsItems "]}, "Type": "SearchableString"}}' \
```

**Output:**

```
{
  "OpsItemId": "oi-1a2b3c4d5e6f"
}
```

For more information, see Creating OpsItems in the AWS Systems Manager User Guide.

- For API details, see CreateOpsItem in AWS CLI Command Reference.

**Java SDK for Java 2.x**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
// Create an SSM OpsItem
public static String createSSMOpsItem(SsmClient ssmClient, String title, String source, String category, String severity) {
    try {
        CreateOpsItemRequest opsItemRequest = CreateOpsItemRequest.builder()
            .description("Created by the Systems Manager Java API")
```
CreateOpsItemResponse itemResponse = 
ssmClient.createOpsItem(opsItemRequest);
return itemResponse.opsItemId();

} catch (SsmException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
return ";";

• For API details, see CreateOpsItem in AWS SDK for Java 2.x API Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use CreatePatchBaseline with an AWS SDK or CLI**

The following code examples show how to use CreatePatchBaseline.

**CLI**

**AWS CLI**

**Example 1: To create a patch baseline with auto-approval**

The following create-patch-baseline example creates a patch baseline for Windows Server that approves patches for a production environment seven days after they are released by Microsoft.

```
aws ssm create-patch-baseline \
  --name "Windows-Production-Baseline-AutoApproval" \
  --operating-system "WINDOWS"
```
--approval-rules
"PatchRules=[[PatchFilterGroup={PatchFilters=[[Key=MSRC_SEVERITY,Values=[Critical,Important,Moderate]],[Key=CLASSIFICATION,Values=[SecurityUpdates,Updates,UpdateRollups,CriticalUpdates]]}]],ApproveAfterDays=7]"

Example 2: To create a patch baseline with an approval cutoff date

The following create-patch-baseline example creates a patch baseline for Windows Server that approves all patches for a production environment that are released on or before July 7, 2020.

```bash
aws ssm create-patch-baseline
   --name "Windows-Production-Baseline-AutoApproval" \
   --operating-system "WINDOWS" \
   --approval-rules
   "PatchRules=[[PatchFilterGroup={PatchFilters=[[Key=MSRC_SEVERITY,Values=[Critical,Important,Moderate]],[Key=CLASSIFICATION,Values=[SecurityUpdates,Updates,UpdateRollups,CriticalUpdates]]}]],ApproveUntilDate=2020-07-07]"
   \
   --description "Baseline containing all updates approved for Windows Server production systems"
```

Output:

```
{
   "BaselineId": "pb-045f10b4f3EXAMPLE"
}
```

Example 3: To create a patch baseline with approval rules stored in a JSON file

The following create-patch-baseline example creates a patch baseline for Amazon Linux 2017.09 that approves patches for a production environment seven days after they are released, specifies approval rules for the patch baseline, and specifies a custom repository for patches.

CreatePatchBaseline

```bash
aws ssm create-patch-baseline
   --name "Amazon-Linux-2017.09-Patch-Baseline" \
   --operating-system "AMAZONLINUX" \
   --approval-rules
   "allow-update=
   "PatchRules=[[PatchFilterGroup={PatchFilters=[[Key=MSRC_SEVERITY,Values=[Critical,Important,Moderate]],[Key=CLASSIFICATION,Values=[SecurityUpdates,Updates,UpdateRollups,CriticalUpdates]]}]],ApproveAfterDays=7]"
   \
   --description "Baseline containing all updates approved for Amazon Linux 2017.09 production systems"
```

Output:

```
{
   "BaselineId": "pb-045f10b4f3EXAMPLE"
}
```
aws ssm create-patch-baseline \
--cli-input-json file://my-amazon-linux-approval-rules-and-repo.json

Contents of my-amazon-linux-approval-rules-and-repo.json:

```json
{
    "Name": "Amazon-Linux-2017.09-Production-Baseline",
    "Description": "My approval rules patch baseline for Amazon Linux 2017.09 instances",
    "OperatingSystem": "AMAZON_LINUX",
    "Tags": [ {
        "Key": "Environment",
        "Value": "Production"
    } ],
    "ApprovalRules": {
        "PatchRules": [ {
            "ApproveAfterDays": 7,
            "EnableNonSecurity": true,
            "PatchFilterGroup": {
                "PatchFilters": [ {
                    "Key": "SEVERITY",
                    "Values": [ "Important", "Critical" ]
                },
                { "Key": "CLASSIFICATION",
                  "Values": [ "Security", "Bugfix" ]
                },
                { "Key": "PRODUCT",
                  "Values": [ "AmazonLinux2017.09" ]
                }
            ]
        } ]
    }
}
```
Example 4: To create a patch baseline that specifies approved and rejected patches

The following `create-patch-baseline` example explicitly specifies patches to approve and reject as exception to the default approval rules.

```bash
aws ssm create-patch-baseline \
  --name "Amazon-Linux-2017.09-Alpha-Baseline" \
  --description "My custom approve/reject patch baseline for Amazon Linux 2017.09 instances" \
  --operating-system "AMAZON_LINUX" \
  --approved-patches "CVE-2018-1234567,example-pkg-EE-2018*.amzn1.noarch" \
  --approved-patches-compliance-level "HIGH" \
  --approved-patches-enable-non-security \
  --tags "Key=Environment,Value=Alpha"
```

For more information, see [Create a Custom Patch Baseline](https://docs.aws.amazon.com/systemsmanager/latest/userguide/patch-baselines.html) in the *AWS Systems Manager User Guide*.

- For API details, see [CreatePatchBaseline](https://docs.aws.amazon.com/cli/latest/reference/ssm/create-patch-baseline.html) in *AWS CLI Command Reference*. 

---

CreatePatchBaseline
Example 1: This example creates a patch baseline that approves patches, seven days after they are released by Microsoft, for managed instances running Windows Server 2019 in a production environment.

```powershell
$rule = New-Object Amazon.SimpleSystemsManagement.Model.PatchRule
$rule.ApproveAfterDays = 7

$ruleFilters = New-Object Amazon.SimpleSystemsManagement.Model.PatchFilterGroup

$patchFilter.Key="PRODUCT"
$patchFilter.Values="WindowsServer2019"

$severityFilter.Key="MSRC_SEVERITY"
$severityFilter.Values.Add("Critical")
$severityFilter.Values.Add("Important")
$severityFilter.Values.Add("Moderate")

$classificationFilter.Key = "CLASSIFICATION"
$classificationFilter.Values.Add("SecurityUpdates")
$classificationFilter.Values.Add("Updates")
$classificationFilter.Values.Add("UpdateRollups")
$classificationFilter.Values.Add("CriticalUpdates")

$ruleFilters.PatchFilters.Add($severityFilter)
$ruleFilters.PatchFilters.Add($classificationFilter)
$ruleFilters.PatchFilters.Add($patchFilter)

$rule.PatchFilterGroup = $ruleFilters

New-SSMPatchBaseline -Name "Production-Baseline-Windows2019" -Description "Baseline containing all updates approved for production systems" -ApprovalRules_PatchRule $rule
```

Output:

```
CreatePatchBaseline
```

```

```
For API details, see CreatePatchBaseline in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DeleteActivation with an AWS SDK or CLI

The following code examples show how to use DeleteActivation.

**CLI**

**AWS CLI**

To delete a managed instance activation

The following delete-activation example deletes a managed instance activation.

```
aws ssm delete-activation \
   --activation-id "aa673477-d926-42c1-8757-1358cEXAMPLE"
```

This command produces no output.

For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the AWS Systems Manager User Guide.

- For API details, see DeleteActivation in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

Example 1: This example deletes an activation. There is no output if the command succeeds.

```
Remove-SSMAactivation -ActivationId "08e51e79-1e36-446c-8e63-9458569c1363"
```
• For API details, see `DeleteActivation` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

**Use DeleteAssociation with an AWS SDK or CLI**

The following code examples show how to use `DeleteAssociation`.

**CLI**

**AWS CLI**

**Example 1: To delete an association using the association ID**

The following `delete-association` example deletes the association for the specified association ID. There is no output if the command succeeds.

```bash
aws ssm delete-association \\
   --association-id "8dfe3659-4309-493a-8755-0123456789ab"
```

This command produces no output.

For more information, see *Editing and creating a new version of an association* in the *AWS Systems Manager User Guide*.

**Example 2: To delete an association**

The following `delete-association` example deletes the association between an instance and a document. There is no output if the command succeeds.

```bash
aws ssm delete-association \\
   --instance-id "i-1234567890abcdef0" \\
   --name "AWS-UpdateSSMAgent"
```

This command produces no output.

For more information, see *Working with associations in Systems Manager* in the *AWS Systems Manager User Guide*. 
• For API details, see DeleteAssociation in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example deletes the association between an instance and a document. There is no output if the command succeeds.

Remove-SSMAssociation -InstanceId "i-0cb2b964d3e14fd9f" -Name "AWS-UpdateSSMAgent"

• For API details, see DeleteAssociation in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DeleteDocument with an AWS SDK or CLI

The following code examples show how to use DeleteDocument.

CLI

AWS CLI

To delete a document

The following delete-document example deletes a Systems Manager document.

aws ssm delete-document \   
   --name "Example"

This command produces no output.

For more information, see Creating Systems Manager Documents in the AWS Systems Manager User Guide.

• For API details, see DeleteDocument in AWS CLI Command Reference.
Java

**SDK for Java 2.x**

```java
// Deletes an AWS Systems Manager document.
public static void deleteDoc(SsmClient ssmClient, String documentName) {
    try {
        DeleteDocumentRequest documentRequest =
            DeleteDocumentRequest.builder()
            .name(documentName)
            .build();

        ssmClient.deleteDocument(documentRequest);
        System.out.println("The Systems Manager document was successfully deleted.");
    }
    catch (SsmException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see [DeleteDocument](#) in *AWS SDK for Java 2.x API Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1**: This example deletes a document. There is no output if the command succeeds.

```bash
Remove-SSMDocument -Name "RunShellScript"
```

- For API details, see [DeleteDocument](#) in *AWS Tools for PowerShell Cmdlet Reference*.  

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DeleteMaintenanceWindow with an AWS SDK or CLI

The following code examples show how to use DeleteMaintenanceWindow.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with Systems Manager

CLI

AWS CLI

To delete a maintenance window

This delete-maintenance-window example removes the specified maintenance window.

```bash
aws ssm delete-maintenance-window \
   --window-id "mw-1a2b3c4d5e6f7g8h9"
```

Output:

```
{
   "WindowId":"mw-1a2b3c4d5e6f7g8h9"
}
```

For more information, see Delete a Maintenance Window (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see DeleteMaintenanceWindow in AWS CLI Command Reference.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static void deleteMaintenanceWindow(SsmClient ssmClient, String winId) {
    try {
        DeleteMaintenanceWindowRequest windowRequest =
            DeleteMaintenanceWindowRequest.builder()
                .windowId(winId)
                .build();

        ssmClient.deleteMaintenanceWindow(windowRequest);
        System.out.println("The maintenance window was successfully deleted.");
    } catch (SsmException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see [DeleteMaintenanceWindow](https://docs.aws.amazon.com/AmazonSSM/latest/APIReference/API_DeleteMaintenanceWindow.html) in [AWS SDK for Java 2.x API Reference](https://docs.aws.amazon.com/sdkforjava/api/latest/)

PowerShell

Tools for PowerShell

**Example 1: This example removes a maintenance window.**

```powershell
Remove-SSMMaintenanceWindow -WindowId "mw-06d59c1a07c022145"
```

Output:
For API details, see DeleteMaintenanceWindow in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DeleteParameter with an AWS SDK or CLI

The following code examples show how to use DeleteParameter.

CLI

AWS CLI

To delete a parameter

The following delete-parameter example deletes the specified single parameter.

```
aws ssm delete-parameter \
   --name "MyParameter"
```

This command produces no output.

For more information, see Working with Parameter Store in the AWS Systems Manager User Guide.

- For API details, see DeleteParameter in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example deletes a parameter. There is no output if the command succeeds.

```
Remove-SSMParameter -Name "helloWorld"
```
• For API details, see `DeleteParameter` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

## Use `DeletePatchBaseline` with an AWS SDK or CLI

The following code examples show how to use `DeletePatchBaseline`.

### CLI

**AWS CLI**

To delete a patch baseline

The following `delete-patch-baseline` example deletes the specified patch baseline.

```bash
aws ssm delete-patch-baseline \\
    --baseline-id "pb-045f10b4f382baeda"
```

Output:

```json
{
    "BaselineId": "pb-045f10b4f382baeda"
}
```

For more information, see *Update or Delete a Patch Baseline (Console)* in the *AWS Systems Manager User Guide*.

• For API details, see `DeletePatchBaseline` in *AWS CLI Command Reference*.

### PowerShell

**Tools for PowerShell**

Example 1: This example deletes a patch baseline.

```powershell
Remove-SSMPatchBaseline -BaselineId "pb-045f10b4f382baeda"
```
Output:

pb-045f10b4f382baeda

- For API details, see `DeletePatchBaseline` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

**Use `DeregisterManagedInstance` with an AWS SDK or CLI**

The following code examples show how to use `DeregisterManagedInstance`.

**CLI**

**AWS CLI**

To deregister a managed instance

The following `deregister-managed-instance` example deregisters the specified managed instance.

```bash
aws ssm deregister-managed-instance
   --instance-id "mi-08ab247cdfEXAMPLE"
```

This command produces no output.

For more information, see *Deregistering Managed Instances in a Hybrid Environment* in the *AWS Systems Manager User Guide*.

- For API details, see `DeregisterManagedInstance` in *AWS CLI Command Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example deregisters a managed instance. There is no output if the command succeeds.**
Unregister-SSMManagedInstance -InstanceId "mi-08ab247cdf1046573"

- For API details, see DeregisterManagedInstance in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use DeregisterPatchBaselineForPatchGroup with an AWS SDK or CLI**

The following code examples show how to use DeregisterPatchBaselineForPatchGroup.

**CLI**

**AWS CLI**

**To deregister a patch group from a patch baseline**

The following deregister-patch-baseline-for-patch-group example deregisters the specified patch group from the specified patch baseline.

```shell
aws ssm deregister-patch-baseline-for-patch-group \
  --patch-group "Production" \
  --baseline-id "pb-0ca44a362fEXAMPLE"
```

Output:

```json
{
  "PatchGroup": "Production",
  "BaselineId": "pb-0ca44a362fEXAMPLE"
}
```

For more information, see Add a Patch Group to a Patch Baseline in the AWS Systems Manager User Guide.

- For API details, see DeregisterPatchBaselineForPatchGroup in AWS CLI Command Reference.
**Tools for PowerShell**

**Example 1: This example deregisters a patch group from a patch baseline.**

```powershell
Unregister-SSMPatchBaselineForPatchGroup -BaselineId "pb-045f10b4f382baeda" -PatchGroup "Production"
```

**Output:**

<table>
<thead>
<tr>
<th>BaselineId</th>
<th>PatchGroup</th>
</tr>
</thead>
<tbody>
<tr>
<td>pb-045f10b4f382baeda</td>
<td>Production</td>
</tr>
</tbody>
</table>

- For API details, see [DeregisterPatchBaselineForPatchGroup](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use DeregisterTargetFromMaintenanceWindow with an AWS SDK or CLI**

The following code examples show how to use `DeregisterTargetFromMaintenanceWindow`.

**CLI**

**AWS CLI**

**To remove a target from a maintenance window**

The following `deregister-target-from-maintenance-window` example removes the specified target from the specified maintenance window.

```bash
aws ssm deregister-target-from-maintenance-window \
  --window-id "mw-ab12cd34ef56gh78" \
  --window-target-id "1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d-1a2"
```
Output:

```json
{
    "WindowId":"mw-ab12cd34ef56gh78",
    "WindowTargetId":"1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d-1a2"
}
```

For more information, see [Update a Maintenance Window (AWS CLI)](https://docs.aws.amazon.com/systems-manager/latest/userguide/updated-window.html) in the *AWS Systems Manager User Guide*.

- For API details, see [DeregisterTargetFromMaintenanceWindow](https://docs.aws.amazon.com/systems-manager/latest/userguide/API_DeregisterTargetFromMaintenanceWindow.html) in *AWS CLI Command Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example removes a target from a maintenance window.**

```powershell
Unregister-SSMTargetFromMaintenanceWindow -WindowTargetId "6ab5c208-9fc4-4697-84b7-b02a6cc25f7d" -WindowId "mw-06cf17cbe4bf4f"
```

**Output:**

<table>
<thead>
<tr>
<th>WindowId</th>
<th>WindowTargetId</th>
</tr>
</thead>
<tbody>
<tr>
<td>mw-06cf17cbe4bf4f</td>
<td>6ab5c208-9fc4-4697-84b7-b02a6cc25f7d</td>
</tr>
</tbody>
</table>

- For API details, see [DeregisterTargetFromMaintenanceWindow](https://docs.aws.amazon.com/systems-manager/latest/userguide/API_DeregisterTargetFromMaintenanceWindow.html) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systems-manager/latest/userguide/using-sdk.html). This topic also includes information about getting started and details about previous SDK versions.

**Use DeregisterTaskFromMaintenanceWindow with an AWS SDK or CLI**

The following code examples show how to use DeregisterTaskFromMaintenanceWindow.
AWS CLI

**To remove a task from a maintenance window**

The following `deregister-task-from-maintenance-window` example removes the specified task from the specified maintenance window.

```bash
aws ssm deregister-task-from-maintenance-window \
   --window-id "mw-ab12cd34ef56gh78" \ 
   --window-task-id "1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d5e6c"
```

Output:

```json
{
   "WindowTaskId":"1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d5e6c",
   "WindowId":"mw-ab12cd34ef56gh78"
}
```

For more information, see Systems Manager Maintenance Windows Tutorials (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see `DeregisterTaskFromMaintenanceWindow` in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example removes a task from a maintenance window.**

```powershell
Unregister-SSMTaskFromMaintenanceWindow -WindowTaskId "f34a2c47-ddfd-4c85-a88d-72366b69af1b" -WindowId "mw-03a342e62c96d31b0"
```

Output:

<table>
<thead>
<tr>
<th>WindowId</th>
<th>WindowTaskId</th>
</tr>
</thead>
<tbody>
<tr>
<td>mw-03a342e62c96d31b0</td>
<td>f34a2c47-ddfd-4c85-a88d-72366b69af1b</td>
</tr>
</tbody>
</table>
For API details, see `DeregisterTaskFromMaintenanceWindow` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeActivations with an AWS SDK or CLI**

The following code examples show how to use `DescribeActivations`.

**CLI**

**AWS CLI**

**To describe activations**

The following `describe-activations` example lists details about the activations in your AWS account.

```bash
aws ssm describe-activations
```

Output:

```json
{
    "ActivationList": [
        {
            "ActivationId": "5743558d-563b-4457-8682-d16c3EXAMPLE",
            "Description": "Example1",
            "IamRole": "HybridWebServersRole",
            "RegistrationLimit": 5,
            "RegistrationsCount": 5,
            "ExpirationDate": 1584316800.0,
            "Expired": false,
            "CreatedDate": 1581954699.792
        },
        {
            "ActivationId": "3ee0322b-f62d-40eb-b672-13ebfEXAMPLE",
            "Description": "Example2",
            "IamRole": "HybridDatabaseServersRole",
            "RegistrationLimit": 5,
            "RegistrationsCount": 5,
        }
    ]
}
```
For more information, see Step 4: Create a Managed-Instance Activation for a Hybrid Environment in the AWS Systems Manager User Guide.

- For API details, see DescribeActivations in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example provides details about the activations on your account.

```
Get-SSMAActivation
```

Output:

```
ActivationId        : 08e51e79-1e36-446c-8e63-9458569c1363
CreatedDate         : 3/1/2017 12:01:51 AM
DefaultInstanceName : MyWebServers
Description         :
ExpirationDate      : 3/2/2017 12:01:51 AM
Expired             : False
IamRole             : AutomationRole
RegistrationLimit   : 10
RegistrationsCount  : 0
```

- For API details, see DescribeActivations in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeAssociation with an AWS SDK or CLI**

The following code examples show how to use DescribeAssociation.
Example 1: To get details of an association

The following describe-association example describes the association for the specified association ID.

```bash
aws ssm describe-association \
  --association-id "8dfe3659-4309-493a-8755-0123456789ab"
```

Output:

```json
{
  "AssociationDescription": {
    "Name": "AWS-GatherSoftwareInventory",
    "AssociationVersion": "1",
    "Date": 1534864780.995,
    "LastUpdateAssociationDate": 1543235759.81,
    "Overview": {
      "Status": "Success",
      "AssociationStatusAggregatedCount": {
        "Success": 2
      }
    },
    "DocumentVersion": "$DEFAULT",
    "Parameters": {
      "applications": [
        "Enabled"
      ],
      "awsComponents": [
        "Enabled"
      ],
      "customInventory": [
        "Enabled"
      ],
      "files": [
        ""
      ],
      "instanceDetailedInformation": [
        "Enabled"
      ]
  }
}
```
"networkConfig": [  "Enabled"
],
"services": [  "Enabled"
],
"windowsRegistry": [  ""
],
"windowsRoles": [  "Enabled"
],
"windowsUpdates": [  "Enabled"
]
},
"AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
"Targets": [
{
  "Key": "InstanceIds",
  "Values": [  "*"
  ]
}
],
"ScheduleExpression": "rate(24 hours)",
"LastExecutionDate": 1550501886.0,
"LastSuccessfulExecutionDate": 1550501886.0,
"AssociationName": "Inventory-Association"
}
]

For more information, see Editing and creating a new version of an association in the AWS Systems Manager User Guide.

Example 2: To get details of an association for a specific instance and document

The following describe-association example describes the association between an instance and a document.

```
aws ssm describe-association \\
  --instance-id "i-1234567890abcdef0" \\
  --name "AWS-UpdateSSMAgent"
```
Output:

```json
{
    "AssociationDescription": {
        "Status": {
            "Date": 1487876122.564,
            "Message": "Associated with AWS-UpdateSSMAgent",
            "Name": "Associated"
        },
        "Name": "AWS-UpdateSSMAgent",
        "InstanceId": "i-1234567890abcdef0",
        "Overview": {
            "Status": "Pending",
            "DetailedStatus": "Associated",
            "AssociationStatusAggregatedCount": {
                "Pending": 1
            }
        },
        "AssociationId": "d8617c07-2079-4c18-9847-1234567890ab",
        "DocumentVersion": "$DEFAULT",
        "LastUpdateAssociationDate": 1487876122.564,
        "Date": 1487876122.564,
        "Targets": [
            {
                "Values": [
                    "i-1234567890abcdef0"
                ],
                "Key": "InstanceIds"
            }
        ]
    }
}
```

For more information, see [Editing and creating a new version of an association](https://docs.aws.amazon.com/systems-manager/latest/userguide/edit-create-association.html) in the *AWS Systems Manager User Guide*.

- For API details, see [DescribeAssociation](https://docs.aws.amazon.com/cli/latest/reference/systems-manager/describe-association.html) in *AWS CLI Command Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1**: This example describes the association between an instance and a document.
For API details, see `DescribeAssociation` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/sms/latest/dv/api/using-systems-manager-sdk.html). This topic also includes information about getting started and details about previous SDK versions.

### Use `DescribeAssociationExecutionTargets` with an AWS SDK or CLI

The following code examples show how to use `DescribeAssociationExecutionTargets`.

**CLI**

**AWS CLI**

To get details of an association execution

The following `describe-association-execution-targets` example describes the specified association execution.

```bash
aws ssm describe-association-execution-targets
  --association-id "8dfe3659-4309-493a-8755-0123456789ab" \
  --execution-id "7abb6378-a4a5-4f10-8312-0123456789ab"
```

Output:

```json
{
```
"AssociationExecutionTargets": [  
  {  
    "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",  
    "AssociationVersion": "1",  
    "ExecutionId": "7abb6378-a4a5-4f10-8312-0123456789ab",  
    "ResourceId": "i-1234567890abcdef0",  
    "ResourceType": "ManagedInstance",  
    "Status": "Success",  
    "DetailedStatus": "Success",  
    "LastExecutionDate": 1550505538.497,  
    "OutputSource": {  
      "OutputSourceId": "97fff367-fc5a-4299-aed8-0123456789ab",  
      "OutputSourceType": "RunCommand"  
    }  
  }  
]  
}

For more information, see [Viewing association histories](#) in the [AWS Systems Manager User Guide](#).

- For API details, see [DescribeAssociationExecutionTargets](#) in [AWS CLI Command Reference](#).

### PowerShell

#### Tools for PowerShell

**Example 1: This example displays the resource ID and its execution status that are part of the association execution targets**

```
Get-SSMAssociationExecutionTarget -AssociationId 123a45a0-c678-9012-3456-78901234db5e -ExecutionId 123a45a0-c678-9012-3456-78901234db5e | Select-Object ResourceId, Status
```

**Output:**

<table>
<thead>
<tr>
<th>ResourceId</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>i-01b2a3456f7a890b</td>
<td>Success</td>
</tr>
<tr>
<td>i-01c12a45d6fc7a89f</td>
<td>Success</td>
</tr>
<tr>
<td>i-01caf234f56d7dc8</td>
<td>Success</td>
</tr>
<tr>
<td>i-012a3fd45af6dbcf</td>
<td>Failed</td>
</tr>
</tbody>
</table>

[DescribeAssociationExecutionTargets](#)
Example 2: This command checks the particular execution of a particular automation since yesterday, where a command document is associated. It further checks if the association execution failed, and if so, it will display the command invocation details for the execution along with the instance id

```
$AssociationExecution = Get-SSMAssociationExecutionTarget -AssociationId 1c234567-890f-1aca-a234-5a678d901cb0 -ExecutionId 12345ca12-3456-2b45-2345-23456789012 | Where-Object {$_.LastExecutionDate -gt (Get-Date -Hour 00 -Minute 00).AddDays(-1)}

foreach ($execution in $AssociationExecution) {
    if($execution.Status -ne 'Success'){
        Write-Output "There was an issue executing the association $($execution.AssociationId) on $($execution.ResourceId)"
        Get-SSMCommandInvocation -CommandId $execution.OutputSource.OutputSourceId -Detail:$true | Select-Object -ExpandProperty CommandPlugins
    }
}
```

Output:

There was an issue executing the association 1c234567-890f-1aca-a234-5a678d901cb0 on i-0a1caf234f56d7dc8

Name : aws:runPowerShellScript

**Use `DescribeAssociationExecutions` with an AWS SDK or CLI**

The following code examples show how to use `DescribeAssociationExecutions`.

**CLI**

**AWS CLI**

**Example 1: To get details of all executions for an association**

The following `describe-association-executions` example describes all executions of the specified association.

```
aws ssm describe-association-executions \
   --association-id "8dfe3659-4309-493a-8755-0123456789ab"
```

Output:

```
{
   "AssociationExecutions": [
      {
         "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
         "AssociationVersion": "1",
         "ExecutionId": "474925ef-1249-45a2-b93d-0123456789ab",
         "Status": "Success",
         "DetailedStatus": "Success",
         "CreatedTime": 1550505827.119,
         "ResourceCountByStatus": "{Success=1}"
      },
      {
         "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
         "AssociationVersion": "1",
```
For more information, see Viewing association histories in the AWS Systems Manager User Guide.

**Example 2: To get details of all executions for an association after a specific date and time**

The following describe-association-executions example describes all executions of an association after the specified date and time.

```bash
aws ssm describe-association-executions \
    --association-id "8dfe3659-4309-493a-8755-0123456789ab" \
    --filters "Key=CreatedTime,Value=2019-02-18T16:00:00Z,Type=GREATER_THAN"
```

Output:

```json
{
    "AssociationExecutions": [
        {
            "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
            "AssociationVersion": "1",
            "ExecutionId": "474925ef-1249-45a2-b93d-0123456789ab",
            "Status": "Success",
            "DetailedStatus": "Success",
            "CreatedTime": 1550505827.119,
            "ResourceCountByStatus": "{Success=1}"
        },
        {
            "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
            "AssociationVersion": "1",
            "ExecutionId": "7abb6378-a4a5-4f10-8312-0123456789ab",
            "Status": "Success",
            "DetailedStatus": "Success",
```
For more information, see Viewing association histories in the AWS Systems Manager User Guide.

- For API details, see DescribeAssociationExecutions in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example returns the executions for the association ID provided**

```powershell
Get-SSMAssociationExecution -AssociationId 123a45a0-c678-9012-3456-78901234db5e
```

**Output:**

```
AssociationId         : 123a45a0-c678-9012-3456-78901234db5e

ResourceCountByStatus : {Success=4}
Status                : Success
```

- For API details, see DescribeAssociationExecutions in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeAutomationExecutions with an AWS SDK or CLI**

The following code examples show how to use DescribeAutomationExecutions.
AWS CLI

To describe an automation execution

The following describe-automation-executions example displays details about an Automation execution.

```bash
aws ssm describe-automation-executions \
   --filters Key=ExecutionId,Values=73c8eef8-f4ee-4a05-820c-e354fEXAMPLE
```

Output:

```json
{
   "AutomationExecutionMetadataList": [
      {
         "AutomationExecutionId": "73c8eef8-f4ee-4a05-820c-e354fEXAMPLE",
         "DocumentName": "AWS-StartEC2Instance",
         "DocumentVersion": "1",
         "AutomationExecutionStatus": "Success",
         "ExecutionStartTime": 1583737233.748,
         "ExecutionEndTime": 1583737234.719,
         "ExecutedBy": "arn:aws:sts::29884EXAMPLE:assumed-role/mw_service_role/OrchestrationService",
         "LogFile": "",
         "Outputs": {},
         "Mode": "Auto",
         "Targets": [],
         "ResolvedTargets": {
            "ParameterValues": [],
            "Truncated": false
         },
         "AutomationType": "Local"
      }
   ]
}
```

For more information, see [Running a Simple Automation Workflow](#) in the [AWS Systems Manager User Guide](#).

- For API details, see [DescribeAutomationExecutions](#) in [AWS CLI Command Reference](#).
Tools for PowerShell

Example 1: This example describes all active and terminated Automation Executions associated with your account.

Get-SSMAutomationExecutionList

Output:

### Use DescribeAutomationStepExecutions with an AWS SDK or CLI

The following code examples show how to use `DescribeAutomationStepExecutions`:

**CLI**

**AWS CLI**

**Example 1: To describe all steps for an automation execution**

The following `describe-automation-step-executions` example displays details about the steps of an Automation execution.

```bash
cmd
aws ssm describe-automation-step-executions
--automation-execution-id 73c8eef8-f4ee-4a05-820c-e354fEXAMPLE
```

**Output:**

```json
{
   "StepExecutions": [
      {
         "StepName": "startInstances",
         "Action": "aws:changeInstanceState",
         "ExecutionStartTime": 1583737234.134,
         "ExecutionEndTime": 1583737234.672,
         "StepStatus": "Success",
         "Inputs": {
            "DesiredState": "\"running\"",
            "InstanceIds": "[\"i-0cb99161f6EXAMPLE\"]"
         },
         "Outputs": {
```

91234d56-7e89-0ac1-2aee-34ea5d6a7c89  AWS-UpdateWindowsAmi

- For API details, see [DescribeAutomationExecutions](#) in [AWS Tools for PowerShell Cmdlet Reference](#).

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

### Use DescribeAutomationStepExecutions with an AWS SDK or CLI

The following code examples show how to use `DescribeAutomationStepExecutions`:

**CLI**

**AWS CLI**

**Example 1: To describe all steps for an automation execution**

The following `describe-automation-step-executions` example displays details about the steps of an Automation execution.

```bash
cmd
aws ssm describe-automation-step-executions
--automation-execution-id 73c8eef8-f4ee-4a05-820c-e354fEXAMPLE
```

**Output:**

```json
{
   "StepExecutions": [
      {
         "StepName": "startInstances",
         "Action": "aws:changeInstanceState",
         "ExecutionStartTime": 1583737234.134,
         "ExecutionEndTime": 1583737234.672,
         "StepStatus": "Success",
         "Inputs": {
            "DesiredState": "\"running\"",
            "InstanceIds": "[\"i-0cb99161f6EXAMPLE\"]"
         },
         "Outputs": {
```
Example 2: To describe a specific step for an automation execution

The following describe-automation-step-executions example displays details about a specific step of an Automation execution.

```bash
aws ssm describe-automation-step-executions
--automation-execution-id 73c8ef8-f4ee-4a05-820c-e354fEXAMPLE
--filters Key=StepExecutionId,Values=95e70479-cf20-4d80-8018-7e4e2EXAMPLE
```

For more information, see Running an Automation Workflow Step by Step (Command Line) in the AWS Systems Manager User Guide.

- For API details, see DescribeAutomationStepExecutions in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example displays information about all active and terminated step executions in an Automation workflow.

```powershell
Get-SSMAutomationStepExecution -AutomationExecutionId e1d2bad3-4567-8901-ae23-456c7c8901be | Select-Object StepName, Action, StepStatus
```

Output:

- For API details, see `DescribeAutomationStepExecutions` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

**Use `DescribeAvailablePatches` with an AWS SDK or CLI**

The following code examples show how to use `DescribeAvailablePatches`.

**CLI**

**AWS CLI**

**To get available patches**

The following `describe-available-patches` example retrieves details about all available patches for Windows Server 2019 that have a MSRC severity of Critical.

```bash
aws ssm describe-available-patches \
   --filters "Key=PRODUCT,Values=WindowsServer2019" \
   "Key=MSRC_SEVERITY,Values=Critical"
```

**Output:**

```json
{
   "Patches": [ 
   { 
```
To get details of a specific patch

DescribeAvailablePatches
The following `describe-available-patches` example retrieves details about the specified patch.

```bash
aws ssm describe-available-patches \
   --filters "Key=PATCH_ID,Values=KB4480979"
```

**Output:**

```json
{
   "Patches": [
      {
         "Id": "680861e3-fb75-432e-818e-d72e5f2be719",
         "ReleaseDate": 1546970408.0,
         "Title": "2019-01 Security Update for Adobe Flash Player for Windows Server 2016 for x64-based Systems (KB4480979)",
         "Description": "A security issue has been identified in a Microsoft software product that could affect your system. You can help protect your system by installing this update from Microsoft. For a complete listing of the issues that are included in this update, see the associated Microsoft Knowledge Base article. After you install this update, you may have to restart your system.",
         "ContentUrl": "https://support.microsoft.com/en-us/kb/4480979",
         "Vendor": "Microsoft",
         "ProductFamily": "Windows",
         "Product": "WindowsServer2016",
         "Classification": "SecurityUpdates",
         "MsrcSeverity": "Critical",
         "KbNumber": "KB4480979",
         "MsrcNumber": ",",
         "Language": "All"
      }
   ]
}
```

For more information, see [How Patch Manager Operations Work](#) in the *AWS Systems Manager User Guide*.

- For API details, see [DescribeAvailablePatches](#) in *AWS CLI Command Reference*. 

---

**DescribeAvailablePatches** 2361
PowerShell

Tools for PowerShell

Example 1: This example gets all available patches for Windows Server 2012 that have a MSRC severity of Critical. The syntax used by this example requires PowerShell version 3 or later.

```powershell
$filter1 = @{Key="PRODUCT";Values=@("WindowsServer2012")}
$filter2 = @{Key="MSRC_SEVERITY";Values=@("Critical")}
Get-SSMAvailablePatch -Filter $filter1,$filter2
```

Output:

<table>
<thead>
<tr>
<th>Classification</th>
<th>SecurityUpdates</th>
</tr>
</thead>
<tbody>
<tr>
<td>ContentUrl</td>
<td><a href="https://support.microsoft.com/en-us/kb/2727528">https://support.microsoft.com/en-us/kb/2727528</a></td>
</tr>
<tr>
<td>Description</td>
<td>A security issue has been identified that could allow an unauthenticated remote attacker to compromise your system and gain control over it. You can help protect your system by installing this update from Microsoft. After you install this update, you may have to restart your system.</td>
</tr>
<tr>
<td>Id</td>
<td>1eb507be-2040-4ebe-803d-abc55700b715</td>
</tr>
<tr>
<td>KbNumber</td>
<td>KB2727528</td>
</tr>
<tr>
<td>Language</td>
<td>All</td>
</tr>
<tr>
<td>MsricNumber</td>
<td>MS12-072</td>
</tr>
<tr>
<td>MsricSeverity</td>
<td>Critical</td>
</tr>
<tr>
<td>Product</td>
<td>WindowsServer2012</td>
</tr>
<tr>
<td>ProductFamily</td>
<td>Windows</td>
</tr>
<tr>
<td>ReleaseDate</td>
<td>11/13/2012 6:00:00 PM</td>
</tr>
<tr>
<td>Title</td>
<td>Security Update for Windows Server 2012 (KB2727528)</td>
</tr>
<tr>
<td>Vendor</td>
<td>Microsoft</td>
</tr>
</tbody>
</table>

Example 2: With PowerShell version 2, you must use New-Object to create each filter.

```powershell
$filter1 = New-Object Amazon.SimpleSystemsManagement.Model.PatchOrchestratorFilter
$filter1.Key = "PRODUCT"
$filter1.Values = "WindowsServer2012"
```

DescribeAvailablePatches
Example 3: This example fetches all the updates which are released in last 20 days and applicable to products matching WindowsServer2019

Output:

<table>
<thead>
<tr>
<th>ReleaseDate</th>
<th>Product</th>
<th>Title</th>
</tr>
</thead>
<tbody>
<tr>
<td>4/2/2019 5:00:06 PM</td>
<td>WindowsServer2019</td>
<td>2019-03 Servicing Stack Update for Windows Server 2019 for x64-based Systems (KB4493510)</td>
</tr>
</tbody>
</table>

For API details, see DescribeAvailablePatches in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DescribeDocument with an AWS SDK or CLI

The following code examples show how to use DescribeDocument.

CLI

AWS CLI

To display details of a document
The following describe-document example displays details about a Systems Manager document in your AWS account.

```
aws ssm describe-document \
--name "Example"
```

Output:

```
{
  "Document": {
    "Hash": "fc2410281f40779e694a8b95975d0f9f316da8a153daa94e3d9921102EXAMPLE",
    "HashType": "Sha256",
    "Name": "Example",
    "Owner": "29884EXAMPLE",
    "CreatedDate": 1583257938.266,
    "Status": "Active",
    "DocumentVersion": "1",
    "Description": "Document Example",
    "Parameters": [
      {
        "Name": "AutomationAssumeRole",
        "Type": "String",
        "Description": "(Required) The ARN of the role that allows Automation to perform the actions on your behalf. If no role is specified, Systems Manager Automation uses your IAM permissions to execute this document.”,
        "DefaultValue": ""
      },
      {
        "Name": "InstanceId",
        "Type": "String",
        "Description": "(Required) The ID of the Amazon EC2 instance.”,
        "DefaultValue": ""
      }
    ],
    "PlatformTypes": [
      "Windows",
      "Linux"
    ],
    "DocumentType": "Automation",
    "SchemaVersion": "0.3",
    "LatestVersion": "1",
    "DefaultVersion": "1"
  }
}
```
For more information, see [Creating Systems Manager Documents](#) in the AWS Systems Manager User Guide.

- For API details, see [DescribeDocument](#) in [AWS CLI Command Reference](#).

### PowerShell

**Tools for PowerShell**

**Example 1:** This example returns information about a document.

```powershell
Get-SSMDocumentDescription -Name "RunShellScript"
```

**Output:**

<table>
<thead>
<tr>
<th>CreatedDate</th>
<th>2/24/2017 5:25:13 AM</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultVersion</td>
<td>1</td>
</tr>
<tr>
<td>Description</td>
<td>Run an updated script</td>
</tr>
<tr>
<td>DocumentType</td>
<td>Command</td>
</tr>
<tr>
<td>DocumentVersion</td>
<td>1</td>
</tr>
<tr>
<td>Hash</td>
<td>f775e5df4904c6fa46686c4722fae9de1950dace25cd9608ff8d622046b68d9b</td>
</tr>
<tr>
<td>HashType</td>
<td>Sha256</td>
</tr>
<tr>
<td>LatestVersion</td>
<td>1</td>
</tr>
<tr>
<td>Name</td>
<td>RunShellScript</td>
</tr>
<tr>
<td>Owner</td>
<td>123456789012</td>
</tr>
<tr>
<td>Parameters</td>
<td>{commands}</td>
</tr>
<tr>
<td>PlatformTypes</td>
<td>{Linux}</td>
</tr>
<tr>
<td>SchemaVersion</td>
<td>2.0</td>
</tr>
<tr>
<td>Sha1</td>
<td></td>
</tr>
<tr>
<td>Status</td>
<td>Active</td>
</tr>
</tbody>
</table>

- For API details, see [DescribeDocument](#) in [AWS Tools for PowerShell Cmdlet Reference](#).
For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeDocumentPermission with an AWS SDK or CLI**

The following code examples show how to use DescribeDocumentPermission.

**CLI**

**AWS CLI**

**To describe document permissions**

The following describe-document-permission example displays permission details about a Systems Manager document that is shared publicly.

```bash
aws ssm describe-document-permission \
   --name "Example" \
   --permission-type "Share"
```

**Output:**

```json
{
   "AccountIds": [ "all" ],
   "AccountSharingInfoList": [ {
      "AccountId": "all",
      "SharedDocumentVersion": "$DEFAULT"
   } ]
}
```

For more information, see Share a Systems Manager Document in the AWS Systems Manager User Guide.

- For API details, see DescribeDocumentPermission in AWS CLI Command Reference.
Tools for PowerShell

Example 1: This example lists all the versions for a document.

```powershell
Get-SSMDocumentVersionList -Name "RunShellScript"
```

Output:

<table>
<thead>
<tr>
<th>CreatedDate</th>
<th>DocumentVersion</th>
<th>IsDefaultVersion</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>2/24/2017 5:25:13 AM</td>
<td>1</td>
<td>True</td>
<td>RunShellScript</td>
</tr>
</tbody>
</table>

For API details, see [DescribeDocumentPermission](#) in [AWS Tools for PowerShell Cmdlet Reference](#).

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeEffectiveInstanceAssociations with an AWS SDK or CLI**

The following code examples show how to use DescribeEffectiveInstanceAssociations.

**CLI**

**AWS CLI**

To get details of the effective associations for an instance

The following `describe-effective-instance-associations` example retrieves details about the effective associations for an instance.

Command:

```bash
aws ssm describe-effective-instance-associations --instance-id "i-1234567890abcdef0"
```

Output:
For API details, see [DescribeEffectiveInstanceAssociations](https://docs.aws.amazon.com/cli/latest/reference/ssm/describe-effective-instance-associations.html) in **AWS CLI Command Reference**.

### PowerShell

**Tools for PowerShell**

**Example 1: This example describes the effective associations for an instance.**

```powershell
Get-SSMEffectiveInstanceAssociationList -InstanceId "i-0000293fffd8c57862" -MaxResult 5
```

**Output:**

<table>
<thead>
<tr>
<th>AssociationId</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Example 2: This example displays the contents of the effective associations for an instance.

(Get-SSMEffectiveInstanceAssociationList -InstanceId "i-000293ff8c57862" -MaxResult 5).Content

Output:

{
   "schemaVersion": "1.2",
   "description": "Update the Amazon SSM Agent to the latest version or specified version.",
   "parameters": {
      "version": {
         "default": "",
         "description": "(Optional) A specific version of the Amazon SSM Agent to install. If not specified, the agent will be updated to the latest version.",
         "type": "String"
      },
      "allowDowngrade": {
         "default": "false",
         "description": "(Optional) Allow the Amazon SSM Agent service to be downgraded to an earlier version. If set to false, the service can be upgraded to newer versions only (default). If set to true, specify the earlier version.",
         "type": "String",
         "allowedValues": [
            "true",
            "false"
         ]
      }
   },
   "runtimeConfig": {
      "aws:updateSsmAgent": {
         "properties": [
            {
               "agentName": "amazon-ssm-agent",
               "source": "https://s3.{Region}.amazonaws.com/amazon-ssm-{Region}/ssm-agent-manifest.json",
            }
         ]
      }
   }
}
• For API details, see `DescribeEffectiveInstanceAssociations` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

**Use `DescribeEffectivePatchesForPatchBaseline` with an AWS SDK or CLI**

The following code examples show how to use `DescribeEffectivePatchesForPatchBaseline`.

**CLI**

**AWS CLI**

**Example 1: To get all patches defined by a custom patch baseline**

The following `describe-effective-patches-for-patch-baseline` example returns the patches defined by a custom patch baseline in the current AWS account. Note that for a custom baseline, only the ID is required for `--baseline-id`.

```bash
aws ssm describe-effective-patches-for-patch-baseline \
    --baseline-id "pb-08b654cf9b9681f04"
```

**Output:**

```
{
    "EffectivePatches": [
        {
            "Patch": {
                "Id": "fe6bd8c2-3752-4c8b-ab3e-1a7ed08767ba",
            
```
"ReleaseDate": 1544047205.0,
"Title": "2018-11 Update for Windows Server 2019 for x64-based Systems (KB4470788)",
"Description": "Install this update to resolve issues in Windows. For a complete listing of the issues that are included in this update, see the associated Microsoft Knowledge Base article for more information. After you install this item, you may have to restart your computer.",
"ContentUrl": "https://support.microsoft.com/en-us/kb/4470788",
"Vendor": "Microsoft",
"ProductFamily": "Windows",
"Product": "WindowsServer2019",
"Classification": "SecurityUpdates",
"MsrSeverity": "Critical",
"KbNumber": "KB4470788",
"MsrNumber": "",
"Language": "All"
},
"PatchStatus": {
"DeploymentStatus": "APPROVED",
"ComplianceLevel": "CRITICAL",
"ApprovalDate": 1544047205.0
}
},
{
"Patch": {
"Id": "915a6b1a-f556-4d83-8f50-b2e75a9a7e58",

"Product": "WindowsServer2019",
"Classification": "SecurityUpdates",
"MsrSeverity": "Important",
"KbNumber": "KB4483452",
"MsrNumber": "",
"Language": "All"
Example 2: To get all patches defined by an AWS managed patch baseline

The following describe-effective-patches-for-patch-baseline example returns the patches defined by an AWS managed patch baseline. Note that for an AWS managed baseline, the complete baseline ARN is required for --baseline-id.

```
aws ssm describe-effective-patches-for-patch-baseline \
--baseline-id "arn:aws:ssm:us-east-2:733109147000:patchbaseline/pb-020d361a05defe4ed"
```

See example 1 for sample output.

For more information, see [How Security Patches Are Selected](#) in the [AWS Systems Manager User Guide](#).

- For API details, see [DescribeEffectivePatchesForPatchBaseline](#) in [AWS CLI Command Reference](#).

PowerShell

**Tools for PowerShell**

**Example 1: This example lists all patch baselines, with a maximum result list of 1.**

```
Get-SSMEffectivePatchesForPatchBaseline -BaselineId "pb-0a2f1059b670ebd31" -MaxResult 1
```

**Output:**
Example 2: This example displays the patch status for all patch baselines, with a maximum result list of 1.

(Get-SSMEffectivePatchesForPatchBaseline -BaselineId "pb-0a2f1059b670ebd31" -MaxResult 1).PatchStatus

Output:

<table>
<thead>
<tr>
<th>ApprovalDate</th>
<th>DeploymentStatus</th>
</tr>
</thead>
<tbody>
<tr>
<td>12/21/2010 6:00:00 PM</td>
<td>APPROVED</td>
</tr>
</tbody>
</table>

- For API details, see DescribeEffectivePatchesForPatchBaseline in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DescribeInstanceAssociationsStatus with an AWS SDK or CLI

The following code examples show how to use DescribeInstanceAssociationsStatus.

CLI

AWS CLI

To describe the status of an instance's associations

This example shows details of the associations for an instance.

Command:
aws ssm describe-instance-associations-status --instance-id "i-1234567890abcdef0"

Output:

```
{
  "InstanceAssociationStatusInfos": [
    {
      "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
      "Name": "AWS-GatherSoftwareInventory",
      "DocumentVersion": "1",
      "AssociationVersion": "1",
      "InstanceId": "i-1234567890abcdef0",
      "ExecutionDate": 1550501886.0,
      "Status": "Success",
      "ExecutionSummary": "1 out of 1 plugin processed, 1 success, 0 failed, 0 timedout, 0 skipped. ",
      "AssociationName": "Inventory-Association"
    },
    {
      "AssociationId": "5c5a31f6-6dae-46f9-944c-0123456789ab",
      "Name": "AWS-UpdateSSMAgent",
      "DocumentVersion": "1",
      "AssociationVersion": "1",
      "InstanceId": "i-1234567890abcdef0",
      "ExecutionDate": 1550505828.548,
      "Status": "Success",
      "DetailedStatus": "Success",
      "AssociationName": "UpdateSSMAgent"
    }
  ]
}
```

- For API details, see [DescribeInstanceAssociationsStatus](https://docs.aws.amazon.com/cli/latest/reference/ssm/describe-instance-associations-status.html) in *AWS CLI Command Reference*.

### PowerShell

**Tools for PowerShell**

**Example 1: This example shows details of the associations for an instance.**

Get-SSMInstanceAssociationsStatus -InstanceId "i-0000293fffd8c57862"
**Output:**

<table>
<thead>
<tr>
<th>AssociationId</th>
<th>d8617c07-2079-4c18-9847-1655fc2698b0</th>
</tr>
</thead>
<tbody>
<tr>
<td>DetailedStatus</td>
<td>Pending</td>
</tr>
<tr>
<td>DocumentVersion</td>
<td>1</td>
</tr>
<tr>
<td>ErrorCode</td>
<td></td>
</tr>
<tr>
<td>ExecutionDate</td>
<td>2/20/2015 8:31:11 AM</td>
</tr>
<tr>
<td>ExecutionSummary</td>
<td>temp_status_change</td>
</tr>

<td>InstanceId</td>
<td>i-0000293ff8c57862</td>
</tr>
<tr>
<td>Name</td>
<td>AWS-UpdateSSMAgent</td>
</tr>
<tr>
<td>OutputUrl</td>
<td></td>
</tr>
<tr>
<td>Status</td>
<td>Pending</td>
</tr>
</tbody>
</table>

**Example 2:** This example checks the instance association status for the given instance id and further, displays the execution status of those associations

```powershell
Get-SSMInstanceAssociationsStatus -InstanceId i-012e3cb4df567e8aa | ForEach-Object {Get-SSMAssociationExecution -AssociationId .AssociationId}
```

**Output:**

<table>
<thead>
<tr>
<th>AssociationId</th>
<th>512a34a5-c678-1234-1234-12345678db9e</th>
</tr>
</thead>
<tbody>
<tr>
<td>AssociationVersion</td>
<td>2</td>
</tr>
<tr>
<td>CreatedTime</td>
<td>3/2/2019 8:53:29 AM</td>
</tr>
<tr>
<td>DetailedStatus</td>
<td></td>
</tr>
<tr>
<td>ExecutionId</td>
<td>512a34a5-c678-1234-1234-12345678db9e</td>
</tr>
<tr>
<td>LastExecutionDate</td>
<td>1/1/0001 12:00:00 AM</td>
</tr>
<tr>
<td>ResourceCountByStatus</td>
<td>{Success=9}</td>
</tr>
<tr>
<td>Status</td>
<td>Success</td>
</tr>
</tbody>
</table>

- For API details, see [DescribeInstanceAssociationsStatus](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeInstanceInformation with an AWS SDK or CLI**

The following code examples show how to use DescribeInstanceInformation.
AWS CLI

Example 1: To describe managed instance information

The following describe-instance-information example retrieves details of each of your managed instances.

```
aws ssm describe-instance-information
```

Example 2: To describe information about a specific managed instance

The following describe-instance-information example shows details of the managed instance i-028ea792daEXAMPLE.

```
aws ssm describe-instance-information
  --filters "Key=InstanceIds,Values=i-028ea792daEXAMPLE"
```

Example 3: To describe information about managed instances with a specific tag key

The following describe-instance-information example shows details for managed instances that have the tag key DEV.

```
aws ssm describe-instance-information
  --filters "Key=tag-key,Values=DEV"
```

Output:

```
{
  "InstanceInformationList": [
    {
      "InstanceId": "i-028ea792daEXAMPLE",
      "PingStatus": "Online",
      "LastPingDateTime": 1582221233.421,
      "AgentVersion": "2.3.842.0",
      "IsLatestVersion": true,
      "PlatformType": "Linux",
      "PlatformName": "SLES",
      "PlatformVersion": "15.1",
    }
  ]
}
```
"ResourceType": "EC2Instance",
"IPAddress": "192.0.2.0",
"ComputerName": "ip-198.51.100.0.us-east-2.compute.internal",
"AssociationStatus": "Success",
"LastAssociationExecutionDate": 1582220806.0,
"LastSuccessfulAssociationExecutionDate": 1582220806.0,
"AssociationOverview": {
    "DetailedStatus": "Success",
    "InstanceAssociationStatusAggregatedCount": {
        "Success": 2
    }
}
]
]

For more information, see Managed Instances in the AWS Systems Manager User Guide.

- For API details, see DescribeInstanceInformation in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example shows details of each of your instances.

Get-SSMInstanceInformation

Output:

<table>
<thead>
<tr>
<th>ActivationId</th>
<th>:</th>
</tr>
</thead>
<tbody>
<tr>
<td>AgentVersion</td>
<td>: 2.0.672.0</td>
</tr>
<tr>
<td>AssociationOverview</td>

<tr>
<td>IsLatestVersion</td>
<td>: True</td>
</tr>
<tr>
<td>LastAssociationExecutionDate</td>
<td>: 2/24/2017 3:18:09 AM</td>
</tr>
</tbody>
</table>
Example 2: This example shows how to use the -Filter parameter to filter results to only those AWS Systems Manager instances in region us-east-1 with an AgentVersion of 2.2.800.0. You can find a list of valid -Filter key values in the InstanceInformation API reference topic (https://docs.aws.amazon.com/systems-manager/latest/APIReference/API_InstanceInformation.html#systemsmanager-Type-InstanceInformation-ActivationId).

```powershell
$Filters = @{
    Key="AgentVersion"
    Values="2.2.800.0"
}
Get-SSMInstanceInformation -Region us-east-1 -Filter $Filters
```

**Output:**

```powershell
ActivationId                           : 
AgentVersion                           : 2.2.800.0
AssociationOverview                    : Amazon.SimpleSystemsManagement.Model.InstanceAggregatedAssociationOverview
AssociationStatus                      : Success
ComputerName                           : EXAMPLE-EXAMPLE.WORKGROUP
IamRole                                 : 
InstanceId                             : i-EXAMPLEb0792d98ce
IPAddress                              : 10.0.0.01
IsLatestVersion                        : False
LastAssociationExecutionDate           : 8/16/2018 12:02:50 AM
LastPingDateTime                       : 8/16/2018 7:40:27 PM
LastSuccessfulAssociationExecutionDate : 8/16/2018 12:02:50 AM
Name                                   : 
PingStatus                             : Online
PlatformName                           : Microsoft Windows Server 2016 Datacenter
PlatformType                           : Windows
PlatformVersion                        : 
RegistrationDate                       : 1/1/0001 12:00:00 AM
ResourceType                           : EC2Instance
```
Example 3: This example shows how to use the -InstanceInformationFilterList parameter to filter results to only those AWS Systems Manager instances in region us-east-1 with PlatformTypes of Windows or Linux. You can find a list of valid -InstanceInformationFilterList key values in the InstanceInformationFilter API reference topic (https://docs.aws.amazon.com/systems-manager/latest/APIReference/API_InstanceInformationFilter.html).

```
$Filters = @{
    Key="PlatformTypes"
    ValueSet=("Windows","Linux")
}
Get-SSMInstanceInformation -Region us-east-1 -InstanceInformationFilterList $Filters
```

Output:

```
ActivationId : 2379
```

DescribeInstanceInformation
Example 4: This example lists ssm managed instances and exports InstanceId, PingStatus, LastPingDateTime and PlatformName to a csv file.
Get-SSMInstanceInformation | Select-Object InstanceId, PingStatus, LastPingDateTime, PlatformName | Export-Csv Instance-details.csv -NoTypeInformation

- For API details, see [DescribeInstanceInformation](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

### Use DescribeInstancePatchStates with an AWS SDK or CLI

The following code examples show how to use DescribeInstancePatchStates.

**CLI**

**AWS CLI**

**To get the patch summary states for instances**

This `describe-instance-patch-states` example gets the patch summary states for an instance.

```
aws ssm describe-instance-patch-states \
--instance-ids "i-1234567890abcdef0"
```

**Output:**

```
{
   "InstancePatchStates": [
       {
           "InstanceId": "i-1234567890abcdef0",
           "PatchGroup": "my-patch-group",
           "BaselineId": "pb-0713accee01234567",
           "SnapshotId": "521c3536-930c-4aa9-950e-01234567abcd",
           "CriticalNonCompliantCount": 2,
           "SecurityNonCompliantCount": 2,
           "OtherNonCompliantCount": 1,
           "InstalledCount": 123,
        }
    ]
}
```
For more information, see About Patch Compliance in the AWS Systems Manager User Guide.

• For API details, see DescribeInstancePatchStates in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

**Example 1: This example gets the patch summary states for an instance.**

```powershell
Get-SSMInstancePatchState -InstanceId "i-08ee91c0b17045407"
```

**Example 2: This example gets the patch summary states for two instances.**

```powershell
Get-SSMInstancePatchState -InstanceId "i-08ee91c0b17045407","i-09a618aec652973a9"
```

• For API details, see DescribeInstancePatchStates in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.
Use `DescribeInstancePatchStatesForPatchGroup` with an AWS SDK or CLI

The following code examples show how to use `DescribeInstancePatchStatesForPatchGroup`.

**CLI**

**AWS CLI**

**Example 1: To get the instance states for a patch group**

The following `describe-instance-patch-states-for-patch-group` example retrieves details about the patch summary states per-instance for the specified patch group.

```
aws ssm describe-instance-patch-states-for-patch-group \
--patch-group "Production"
```

**Output:**

```json
{
  "InstancePatchStates": [
    {
      "InstanceId": "i-02573cafcfEXAMPLE",
      "PatchGroup": "Production",
      "BaselineId": "pb-0c10e65780EXAMPLE",
      "SnapshotId": "a3f5ff34-9bc4-4d2c-a665-4d1c1EXAMPLE",
      "OwnerInformation": "",
      "InstalledCount": 32,
      "InstalledOtherCount": 1,
      "InstalledPendingRebootCount": 0,
      "InstalledRejectedCount": 0,
      "MissingCount": 2,
      "FailedCount": 0,
      "UnreportedNotApplicableCount": 2671,
      "NotApplicableCount": 400,
      "OperationStartTime": "2021-08-04T11:03:50.590000-07:00",
      "OperationEndTime": "2021-08-04T11:04:21.555000-07:00",
      "Operation": "Scan",
      "RebootOption": "NoReboot",
      "CriticalNonCompliantCount": 0,
      "SecurityNonCompliantCount": 1,
```
"OtherNonCompliantCount": 0
},
{
  "InstanceId": "i-0471e04240EXAMPLE",
  "PatchGroup": "Production",
  "BaselineId": "pb-09ca3fb51fEXAMPLE",
  "SnapshotId": "05d8ff80-1bbe-4812-ba2d-d9b7bEXAMPLE",
  "OwnerInformation": "",
  "InstalledCount": 32,
  "InstalledOtherCount": 1,
  "InstalledPendingRebootCount": 0,
  "InstalledRejectedCount": 0,
  "MissingCount": 2,
  "FailedCount": 0,
  "UnreportedNotApplicableCount": 2671,
  "NotApplicableCount": 400,
  "OperationStart_Time": "2021-08-04T22:06:20.340000-07:00",
  "OperationEnd_Time": "2021-08-04T22:07:11.220000-07:00",
  "Operation": "Scan",
  "RebootOption": "NoReboot",
  "CriticalNonCompliantCount": 0,
  "SecurityNonCompliantCount": 1,
  "OtherNonCompliantCount": 0
}
]
}

Example 2: To get the instance states for a patch group with more than five missing patches

The following describe-instance-patch-states-for-patch-group example retrieves details about the patch summary states for the specified patch group for instances with more than five missing patches.

```bash
aws ssm describe-instance-patch-states-for-patch-group \
  --filters Key=MissingCount,Type=GreaterThan,Values=5 \
  --patch-group "Production"
```

Output:

```json
{
  "InstancePatchStates": [
```
Example 3: To get the instance states for a patch group with fewer than ten instances that require a reboot

The following `describe-instance-patch-states-for-patch-group` example retrieves details about the patch summary states for the specified patch group for instances with fewer than ten instances requiring a reboot.

```
aws ssm describe-instance-patch-states-for-patch-group \
    --filters Key=InstalledPendingRebootCount,Type=LessThan,Values=10 \
    --patch-group "Production"
```

Output:

```
{
    "InstancePatchStates": [ 
        {
            "InstanceId": "i-02573cafcfEXAMPLE",
```
"BaselineId": "pb-0c10e65780EXAMPLE",
"SnapshotId": "a3f5ff34-9bc4-4d2c-a665-4d1c1EXAMPLE",
"PatchGroup": "Production",
"OwnerInformation": "",
"InstalledCount": 32,
"InstalledOtherCount": 1,
"InstalledPendingRebootCount": 4,
"InstalledRejectedCount": 0,
"MissingCount": 2,
"FailedCount": 0,
"UnreportedNotApplicableCount": 846,
"NotApplicableCount": 212,
"OperationStartTime": "2021-08-04T11:03:50.590000-07:00",
"OperationEndTime": "2021-08-06T11:04:21.555000-07:00",
"Operation": "Scan",
"RebootOption": "NoReboot",
"CriticalNonCompliantCount": 0,
"SecurityNonCompliantCount": 1,
"OtherNonCompliantCount": 0

For more information, see Understanding patch compliance state values in the AWS Systems Manager User Guide.

- For API details, see DescribeInstancePatchStatesForPatchGroup in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example gets the patch summary states per-instance for a patch group.

Get-SSMInstancePatchStatesForPatchGroup -PatchGroup "Production"

- For API details, see DescribeInstancePatchStatesForPatchGroup in AWS Tools for PowerShell Cmdlet Reference.
For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeInstancePatches with an AWS SDK or CLI**

The following code examples show how to use DescribeInstancePatches.

**CLI**

**AWS CLI**

**Example 1: To get the patch state details for an instance**

The following `describe-instance-patches` example retrieves details about the patches for the specified instance.

```bash
aws ssm describe-instance-patches \
   --instance-id "i-1234567890abcdef0"
```

Output:

```json
{
   "Patches": [
       {
         "Title": "2019-01 Security Update for Adobe Flash Player for Windows Server 2016 for x64-based Systems (KB4480979)",
         "KBId": "KB4480979",
         "Classification": "SecurityUpdates",
         "Severity": "Critical",
         "State": "Installed",
         "InstalledTime": "2019-01-09T00:00:00+00:00"
       },
       {
         "Title": "",
         "KBId": "KB4481031",
         "Classification": "",
         "Severity": "",
         "State": "InstalledOther",
         "InstalledTime": "2019-02-08T00:00:00+00:00"
       }
   ]
}
```
Example 2: To get a list of patches in the Missing state for an instance

The following describe-instance-patches example retrieves information about patches that are in the Missing state for the specified instance.

```
aws ssm describe-instance-patches \
   --instance-id "i-1234567890abcdef0" \
   --filters Key=State,Values=Missing
```

Output:

```
{
   "Patches": [
      {
         "Title": "Windows Malicious Software Removal Tool x64 - February 2019 (KB890830)",
         "KBId": "KB890830",
         "Classification": "UpdateRollups",
         "Severity": "Unspecified",
         "State": "Missing",
         "InstalledTime": "1970-01-01T00:00:00+00:00"
      },
      ...
   ],
   "NextToken": "--token string truncated--"
}
```

For more information, see [About Patch Compliance States](https://aws.amazon.com/documentation/systemsmanager/#patch-compliance-states) in the AWS Systems Manager User Guide.

Example 3: To get a list of patches installed since a specified InstalledTime for an instance

The following describe-instance-patches example retrieves information about patches installed since a specified time for the specified instance by combining the use of --filters and --query.
aws ssm describe-instance-patches \
   --instance-id "i-1234567890abcdef0" \
   --filters Key=State,Values=Installed \
   --query "Patches[?InstalledTime >= `2023-01-01T16:00:00`]"

Output:

```
{
   "Patches": [
   {
      "Title": "2023-03 Cumulative Update for Windows Server 2019 (1809) for x64-based Systems (KB5023702)",
      "KBId": "KB5023702",
      "Classification": "SecurityUpdates",
      "Severity": "Critical",
      "State": "Installed",
      "InstalledTime": "2023-03-16T11:00:00+00:00"
   },
   ...
   ],
   "NextToken": "--token string truncated--"
}
```

- For API details, see `DescribeInstancePatches` in **AWS CLI Command Reference**.

PowerShell

**Tools for PowerShell**

**Example 1: This example gets the patch compliance details for an instance.**

```
Get-SSMInstancePatch -InstanceId "i-08ee91c0b17045407"
```

- For API details, see `DescribeInstancePatches` in **AWS Tools for PowerShell Cmdlet Reference**.

For a complete list of AWS SDK developer guides and code examples, see **Using Systems Manager with an AWS SDK**. This topic also includes information about getting started and details about previous SDK versions.
Use DescribeMaintenanceWindowExecutionTaskInvocations with an AWS SDK or CLI

The following code examples show how to use DescribeMaintenanceWindowExecutionTaskInvocations.

**CLI**

**AWS CLI**

To get the specific task invocations performed for a maintenance window task execution

The following describe-maintenance-window-execution-task-invocations example lists the invocations for the specified task executed as part of the specified maintenance window execution.

```bash
aws ssm describe-maintenance-window-execution-task-invocations
  --window-execution-id "518d5565-5969-4cca-8f0e-da3b2a638355" \
  --task-id "ac0c6ae1-daa3-4a89-832e-d384503b6586"
```

Output:

```json
{
  "WindowExecutionTaskInvocationIdentities": [
    {
      "Status": "SUCCESS",
      "Parameters": "{\"documentName\":\"AWS-RunShellScript\",\n      \"instanceIds\":\[\"i-0000293ff8d57862\"]},\n      \"parameters\":{\"commands\":[\"df\"]},\n      \"maxConcurrency\":\"1\",\n      \"maxErrors\":\"1\"},
      "InvocationId": "e274b6e1-fe56-4e32-bd2a-8073c6381d8b",
      "StartTime": 1487692834.723,
      "EndTime": 1487692834.871,
      "WindowExecutionId": "518d5565-5969-4cca-8f0e-da3b2a638355",
      "TaskExecutionId": "ac0c6ae1-daa3-4a89-832e-d384503b6586"
    }
  ]
}
```

For more information, see View Information About Tasks and Task Executions (AWS CLI) in the AWS Systems Manager User Guide.
For API details, see [DescribeMaintenanceWindowExecutionTaskInvocations](https://docs.aws.amazon.com/cli/latest/reference/ssm/describemaintenancewindowexecutiontaskinvocations) in *AWS CLI Command Reference*.

### PowerShell

#### Tools for PowerShell

**Example 1:** This example lists the invocations for a task executed as part of a maintenance window execution.

```powershell
Get-SSMMaintenanceWindowExecutionTaskInvocationList -TaskId "ac0c6ae1-daa3-4a89-832e-d384503b6586" -WindowExecutionId "518d5565-5969-4cca-8f0e-da3b2a638355"
```

**Output:**

```
EndTime           : 2/21/2017 4:00:34 PM
ExecutionId       :
InvocationId      : e274b6e1-fe56-4e32-bd2a-8073c6381d8b
OwnerInformation  :
Parameters        : {"documentName":"AWS-RunShellScript","instanceIds": ["i-0000293ffd8c57862"],"parameters":{"commands": ["df"],"maxConcurrency": "1", "maxErrors": "1"}
StartTime         : 2/21/2017 4:00:34 PM
Status            : FAILED
StatusDetails     : The instance IDs list contains an invalid entry.
TaskExecutionId   : ac0c6ae1-daa3-4a89-832e-d384503b6586
WindowExecutionId : 518d5565-5969-4cca-8f0e-da3b2a638355
WindowTargetId    :
```

For API details, see [DescribeMaintenanceWindowExecutionTaskInvocations](https://docs.aws.amazon.com/tools-powershell/latest/reference/ssm/describemaintenancewindowexecutiontaskinvocations) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systems-manager/latest/userguide/using-sdk.html). This topic also includes information about getting started and details about previous SDK versions.
Use DescribeMaintenanceWindowExecutionTasks with an AWS SDK or CLI

The following code examples show how to use DescribeMaintenanceWindowExecutionTasks.

CLI

AWS CLI

To list all tasks associated with a maintenance window execution

The following ssm describe-maintenance-window-execution-tasks example lists the tasks associated with the specified maintenance window execution.

```
aws ssm describe-maintenance-window-execution-tasks \
    --window-execution-id "518d5565-5969-4cca-8f0e-da3b2EXAMPLE"
```

Output:

```
{
    "WindowExecutionTaskIdentities": [
        {
            "Status": "SUCCESS",
            "TaskArn": "AWS-RunShellScript",
            "StartTime": 1487692834.684,
            "TaskType": "RUN_COMMAND",
            "EndTime": 1487692835.005,
            "WindowExecutionId": "518d5565-5969-4cca-8f0e-da3b2EXAMPLE",
            "TaskExecutionId": "ac0c6ae1-daa3-4a89-832e-d3845EXAMPLE"
        }
    ]
}
```

For more information, see View Information About Tasks and Task Executions (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see DescribeMaintenanceWindowExecutionTasks in AWS CLI Command Reference.
PowerShell

Tools for PowerShell

**Example 1: This example lists the tasks associated with a maintenance window execution.**

```powershell
Get-SSMMaintenanceWindowExecutionTaskList -WindowExecutionId "518d5565-5969-4cca-8f0e-da3b2a638355"
```

**Output:**

<table>
<thead>
<tr>
<th></th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndTime</td>
<td>2/21/2017 4:00:35 PM</td>
</tr>
<tr>
<td>StartTime</td>
<td>2/21/2017 4:00:34 PM</td>
</tr>
<tr>
<td>Status</td>
<td>SUCCESS</td>
</tr>
<tr>
<td>TaskArn</td>
<td>AWS-RunShellScript</td>
</tr>
<tr>

</tbody>
</table>

- For API details, see [DescribeMaintenanceWindowExecutionTasks](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeMaintenanceWindowExecutions with an AWS SDK or CLI**

The following code examples show how to use DescribeMaintenanceWindowExecutions.

**CLI**

**AWS CLI**

**Example 1: To list all executions for a maintenance window**

The following describe-maintenance-window-executions example lists all of the executions for the specified maintenance window.

```bash
aws ssm describe-maintenance-window-executions \
```
Example 2: To list all executions for a maintenance window before a specified date

The following `describe-maintenance-window-executions` example lists all of the executions for the specified maintenance window before the specified date.

```bash
aws ssm describe-maintenance-window-executions \\   --window-id "mw-ab12cd34eEXAMPLE" \\   --filters "Key=ExecutedBefore,Values=2021-08-03T00:00:00Z"
```

Output:

```
DescribeMaintenanceWindowExecutions
2394
```
Example 3: To list all executions for a maintenance window after a specified date

The following `describe-maintenance-window-executions` example lists all of the executions for the specified maintenance window after the specified date.

```
aws ssm describe-maintenance-window-executions \
  --window-id "mw-ab12cd34eEXAMPLE" \
  --filters "Key=ExecutedAfter,Values=2021-08-04T00:00:00Z"
```

Output:

```
{
  "WindowExecutions": [
  {
    "WindowId": "mw-ab12cd34eEXAMPLE",
    "WindowExecutionId": "6027b513-64fe-4cf0-be7d-1191aEXAMPLE",
    "Status": "IN_PROGRESS",
    "StartTime": "2021-08-04T11:00:00.000000-07:00"
  }
  ]
}
```

For more information, see View information about tasks and task executions (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see DescribeMaintenanceWindowExecutions in AWS CLI Command Reference.
**Tools for PowerShell**

**Example 1: This example lists all of the executions for a maintenance window.**

```
Get-SSMMaintenanceWindowExecutionList -WindowId "mw-03eb9db42890fb82d"
```

**Output:**

```
EndTime           : 2/20/2017 6:30:17 PM
StartTime         : 2/20/2017 6:30:16 PM
Status            : FAILED
StatusDetails     : One or more tasks in the orchestration failed.
WindowExecutionId : 6f3215cf-4101-4fa0-9b7b-9523269599c7
WindowId          : mw-03eb9db42890fb82d
```

**Example 2: This example lists all of the executions for a maintenance window before a specified date.**

```
$option1 = @{Key="ExecutedBefore";Values=@("2016-11-04T05:00:00Z")}
Get-SSMMaintenanceWindowExecutionList -WindowId "mw-03eb9db42890fb82d" -Filter $option1
```

**Example 3: This example lists all of the executions for a maintenance window after a specified date.**

```
$option1 = @{Key="ExecutedAfter";Values=@("2016-11-04T05:00:00Z")}
Get-SSMMaintenanceWindowExecutionList -WindowId "mw-03eb9db42890fb82d" -Filter $option1
```

- For API details, see [DescribeMaintenanceWindowExecutions](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.
Use DescribeMaintenanceWindowTargets with an AWS SDK or CLI

The following code examples show how to use DescribeMaintenanceWindowTargets.

CLI

**AWS CLI**

**Example 1: To list all targets for a Maintenance Window**

The following describe-maintenance-window-targets example lists all of the targets for a maintenance window.

```bash
aws ssm describe-maintenance-window-targets "--window-id "mw-06cf17cbefEXAMPLE"
```

Output:

```json
{
   "Targets": [
   {
      "ResourceType": "INSTANCE",
      "OwnerInformation": "Single instance",
      "WindowId": "mw-06cf17cbefEXAMPLE",
      "Targets": [
      {
         "Values": [
            "i-0000293ffdEXAMPLE"
         ],
         "Key": "InstanceIds"
      }
   ],
   "WindowTargetId": "350d44e6-28cc-44e2-951f-4b2c9EXAMPLE"
   },
   {
      "ResourceType": "INSTANCE",
      "OwnerInformation": "Two instances in a list",
      "WindowId": "mw-06cf17cbefEXAMPLE",
      "Targets": [
      {
         "Values": [
            "i-0000293ffdEXAMPLE",
            "i-0000293ffdEXAMPLE"
         ],
         "Key": "InstanceIds"
      }
   ],
   "WindowTargetId": "350d44e6-28cc-44e2-951f-4b2c9EXAMPLE"
   }
}
```
Example 2: To list all targets for a maintenance window matching a specific owner information value

This describe-maintenance-window-targets example lists all of the targets for a maintenance window with a specific value.

```
aws ssm describe-maintenance-window-targets
   --window-id "mw-0ecb1226ddEXAMPLE"
   --filters "Key=OwnerInformation,Values=CostCenter1"
```

Output:

```
{
   "Targets": [
      {
         "WindowId": "mw-0ecb1226ddEXAMPLE",
         "WindowTargetId": "da89dcc3-7f9c-481d-ba2b-edcb7d0057f9",
         "ResourceType": "INSTANCE",
         "Targets": [
            {
               "Key": "tag:Environment",
               "Values": [
                  "Prod"
               ]
            },
            {
               "OwnerInformation": "CostCenter1",
               "Name": "ProdTarget1"
            }
         ]
      }
   ]
}
```
For more information, see View Information About Maintenance Windows (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see DescribeMaintenanceWindowTargets in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example lists all of the targets for a maintenance window.

Get-SSMMaintenanceWindowTarget -WindowId "mw-06cf17cbeefcb4bf4f"

Output:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>OwnerInformation</td>
<td>Single instance</td>
</tr>
<tr>
<td>ResourceType</td>
<td>INSTANCE</td>
</tr>
<tr>

<td>e078a987-2866-47be-bedd-d9cf49177d3a</td>
</tr>
</tbody>
</table>

- For API details, see DescribeMaintenanceWindowTargets in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DescribeMaintenanceWindowTasks with an AWS SDK or CLI

The following code examples show how to use DescribeMaintenanceWindowTasks.
AWS CLI

Example 1: To list all tasks for a maintenance window

The following `describe-maintenance-window-tasks` example lists all of the tasks for the specified maintenance window.

```bash
aws ssm describe-maintenance-window-tasks \
   --window-id "mw-06cf17cbefEXAMPLE"
```

Output:

```json
{
   "Tasks": [
      {
         "WindowId": "mw-06cf17cbefEXAMPLE",
         "WindowTaskId": "018b31c3-2d77-4b9e-bd48-c91edEXAMPLE",
         "TaskArn": "AWS-RestartEC2Instance",
         "TaskParameters": {},
         "Type": "AUTOMATION",
         "Description": "Restarting EC2 Instance for maintenance",
         "MaxConcurrency": "1",
         "MaxErrors": "1",
         "Name": "My-Automation-Example-Task",
         "Priority": 0,
         "ServiceRoleArn": "arn:aws:iam::111222333444:role/aws-service-role/ssm.amazonaws.com/AWSServiceRoleForAmazonSSM",
         "Targets": [
            {
               "Key": "WindowTargetIds",
               "Values": [
                  "da89dccc3-7f9c-481d-ba2b-edcb7EXAMPLE"
               ]
            }
         ]
      },
      {
         "WindowId": "mw-06cf17cbefEXAMPLE",
         "WindowTaskId": "1943dee0-0a17-4978-9bf4-3cc2fEXAMPLE",
         "TaskArn": "AWS-DisableS3BucketPublicReadWrite",
         "TaskParameters": {}
      }
   ]
}
```
Example 2: To list all tasks for a maintenance window that invokes the AWS-RunPowerShellScript command document

The following describe-maintenance-window-tasks example lists all of the tasks for the specified maintenance window that invokes the AWS-RunPowerShellScript command document.

```bash
aws ssm describe-maintenance-window-tasks
  --window-id "mw-ab12cd34eEXAMPLE"
  --filters "Key=TaskArn,Values=AWS-RunPowerShellScript"
```

Output:

```json
{
  "Tasks": [
    {
      "WindowId": "mw-ab12cd34eEXAMPLE",
      "WindowTaskId": "0d36e6b4-3a4f-411e-adcb-3558eEXAMPLE",
      "TaskArn": "AWS-RunPowerShellScript",
      "Type": "RUN_COMMAND",
      "Targets": [
      ...
```
Example 3: To list all tasks for a maintenance window that have a Priority of 3

The following describe-maintenance-window-tasks example lists all of the tasks for the specified maintenance window that have a Priority of 3.

```bash
aws ssm describe-maintenance-window-tasks \
--window-id "mw-ab12cd34eEXAMPLE" \
--filters "Key=Priority,Values=3"
```

Output:

```
{
  "Tasks": [
    {
      "WindowId": "mw-ab12cd34eEXAMPLE",
      "WindowTaskId": "0d36e6b4-3a4f-411e-adcb-3558eEXAMPLE",
      "TaskArn": "AWS-RunPowerShellScript",
      "Type": "RUN_COMMAND",
      "Targets": [
        {
          "Key": "WindowTargetIds",
          "Values": [
            "da89dccc3-7f9c-481d-ba2b-edcb7EXAMPLE"
          ]
        }
      ]
    }
  ]
}
```
Example 4: To list all tasks for a maintenance window that have a Priority of 1 and use Run Command

This describe-maintenance-window-tasks example lists all of the tasks for the specified maintenance window that have a Priority of 1 and use Run Command.

```
aws ssm describe-maintenance-window-tasks
  --window-id "mw-ab12cd34eEXAMPLE"
```
Output:

```
{
  "Tasks": [
    {
      "WindowId": "mw-ab12cd34eEXAMPLE",
      "WindowTaskId": "0d36e6b4-3a4f-411e-adcb-3558eEXAMPLE",
      "TaskArn": "AWS-RunPowerShellScript",
      "Type": "RUN_COMMAND",
      "Targets": [
        {
          "Key": "WindowTargetIds",
          "Values": [
            "da89dcc3-7f9c-481d-ba2b-edcb7EXAMPLE"
          ]
        }
      ],
      "TaskParameters": {},
      "Priority": 1,
      "ServiceRoleArn": "arn:aws:iam::111222333444:role/aws-service-role/ssm.amazonaws.com/AWSServiceRoleForAmazonSSM",
      "MaxConcurrency": "1",
      "MaxErrors": "1",
      "Name": "MyRunCommandTask"
    }
  ]
}
```

**PowerShell**

**Tools for PowerShell**

**Example 1:** This example lists all of the tasks for a maintenance window.

```
Get-SSMMaintenanceWindowTaskList -WindowId "mw-06cf17cbefcb4bf4f"
```
Output:

```
LoggingInfo : 
MaxConcurrency : 1
MaxErrors : 1
Priority : 10
ServiceRoleArn : arn:aws:iam::123456789012:role/MaintenanceWindowsRole
Targets : {InstanceIds}
TaskArn : AWS-RunShellScript
TaskParameters : {[commands,
Type : RUN_COMMAND
WindowId : mw-06cf17cbefcb4bf4f
WindowTaskId : a23e338d-ff30-4398-8a3-09cd052ebf17
```

- For API details, see [DescribeMaintenanceWindowTasks](https://docs.aws.amazon.com/AWSSimpleSystemsManagement/latest/APIReference/API_DescribeMaintenanceWindowTasks.html) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systemsmanager/latest/userguide/using-with-aws-sdk.html). This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeMaintenanceWindows with an AWS SDK or CLI**

The following code examples show how to use `DescribeMaintenanceWindows`.

**CLI**

**AWS CLI**

**Example 1: To list all maintenance windows**

The following `describe-maintenance-windows` example lists all maintenance windows in your AWS account in the current Region.

```
aws ssm describe-maintenance-windows
```

Output:

```
{
```
"WindowIdentities": [
  {
    "WindowId": "mw-0ecb1226ddEXAMPLE",
    "Name": "MyMaintenanceWindow-1",
    "Enabled": true,
    "Duration": 2,
    "Cutoff": 1,
    "Schedule": "rate(180 minutes)",
    "NextExecutionTime": "2020-02-12T23:19:20.596Z"
  },
  {
    "WindowId": "mw-03eb9db428EXAMPLE",
    "Name": "MyMaintenanceWindow-2",
    "Enabled": true,
    "Duration": 3,
    "Cutoff": 1,
    "Schedule": "rate(7 days)",
    "NextExecutionTime": "2020-02-17T23:22:00.956Z"
  }
],

Example 2: To list all enabled maintenance windows

The following describe-maintenance-windows example lists all enabled maintenance windows.

```bash
aws ssm describe-maintenance-windows \\
  --filters "Key=Enabled,Values=true"
```

Example 3: To list maintenance windows matching a specific name

This describe-maintenance-windows example lists all maintenance windows with the specified name.

```bash
aws ssm describe-maintenance-windows \\
  --filters "Key=Name,Values=MyMaintenanceWindow"
```

For more information, see View Information About Maintenance Windows (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see DescribeMaintenanceWindows in AWS CLI Command Reference.
PowerShell

**Tools for PowerShell**

*Example 1: This example lists all maintenance windows on your account.*

```powershell
Get-SSMMaintenanceWindowList
```

**Output:**

<table>
<thead>
<tr>
<th>Cutoff</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duration</td>
<td>4</td>
</tr>
<tr>
<td>Enabled</td>
<td>True</td>
</tr>
<tr>
<td>Name</td>
<td>My-First-Maintenance-Window</td>
</tr>
<tr>
<td>WindowId</td>
<td>mw-06d59c1a07c022145</td>
</tr>
</tbody>
</table>

- For API details, see [DescribeMaintenanceWindows](#) in *AWS Tools for PowerShell Cmdlet Reference.*

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use DescribeOpsItems with an AWS SDK or CLI**

The following code examples show how to use DescribeOpsItems.

**CLI**

**AWS CLI**

*To list a set of OpsItems*

The following `describe-ops-items` example displays a list of all open OpsItems in your AWS account.

```bash
aws ssm describe-ops-items \
   --ops-item-filters "Key=Status,Values=Open,Operator=Equal"
```

**Output:**
{  "OpsItemSummaries": [  {   "CreatedBy": "arn:aws:sts::111222333444:assumed-role/OpsItem-CWE-Role/fbf77cbe264a33509569f23e4EXAMPLE",   "CreatedTime": "2020-03-14T17:02:46.375000-07:00",   "LastModifiedBy": "arn:aws:sts::111222333444:assumed-role/OpsItem-CWE-Role/fbf77cbe264a33509569f23e4EXAMPLE",   "LastModifiedTime": "2020-03-14T17:02:46.375000-07:00",   "Source": "SSM",   "Status": "Open",   "OpsItemId": "oi-7cfc5EXAMPLE",   "Title": "SSM Maintenance Window execution failed",   "OperationalData": {    "/aws/dedup": {      "Value": "{""dedupString"":"SSMOpsItems-SSM-maintenance-window-execution-failed""}"",      "Type": "SearchableString"    },    "/aws/resources": {      "Value": "{""arn"":"arn:aws:ssm:us-east-2:111222333444:maintenancewindow/mw-034093d322EXAMPLE""}"",      "Type": "SearchableString"    }   },   "Category": "Availability",   "Severity": "3"  },  {   "CreatedBy": "arn:aws:sts::1112223233444:assumed-role/OpsItem-CWE-Role/fbf77cbe264a33509569f23e4EXAMPLE",   "CreatedTime": "2020-02-26T11:43:15.426000-08:00",   "LastModifiedBy": "arn:aws:sts::111222333444:assumed-role/OpsItem-CWE-Role/fbf77cbe264a33509569f23e4EXAMPLE",   "LastModifiedTime": "2020-02-26T11:43:15.426000-08:00",   "Source": "EC2",   "Status": "Open",   "OpsItemId": "oi-6f966EXAMPLE",   "Title": "EC2 instance stopped",   "OperationalData": {    "/aws/automations": {      "Value": "[ { "automationType": "AWS:SSM:Automation", "automationId": "AWS-RestartEC2Instance" } ]",   }  }]}
For more information, see Working with OpsItems in the AWS Systems Manager User Guide.

- For API details, see DescribeOpsItems in AWS CLI Command Reference.

Java

SDK for Java 2.x

```
public static void describeOpsItems(SsmClient ssmClient, String key) {
    try {
        OpsItemFilter filter = OpsItemFilter.builder()
            .key(OpsItemFilterKey.OPS_ITEM_ID)
            .values(key)
            .operator(OpsItemFilterOperator.EQUAL)
            .build();
```
DescribeOpsItemsRequest itemsRequest =
    DescribeOpsItemsRequest.builder()
    .maxResults(10)
    .opsItemFilters(filter)
    .build();

DescribeOpsItemsResponse itemsResponse =
    ssmClient.describeOpsItems(itemsRequest);
    List<OpsItemSummary> items = itemsResponse.opsItemSummaries();
    for (OpsItemSummary item : items) {
        System.out.println("The item title is " + item.title() + " and the status is "+item.status().toString());
    }
}
} catch (SsmException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see DescribeOpsItems in AWS SDK for Java 2.x API Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DescribeParameters with an AWS SDK or CLI

The following code examples show how to use DescribeParameters.

CLI

AWS CLI

Example 1: To list all parameters

The following describe-parameters example lists all parameters in the current AWS account and Region.

aws ssm describe-parameters
Output:

```json
{
  "Parameters": [
    {
      "Name": "MySecureStringParameter",
      "Type": "SecureString",
      "KeyId": "alias/aws/ssm",
      "LastModifiedDate": 1582155479.205,
      "LastModifiedUser": "arn:aws:sts::111222333444:assumed-role/Admin/Richard-Roe-Managed",
      "Description": "This is a SecureString parameter",
      "Version": 2,
      "Tier": "Advanced",
      "Policies": [
        {
          "PolicyText": "{"Type":"Expiration","Version":"1.0","Attributes":{"Timestamp":"2020-07-07T22:30:00Z"}}",
          "PolicyType": "Expiration",
          "PolicyStatus": "Pending"
        },
        {
          "PolicyText": "{"Type":"ExpirationNotification","Version":"1.0","Attributes":{"Before":"12","Unit":"Hours"}}",
          "PolicyType": "ExpirationNotification",
          "PolicyStatus": "Pending"
        }
      ]
    },
    {
      "Name": "MyStringListParameter",
      "Type": "StringList",
      "LastModifiedDate": 1582154764.222,
      "LastModifiedUser": "arn:aws:iam::111222333444:user/Mary-Major",
      "Description": "This is a StringList parameter",
      "Version": 1,
      "Tier": "Standard",
      "Policies": []
    },
    {
      "Name": "MyStringParameter",
      "Type": "String",
      "LastModifiedDate": 1582154711.976,
      "LastModifiedUser": "arn:aws:iam::111222333444:user/Mary-Major",
      "Description": "This is a String parameter",
      "Version": 1,
      "Tier": "Standard",
      "Policies": []
    }
  ]
}
```
Example 2: To list all parameters matching specific metadata

This describe-parameters example lists all parameters matching a filter.

```bash
aws ssm describe-parameters --filters "Key=Type,Values=StringList"
```

Output:

```json
{
  "Parameters": [
    {
      "Name": "MyStringListParameter",
      "Type": "StringList",
      "LastModifiedDate": 1582154764.222,
      "LastModifiedUser": "arn:aws:iam::111222333444:user/Mary-Major",
      "Description": "This is a StringList parameter",
      "Version": 1,
      "Tier": "Standard",
      "Policies": []
    }
  ]
}
```
Java SDK for Java 2.x

```java

 System.exit(1);
 }
}
```

- For API details, see [DescribeParameters](#) in *AWS SDK for Java 2.x API Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example lists all parameters.**

Get-SSMParameterList
Output:

<table>
<thead>
<tr>
<th>Description</th>
<th>KeyId</th>
<th>LastModifiedDate</th>
<th>LastModifiedUser</th>
<th>Name</th>
<th>Type</th>
</tr>
</thead>
</table>

- For API details, see [DescribeParameters](#) in *AWS Tools for PowerShell Cmdlet Reference*.

### Rust

#### SDK for Rust

```rust
async fn show_parameters(client: &Client) -> Result<(), Error> {
    let resp = client.describe_parameters().send().await?

    for param in resp.parameters() {
        println!("{}", param.name().unwrap_or_default());
    }

    Ok(())
}
```

- For API details, see [DescribeParameters](#) in *AWS SDK for Rust API reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.
Use DescribePatchBaselines with an AWS SDK or CLI

The following code examples show how to use DescribePatchBaselines.

CLI

AWS CLI

Example 1: To list all patch baselines

The following describe-patch-baselines example retrieves details for all patch baselines in your account in the current Region.

```
aws ssm describe-patch-baselines
```

Output:

```json
{
  "BaselineIdentities": [
    {
      "BaselineName": "AWS-SuseDefaultPatchBaseline",
      "DefaultBaseline": true,
      "BaselineDescription": "Default Patch Baseline for Suse Provided by AWS.",
      "BaselineId": "arn:aws:ssm:us-east-2:733109147000:patchbaseline/pb-0123fdb36e334a3b2",
      "OperatingSystem": "SUSE"
    },
    {
      "BaselineName": "AWS-DefaultPatchBaseline",
      "DefaultBaseline": false,
      "BaselineDescription": "Default Patch Baseline Provided by AWS.",
      "OperatingSystem": "WINDOWS"
    },
    ...
  ]
}
```
Example 2: To list all patch baselines provided by AWS

The following `describe-patch-baselines` example lists all patch baselines provided by AWS.

```
aws ssm describe-patch-baselines \
    --filters "Key=OWNER,Values=[AWS]"
```

Example 3: To list all patch baselines that you own

The following `describe-patch-baselines` example lists all custom patch baselines created in your account in the current Region.

```
aws ssm describe-patch-baselines \
    --filters "Key=OWNER,Values=[Self]"
```

For more information, see About Predefined and Custom Patch Baselines in the AWS Systems Manager User Guide.

- For API details, see DescribePatchBaselines in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example lists all patch baselines.

```
Get-SSMPatchBaseline
```

Output:

<table>
<thead>
<tr>
<th>BaselineDescription</th>
<th>BaselineId</th>
<th>BaselineName</th>
</tr>
</thead>
<tbody>
<tr>
<td>---------------------</td>
<td>----------</td>
<td>--------------</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------</td>
<td>--------------</td>
</tr>
</tbody>
</table>

Default Patch Baseline Provided by AWS. arn:aws:ssm:us-west-2:123456789012:patchbaseline/pb-04fb4ae6142167966 AWS-DefaultPatchBaseline
Baseline containing all updates approved for production systems
pb-045f10b4f382baeda
Production-B...
Baseline containing all updates approved for production systems pb-0a2f1059b670ebd31 Production-B...

Example 2: This example lists all patch baselines provided by AWS. The syntax used by this example requires PowerShell version 3 or later.

```powershell
$filter1 = @{Key="OWNER";Values=@("AWS")}

Get-SSMPatchBaseline -Filter $filter1
```

Output:

Example 3: This example lists all patch baselines with you as the owner. The syntax used by this example requires PowerShell version 3 or later.

```powershell
$filter1 = @{Key="OWNER";Values=@("Self")}

Get-SSMPatchBaseline -Filter $filter1
```

Output:

Example 4: With PowerShell version 2, you must use New-Object to create each tag.

```powershell
$filter1 = New-Object Amazon.SimpleSystemsManagement.Model.PatchOrchestratorFilter
$filter1.Key = "OWNER"
$filter1.Values = "AWS"

Get-SSMPatchBaseline -Filter $filter1
```

Output:

<table>
<thead>
<tr>
<th>BaselineDescription</th>
<th>BaselineId</th>
<th>BaselineName</th>
<th>DefaultBaseline</th>
</tr>
</thead>
<tbody>
<tr>
<td>DescribePatchBaselines</td>
<td>2418</td>

Default Patch Baseline Provided by AWS. arn:aws:ssm:us-west-2:123456789012:patchbaseline/pb-04fb4ae6142167966 AWS-DefaultPatchBaseline True

- For API details, see DescribePatchBaselines in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use DescribePatchGroupState with an AWS SDK or CLI**

The following code examples show how to use DescribePatchGroupState.

**CLI**

**AWS CLI**

To get the state of a patch group

The following describe-patch-group-state example retrieves the high-level patch compliance summary for a patch group.

```
aws ssm describe-patch-group-state \
--patch-group "Production"
```

**Output:**

```
{
 "Instances": 21,
 "InstancesWithCriticalNonCompliantPatches": 1,
 "InstancesWithFailedPatches": 2,
 "InstancesWithInstalledOtherPatches": 3,
 "InstancesWithInstalledPatches": 21,
 "InstancesWithInstalledPendingRebootPatches": 2,
 "InstancesWithInstalledRejectedPatches": 1,
 "InstancesWithMissingPatches": 3,
```
For more information, see About patch groups <https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-patch-patchgroups.html> and Understanding patch compliance state values in the AWS Systems Manager User Guide.

- For API details, see DescribePatchGroupState in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example gets the high-level patch compliance summary for a patch group.

Get-SSMPatchGroupState -PatchGroup "Production"

Output:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instances</td>
<td>4</td>
</tr>
<tr>
<td>InstancesWithFailedPatches</td>
<td>1</td>
</tr>
<tr>
<td>InstancesWithInstalledOtherPatches</td>
<td>4</td>
</tr>
<tr>
<td>InstancesWithInstalledPatches</td>
<td>3</td>
</tr>
<tr>
<td>InstancesWithMissingPatches</td>
<td>0</td>
</tr>
<tr>
<td>InstancesWithNotApplicablePatches</td>
<td>0</td>
</tr>
</tbody>
</table>

- For API details, see DescribePatchGroupState in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use DescribePatchGroups with an AWS SDK or CLI

The following code examples show how to use DescribePatchGroups.
CLI

AWS CLI

To display patch group registrations

The following describe-patch-groups example lists the patch group registrations.

```
aws ssm describe-patch-groups
```

Output:

```
{
    "Mappings": [
        {
            "PatchGroup": "Production",
            "BaselineIdentity": {
                "BaselineId": "pb-0123456789abcdef0",
                "BaselineName": "ProdPatching",
                "OperatingSystem": "WINDOWS",
                "BaselineDescription": "Patches for Production",
                "DefaultBaseline": false
            }
        },
        {
            "PatchGroup": "Development",
            "BaselineIdentity": {
                "BaselineId": "pb-0713accee01234567",
                "BaselineName": "DevPatching",
                "OperatingSystem": "WINDOWS",
                "BaselineDescription": "Patches for Development",
                "DefaultBaseline": true
            }
        },
        ...
    ]
}
```

For more information, see Create a Patch Group <https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-patch-group-tagging.html> and Add a Patch Group to a Patch Baseline in the AWS Systems Manager User Guide.

- For API details, see DescribePatchGroups in AWS CLI Command Reference.
Tools for PowerShell

Example 1: This example lists the patch group registrations.

```powershell
Get-SSMPatchGroup
```

Output:

```
BaselineIdentity                                           PatchGroup
----------------                                           ----------
Amazon.SimpleSystemsManagement.Model.PatchBaselineIdentity Production
```

- For API details, see `DescribePatchGroups` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

Use `GetAutomationExecution` with an AWS SDK or CLI

The following code examples show how to use `GetAutomationExecution`.

CLI

AWS CLI

To display details about an automation execution

The following `get-automation-execution` example displays detailed information about an Automation execution.

```
aws ssm get-automation-execution \
  --automation-execution-id 73c8eef8-f4ee-4a05-820c-e354fEXAMPLE
```

Output:

```
{
  "AutomationExecution": {
    "AutomationExecutionId": "73c8eef8-f4ee-4a05-820c-e354fEXAMPLE",
```
"DocumentName": "AWS-StartEC2Instance",
"DocumentVersion": "1",
"ExecutionStartTime": 1583737233.748,
"ExecutionEndTime": 1583737234.719,
"AutomationExecutionStatus": "Success",
"StepExecutions": [

  {
    "StepName": "startInstances",
    "Action": "aws:changeInstanceState",
    "ExecutionStartTime": 1583737234.134,

"Targets": [],
"ResolvedTargets": {
  "ParameterValues": [],
  "Truncated": false
} 
}
For more information, see Walkthrough: Patch a Linux AMI (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see GetAutomationExecution in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example displays the details of an Automation Execution.**

```powershell
Get-SSMAutomationExecution -AutomationExecutionId "4105a4fc-f944-11e6-9d32-8fb2db27a909"
```

**Output:**

```plaintext
AutomationExecutionId     : 4105a4fc-f944-11e6-9d32-8fb2db27a909
AutomationExecutionStatus : Failed
DocumentName              : AWS-UpdateLinuxAmi

</tbody>
</table>

For API details, see `GetAutomationExecution` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.
Use GetCommandInvocation with an AWS SDK or CLI

The following code examples show how to use GetCommandInvocation.

CLI

AWS CLI

To display the details of a command invocation

The following get-command-invocation example lists all the invocations of the specified command on the specified instance.

```bash
aws ssm get-command-invocation \
  --command-id "ef7fd8-9b57-4151-a15c-db9a12345678" \
  --instance-id "i-1234567890abcdef0"
```

Output:

```json
{
  "CommandId": "ef7fd8-9b57-4151-a15c-db9a12345678",
  "InstanceId": "i-1234567890abcdef0",
  "Comment": "b48291dd-ba76-43e0-b9df-13e11ddac26:6960febb-2907-4b59-8e1a-d6ce8EXAMPLE",
  "DocumentName": "AWS-UpdateSSMAgent",
  "DocumentVersion": "",
  "PluginName": "aws:updateSsmAgent",
  "ResponseCode": 0,
  "ExecutionStartDateTime": "2020-02-19T18:18:03.419Z",
  "ExecutionElapsedTime": "PT0.091S",
  "ExecutionEndDateTime": "2020-02-19T18:18:03.419Z",
  "Status": "Success",
  "StatusDetails": "Success",
  "StandardOutputContent": "Updating amazon-ssm-agent from 2.3.842.0 to latest
amazon-ssm-agent 2.3.842.0 has already been installed, update skipped"
  "StandardOutputUrl": "",
  "StandardErrorContent": "",
  "StandardErrorUrl": "",
  "CloudWatchOutputConfig": {
    "CloudWatchLogGroupName": "",
  }
}```
For more information, see Understanding Command Statuses in the AWS Systems Manager User Guide.

- For API details, see GetCommandInvocation in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example displays the details of a command executed on an instance.**

```powershell
Get-SSMCommandInvocationDetail -InstanceId "i-0cb2b964d3e14fd9f" -CommandId "b8eac879-0541-439d-94ec-47a80d554f44"
```

**Output:**

```plaintext
CommandId : b8eac879-0541-439d-94ec-47a80d554f44
Comment : IP config
DocumentName : AWS-RunShellScript
ExecutionElapsedTime : PT0.004S
ExecutionEndDateTime : 2017-02-22T20:13:16.651Z
ExecutionStartDate : 2017-02-22T20:13:16.651Z
InstanceId : i-0cb2b964d3e14fd9f
PluginName : aws:runShellScript
ResponseCode : 0
StandardErrorContent :
StandardErrorUrl :
StandardOutputContent :
StandardOutputUrl :
Status : Success
StatusDetails : Success
```

- For API details, see GetCommandInvocation in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.
Use GetConnectionStatus with an AWS SDK or CLI

The following code examples show how to use GetConnectionStatus.

CLI

AWS CLI

To display the connection status of a managed instance

This get-connection-status example returns the connection status of the specified managed instance.

```
aws ssm get-connection-status \
  --target i-1234567890abcdef0
```

Output:

```
{
  "Target": "i-1234567890abcdef0",
  "Status": "connected"
}
```

• For API details, see [GetConnectionStatus](#) in [AWS CLI Command Reference](#).

PowerShell

Tools for PowerShell

Example 1: This example retrieves the Session Manager connection status for an instance to determine whether it is connected and ready to receive Session Manager connections.

```
Get-SSMConnectionStatus -Target i-0a1caf234f12d3dc4
```

Output:

```
    Status    Target
    ---------    ------
       Connected i-0a1caf234f12d3dc4
```

• For API details, see [GetConnectionStatus](#) in [AWS Tools for PowerShell Cmdlet Reference](#).
For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use GetDefaultPatchBaseline with an AWS SDK or CLI**

The following code examples show how to use GetDefaultPatchBaseline.

**CLI**

**AWS CLI**

**Example 1: To display the default Windows patch baseline**

The following `get-default-patch-baseline` example retrieves details for the default patch baseline for Windows Server.

```bash
aws ssm get-default-patch-baseline
```

Output:

```json
{
   "BaselineId": "pb-0713accee01612345",
   "OperatingSystem": "WINDOWS"
}
```

**Example 2: To display the default patch baseline for Amazon Linux**

The following `get-default-patch-baseline` example retrieves details for the default patch baseline for Amazon Linux.

```bash
aws ssm get-default-patch-baseline \
   --operating-system AMAZON_LINUX
```

Output:

```json
{
   "BaselineId": "pb-047c6eb9c8fc12345",
   "OperatingSystem": "AMAZON_LINUX"
}
```
For more information, see About Predefined and Custom Patch Baselines <https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-patch-baselines.html> and Set an Existing Patch Baseline as the Default in the AWS Systems Manager User Guide.

- For API details, see GetDefaultPatchBaseline in AWS CLI Command Reference.

PowerShell

**Tools for PowerShell**

**Example 1: This example displays the default patch baseline.**

```powershell
Get-SSMDefaultPatchBaseline
```

**Output:**

```
```

- For API details, see GetDefaultPatchBaseline in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use GetDeployablePatchSnapshotForInstance with an AWS SDK or CLI**

The following code examples show how to use GetDeployablePatchSnapshotForInstance.

**CLI**

**AWS CLI**

**To retrieve the current snapshot for the patch baseline an instance uses**

The following get-deployable-patch-snapshot-for-instance example retrieves details for the current snapshot for the specified patch baseline used by an instance. This command must be run from the instance using the instance credentials. To ensure it uses the instance credentials, run aws configure and specify only the Region of your instance. Leave the Access Key and Secret Key fields empty.
Tip: Use `uuidgen` to generate a snapshot-id.

```
aws ssm get-deployable-patch-snapshot-for-instance \
   --instance-id "i-1234567890abcdef0" \
   --snapshot-id "521c3536-930c-4aa9-950e-01234567abcd"
```

Output:

```
{
   "InstanceId": "i-1234567890abcdef0",
   "SnapshotId": "521c3536-930c-4aa9-950e-01234567abcd",
   "Product": "AmazonLinux2018.03",
   "SnapshotDownloadUrl": "https://patch-baseline-snapshot-us-east-1.s3.amazonaws.com/ed85194ef27214f5984f28b4d664d14f7313568f5a7d4b6ac6c10ad1f729d7e7-773304212436/AMAZON_LINUX-521c3536-930c-4aa9-950e-01234567abcd?X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Date=20190215T164031Z&X-Amz-SignedHeaders=host&X-Amz-Expires=86400&X-Amz-Credential=AKIAJ5C56P35AEBRX2QQ%2F20190215%2Fus-east-1%2Fs3%2Faws4_request&X-Amz-Signature=efaaaf6e3878e77f48a6697e015efdbda9c426b09c5822055075c062f6ad2149"
}
```

For more information, see Parameter name: Snapshot ID in the AWS Systems Manager User Guide.

- For API details, see GetDeployablePatchSnapshotForInstance in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1:** This example displays the current snapshot for the patch baseline used by an Instance. This command must be run from the instance using the instance credentials. To ensure it uses the instance credentials, the example passes an `Amazon.Runtime.InstanceProfileAWSCredentials` object to the Credentials parameter.

```
$credentials = [Amazon.Runtime.InstanceProfileAWSCredentials]::new()
Get-SSMDeployablePatchSnapshotForInstance -SnapshotId "4681775b-098f-4435-a956-0ef33373ac11" -InstanceId "i-0cb2b964d3e14fd9f" -Credentials $credentials
```
Output:

<table>
<thead>
<tr>
<th>InstanceId</th>
<th>SnapshotDownloadUrl</th>
</tr>
</thead>
<tbody>
<tr>
<td>i-0cb2b964d3e14fd9f</td>
<td><a href="https://patch-baseline-snapshot-us-west-2.s3-us-west-2.amazonaws.com/853d0d3db0f0cafe...1692/4681775b-098f-4435">https://patch-baseline-snapshot-us-west-2.s3-us-west-2.amazonaws.com/853d0d3db0f0cafe...1692/4681775b-098f-4435</a>...</td>
</tr>
</tbody>
</table>

**Example 2:** This example shows how to get the full SnapshotDownloadUrl. This command must be run from the instance using the instance credentials. To ensure it uses the instance credentials, the example configures the PowerShell session to use an Amazon.Runtime.InstanceProfileAWSCredentials object.

```powershell
Set-AWSCredential -Credential ([Amazon.Runtime.InstanceProfileAWSCredentials]::new()) (Get-SSMDeployablePatchSnapshotForInstance -SnapshotId "4681775b-098f-4435-a956-0ef33373ac11" -InstanceId "i-0cb2b964d3e14fd9f").SnapshotDownloadUrl
```

Output:

https://patch-baseline-snapshot-us-west-2.s3-us-west-2.amazonaws.com/853d0d3db0f0cafe...

- For API details, see [GetDeployablePatchSnapshotForInstance](https://docs.aws.amazon.com/AWSPowerShell/latest冶炼:GetDeployablePatchSnapshotForInstance) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systems-manager/latest/userguide/using-sdk.html). This topic also includes information about getting started and details about previous SDK versions.

**Use GetDocument with an AWS SDK or CLI**

The following code examples show how to use GetDocument.

**CLI**

**AWS CLI**

To get document content
The following get-document example displays the content of a Systems Manager document.

```
aws ssm get-document \
   --name "AWS-RunShellScript"
```

Output:

```
{
   "Name": "AWS-RunShellScript",
   "DocumentVersion": "1",
   "Status": "Active",
   "Content": "{
      "schemaVersion": "1.2",
      "description": "Run a shell script or specify the commands to run.\n      
      Optional) The path to the working directory on your instance.\n      
      maxChars: 4096\n      
      allowedPattern": \"([1-9][0-9]{0,4})|([1]-[6][0-9]{3})|([1]7[2][0-7][0-9]{2})|([1]72800)\"\n      "runtimeConfig": {\n         "aws:runShellScript": {\n            "properties": [\n               \n               "id": "0.aws:runShellScript",
               "runCommand": "{{ commands }}",
               "workingDirectory": "{{ workingDirectory }}",
               "timeoutSeconds": "{{ executionTimeout }}",
               "DocumentType": "Command",
               "DocumentFormat": "JSON"
            ]\n         }\n      }\n   },\n   "parameters": {\n      "commands": {\n         "type": "StringList",
         "description": "(Required) Specify a shell script or a command to run.\n         
         minItems": 1,\n         "displayType": "textarea\n         
         workingDirectory": {\n         "type": "String",
         "default": "",
         "description": "(Optional) The path to the working directory on your instance.\n         
         maxChars: 4096\n         
         allowedPattern": \"([1-9][0-9]{0,4})|([1]-[6][0-9]{3})|([1]7[2][0-7][0-9]{2})|([1]72800)\"\n         "runtimeConfig": {\n            "aws:runShellScript": {\n               "properties": [\n                  "id": "0.aws:runShellScript",
                  "runCommand": "{{ commands }}",
                  "workingDirectory": "{{ workingDirectory }}",
                  "timeoutSeconds": "{{ executionTimeout }}",
                  "DocumentType": "Command",
                  "DocumentFormat": "JSON"
               ]\n            }\n         }
      },\n      "executionTimeout": {\n         "type": "String",
         "default": "3600",
         "description": "(Optional) The time in seconds for a command to complete before it is considered to have failed. Default is 3600 (1 hour). Maximum is 172800 (48 hours).\n         "allowedPattern": "([0-9-])|([1-9][0-9]{0,4})|([1]-[6][0-9]{3})|([1]72800)\"\n      }
   }
}
```

For more information, see **AWS Systems Manager Documents** in the **AWS Systems Manager User Guide**.

- For API details, see **GetDocument** in **AWS CLI Command Reference**.
PowerShell

**Tools for PowerShell**

**Example 1: This example returns the content of a document.**

```powershell
Get-SSMDocument -Name "RunShellScript"
```

**Output:**

```
Content
-------
{...
```

**Example 2: This example displays the complete contents of a document.**

```powershell
(Get-SSMDocument -Name "RunShellScript").Content
{
  "schemaVersion":"2.0",
  "description":"Run an updated script",
  "parameters":{
    "commands":{
      "type":"StringList",
      "description": "(Required) Specify a shell script or a command to run.",
      "minItems":1,
      "displayType":"textarea"
    }
  },
  "mainSteps":[
    {
      "action":"aws:runShellScript",
      "name":"runShellScript",
      "inputs":{
        "commands":"{{ commands }}"
      }
    },
    {
      "action":"aws:runPowerShellScript",
      "name":"runPowerShellScript",
      "inputs":{
        "commands":"{{ commands }}"
      }
    }
  ]
}
```
Use GetInventory with an AWS SDK or CLI

The following code examples show how to use GetInventory.

CLI

**AWS CLI**

**To view your inventory**

This example gets the custom metadata for your inventory.

Command:

```bash
aws ssm get-inventory
```

Output:

```json
{
  "Entities": [
    {
      "Data": {
        "AWS:InstanceInformation": {
          "Content": [
            {
              "ComputerName": "ip-172-31-44-222.us-west-2.compute.internal",
              "InstanceId": "i-0cb2b964d3e14fd9f",
              "IpAddress": "172.31.44.222",
              "AgentType": "amazon-ssm-agent",
              "ResourceType": "EC2Instance",
            }
          ]
        }
      }
    }
  ]
}
```

- For API details, see [GetDocument](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

---

GetInventory

2435
For API details, see [GetInventory](https://docs.aws.amazon.com/cli/latest/reference/ssm/get-inventory.html) in *AWS CLI Command Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1:** This example gets the custom metadata for your inventory.

```powershell
Get-SSMInventory
```

**Output:**

```
Data
Id
---- --
{{[AWS:InstanceInformation, Amazon.SimpleSystemsManagement.Model.InventoryResultItem]} i-0cb2b964d3e14fd9f
```

For API details, see [GetInventory](https://docs.aws.amazon.com/powershell/latest/reference/ssm/get-inventory.html) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/ssm/latest/dg/developer-guide-sdk.html). This topic also includes information about getting started and details about previous SDK versions.
Use `GetInventorySchema` with an AWS SDK or CLI

The following code examples show how to use `GetInventorySchema`.

CLI

**AWS CLI**

**To view your inventory schema**

This example returns a list of inventory type names for the account.

**Command:**

```
aws ssm get-inventory-schema
```

**Output:**

```
{
   "Schemas": [
   {
      "TypeName": "AWS:AWSComponent",
      "Version": "1.0",
      "Attributes": [
         {
            "Name": "Name",
            "DataType": "STRING"
         },
         {
            "Name": "ApplicationType",
            "DataType": "STRING"
         },
         {
            "Name": "Publisher",
            "DataType": "STRING"
         },
         {
            "Name": "Version",
            "DataType": "STRING"
         },
         {
            "Name": "InstalledTime",
```
To view the inventory schema for a specific inventory type

This example return the inventory schema for a the AWS:AWSComponent inventory type.

Command:

```bash
aws ssm get-inventory-schema --type-name "AWS:AWSComponent"
```

- For API details, see [GetInventorySchema](#) in *AWS CLI Command Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1:** This example returns a list of inventory type names for the account.

```powershell
Get-SSMInventorySchema
```

- For API details, see [GetInventorySchema](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.
Use GetMaintenanceWindow with an AWS SDK or CLI

The following code examples show how to use GetMaintenanceWindow.

CLI

AWS CLI

To get information about a maintenance window

The following get-maintenance-window example retrieves details about the specified maintenance window.

```
aws ssm get-maintenance-window \
   --window-id "mw-03eb9db428EXAMPLE"
```

Output:

```
{
   "AllowUnassociatedTargets": true,
   "CreatedDate": 1515006912.957,
   "Cutoff": 1,
   "Duration": 6,
   "Enabled": true,
   "ModifiedDate": 2020-01-01T10:04:04.099Z,
   "Name": "My-Maintenance-Window",
   "Schedule": "rate(3 days)",
   "WindowId": "mw-03eb9db428EXAMPLE",
   "NextExecutionTime": "2020-02-25T00:08:15.099Z"
}
```

For more information, see View information about maintenance windows (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see GetMaintenanceWindow in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example gets details about a maintenance window.
Get-SSMMaintenanceWindow -WindowId "mw-03eb9db42890fb82d"

**Output:**

<table>
<thead>
<tr>
<th>AllowUnassociatedTargets</th>
<th>False</th>
</tr>
</thead>
<tbody>
<tr>
<td>CreatedDate</td>
<td>2/20/2017 6:14:05 PM</td>
</tr>
<tr>
<td>Cutoff</td>
<td>1</td>
</tr>
<tr>
<td>Duration</td>
<td>2</td>
</tr>
<tr>
<td>Enabled</td>
<td>True</td>
</tr>
<tr>
<td>ModifiedDate</td>
<td>2/20/2017 6:14:05 PM</td>
</tr>
<tr>
<td>Name</td>
<td>TestMaintWin</td>
</tr>
<tr>
<td>Schedule</td>
<td>cron(0 */30 * * * ? *)</td>
</tr>
<tr>
<td>WindowId</td>
<td>mw-03eb9db42890fb82d</td>
</tr>
</tbody>
</table>

- For API details, see [GetMaintenanceWindow](https://aws.amazon.com/tools/doc/powerShell/index.html#GetMaintenanceWindow) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://aws.amazon.com/tools/doc/powerShell/index.html#UsingSystemsManager). This topic also includes information about getting started and details about previous SDK versions.

## Use GetMaintenanceWindowExecution with an AWS SDK or CLI

The following code examples show how to use `GetMaintenanceWindowExecution`.

### CLI

**AWS CLI**

**To get information about a maintenance window task execution**

The following `get-maintenance-window-execution` example lists information about a task executed as part of the specified maintenance window execution.

```
aws ssm get-maintenance-window-execution \
   --window-execution-id "518d5565-5969-4cca-8f0e-da3b2EXAMPLE"
```

**Output:**

```
{
   "Status": "SUCCESS",
   "TaskIds": [
```

For more information, see View Information About Tasks and Task Executions (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see GetMaintenanceWindowExecution in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example lists information about a task executed as part of a maintenance window execution.

Get-SSMMaintenanceWindowExecution -WindowExecutionId "518d5565-5969-4cca-8f0e-da3b2a638355"

Output:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndTime</td>
<td>2/21/2017 4:00:35 PM</td>
</tr>
<tr>
<td>StartTime</td>
<td>2/21/2017 4:00:34 PM</td>
</tr>
<tr>
<td>Status</td>
<td>FAILED</td>
</tr>
<tr>
<td>StatusDetails</td>
<td>One or more tasks in the orchestration failed.</td>
</tr>
<tr>
<td>TaskIds</td>
<td>{ac0c6ae1-daa3-4a89-832e-d384503b6586}</td>
</tr>
<tr>
<td>WindowExecutionId</td>
<td>518d5565-5969-4cca-8f0e-da3b2a638355</td>
</tr>
</tbody>
</table>

- For API details, see GetMaintenanceWindowExecution in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use GetMaintenanceWindowExecutionTask with an AWS SDK or CLI

The following code examples show how to use GetMaintenanceWindowExecutionTask.
AWS CLI

To get information about a maintenance window task execution

The following `get-maintenance-window-execution-task` example lists information about a task that is part of the specified maintenance window execution.

```
aws ssm get-maintenance-window-execution-task \
  --window-execution-id "518d5565-5969-4cca-8f0e-da3b2EXAMPLE" \
  --task-id "ac0c6ae1-daa3-4a89-832e-d3845EXAMPLE"
```

Output:

```
{
  "WindowExecutionId": "518d5565-5969-4cca-8f0e-da3b2EXAMPLE",
  "TaskExecutionId": "ac0c6ae1-daa3-4a89-832e-d3845EXAMPLE",
  "TaskArn": "AWS-RunPatchBaseline",
  "ServiceRole": "arn:aws:iam::111222333444:role/aws-service-role/ssm.amazonaws.com/AWSServiceRoleForAmazonSSM",
  "Type": "RUN_COMMAND",
  "TaskParameters": [
    {
      "BaselineOverride": {
        "Values": [
          ""
        ]
      },
      "InstallOverrideList": {
        "Values": [
          ""
        ]
      },
      "Operation": {
        "Values": [
          "Scan"
        ]
      },
      "RebootOption": {
        "Values": [
          "RebootIfNeeded"
        ]
      }
    }
  ]
}
```
For more information, see View information about tasks and task executions (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see GetMaintenanceWindowExecutionTask in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example lists information about a task that was part of a maintenance window execution.**

```powershell
Get-SSMMaintenanceWindowExecutionTask -TaskId "ac0c6ae1-daa3-4a89-832e-d384503b6586" -WindowExecutionId "518d5565-5969-4cca-8f0e-da3b2a638355"
```

**Output:**

<table>
<thead>
<tr>
<th>EndTime</th>
</tr>
</thead>
<tbody>
<tr>
<td>2/21/2017 4:00:35 PM</td>
</tr>
</tbody>
</table>
MaxConcurrency : 1

- For API details, see [GetMaintenanceWindowExecutionTask](#) in *AWS Tools for PowerShell Cmdlet Reference.*

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use GetParameterHistory with an AWS SDK or CLI**

The following code examples show how to use GetParameterHistory.

**CLI**

**AWS CLI**

**To get a value history for a parameter**

The following *get-parameter-history* example lists the history of changes for the specified parameter, including its value.

```bash
aws ssm get-parameter-history \
  --name "MyStringParameter"
```

Output:

```json
{
```
"Parameters": [
  {
    "Name": "MyStringParameter",
    "Type": "String",
    "LastModifiedDate": 1582154711.976,
    "LastModifiedUser": "arn:aws:iam::111222333444:user/Mary-Major",
    "Description": "This is the first version of my String parameter",
    "Value": "Veni",
    "Version": 1,
    "Labels": [],
    "Tier": "Standard",
    "Policies": []
  },
  {
    "Name": "MyStringParameter",
    "Type": "String",
    "LastModifiedDate": 1582156093.471,
    "LastModifiedUser": "arn:aws:iam::111222333444:user/Mary-Major",
    "Description": "This is the second version of my String parameter",
    "Value": "Vidi",
    "Version": 2,
    "Labels": [],
    "Tier": "Standard",
    "Policies": []
  },
  {
    "Name": "MyStringParameter",
    "Type": "String",
    "LastModifiedDate": 1582156117.545,
    "LastModifiedUser": "arn:aws:iam::111222333444:user/Mary-Major",
    "Description": "This is the third version of my String parameter",
    "Value": "Vici",
    "Version": 3,
    "Labels": [],
    "Tier": "Standard",
    "Policies": []
  }
]
}

For more information, see Working with parameter versions in the AWS Systems Manager User Guide.

- For API details, see GetParameterHistory in AWS CLI Command Reference.
PowerShell

Tools for PowerShell

Example 1: This example lists the value history for a parameter.

Get-SSMParameterHistory -Name "Welcome"

Output:

Description : 
KeyId : 
LastModifiedDate : 3/3/2017 6:55:25 PM
LastModifiedUser : arn:aws:iam::123456789012:user/admin
Name : Welcome
Type : String
Value : helloWorld

For API details, see GetParameterHistory in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use GetParameters with an AWS SDK or CLI

The following code examples show how to use GetParameters.

CLI

AWS CLI

Example 1: To list the values for a parameter

The following get-parameters example lists the values for the three specified parameters.

aws ssm get-parameters \
   --names "MyStringParameter" "MyStringListParameter" "MyInvalidParameterName"

Output:
For more information, see [Working with Parameter Store](#) in the *AWS Systems Manager User Guide*.

**Example 2: To list names and values of multiple parameters using the `--query` option**

The following `get-parameters` example lists the names and values for the specified parameters.

```
aws ssm get-parameters
  --names MyStringParameter MyStringListParameter
  --query "Parameters[*].{Name:Name,Value:Value}"
```

Output:
For more information, see Working with Parameter Store in the AWS Systems Manager User Guide.

Example 3: To display the value of a parameter using labels

The following get-parameter example lists the value for the specified single parameter with a specified label.

```
aws ssm get-parameter \
   --name "MyParameter:label"
```

Output:

```json
{
   "Parameters": [
      {
        "Name": "MyLabelParameter",
        "Type": "String",
        "Value": "parameter by label",
        "Version": 1,
        "Selector": ":label",
        "LastModifiedDate": "2021-07-12T09:49:15.865000-07:00",
        "DataType": "text"
      },
      {
        "Name": "MyVersionParameter",
        "Type": "String",
        "Value": "parameter by version",
        "Version": 2,
```
For more information, see [Working with parameter labels](#) in the *AWS Systems Manager User Guide*.

- For API details, see [GetParameters](#) in *AWS CLI Command Reference*.

### PowerShell

**Tools for PowerShell**

**Example 1: This example lists the values for a parameter.**

```powershell
Get-SSMParameterValue -Name "Welcome"
```

**Output:**

```
InvalidParameters Parameters
----------------- ----------
{}                {Welcome}
```

**Example 2: This example lists the details of the value.**

```powershell
(Get-SSMParameterValue -Name "Welcome").Parameters
```

**Output:**

```
Name    Type   Value
----    ----   -----  
Welcome String Good day, Sunshine!
```

- For API details, see [GetParameters](#) in *AWS Tools for PowerShell Cmdlet Reference*. 

---

GetParameters 2449
For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use GetPatchBaseline with an AWS SDK or CLI**

The following code examples show how to use GetPatchBaseline.

**CLI**

**AWS CLI**

To display a patch baseline

The following get-patch-baseline example retrieves the details for the specified patch baseline.

```bash
aws ssm get-patch-baseline --baseline-id "pb-0123456789abcdef0"
```

Output:

```json
{
   "BaselineId": "pb-0123456789abcdef0",
   "Name": "WindowsPatching",
   "OperatingSystem": "WINDOWS",
   "GlobalFilters": {
      "PatchFilters": []
   },
   "ApprovalRules": {
      "PatchRules": [
      {
         "PatchFilterGroup": {
            "PatchFilters": [
            {
               "Key": "PRODUCT",
               "Values": ["WindowsServer2016"]
            }
            ]
         }
      ]
   }
}
```
For more information, see [About Patch Baselines](#) in the [AWS Systems Manager User Guide](#).

- For API details, see [GetPatchBaseline](#) in [AWS CLI Command Reference](#).

### PowerShell

#### Tools for PowerShell

**Example 1: This example displays the details for a patch baseline.**

```
Get-SSMPatchBaselineDetail -BaselineId "pb-03da896ca3b68b639"
```

**Output:**

```
ApprovedPatches    : {}
BaselineId         : pb-03da896ca3b68b639
CreatedDate        : 3/3/2017 5:02:19 PM
Description        : Baseline containing all updates approved for production systems
ModifiedDate       : 3/3/2017 5:02:19 PM
```
Name            : Production-Baseline  
PatchGroups     : {}  
RejectedPatches : {}

- For API details, see GetPatchBaseline in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use GetPatchBaselineForPatchGroup with an AWS SDK or CLI**

The following code examples show how to use GetPatchBaselineForPatchGroup.

**CLI**

**AWS CLI**

**To display the patch baseline for a patch group**

The following get-patch-baseline-for-patch-group example retrieves details about the patch baseline for the specified patch group.

```bash
aws ssm get-patch-baseline-for-patch-group 
   --patch-group "DEV"
```

Output:

```
{
   "PatchGroup": "DEV",
   "BaselineId": "pb-0123456789abcdef0",
   "OperatingSystem": "WINDOWS"
}
```

For more information, see Create a Patch Group <https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-patch-group-tagging.html> and Add a Patch Group to a Patch Baseline in the AWS Systems Manager User Guide.

- For API details, see GetPatchBaselineForPatchGroup in AWS CLI Command Reference.
PowerShell

Tools for PowerShell

Example 1: This example displays the patch baseline for a patch group.

Get-SSMPatchBaselineForPatchGroup -PatchGroup "Production"

Output:

```
BaselineId       PatchGroup
-------------    ----------
pb-045f10b4f382baeda Production
```

- For API details, see [GetPatchBaselineForPatchGroup](#) in [AWS Tools for PowerShell Cmdlet Reference](#).

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use ListAssociationVersions with an AWS SDK or CLI**

The following code examples show how to use ListAssociationVersions.

**CLI**

**AWS CLI**

To list all versions of an association for a specific association ID

The following `list-association-versions` example lists all versions of the specified associations.

```
aws ssm list-association-versions \
  --association-id "8dfe3659-4309-493a-8755-0123456789ab"
```

Output:

```
{
  "AssociationVersions": [ ...
```
For more information, see Working with associations in Systems Manager in the AWS Systems Manager User Guide.

- For API details, see ListAssociationVersions in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example retrieves all versions of the association provided.

```powershell
Get-SSMAssociationVersionList -AssociationId 123a45a0-c678-9012-3456-78901234db5e
```

Output:

```plaintext
AssociationId : 123a45a0-c678-9012-3456-78901234db5e
```
For API details, see ListAssociationVersions in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use ListAssociations with an AWS SDK or CLI**

The following code examples show how to use ListAssociations.

**CLI**

**AWS CLI**

Example 1: To list your associations for a specific instance
The following list-associations example lists all associations with the AssociationName, UpdateSSMAgent.

```
aws ssm list-associations /
   --association-filter-list "key=AssociationName,value=UpdateSSMAgent"
```

Output:

```
{
   "Associations": [
   {
      "Name": "AWS-UpdateSSMAgent",
      "InstanceId": "i-1234567890abcdef0",
      "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
      "AssociationVersion": "1",
      "Targets": [
         { "Key": "InstanceIds", "Values": [ "i-016648b75dd622dab" ] }
      ],
      "Overview": {
         "Status": "Pending",
         "DetailedStatus": "Associated",
         "AssociationStatusAggregatedCount": {
            "Pending": 1
         }
      },
      "ScheduleExpression": "cron(0 00 12 ? * SUN *)",
      "AssociationName": "UpdateSSMAgent"
   }
   ]
}
```

For more information, see Working with associations in Systems Manager in the Systems Manager User Guide.

**Example 2: To list your associations for a specific document**

The following list-associations example lists all associations for the specified document.
aws ssm list-associations /
   --association-filter-list "key=Name,value=AWS-UpdateSSMAgent"

Output:

```json
{
  "Associations": [
    {
      "Name": "AWS-UpdateSSMAgent",
      "InstanceId": "i-1234567890abcdef0",
      "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
      "AssociationVersion": "1",
      "Targets": [
        {
          "Key": "InstanceIds",
          "Values": [
            "i-1234567890abcdef0"
          ]
        }
      ],
      "LastExecutionDate": 1550505828.548,
      "Overview": {
        "Status": "Success",
        "DetailedStatus": "Success",

          ]
        }
      ]
    }
  ]
}
```
For more information, see Working with associations in Systems Manager in the Systems Manager User Guide.

- For API details, see ListAssociations in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example lists all the associations for an instance. The syntax used by this example requires PowerShell version 3 or later.

```powershell
$filter1 = @{Key="InstanceId";Value=@("i-0000293ffd8c57862")}
Get-SSMAssociationList -AssociationFilterList $filter1
```

Output:

```
AssociationId      : d8617c07-2079-4c18-9847-1655fc2698b0
DocumentVersion    :
InstanceId         : i-0000293ffd8c57862
LastExecutionDate  : 2/20/2015 8:31:11 AM
Name               : AWS-UpdateSSMAgent
Overview           : Amazon.SimpleSystemsManagement.Model.AssociationOverview
ScheduleExpression :
Targets            : {InstanceIds}
```

Example 2: This example lists all associations for a configuration document. The syntax used by this example requires PowerShell version 3 or later.

```powershell
$filter2 = @{Key="Name";Value=@("AWS-UpdateSSMAgent"))
ListAssociations $filter2
```

ListAssociations
Get-SSMAssociationList -AssociationFilterList $filter2

Output:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AssociationId</td>
<td>d8617c07-2079-4c18-9847-1655fc2698b0</td>
</tr>
<tr>
<td>DocumentVersion</td>
<td></td>
</tr>
<tr>
<td>InstanceId</td>
<td>i-0000293fffd8c57862</td>
</tr>
<tr>
<td>LastExecutionDate</td>
<td>2/20/2015 8:31:11 AM</td>
</tr>
<tr>
<td>Name</td>
<td>AWS-UpdateSSMAgent</td>
</tr>
<tr>
<td>Overview</td>
<td>Amazon.SimpleSystemsManagement.Model.AssociationOverview</td>
</tr>
<tr>
<td>ScheduleExpression</td>
<td></td>
</tr>
<tr>
<td>Targets</td>
<td>{InstanceIds}</td>
</tr>
</tbody>
</table>

Example 3: With PowerShell version 2, you must use New-Object to create each filter.

```
$filter1 = New-Object Amazon.SimpleSystemsManagement.Model.AssociationFilter
$filter1.Key = "InstanceId"
$filter1.Value = "i-0000293fffd8c57862"
```

Get-SSMAssociationList -AssociationFilterList $filter1

Output:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AssociationId</td>
<td>d8617c07-2079-4c18-9847-1655fc2698b0</td>
</tr>
<tr>
<td>DocumentVersion</td>
<td></td>
</tr>
<tr>
<td>InstanceId</td>
<td>i-0000293fffd8c57862</td>
</tr>
<tr>
<td>LastExecutionDate</td>
<td>2/20/2015 8:31:11 AM</td>
</tr>
<tr>
<td>Name</td>
<td>AWS-UpdateSSMAgent</td>
</tr>
<tr>
<td>Overview</td>
<td>Amazon.SimpleSystemsManagement.Model.AssociationOverview</td>
</tr>
<tr>
<td>ScheduleExpression</td>
<td></td>
</tr>
<tr>
<td>Targets</td>
<td>{InstanceIds}</td>
</tr>
</tbody>
</table>

- For API details, see [ListAssociations](#) in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use ListCommandInvocations with an AWS SDK or CLI**

The following code examples show how to use ListCommandInvocations.
AWS CLI

To list the invocations of a specific command

The following list-command-invocations example lists all the invocations of a command.

```bash
aws ssm list-command-invocations \
  --command-id "ef7fd8d8-9b57-4151-a15c-db9a12345678" \
  --details
```

Output:

```json
{
  "CommandInvocations": [
    {
      "CommandId": "ef7fd8d8-9b57-4151-a15c-db9a12345678",

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use ListCommands with an AWS SDK or CLI**

The following code examples show how to use ListCommands.

**CLI**

**AWS CLI**

**Example 1: To get the status of a specific command**

The following `list-commands` example retrieves and displays the status of the specified command.

```bash
aws ssm list-commands \
   --command-id "0831e1a8-a1ac-4257-a1fd-c831bEXAMPLE"
```

**Example 2: To get the status of commands requested after a specific date**

The following `list-commands` example retrieves the details of commands requested after the specified date.

```bash
aws ssm list-commands \
   --filter "key=InvokedAfter,value=2020-02-01T00:00:00Z"
```

**Example 3: To list all commands requested in an AWS account**

The following `list-commands` example lists all commands requested by users in the current AWS account and Region.

```bash
aws ssm list-commands
```

**Output:**

```json
{
   "Commands": [
      {
         "CommandId": "8bee3135-398c-4d31-99b6-e42d2EXAMPLE",

**Use ListComplianceItems with an AWS SDK or CLI**

The following code examples show how to use ListComplianceItems.

**CLI**

**AWS CLI**

**To list compliance items for a specific instance**

This example lists all compliance items for the specified instance.

**Command:**

```
aws ssm list-compliance-items --resource-ids "i-1234567890abcdef0" --resource-types "ManagedInstance"
```

**Output:**

```
{
   "ComplianceItems": [
   {
      "ComplianceType": "Association",
      "ResourceType": "ManagedInstance",
      "ResourceId": "i-1234567890abcdef0",
      "Id": "8dfe3659-4309-493a-8755-0123456789ab",
      "Title": "",
      "Status": "COMPLIANT",
      "Severity": "UNSPECIFIED",
      "ExecutionSummary": {
         "ExecutionTime": 1550408470.0
      },
      "Details": {
         "DocumentName": "AWS-GatherSoftwareInventory",
         "DocumentVersion": "1"
      }
  },
  {
   
```
"ComplianceType": "Association",
"ResourceType": "ManagedInstance",
"ResourceId": "i-1234567890abcdef0",
"Id": "e4c2ed6d-516f-41aa-aa2a-0123456789ab",
"Title": "",
"Status": "COMPLIANT",
"Severity": "UNSPECIFIED",
"ExecutionSummary": {
  "ExecutionTime": 1550508475.0
},
"Details": {
  "DocumentName": "AWS-UpdateSSMAgent",
  "DocumentVersion": "1"
}
}, ...
"NextToken": "--token string truncated--"
}

To list compliance items for a specific instance and association ID

This example lists all compliance items for the specified instance and association ID.

Command:

```
aws ssm list-compliance-items --resource-ids "i-1234567890abcdef0" --resource-types "ManagedInstance" --filters
  "Key=ComplianceType,Values=Association,Type=EQUAL"
  "Key=Id,Values=e4c2ed6d-516f-41aa-aa2a-0123456789ab,Type=EQUAL"
```

To list compliance items for a instance after a specific date and time

This example lists all compliance items for an instance after the specified date and time.

Command:

```
aws ssm list-compliance-items --resource-ids "i-1234567890abcdef0" --resource-types "ManagedInstance" --filters
  "Key=ExecutionTime,Values=2019-02-18T16:00:00Z,Type=GREATER_THAN"
```

- For API details, see ListComplianceItems in AWS CLI Command Reference.
PowerShell

Tools for PowerShell

Example 1: This example lists compliance items list for the given resource id and type, filtering compliance-type being 'Association'

```powershell
Get-SSMComplianceItemList -ResourceId i-1a2caf345f67d0dc2 -ResourceType ManagedInstance -Filter @{Key="ComplianceType";Values="Association"}
```

Output:

```
ComplianceType : Association
Details          : {
[DocumentName, AWS-GatherSoftwareInventory],
  [DocumentVersion, 1]}
ExecutionSummary :
  Amazon.SimpleSystemsManagement.Model.ComplianceExecutionSummary
Id               : 123a45a1-c234-1234-1245-67891236db4e
ResourceId       : i-1a2caf345f67d0dc2
ResourceType     : ManagedInstance
Severity         : UNSPECIFIED
Status           : COMPLIANT
Title            :
```

- For API details, see [ListComplianceItems](https://docs.aws.amazon.com/systems-manager/latest/userguide/list-complianceitems.html) in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use ListComplianceSummaries with an AWS SDK or CLI**

The following code examples show how to use ListComplianceSummaries.

CLI

**AWS CLI**

To list compliance summaries for all compliance types

This example lists compliance summaries for all compliance types in your account.
Command:

```bash
aws ssm list-compliance-summaries
```

Output:

```json
{
   "ComplianceSummaryItems": [
      {
         "ComplianceType": "Association",
         "CompliantSummary": {
            "CompliantCount": 2,
            "SeveritySummary": {
               "CriticalCount": 0,
               "HighCount": 0,
               "MediumCount": 0,
               "LowCount": 0,
               "InformationalCount": 0,
               "UnspecifiedCount": 2
            }
         },
         "NonCompliantSummary": {
            "NonCompliantCount": 0,
            "SeveritySummary": {

To list compliance summaries for a specific compliance type

This example lists the compliance summary for the Patch compliance type.

Command:

```
aws ssm list-compliance-summaries --filters
  "Key=ComplianceType,Values=Patch,Type=EQUAL"
```

- For API details, see [ListComplianceSummaries](https://docs.aws.amazon.com/cli/latest/reference/ssm/list-compliance-summaries.html) in *AWS CLI Command Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1:** This example returns a summary count of compliant and non-compliant resources for all compliance types.

```
Get-SSMComplianceSummaryList
```

**Output:**
For API details, see [ListComplianceSummaries](#) in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

### Use ListDocumentVersions with an AWS SDK or CLI

The following code examples show how to use ListDocumentVersions.

**CLI**

**AWS CLI**

**To list document versions**

The following list-document-versions example lists all versions for a Systems Manager document.

```bash
aws ssm list-document-versions \
   --name "Example"
```

**Output:**

```json
{
   "DocumentVersions": [
```
Example 1: This example returns the permission list for a document.

```
Get-SSMDocumentPermission -Name "RunShellScript" -PermissionType "Share"
```

**Output:**

```
all
```

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systemsmanager/latest/userguide/using-systems-manager-with-sdk.html). This topic also includes information about getting started and details about previous SDK versions.

### Use ListDocuments with an AWS SDK or CLI

The following code examples show how to use ListDocuments.
**Example 1: To list documents**

The following `list-documents` example lists documents owned by the requesting account tagged with the custom tag.

```
aws ssm list-documents \\
   --filters Key=Owner,Values=Self Key=tag:DocUse,Values=Testing
```

Output:

```
{
   "DocumentIdentifiers": [
      {
         "Name": "Example",
         "Owner": "29884EXAMPLE",
         "PlatformTypes": [
            "Windows",
            "Linux"
         ],
         "DocumentVersion": "1",
         "DocumentType": "Automation",
         "SchemaVersion": "0.3",
         "DocumentFormat": "YAML",
         "Tags": [
            {
               "Key": "DocUse",
               "Value": "Testing"
            }
         ]
      }
   ]
}
```

For more information, see [AWS Systems Manager Documents](https://docs.aws.amazon.com/systems-manager/latest/userguide) in the *AWS Systems Manager User Guide*.

**Example 2: To list shared documents**
The following list-documents example lists shared documents, including private shared documents not owned by AWS.

```bash
aws ssm list-documents
   --filters Key=Name,Values=sharedDocNamePrefix  Key=Owner,Values=Private
```

Output:

```json
{
   "DocumentIdentifiers": [
      {
         "Name": "Example",
         "Owner": "12345EXAMPLE",
         "PlatformTypes": [
            "Windows",
            "Linux"
         ],
         "DocumentVersion": "1",
         "DocumentType": "Command",
         "SchemaVersion": "0.3",
         "DocumentFormat": "YAML",
         "Tags": []
      }
   ]
}
```

For more information, see [AWS Systems Manager Documents](http://aws.amazon.com) in the [AWS Systems Manager User Guide](http://aws.amazon.com).

- For API details, see [ListDocuments](http://aws.amazon.com) in [AWS CLI Command Reference](http://aws.amazon.com).

**PowerShell**

**Tools for PowerShell**

**Example 1: Lists all the configuration documents in your account.**

```powershell
Get-SSMDocumentList
```

**Output:**

```yaml
DocumentType : Command
```
### Example 2: This example retrieves all automation documents with name matching 'Platform'

```
Get-SSMDocumentList -DocumentFilterList @{Key="DocumentType";Value="Automation"} | Where-Object Name -Match "Platform"
```

**Output:**

```
DocumentFormat : JSON
DocumentType    : Automation
DocumentVersion : 7
Name            : KT-Get-Platform
Owner           : 987654123456
PlatformTypes   : {Windows, Linux}
SchemaVersion   : 0.3
Tags            :
TargetType      :
VersionName     : 
```

- For API details, see [ListDocuments](https://docs.aws.amazon.com/system-manager/latest/userguide/API_SSM_ListDocuments.html) in AWS Tools for PowerShell Cmdlet Reference.
For a complete list of AWS SDK developer guides and code examples, see `Using Systems Manager with an AWS SDK`. This topic also includes information about getting started and details about previous SDK versions.

**Use ListInventoryEntries with an AWS SDK or CLI**

The following code examples show how to use `ListInventoryEntries`.

**CLI**

**AWS CLI**

**Example 1: To view specific inventory type entries for an instance**

This following `list-inventory-entries` example lists the inventory entries for the `AWS:Application` inventory type on a specific instance.

```
aws ssm list-inventory-entries \
   --instance-id "i-1234567890abcdef0" \ 
   --type-name "AWS:Application"
```

Output:

```
{
   "TypeName": "AWS:Application",
   "InstanceId": "i-1234567890abcdef0",
   "SchemaVersion": "1.1",
   "Entries": [
      {
         "Architecture": "i386",
         "Name": "Amazon SSM Agent",
         "PackageId": "{88a60be2-89a1-4df8-812a-80863c2a2b68}",
         "Publisher": "Amazon Web Services",
         "Version": "2.3.274.0"
      },
      {
         "Architecture": "x86_64",
         "InstalledTime": "2018-05-03T13:42:34Z",
         "Name": "AmazonCloudWatchAgent",
         "Publisher": ",",
         "Version": "1.200442.0"
      }
   ]
}
```
Example 2: To view custom inventory entries assigned to an instance

The following `list-inventory-entries` example lists a custom inventory entry assigned to an instance.

```bash
aws ssm list-inventory-entries \
   --instance-id "i-1234567890abcdef0" \
   --type-name "Custom:RackInfo"
```

Output:

```
{
   "TypeName": "Custom:RackInfo",
   "InstanceId": "i-1234567890abcdef0",
   "SchemaVersion": "1.0",
   "CaptureTime": "2021-05-22T10:01:01Z",
   "Entries": [
      {
         "RackLocation": "Bay B/Row C/Rack D/Shelf E"
      }
   ]
}
```

- For API details, see [ListInventoryEntries](#) in *AWS CLI Command Reference*.

PowerShell

**Tools for PowerShell**

**Example 1: This example lists all the custom inventory entries for an instance.**

```
Get-SSMInventoryEntriesList -InstanceId "i-0cb2b964d3e14fd9f" -TypeName "Custom:RackInfo"
```

**Output:**

```
CaptureTime : 2016-08-22T10:01:01Z
```
Example 2: This example lists the details.

```powershell
(Get-SSMInventoryEntriesList -InstanceId "i-0cb2b964d3e14fd9f" -TypeName "Custom:RackInfo").Entries
```

Output:

```
Key          Value
---          -----  
RackLocation Bay B/Row C/Rack D/Shelf E
```

- For API details, see [ListInventoryEntries](https://docs.aws.amazon.com/systemsmanager/latest/userguide SSMDocReference.html) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systemsmanager/latest/userguide SSMDocReference.html). This topic also includes information about getting started and details about previous SDK versions.

**Use ListResourceComplianceSummaries with an AWS SDK or CLI**

The following code examples show how to use ListResourceComplianceSummaries.

**CLI**

**AWS CLI**

To list resource-level compliance summary counts

This example lists resource-level compliance summary counts.

Command:

```
aws ssm list-resource-compliance-summaries
```
Output:

```json
{
    "ResourceComplianceSummaryItems": [
        {
            "ComplianceType": "Association",
            "ResourceType": "ManagedInstance",
            "ResourceId": "i-1234567890abcdef0",
            "Status": "COMPLIANT",
            "OverallSeverity": "UNSPECIFIED",
            "ExecutionSummary": {
                "ExecutionTime": 1550509273.0
            },
            "CompliantSummary": {
                "CompliantCount": 2,
                "SeveritySummary": {
                    "CriticalCount": 0,
                    "HighCount": 0,
                    "MediumCount": 0,
                    "LowCount": 0,
                    "InformationalCount": 0,
                    "UnspecifiedCount": 2
                }
            },
            "NonCompliantSummary": {
                "NonCompliantCount": 0,
                "SeveritySummary": {
                    "CriticalCount": 0,
                    "HighCount": 0,
                    "MediumCount": 0,
                    "LowCount": 0,
                    "InformationalCount": 0,
                    "UnspecifiedCount": 0
                }
            }
        },
        {
            "ComplianceType": "Patch",
            "ResourceType": "ManagedInstance",
            "ResourceId": "i-9876543210abcdef0",
            "Status": "COMPLIANT",
            "OverallSeverity": "UNSPECIFIED",
            "ExecutionSummary": {
                "ExecutionTime": 1550248550.0
            }
        }
    ]
}
```
To list resource-level compliance summaries for a specific compliance type

This example lists resource-level compliance summaries for the Patch compliance type.

Command:

```
aws ssm list-resource-compliance-summaries --filters
  "Key=ComplianceType,Values=Patch,Type=EQUAL"
```

- For API details, see [ListResourceComplianceSummaries](#) in [AWS CLI Command Reference](#).
PowerShell

**Tools for PowerShell**

Example 1: This example gets a resource-level summary count. The summary includes information about compliant and non-compliant statuses and detailed compliance-item severity counts for products that match "Windows10". Because the MaxResult default is 100 if the parameter is not specified, and this value is not valid, MaxResult parameter is added, and the value is set to 50.

```powershell
$FilterValues = @{
    "Key"="Product"
    "Type"="EQUAL"
    "Values"="Windows10"
}
Get-SSMResourceComplianceSummaryList -Filter $FilterValues -MaxResult 50
```

- For API details, see [ListResourceComplianceSummaries](#) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

**Use ListTagsForResource with an AWS SDK or CLI**

The following code examples show how to use ListTagsForResource.

**CLI**

**AWS CLI**

To list the tags applied to a patch baseline

The following `list-tags-for-resource` example lists the tags for a patch baseline.

```bash
aws ssm list-tags-for-resource \
    --resource-type "PatchBaseline" \
    --resource-id "pb-0123456789abcdef0"
```

Output:
For more information, see [Tagging AWS Resources](https://docs.aws.amazon.com/awsgeneralref/latest/en_us/aws-general-ref.html) in the *AWS General Reference*.

- For API details, see [ListTagsForResource](https://docs.aws.amazon.com/cli/latest/reference/ssm/list-tags-for-resource.html) in *AWS CLI Command Reference*.

### PowerShell

**Tools for PowerShell**

**Example 1:** This example lists the tags for a maintenance window.

```powershell
Get-SSMResourceTag -ResourceId "mw-03eb9db42890fb82d" -ResourceType "MaintenanceWindow"
```

**Output:**

```
Key   Value
---   -----
Stack Production
```

- For API details, see [ListTagsForResource](https://docs.aws.amazon.com/toolsforpowershell/cmdlet-ref.html) in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systemsmanager/latest/userguide/using-sdk.html). This topic also includes information about getting started and details about previous SDK versions.

**Use ModifyDocumentPermission with an AWS SDK or CLI**

The following code examples show how to use ModifyDocumentPermission.
CLI

AWS CLI

To modify document permissions

The following modify-document-permission example shares a Systems Manager document publicly.

```
aws ssm modify-document-permission \
   --name "Example" \
   --permission-type "Share" \
   --account-ids-to-add "All"
```

This command produces no output.

For more information, see Share a Systems Manager Document in the AWS Systems Manager User Guide.

- For API details, see ModifyDocumentPermission in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example adds "share" permissions to all accounts for a document. There is no output if the command succeeds.

```
Edit-SSMDocumentPermission -Name "RunShellScript" -PermissionType "Share" -AccountIdsToAdd all
```

Example 2: This example adds "share" permissions to a specific account for a document. There is no output if the command succeeds.

```
Edit-SSMDocumentPermission -Name "RunShellScriptNew" -PermissionType "Share" -AccountIdsToAdd "123456789012"
```

- For API details, see ModifyDocumentPermission in AWS Tools for PowerShell Cmdlet Reference.
For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use PutComplianceItems with an AWS SDK or CLI

The following code examples show how to use PutComplianceItems.

CLI

AWS CLI

To register a compliance type and compliance details to a designated instance

This example registers the compliance type Custom:AVCheck to the specified managed instance. There is no output if the command succeeds.

Command:

```bash
aws ssm put-compliance-items --resource-id "i-1234567890abcdef0" --resource-type "ManagedInstance" --compliance-type "Custom:AVCheck" --execution-summary "ExecutionTime=2019-02-18T16:00:00Z" --items "Id=Version2.0,Title=ScanHost,Severity=CRITICAL,Status=COMPLIANT"
```

• For API details, see PutComplianceItems in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example writes a custom compliance item for the given managed instance

```powershell
$item = [Amazon.SimpleSystemsManagement.Model.ComplianceItemEntry]:new()
$item.Id = "07Jun2019-3"
$item.Severity="LOW"
$item.Status="COMPLIANT"
$item.Title="Fin-test-1 - custom"
Write-SSMComplianceItem -ResourceId mi-012dcb3ecea45b678 -ComplianceType Custom:VSSCompliant2 -ResourceType ManagedInstance -Item $item -ExecutionSummary_ExecutionTime "07-Jun-2019"
```
For API details, see **PutComplianceItems** in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

### Use **PutInventory** with an AWS SDK or CLI

The following code examples show how to use **PutInventory**.

**CLI**

#### AWS CLI

**To assign customer metadata to an instance**

This example assigns rack location information to an instance. There is no output if the command succeeds.

Command (Linux):

```bash
aws ssm put-inventory --instance-id "i-016648b75dd622dab" --items
'[
"TypeName": "Custom:RackInfo","SchemaVersion": "1.0","CaptureTime":
"2019-01-22T10:01:01Z","Content":[
"RackLocation": "Bay B/Row C/Rack D/Shelf E""]
]'
```

Command (Windows):

```bash
aws ssm put-inventory --instance-id "i-016648b75dd622dab" --items
"TypeName=Custom:RackInfo,SchemaVersion=1.0,CaptureTime=2019-01-22T10:01:01Z,Content=[{RackLocation='Bay B/Row C/Rack D/Shelf E'}]"
```

For API details, see **PutInventory** in *AWS CLI Command Reference*.

**PowerShell**

#### Tools for PowerShell

**Example 1:** This example assigns rack location information to an instance. There is no output if the command succeeds.
$data.Add("RackLocation", "Bay B/Row C/Rack D/Shelf F")

$items.Add($data)

$customInventoryItem = New-Object Amazon.SimpleSystemsManagement.Model.InventoryItem
$customInventoryItem.CaptureTime = "2016-08-22T10:01:01Z"
$customInventoryItem.Content = $items
$customInventoryItem.TypeName = "Custom:TestRackInfo2"
$customInventoryItem.SchemaVersion = "1.0"

$inventoryItems = @($customInventoryItem)
Write-SSMInventory -InstanceId "i-0cb2b964d3e14fd9f" -Item $inventoryItems

- For API details, see [PutInventory](https://docs.aws.amazon.com/AWSSDK/latest/APIReference/API_PutInventory.html) in [AWS Tools for PowerShell Cmdlet Reference](https://docs.aws.amazon.com/AWSSDK/latest/PowerShellGuide/).

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systemsmanager/latest/userguide/). This topic also includes information about getting started and details about previous SDK versions.

**Use PutParameter with an AWS SDK or CLI**

The following code examples show how to use PutParameter.

**CLI**

**AWS CLI**

**Example 1: To change a parameter value**

The following put-parameter example changes the value of the specified parameter.

```bash
aws ssm put-parameter \  
   --name "MyStringParameter" \  
   --type "String" \  
```
--value "Vici" \
--overwrite

Output:

{
    "Version": 2,
    "Tier": "Standard"
}

For more information, see Create a Systems Manager parameter (AWS CLI), 'Managing parameter tiers <https://docs.aws.amazon.com/systems-manager/latest/userguide/parameter-store-advanced-parameters.html>`__, and Working with parameter policies in the AWS Systems Manager User Guide.

Example 2: To create an advanced parameter

The following put-parameter example creates an advanced parameter.

```
aws ssm put-parameter \
    --name "MyAdvancedParameter" \
    --description "This is an advanced parameter" \
    --value "Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat [truncated]" \
    --type "String" \
    --tier Advanced
```

Output:

```
{
    "Version": 1,
    "Tier": "Advanced"
}
```

For more information, see Create a Systems Manager parameter (AWS CLI), 'Managing parameter tiers <https://docs.aws.amazon.com/systems-manager/latest/userguide/parameter-store-advanced-parameters.html>`__, and Working with parameter policies in the AWS Systems Manager User Guide.
Example 3: To convert a standard parameter to an advanced parameter

The following put-parameter example converts a existing standard parameter into an advanced parameter.

```bash
aws ssm put-parameter \
    --name "MyConvertedParameter" \
    --value "abc123" \
    --type "String" \
    --tier Advanced \
    --overwrite
```

Output:

```json
{
    "Version": 2,
    "Tier": "Advanced"
}
```

For more information, see Create a Systems Manager parameter (AWS CLI), 'Managing parameter tiers <https://docs.aws.amazon.com/systems-manager/latest/userguide/parameter-store-advanced-parameters.html>`__, and Working with parameter policies in the AWS Systems Manager User Guide.

Example 4: To create a parameter with a policy attached

The following put-parameter example creates an advanced parameter with a parameter policy attached.

```bash
aws ssm put-parameter \
    --name "/Finance/Payroll/q2accesskey" \
    --value "P@ssSwW)rd" \
    --type "SecureString" \
    --tier Advanced \
    --policies "[\"Type\":\"Expiration\",\"Version\":\"1.0\",\"Attributes\":\{"Timestamp\":\"2020-06-30T00:00:00.000Z\"\},\"Type\":\"ExpirationNotification\",\"Version\":\"1.0\",\"Attributes\":\{"Before\":\"5\",\"Unit\":\"Days\"\}],\"Type\":\"NoChangeNotification\",\"Version\":\"1.0\",\"Attributes\":\{"After\":\"60\",\"Unit\":\"Days\"\}]"
```

Output:
For more information, see Create a Systems Manager parameter (AWS CLI), 'Managing parameter tiers <https://docs.aws.amazon.com/systems-manager/latest/userguide/parameter-store-advanced-parameters.html>`__, and Working with parameter policies in the AWS Systems Manager User Guide.

**Example 5: To add a policy to an existing parameter**

The following put-parameter example attaches a policy to an existing advanced parameter.

```
aws ssm put-parameter \
   --name "/Finance/Payroll/q2accesskey" \
   --value "N3wP@sSwW)rd" \
   --type "SecureString" \
   --tier Advanced \
   --policies "[{{"Type":"Expiration","Version":"1.0","Attributes":{{"Timestamp":"2020-06-30T00:00:00.000Z"}},{"Type":"ExpirationNotification","Version":"1.0","Attributes":{"Before":"5","Unit":"Days"}},{{"Type":"NoChangeNotification","Version":"1.0","Attributes":{"After":"60","Unit":"Days"}}}]}"
   --overwrite
```

Output:

```
{
   "Version": 2,
   "Tier": "Advanced"
}
```

For more information, see Create a Systems Manager parameter (AWS CLI), 'Managing parameter tiers <https://docs.aws.amazon.com/systems-manager/latest/userguide/parameter-store-advanced-parameters.html>`__, and Working with parameter policies in the AWS Systems Manager User Guide.

- For API details, see PutParameter in AWS CLI Command Reference.
public class PutParameter {
    public static void main(String[] args) {
        final String usage = ""
        Usage:
        <paraName>
        Where:
        paraName - The name of the parameter.
        paraValue - The value of the parameter.
        ""
        
        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }
        
        String paraName = args[0];
        String paraValue = args[1];
        Region region = Region.US_EAST_1;
        SsmClient ssmClient = SsmClient.builder()
                .region(region)
                .build();
        
        putParaValue(ssmClient, paraName, paraValue);
    }
}
public static void putParaValue(SsmClient ssmClient, String paraName, String value) {
    try {
        PutParameterRequest parameterRequest = PutParameterRequest.builder()
            .name(paraName)
            .type(ParameterType.STRING)
            .value(value)
            .build();

        ssmClient.putParameter(parameterRequest);
        System.out.println("The parameter was successfully added.");
    } catch (SsmException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

• For API details, see PutParameter in AWS SDK for Java 2.x API Reference.

PowerShell

Tools for PowerShell

Example 1: This example creates a parameter. There is no output if the command succeeds.

Write-SSMParameter -Name "Welcome" -Type "String" -Value "helloWorld"

Example 2: This example changes a parameter. There is no output if the command succeeds.

Write-SSMParameter -Name "Welcome" -Type "String" -Value "Good day, Sunshine!" -Overwrite $true

• For API details, see PutParameter in AWS Tools for PowerShell Cmdlet Reference.

with an AWS SDK. This topic also includes information about getting started and details about
previous SDK versions.

Use RegisterDefaultPatchBaseline with an AWS SDK or CLI
The following code examples show how to use RegisterDefaultPatchBaseline.
RegisterDefaultPatchBaseline

2496


AWS CLI

To set the default patch baseline

The following register-default-patch-baseline example registers the specified custom patch baseline as the default patch baseline for the operating system type that it supports.

```bash
aws ssm register-default-patch-baseline \
   --baseline-id "pb-abc123cf9bEXAMPLE"
```

Output:

```
{
   "BaselineId":"pb-abc123cf9bEXAMPLE"
}
```

The following register-default-patch-baseline example registers the default patch baseline provided by AWS for CentOS as the default patch baseline.

```bash
aws ssm register-default-patch-baseline \
   --baseline-id "arn:aws:ssm:us-east-2:733109147000:patchbaseline/pb-0574b43a65ea646ed"
```

Output:

```
{
   "BaselineId":"pb-abc123cf9bEXAMPLE"
}
```

For more information, see About Predefined and Custom Patch Baselines in the AWS Systems Manager User Guide.

- For API details, see RegisterDefaultPatchBaseline in AWS CLI Command Reference.
PowerShell

**Tools for PowerShell**

**Example 1: This example registers a patch baseline as the default patch baseline.**

```
Register-SSMDefaultPatchBaseline -BaselineId "pb-03da896ca3b68b639"
```

**Output:**

```
pb-03da896ca3b68b639
```

- For API details, see [RegisterDefaultPatchBaseline](#) in *AWS Tools for PowerShell Cmdlet Reference*.

---

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

**Use RegisterPatchBaselineForPatchGroup with an AWS SDK or CLI**

The following code examples show how to use `RegisterPatchBaselineForPatchGroup`.

**CLI**

**AWS CLI**

**To register a patch baseline for a patch group**

The following `register-patch-baseline-for-patch-group` example registers a patch baseline for a patch group.

```
aws ssm register-patch-baseline-for-patch-group \
  --baseline-id "pb-045f10b4f382baeda" \
  --patch-group "Production"
```

**Output:**

```
For more information, see Create a Patch Group <https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-patch-group-tagging.html> and Add a Patch Group to a Patch Baseline in the AWS Systems Manager User Guide.

- For API details, see `RegisterPatchBaselineForPatchGroup` in AWS CLI Command Reference.

PowerShell

**Tools for PowerShell**

**Example 1: This example registers a patch baseline for a patch group.**

```
Register-SSMPatchBaselineForPatchGroup -BaselineId "pb-03da896ca3b68b639" -PatchGroup "Production"
```

**Output:**

```
BaselineId   PatchGroup
----------   ----------
pb-03da896ca3b68b639  Production
```

- For API details, see `RegisterPatchBaselineForPatchGroup` in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use RegisterTargetWithMaintenanceWindow with an AWS SDK or CLI**

The following code examples show how to use `RegisterTargetWithMaintenanceWindow`. 
Example 1: To register a single target with a maintenance window

The following `register-target-with-maintenance-window` example registers an instance with a maintenance window.

```
aws ssm register-target-with-maintenance-window \
   --window-id "mw-ab12cd34ef56gh78" \
   --target "Key=InstanceIds,Values=i-0000293ff8c57862" \
   --owner-information "Single instance" \
   --resource-type "INSTANCE"
```

Output:

```
{
   "WindowTargetId":"1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d-1a2"
}
```

Example 2: To register multiple targets with a maintenance window using instance IDs

The following `register-target-with-maintenance-window` example registers two instances with a maintenance window by specifying their instance IDs.

```
aws ssm register-target-with-maintenance-window \
   --window-id "mw-ab12cd34ef56gh78" \
   --target "Key=InstanceIds,Values=i-0000293ff8c57862,i-0cb2b9643e14fd9f" \
   --owner-information "Two instances in a list" \
   --resource-type "INSTANCE"
```

Output:

```
{
   "WindowTargetId":"1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d-1a2"
}
```

Example 3: To register targets with a maintenance window using resource tags
The following `register-target-with-maintenance-window` example registers instances with a maintenance window by specifying resource tags that have been applied to the instances.

```bash
aws ssm register-target-with-maintenance-window \
   --window-id "mw-06cf17cbefcb4bf4f" \
   --targets "Key=tag:Environment,Values=Prod" "Key=Role,Values=Web" \
   --owner-information "Production Web Servers" \
   --resource-type "INSTANCE"
```

Output:

```json
{
   "WindowTargetId":"1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d-1a2"
}
```

**Example 4: To register targets using a group of tag keys**

The following `register-target-with-maintenance-window` example register instances that all have one or more tag keys assigned to them, regardless of their key values.

```bash
aws ssm register-target-with-maintenance-window \
   --window-id "mw-0c50858d01EXAMPLE" \
   --resource-type "INSTANCE" \
   --target "Key=tag-key,Values=Name,Instance-Type,CostCenter"
```

Output:

```json
{
   "WindowTargetId":"1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d-1a2"
}
```

**Example 5: To register targets using a resource group name**

The following `register-target-with-maintenance-window` example register a specified resource group, regardless of the type of resources it contains.

```bash
aws ssm register-target-with-maintenance-window \
   --window-id "mw-0c50858d01EXAMPLE" \
   --resource-type "RESOURCE_GROUP" \
   --target "Key=resource-groups:Name,Values=MyResourceGroup"
```
For more information, see Register a Target Instance with the Maintenance Window (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see RegisterTargetWithMaintenanceWindow in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example registers an instance with a maintenance window.**

```powershell
$option1 = @{Key="InstanceIds";Values=@("i-0000293fffd8c57862")}
Register-SSMTargetWithMaintenanceWindow -WindowId "mw-06cf17cbe4bf4f" -Target $option1 -OwnerInformation "Single instance" -ResourceType "INSTANCE"
```

**Output:**

d8e47760-23ed-46a5-9f28-927337725398

**Example 2: This example registers multiple instances with a maintenance window.**

```powershell
$option1 =
    @{Key="InstanceIds";Values=@("i-0000293fffd8c57862","i-0cb2b964d3e14fd9f")}
Register-SSMTargetWithMaintenanceWindow -WindowId "mw-06cf17cbe4bf4f" -Target $option1 -OwnerInformation "Single instance" -ResourceType "INSTANCE"
```

**Output:**

6ab5c208-9fc4-4697-84b7-b02a6cc25f7d

**Example 3: This example registers an instance with a maintenance window using EC2 tags.**

```powershell
$options1 = @{Key="tag:Environment";Values=@("Production")}
```

RegisterTargetWithMaintenanceWindow
Register-SSMTargetWithMaintenanceWindow -WindowId "mw-06cf17cbefcb4bf4f" -Target $option1 -OwnerInformation "Production Web Servers" -ResourceType "INSTANCE"

Output:

2994977e-aefb-4a71-beac-df620352f184

- For API details, see RegisterTargetWithMaintenanceWindow in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use RegisterTaskWithMaintenanceWindow with an AWS SDK or CLI

The following code examples show how to use RegisterTaskWithMaintenanceWindow.

CLI

AWS CLI

Example 1: To register an Automation task with a maintenance window

The following register-task-with-maintenance-window example registers an Automation task with a maintenance window that is targeted at an instance.

```bash
aws ssm register-task-with-maintenance-window \
    --window-id "mw-082dcd7649EXAMPLE" \
    --targets Key=InstanceIds,Values=i-1234520122EXAMPLE \
    --task-arn AWS-RestartEC2Instance \
    --service-role-arn arn:aws:iam::111222333444:role/SSM --task-type AUTOMATION \
    --task-invocation-parameters "{"Automation":{"DocumentVersion":","Parameters":{"InstanceId":["{{RESOURCE_ID}}"]}}}" \
    --priority 0 \
    --max-concurrency 1 \
    --max-errors 1 \
    --name "AutomationExample" \
    --description "Restarting EC2 Instance for maintenance"
```
Output:

```
{
   "WindowTaskId":"11144444-5555-6666-7777-88888888"
}
```

For more information, see [Register a Task with the Maintenance Window (AWS CLI)](https://docs.aws.amazon.com/systemsmanager/latest/userguide/registration.html) in the [AWS Systems Manager User Guide](https://docs.aws.amazon.com/systemsmanager/latest/userguide/registration.html).

**Example 2: To register a Lambda task with a Maintenance Window**

The following `register-task-with-maintenance-window` example registers a Lambda task with a Maintenance Window that is targeted at an instance.

```
aws ssm register-task-with-maintenance-window \
   --window-id "mw-082dcd7649dee04e4" \
   --targets Key=InstanceIds,Values=i-12344d305eEXAMPLE \
   --task-arn arn:aws:lambda:us-east-1:11122233444:function:SSMTestLAMBDA \
   --service-role-arn arn:aws:iam::11122233444:role/SSM \
   --task-type LAMBDA \
   --task-invocation-parameters '{"Lambda":{"Payload":"{"InstanceId":"{{RESOURCE_ID}}","targetType":"{{TARGET_TYPE}}"}","Qualifier":"$LATEST"}}' \
   --priority 0 \
   --max-concurrency 10 \
   --max-errors 5 \
   --name "Lambda_Example" \
   --description "My Lambda Example"
```

Output:

```
{
   "WindowTaskId":"22244444-5555-6666-7777-88888888"
}
```

For more information, see [Register a Task with the Maintenance Window (AWS CLI)](https://docs.aws.amazon.com/systemsmanager/latest/userguide/registration.html) in the [AWS Systems Manager User Guide](https://docs.aws.amazon.com/systemsmanager/latest/userguide/registration.html).

**Example 3: To register a Run Command task with a maintenance window**

The following `register-task-with-maintenance-window` example registers a Run Command task with a maintenance window that is targeted at an instance.
aws ssm register-task-with-maintenance-window
   --window-id "mw-082dcd7649dee04e4" \
   --targets "Key=InstanceIds,Values=i-1234d305eEXAMPLE" \
   --service-role-arn "arn:aws:iam::111222333444:role/SSM" \
   --task-type "RUN_COMMAND" \
   --name "SSMInstallPowerShellModule" \
   --task-arn "AWS-InstallPowerShellModule" \
   --max-concurrency 1 \
   --max-errors 1 \
   --priority 10

Output:

{
   "WindowTaskId":"33344444-5555-6666-7777-88888888"
}

For more information, see Register a Task with the Maintenance Window (AWS CLI) in the AWS Systems Manager User Guide.

Example 4: To register a Step Functions task with a maintenance window

The following register-task-with-maintenance-window example registers a Step Functions task with a maintenance window that is targeted at an instance.

aws ssm register-task-with-maintenance-window
   --window-id "mw-1234d787d6EXAMPLE" \
   --targets "Key=WindowTargetIds,Values=12347414-69c3-49f8-95b8-ed2dcEXAMPLE" \
   --task-arn arn:aws:states:us-east-1:111222333444:stateMachine:SSMTestStateMachine \
   --service-role-arn arn:aws:iam::111222333444:role/MaintenanceWindows \
   --task-type STEP_FUNCTIONS \
   --task-invocation-parameters '{"StepFunctions":{"Input":{"InstanceId":null}}}' \
   --priority 0 \
   --max-concurrency 10 \
   --max-errors 5
--name "Step_Functions_Example" \
--description "My Step Functions Example"

Output:

```
{
  "WindowTaskId":"44444444-5555-6666-7777-88888888"
}
```

For more information, see Register a Task with the Maintenance Window (AWS CLI) in the AWS Systems Manager User Guide.

**Example 5: To register a task using a maintenance windows target ID**

The following `register-task-with-maintenance-window` example registers a task using a maintenance window target ID. The maintenance window target ID was in the output of the `aws ssm register-target-with-maintenance-window` command. You can also retrieve it from the output of the `aws ssm describe-maintenance-window-targets` command.

```
aws ssm register-task-with-maintenance-window \
  --targets "Key=WindowTargetIds,Values=350d44e6-28cc-44e2-951f-4b2c9EXAMPLE" \
  --task-arn "AWS-RunShellScript" \
  --service-role-arn "arn:aws:iam::111222333444:role/MaintenanceWindowsRole" \
  --window-id "mw-ab12cd34eEXAMPLE" \
  --task-type "RUN_COMMAND" \
  --task-parameters "{\"commands\":{\"Values\":{\"df\":[]}}}" \
  --max-concurrency 1 \
  --max-errors 1 \
  --priority 10
```

Output:

```
{
  "WindowTaskId":"33344444-5555-6666-7777-88888888"
}
```

For more information, see Register a Task with the Maintenance Window (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see RegisterTaskWithMaintenanceWindow in AWS CLI Command Reference.
PowerShell

Tools for PowerShell

Example 1: This example registers a task with a maintenance window using an instance ID. The output is the Task ID.

```powershell

Register-SSMTaskWithMaintenanceWindow -WindowId "mw-03a342e62c96d31b0" -ServiceRoleArn "arn:aws:iam::123456789012:role/MaintenanceWindowsRole" -MaxConcurrency 1 -MaxError 1 -TaskArn "AWS-RunShellScript" -Target @{ Key="InstanceIds";Values="i-0000293ff8c57862" } -TaskType "RUN_COMMAND" -Priority 10 -TaskParameter $parameters

Output:

f34a2c47-ddfd-4c85-a88d-72366b69af1b
```

Example 2: This example registers a task with a maintenance window using a target ID. The output is the Task ID.

```powershell

RegisterSSMTaskWithMaintenanceWindow -WindowId "mw-03a342e62c96d31b0" -ServiceRoleArn "arn:aws:iam::123456789012:role/MaintenanceWindowsRole" -MaxConcurrency 1 -MaxError 1 -TaskArn "AWS-RunShellScript" -Target @{ Key="WindowTargetIds";Values="350d44e6-28cc-44e2-951f-4b2c985838f6" } -TaskType "RUN_COMMAND" -Priority 10 -TaskParameter $parameters

Output:

f34a2c47-ddfd-4c85-a88d-72366b69af1b
```
Example 3: This example creates a parameter object for the run command document `AWS-RunPowerShellScript` and creates a task with given maintenance window using target ID. The return output is the task ID.

```powershell
$parameters.Add("commands", @("ipconfig","dir env:\computername"))
$parameters.Add("executionTimeout", (3600))

$props = @{
    WindowId = "mw-0123e4c56ff78ae"
    ServiceRoleArn = "arn:aws:iam::123456789012:role/MaintenanceWindowsRole"
    MaxConcurrency = 1
    MaxError = 1
    TaskType = "RUN_COMMAND"
    TaskArn = "AWS-RunPowerShellScript"
    Target = @{Key="WindowTargetIds";Values="fe1234ea-56d7-890b-12f3-456b789bee0f"}
    Priority = 1
    RunCommand_Parameter = $parameters
    Name = "set-via-cmdlet"
}

Register-SSMTaskWithMaintenanceWindow @props
```

Output:

```
f1e2ef34-5678-12e3-456a-12334c5c6cbe
```

Example 4: This example registers an AWS Systems Manager Automation task by using a document named `Create-Snapshots`.

```powershell
$automationParameters = @{}
$automationParameters.Add( "instanceId", @("{{ TARGET_ID }}") )
$automationParameters.Add( "AutomationAssumeRole", @("arn:aws:iam::111111111111:role/AutomationRole") )
$automationParameters.Add( "SnapshotTimeout", @("PT20M") )
Register-SSMTaskWithMaintenanceWindow -WindowId mw-123EXAMPLE456 -ServiceRoleArn "arn:aws:iam::123456789012:role/MW-Role" -MaxConcurrency 1 -MaxError 1 -TaskArn "CreateVolumeSnapshots" -Target @{ Key="WindowTargetIds";Values="4b5acdf4-946c-4355-bd68-4329a43a5fd1" }
```

RegisterTaskWithMaintenanceWindow 2508
For API details, see `RegisterTaskWithMaintenanceWindow` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

**Use RemoveTagsFromResource with an AWS SDK or CLI**

The following code examples show how to use RemoveTagsFromResource.

**CLI**

**AWS CLI**

**To remove a tag from a patch baseline**

The following `remove-tags-from-resource` example removes tags from a patch baseline.

```bash
aws ssm remove-tags-from-resource \
   --resource-type "PatchBaseline" \
   --resource-id "pb-0123456789abcdef0" \
   --tag-keys "Region"
```

This command produces no output.

For more information, see *Tagging AWS Resources* in the *AWS General Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1:** This example removes a tag from a maintenance window. There is no output if the command succeeds.
Remove-SSMResourceTag -ResourceId "mw-03eb9db42890fb82d" -ResourceType "MaintenanceWindow" -TagKey "Production"

- For API details, see [RemoveTagsFromResource](#) in [AWS Tools for PowerShell Cmdlet Reference](#).

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Use SendCommand with an AWS SDK or CLI

The following code examples show how to use SendCommand.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with Systems Manager](#)

### CLI

#### AWS CLI

**Example 1: To run a command on one or more remote instances**

The following `send-command` example runs an `echo` command on a target instance.

```bash
aws ssm send-command \
  --document-name "AWS-RunShellScript" \
  --parameters 'commands=['echo HelloWorld']' \
  --targets "Key=instanceids,Values=i-1234567890abcdef0" \
  --comment "echo HelloWorld"
```

**Output:**

```json
{
   "Command": {
      "CommandId": "92853adf-ba41-4cd6-9a88-142d1EXAMPLE",
      "DocumentName": "AWS-RunShellScript",
      "DocumentVersion": "",
```
"Comment": "echo HelloWorld",
"ExpiresAfter": 1550181014.717,
"Parameters": {
    "commands": [
        "echo HelloWorld"
    ]
},
"InstanceIds": [
    "i-0f00f008a2dcbe2e"
],
"Targets": [],
"RequestedDateTime": 1550173814.717,
"Status": "Pending",
"StatusDetails": "Pending",
"OutputS3BucketName": "",
"OutputS3KeyPrefix": "",
"MaxConcurrency": "50",
"MaxErrors": "0",
"TargetCount": 1,
"CompletedCount": 0,
"ErrorCount": 0,
"DeliveryTimedOutCount": 0,
"ServiceRole": "",
"NotificationConfig": {
    "NotificationArn": "",
    "NotificationEvents": [],
    "NotificationType": ""
},
"CloudWatchOutputConfig": {
    "CloudWatchLogGroupName": "",
    "CloudWatchOutputEnabled": false
}
}

For more information, see Running Commands Using Systems Manager Run Command in the AWS Systems Manager User Guide.

Example 2: To get IP information about an instance

The following send-command example retrieves the IP information about an instance.

```
aws ssm send-command
```
See example 1 for sample output.

For more information, see Running Commands Using Systems Manager Run Command in the AWS Systems Manager User Guide.

**Example 3: To run a command on instances with specific tags**

The following send-command example runs a command on instances that have the tag key "ENV" and the value "Dev".

```bash
aws ssm send-command \
  --targets "Key=tag:ENV,Values=Dev" \
  --document-name "AWS-RunShellScript" \
  --parameters "commands=ifconfig"
```

See example 1 for sample output.

For more information, see Running Commands Using Systems Manager Run Command in the AWS Systems Manager User Guide.

**Example 4: To run a command that sends SNS notifications**

The following send-command example runs a command that sends SNS notifications for all notification events and the Command notification type.

```bash
aws ssm send-command \
  --instance-ids "i-1234567890abcdef0" \
  --document-name "AWS-RunShellScript" \
  --comment "IP config" \
  --parameters "commands=ifconfig" \
  --service-role-arn "arn:aws:iam::123456789012:role/SNS_Role" \
  --notification-config "NotificationArn=arn:aws:sns:us-east-1:123456789012:SNSTopicName,NotificationEvents=All,NotificationType=Command"
```

See example 1 for sample output.

For more information, see Running Commands Using Systems Manager Run Command in the AWS Systems Manager User Guide.
Example 5: To run a command that outputs to S3 and CloudWatch

The following send-command example runs a command that outputs command details to an S3 bucket and to a CloudWatch Logs log group.

```
aws ssm send-command \\
   --instance-ids "i-1234567890abcdef0" \\
   --document-name "AWS-RunShellScript" \\
   --comment "IP config" \\
   --parameters "commands=ifconfig" \\
   --output-s3-bucket-name "s3-bucket-name" \\
   --output-s3-key-prefix "runcommand" \\
   --cloud-watch-output-config "CloudWatchOutputEnabled=true,CloudWatchLogGroupName=CWLGroupName"
```

See example 1 for sample output.

For more information, see Running Commands Using Systems Manager Run Command in the AWS Systems Manager User Guide.

Example 6: To run commands on multiple instances with different tags

The following send-command example runs a command on instances with two different tag keys and values.

```
aws ssm send-command \\
   --document-name "AWS-RunPowerShellScript" \\
   --parameters commands=["echo helloWorld"] \\
   --targets Key=tag:Env,Values=Dev Key=tag:Role,Values=WebServers
```

See example 1 for sample output.

For more information, see Running Commands Using Systems Manager Run Command in the AWS Systems Manager User Guide.

Example 7: To target multiple instances with the same tag key

The following send-command example runs a command on instances that have the same tag key but with different values.

```
aws ssm send-command \\
   --document-name "AWS-RunPowerShellScript" \\
   --parameters commands=["echo helloWorld"] \\
```
See example 1 for sample output.

For more information, see Running Commands Using Systems Manager Run Command in the AWS Systems Manager User Guide.

Example 8: To run a command that uses a shared document

The following send-command example runs a shared document on a target instance.

```
aws ssm send-command
   --targets "Key=instanceids,Values=i-1234567890abcdef0"
```

See example 1 for sample output.

For more information, see Using shared SSM documents in the AWS Systems Manager User Guide.

- For API details, see SendCommand in AWS CLI Command Reference.

Java

SDK for Java 2.x

```java
public static String sendSSMCommand(SsmClient ssmClient, String documentName,
            String instanceId) throws InterruptedException {
    // Before we use Document to send a command - make sure it is active.
    boolean isDocumentActive = false;
    DescribeDocumentRequest request = DescribeDocumentRequest.builder()
        .name(documentName)
        .build();
```
while (!isDocumentActive) {
    DescribeDocumentResponse response = 
    ssmClient.describeDocument(request);
    String documentStatus = response.document().statusAsString();
    if (documentStatus.equals("Active")) {
        System.out.println("The Systems Manager document is active and 
        ready to use.");
        isDocumentActive = true;
    } else {
        System.out.println("The Systems Manager document is not active. 
        Status: " + documentStatus);
        try {
            // Add a delay to avoid making too many requests.
            Thread.sleep(5000); // Wait for 5 seconds before checking 
            again
        } catch (InterruptedException e) {
            e.printStackTrace();
        }
    }
}

// Create the SendCommandRequest.
SendCommandRequest commandRequest = SendCommandRequest.builder()
    .documentName(documentName)
    .instanceIds(instanceId)
    .build();

// Send the command.
SendCommandResponse commandResponse = 
    ssmClient.sendCommand(commandRequest);
String commandId = commandResponse.command().commandId();
System.out.println("The command Id is " + commandId);

// Wait for the command execution to complete.
GetCommandInvocationRequest invocationRequest = 
    GetCommandInvocationRequest.builder()
    .commandId(commandId)
    .instanceId(instanceId)
    .build();

System.out.println("Wait 5 secs");
TimeUnit.SECONDS.sleep(5);

// Retrieve the command execution details.
GetCommandInvocationResponse commandInvocationResponse = ssmClient.getCommandInvocation(invocationRequest);

    // Check the status of the command execution.
    CommandInvocationStatus status = commandInvocationResponse.status();
    if (status == CommandInvocationStatus.SUCCESS) {
        System.out.println("Command execution successful.");
    } else {
        System.out.println("Command execution failed. Status: " + status);
    }
    return commandId;
}

• For API details, see SendCommand in AWS SDK for Java 2.x API Reference.

PowerShell

Tools for PowerShell

Example 1: This example runs an echo command on a target instance.

Send-SSMCommand -DocumentName "AWS-RunPowerShellScript" -Parameter @{commands = "echo helloWorld"} -Target @{Key="instanceids";Values=@("i-0cb2b964d3e14fd9f")}

Output:

<table>

Example 2: This example shows how to run a command that accepts nested parameters.

Send-SSMCommand -DocumentName "AWS-RunRemoteScript" -Parameter
@{ sourceType="GitHub";sourceInfo='{"owner": "me","repository": "amazon-ssm","path": "Examples/Install-Win32OpenSSH"}; "commandLine"=".\Install-Win32OpenSSH.ps1"} -InstanceId i-0cb2b964d3e14fd9f

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systems-manager/latest/userguide/using-ssm-sdk.html). This topic also includes information about getting started and details about previous SDK versions.

**Use StartAutomationExecution with an AWS SDK or CLI**

The following code examples show how to use StartAutomationExecution.

**CLI**

**AWS CLI**

**Example 1: To execute an automation document**

The following `start-automation-execution` example runs an Automation document.

```
aws ssm start-automation-execution \
  --document-name "AWS-UpdateLinuxAmi" \
  --parameters "AutomationAssumeRole=arn:aws:iam::123456789012:role/SSMAutomationRole,SourceAmiId=ami-EXAMPLE,IamInstanceProfileName=EC2InstanceRole"
```

Output:

```json
{}
```
Example 2: To run a shared automation document

The following `start-automation-execution` example runs a shared Automation document.

```bash
aws ssm start-automation-execution \
```

Output:

```json
{
  "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0a1b2EXAMPLE"
}
```

- For API details, see [StartAutomationExecution](https://docs.aws.amazon.com/cli/latest/reference/ssm/start-automation-execution.html) in *AWS CLI Command Reference*.

**PowerShell**

**Tools for PowerShell**

Example 1: This example runs a document specifying an Automation role, an AMI source ID, and an Amazon EC2 instance role.

```powershell
Start-SSMAutomationExecution -DocumentName AWS-UpdateLinuxAmi -Parameter @{'AutomationAssumeRole'='arn:aws:iam::123456789012:role/SSMAutomationRole';'SourceAmiId'='ami-f173cc91';'InstanceIamRole'='EC2InstanceRole'}
```

Output:

```
3a532a4f-0382-11e7-9df7-6f11185f6dd1
```
For API details, see `StartAutomationExecution` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Systems Manager with an AWS SDK*. This topic also includes information about getting started and details about previous SDK versions.

**Use StopAutomationExecution with an AWS SDK or CLI**

The following code examples show how to use StopAutomationExecution.

**CLI**

**AWS CLI**

To stop an automation execution

The following `stop-automation-execution` example stops an Automation document.

```
aws ssm stop-automation-execution
    --automation-execution-id "4105a4fc-f944-11e6-9d32-0a1b2EXAMPLE"
```

This command produces no output.

For more information, see [Running an Automation Workflow Manually](https://docs.aws.amazon.com/systems-manager/latest/userguide/) in the *AWS Systems Manager User Guide*.

- For API details, see `StopAutomationExecution` in *AWS CLI Command Reference*.

**PowerShell**

**Tools for PowerShell**

Example 1: This example stops an Automation Execution. There is no output if the command succeeds.

```
Stop-SSMAutomationExecution -AutomationExecutionId "4105a4fc-f944-11e6-9d32-8fb2db27a909"
```

- For API details, see `StopAutomationExecution` in *AWS Tools for PowerShell Cmdlet Reference*. 

StopAutomationExecution
For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systems-manager/latest/userguide/index.html). This topic also includes information about getting started and details about previous SDK versions.

**Use UpdateAssociation with an AWS SDK or CLI**

The following code examples show how to use `UpdateAssociation`.

**CLI**

**AWS CLI**

**Example 1: To update a document association**

The following update-association example updates an association with a new document version.

```
aws ssm update-association \
    --association-id "8dfe3659-4309-493a-8755-0123456789ab" \
    --document-version "\$LATEST"
```

Output:

```
{
    "AssociationDescription": {
        "Name": "AWS-UpdateSSMAgent",
        "AssociationVersion": "2",
        "Date": 1550508093.293,
        "LastUpdateAssociationDate": 1550508106.596,
        "Overview": {
            "Status": "Pending",
            "DetailedStatus": "Creating"
        },
        "DocumentVersion": "\$LATEST",
        "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
        "Targets": [
            {
                "Key": "tag:Name",
                "Values": ["Linux"
            ]
        ],
```
For more information, see Editing and creating a new version of an association in the AWS Systems Manager User Guide.

Example 2: To update the schedule expression of an association

The following update-association example updates the schedule expression for the specified association.

```bash
aws ssm update-association \
  --association-id "8dfe3659-4309-493a-8755-0123456789ab" \
  --schedule-expression "cron(0 0 0/4 1/1 * ? *)"
```

Output:

```
{
  "AssociationDescription": {
    "Name": "AWS-HelloWorld",
    "AssociationVersion": "2",
    "Date": "2021-02-08T13:54:19.203000-08:00",
    "LastUpdateAssociationDate": "2021-06-29T11:51:07.933000-07:00",
    "Overview": {
      "Status": "Pending",
      "DetailedStatus": "Creating"
    },
    "DocumentVersion": "$DEFAULT",
    "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
    "Targets": [
      {
        "Key": "aws:NoOpAutomationTag",
        "Values": [
          "AWS-NoOpAutomationTarget-Value"
        ]
      }
    ],
    "ScheduleExpression": "cron(0 0 0/4 1/1 * ? *)",
    "LastExecutionDate": "2021-06-26T19:00:48.110000-07:00",
    "ApplyOnlyAtCronInterval": false
  }
}
```
For more information, see Editing and creating a new version of an association in the AWS Systems Manager User Guide.

- For API details, see UpdateAssociation in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

**Example 1: This example updates an association with a new document version.**

```powershell
Update-SSMAssociation -AssociationId "93285663-92df-44cb-9f26-2292d4ecc439" -DocumentVersion "1"
```

**Output:**

<table>
<thead>
<tr>
<th>Name</th>
<th>AWS-UpdateSSMAgent</th>
</tr>
</thead>
<tbody>
<tr>
<td>InstanceId</td>
<td></td>
</tr>
<tr>
<td>Date</td>
<td>3/1/2017 6:22:21 PM</td>
</tr>
<tr>
<td>Status.Name</td>
<td></td>
</tr>
<tr>
<td>Status.Date</td>
<td></td>
</tr>
<tr>
<td>Status.Message</td>
<td></td>
</tr>
<tr>
<td>Status.AdditionalInfo</td>
<td></td>
</tr>
</tbody>
</table>

- For API details, see UpdateAssociation in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use UpdateAssociationStatus with an AWS SDK or CLI**

The following code examples show how to use UpdateAssociationStatus.

**CLI**

**AWS CLI**

To update the association status
The following `update-association-status` example updates the association status of the association between an instance and a document.

```
aws ssm update-association-status \
   --name "AWS-UpdateSSMAgent" \
   --instance-id "i-1234567890abcdef0" \
   --association-status \
   "Date=1424421071.939,Name=Pending,Message=temp_status_change,AdditionalInfo=Additional-Config-Needed"
```

Output:

```
{
   "AssociationDescription": {
      "Name": "AWS-UpdateSSMAgent",
      "InstanceId": "i-1234567890abcdef0",
      "AssociationVersion": "1",
      "Date": 1550507529.604,
      "LastUpdateAssociationDate": 1550507806.974,
      "Status": {
         "Date": 1424421071.0,
         "Name": "Pending",
         "Message": "temp_status_change",
         "AdditionalInfo": "Additional-Config-Needed"
      },
      "Overview": {
         "Status": "Success",
         "AssociationStatusAggregatedCount": {
            "Success": 1
         }
      },
      "DocumentVersion": "$DEFAULT",
      "AssociationId": "8dfe3659-4309-493a-8755-0123456789ab",
      "Targets": [
         {
            "Key": "InstanceIds",
            "Values": [
               "i-1234567890abcdef0"
            ]
         }
      ],
      "LastExecutionDate": 1550507808.0,
      "LastSuccessfulExecutionDate": 1550507808.0
   }
}
```
For more information, see Working with associations in Systems Manager in the AWS Systems Manager User Guide.

- For API details, see UpdateAssociationStatus in AWS CLI Command Reference.

PowerShell

**Tools for PowerShell**

**Example 1:** This example updates the association status of the association between an instance and a configuration document.

```powershell
Update-SSMAssociationStatus -Name "AWS-UpdateSSMAgent" -InstanceId "i-0000293ffd8c57862" -AssociationStatus_Date "2015-02-20T08:31:11Z" -AssociationStatus_Name "Pending" -AssociationStatus_Message "temporary_status_change" -AssociationStatus_AdditionalInfo "Additional-Config-Needed"
```

**Output:**

<table>
<thead>
<tr>
<th>Name</th>
<th>AWS-UpdateSSMAgent</th>
</tr>
</thead>
<tbody>
<tr>
<td>InstanceId</td>
<td>i-0000293ffd8c57862</td>
</tr>
<tr>
<td>Date</td>
<td>2/23/2017 6:55:22 PM</td>
</tr>
<tr>
<td>Status.Name</td>
<td>Pending</td>
</tr>
<tr>
<td>Status.Date</td>
<td>2/20/2015 8:31:11 AM</td>
</tr>
<tr>
<td>Status.Message</td>
<td>temporary_status_change</td>
</tr>
<tr>
<td>Status.AdditionalInfo</td>
<td>Additional-Config-Needed</td>
</tr>
</tbody>
</table>

- For API details, see UpdateAssociationStatus in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

**Use UpdateDocument with an AWS SDK or CLI**

The following code examples show how to use UpdateDocument.
AWS CLI

To create a new version of a document

The following update-document example creates a new version of a document when run on a Windows computer. The document specified by --document must be in JSON format. Note that file:// must be referenced followed by the path of the content file. Because of the $ at the beginning of the --document-version parameter, On Windows you must surround the value with double quotes. On Linux, MacOS, or at a PowerShell prompt, you must surround the value with single quotes.

Windows version:

```
aws ssm update-document \
   --name "RunShellScript" \ 
   --content "file://RunShellScript.json" \ 
   --document-version "$LATEST"
```

Linux/Mac version:

```
aws ssm update-document \
   --name "RunShellScript" \ 
   --content "file://RunShellScript.json" \ 
   --document-version '$LATEST'
```

Output:

```
{
   "DocumentDescription": {
      "Status": "Updating",
      "Hash": "f775e5df4904c6fa46686c4722fae9de1950dace25cd9608ff8d622046b68d9b",
      "Name": "RunShellScript",
      "Parameters": [
         {
            "Type": "StringList",
            "Name": "commands",
            "Description": "(Required) Specify a shell script or a command to run."
         }
      ]
   }
}
```
For API details, see UpdateDocument in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This creates a new version of a document with the updated contents of the json file you specify. The document must be in JSON format. You can obtain the document version with the "Get-SSMDocumentVersionList" cmdlet.

```
Update-SSMDocument -Name RunShellScript -DocumentVersion "1" -Content (Get-Content -Raw "c:\temp\RunShellScript.json")
```

Output:

```
CreatedDate     : 3/1/2017 2:59:17 AM
DefaultVersion  : 1
Description     : Run an updated script
DocumentType    : Command
DocumentVersion : 2
Hash            :
  1d5ce820e99ff051eb4841ed887593daf77120fd76cae0d18a53cc42e4e22c1
HashType        : Sha256
LatestVersion   : 2
Name            : RunShellScript
Owner           : 809632081692
Parameters      : {commands}
```

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systemsmanager/latest/userguide/). This topic also includes information about getting started and details about previous SDK versions.

**Use UpdateDocumentDefaultVersion with an AWS SDK or CLI**

The following code examples show how to use UpdateDocumentDefaultVersion.

**CLI**

**AWS CLI**

**To update the default version of a document**

The following `update-document-default-version` example updates the default version of a Systems Manager document.

```
aws ssm update-document-default-version \
   --name "Example" \
   --document-version "2"
```

Output:

```
{
   "Description": {
      "Name": "Example",
      "DefaultVersion": "2"
   }
}
```

For more information, see [Writing SSM Document Content](https://docs.aws.amazon.com/systemsmanager/latest/userguide/). This topic also includes information about getting started and details about previous SDK versions.

**UpdateDocumentDefaultVersion**

For API details, see [UpdateDocumentDefaultVersion](https://docs.aws.amazon.com/aws-cli/latest/ug/index.html) in *AWS CLI Command Reference*. 

---

UpdateDocumentDefaultVersion

2527
PowerShell

Tools for PowerShell

Example 1: This updates the default version of a document. You can obtain the available document versions with the "Get-SSMDocumentVersionList" cmdlet.

```
Update-SSMDocumentDefaultVersion -Name "RunShellScript" -DocumentVersion "2"
```

Output:

```
DefaultVersion Name
-------------- ----
2              RunShellScript
```

• For API details, see `UpdateDocumentDefaultVersion` in *AWS Tools for PowerShell Cmdlet Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](link). This topic also includes information about getting started and details about previous SDK versions.

**Use UpdateMaintenanceWindow with an AWS SDK or CLI**

The following code examples show how to use UpdateMaintenanceWindow.

**CLI**

**AWS CLI**

Example 1: To update a maintenance window

The following `update-maintenance-window` example updates the name of a maintenance window.

```
aws ssm update-maintenance-window \
    --window-id "mw-1a2b3c4d5e6f7g8h9" \
    --name "My-Renamed-MW"
```

Output:
Example 2: To disable a maintenance window

The following update-maintenance-window example disables a maintenance window.

```bash
aws ssm update-maintenance-window \
    --window-id "mw-1a2b3c4d5e6f7g8h9" \
    --no-enabled
```

Example 3: To enable a maintenance window

The following update-maintenance-window example enables a maintenance window.

```bash
aws ssm update-maintenance-window \
    --window-id "mw-1a2b3c4d5e6f7g8h9" \
    --enabled
```

For more information, see Update a Maintenance Window (AWS CLI) in the AWS Systems Manager User Guide.

- For API details, see UpdateMaintenanceWindow in AWS CLI Command Reference.

Java

SDK for Java 2.x

ℹ️ Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
For API details, see `UpdateMaintenanceWindow` in *AWS SDK for Java 2.x API Reference*.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example updates the name of a maintenance window.**

```
Update-SSMMaintenanceWindow -WindowId "mw-03eb9db42890fb82d" -Name "My-Renamed-MW"
```

**Output:**

```
AllowUnassociatedTargets : False
Cutoff                 : 1
Duration               : 2
```
Example 2: This example enables a maintenance window.

```
Update-SSMMaintenanceWindow -WindowId "mw-03eb9db42890fb82d" -Enabled $true
```

Output:

```
AllowUnassociatedTargets : False
Cutoff                   : 1
Duration                 : 2
Enabled                  : True
Name                     : My-Renamed-MW
Schedule                 : cron(0 */30 * * ? *)
WindowId                 : mw-03eb9db42890fb82d
```

Example 3: This example disables a maintenance window.

```
Update-SSMMaintenanceWindow -WindowId "mw-03eb9db42890fb82d" -Enabled $false
```

Output:

```
AllowUnassociatedTargets : False
Cutoff                   : 1
Duration                 : 2
Enabled                  : False
Name                     : My-Renamed-MW
Schedule                 : cron(0 */30 * * ? *)
WindowId                 : mw-03eb9db42890fb82d
```

• For API details, see UpdateMaintenanceWindow in **AWS Tools for PowerShell Cmdlet Reference**.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.
Use UpdateManagedInstanceRole with an AWS SDK or CLI

The following code examples show how to use UpdateManagedInstanceRole.

CLI

AWS CLI

To update the IAM role of a managed instance

The following update-managed-instance-role example updates the IAM instance profile of a managed instance.

```
aws ssm update-managed-instance-role \\
   --instance-id "mi-08ab247cdfEXAMPLE" \\
   --iam-role "ExampleRole"
```

This command produces no output.

For more information, see Step 4: Create an IAM Instance Profile for Systems Manager in the AWS Systems Manager User Guide.

• For API details, see UpdateManagedInstanceRole in AWS CLI Command Reference.

PowerShell

Tools for PowerShell

Example 1: This example updates the role of a managed instance. There is no output if the command succeeds.

```
Update-SSMManagedInstanceRole -InstanceId "mi-08ab247cdf1046573" -IamRole "AutomationRole"
```

• For API details, see UpdateManagedInstanceRole in AWS Tools for PowerShell Cmdlet Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.
Use UpdateOpsItem with an AWS SDK or CLI

The following code examples show how to use UpdateOpsItem.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with Systems Manager

CLI

AWS CLI

To update an OpsItem

The following update-ops-item example updates the description, priority, and category for an OpsItem. In addition, the command specifies an SNS topic where the notifications are sent when this OpsItem is edited or changed.

```
aws ssm update-ops-item \
    --ops-item-id "oi-287b5EXAMPLE" \
    --description "Primary OpsItem for failover event 2020-01-01-fh398yf" \
    --priority 2 \
    --category "Security" \
```

Output:

This command produces no output.

For more information, see Working with OpsItems in the AWS Systems Manager User Guide.

- For API details, see UpdateOpsItem in AWS CLI Command Reference.
Java

**SDK for Java 2.x**

```java
public static void resolveOpsItem(SsmClient ssmClient, String opsID) {
    try {
        UpdateOpsItemRequest opsItemRequest = UpdateOpsItemRequest.builder()
            .opsItemId(opsID)
            .status(OpsItemStatus.RESOLVED)
            .build();

        ssmClient.updateOpsItem(opsItemRequest);
    } catch (SsmException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see [UpdateOpsItem](https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/smm-java-2-api-reference.html#smm-java-2-opsi) in *AWS SDK for Java 2.x API Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Systems Manager with an AWS SDK](https://docs.aws.amazon.com/systems-manager/latest/userguide/using-aws-sdk.html). This topic also includes information about getting started and details about previous SDK versions.

**Use UpdatePatchBaseline with an AWS SDK or CLI**

The following code examples show how to use UpdatePatchBaseline.

**CLI**

**AWS CLI**

**Example 1: To update a patch baseline**
The following `update-patch-baseline` example adds the specified two patches as rejected and one patch as approved to the specified patch baseline.

```
aws ssm update-patch-baseline \
  --baseline-id "pb-0123456789abcdef0" \
  --rejected-patches "KB2032276" "MS10-048" \
  --approved-patches "KB2124261"
```

Output:

```json
{
  "BaselineId": "pb-0123456789abcdef0",
  "Name": "WindowsPatching",
  "OperatingSystem": "WINDOWS",
  "GlobalFilters": {
    "PatchFilters": []
  },
  "ApprovalRules": {
    "PatchRules": [
      {
        "PatchFilterGroup": {
          "PatchFilters": [
            {
              "Key": "PRODUCT",
              "Values": [
                "WindowsServer2016"
              ]
            }
          ],
          "ComplianceLevel": "CRITICAL",
          "ApproveAfterDays": 0,
          "EnableNonSecurity": false
        }
      ]
    },
    "ApprovedPatches": ["KB2124261"],
    "ApprovedPatchesComplianceLevel": "UNSPECIFIED",
    "ApprovedPatchesEnableNonSecurity": false,
    "RejectedPatches": ["KB2032276"],
    "RejectedPatchesComplianceLevel": "UNSPECIFIED",
    "RejectedPatchesEnableNonSecurity": false
  }
}
```
"MS10-048",
"RejectedPatchesAction": "ALLOW_AS_DEPENDENCY",
"CreatedDate": 1550244180.465,
"ModifiedDate": 1550244180.465,
"Description": "Patches for Windows Servers",
"Sources": []
}

**Example 2: To rename a patch baseline**

The following `update-patch-baseline` example renames the specified patch baseline.

```bash
aws ssm update-patch-baseline
   --baseline-id "pb-0713accee01234567"
   --name "Windows-Server-2012-R2-Important-and-Critical-Security-Updates"
```

For more information, see Update or Delete a Patch Baseline [https://docs.aws.amazon.com/systems-manager/latest/userguide/patch-baseline-update-or-delete.html](https://docs.aws.amazon.com/systems-manager/latest/userguide/patch-baseline-update-or-delete.html) in the AWS Systems Manager User Guide.

- For API details, see [UpdatePatchBaseline](https://docs.aws.amazon.com/systems-manager/latest/api/API_UpdatePatchBaseline.html) in AWS CLI Command Reference.

**PowerShell**

**Tools for PowerShell**

**Example 1: This example adds two patches as rejected and one patch as approved to an existing patch baseline.**

```
Update-SSMPatchBaseline -BaselineId "pb-03da896ca3b68b639" -RejectedPatch "KB2032276","MS10-048" -ApprovedPatch "KB2124261"
```

**Output:**

<table>

Scenarios for Systems Manager using AWS SDKs

The following code examples show you how to implement common scenarios in Systems Manager with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Systems Manager. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- Get started with Systems Manager using an AWS SDK

Get started with Systems Manager using an AWS SDK

The following code example shows how to work with Systems Manager maintenance windows, documents, and OpsItems.

Java

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ssm.SsmClient;
import software.amazon.awssdk.services.ssm.model.CommandInvocation;
import software.amazon.awssdk.services.ssm.model.CommandInvocationStatus;
```

### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
```
Get started with Systems Manager

```java
import software.amazon.awssdk.services.ssm.model.CreateDocumentRequest;
import software.amazon.awssdk.services.ssm.model.CreateDocumentResponse;

/**
* Before running this Java V2 code example, set up your development environment, including your credentials.
*
* For more information, see the following documentation topic:
*
* https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/setup.html
*
* This Java program performs these tasks:
* 1. Creates an AWS Systems Manager maintenance window with a default name or a user-provided name.
* 2. Modifies the maintenance window schedule.
* 3. Creates a Systems Manager document with a default name or a user-provided name.
* 4. Sends a command to a specified EC2 instance using the created Systems Manager document and displays the time when the command was invoked.
* 5. Creates a Systems Manager OpsItem with a predefined title, source, category, and severity.
* 6. Updates and resolves the created OpsItem.
* 7. Deletes the Systems Manager maintenance window, OpsItem, and document.
*/

    CreateDocumentResponse response = ssmClient.createDocument(request);
    System.out.println("The status of the document is "+
        response.documentDescription().status());
}

public static void describeOpsItems(SsmClient ssmClient, String key) {
    try {
        OpsItemFilter filter = OpsItemFilter.builder()
            .key(OpsItemFilterKey.OPS_ITEM_ID)
            .values(key)
            .operator(OpsItemFilterOperator.EQUAL)
            .build();

        DescribeOpsItemsRequest itemsRequest = DescribeOpsItemsRequest.builder()
            .maxResults(10)
            .opsItemFilters(filter)
            .build();

        DescribeOpsItemsResponse itemsResponse = ssmClient.describeOpsItems(itemsRequest);
        List<OpsItemSummary> items = itemsResponse.opsItemSummaries();
        for (OpsItemSummary item : items) {
            System.out.println("The item title is " + item.title() +" and the status is "+item.status().toString());
        }
    }
    catch (SsmException e) {
        System.err.println(e.getMessage());
    }
}

Get started with Systems Manager
public static void deleteOpsItem(SsmClient ssmClient, String opsId) {  
    try {  
        DeleteOpsItemRequest deleteOpsItemRequest = DeleteOpsItemRequest.builder()
            .opsItemId(opsId)
            .build();

        ssmClient.deleteOpsItem(deleteOpsItemRequest);
        System.out.println(opsId +" Opsitem was deleted");
    } catch (SsmException e) {  
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

For API details, see the following topics in AWS SDK for Java 2.x API Reference.

- CommandInvocations
- CreateDocument
- CreateMaintenanceWindow
- CreateOpsItem
- DeleteMaintenanceWindow
- SendCommand
- UpdateOpsItem

For a complete list of AWS SDK developer guides and code examples, see Using Systems Manager with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.
Monitoring AWS Systems Manager

Monitoring is an important part of maintaining the reliability, availability, and performance of AWS Systems Manager and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can debug a multipoint failure if one occurs. But before you start monitoring Systems Manager, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who performs the monitoring tasks?
- Who should be notified when something goes wrong?

After you have defined your monitoring goals and have created your monitoring plan, the next step is to establish a baseline for normal Systems Manager performance in your environment. You should measure Systems Manager performance at various times and under different load conditions. As you monitor Systems Manager, you should store a history of monitoring data that you've collected. You can compare current Systems Manager performance to this historical data to help you to identify normal performance patterns and performance anomalies, and create methods to address them.

For example, you can monitor the success or failure of operations such as Automation workflows, the application of patch baselines, maintenance window events, and configuration compliance. Automation is a capability of AWS Systems Manager.

You can also monitor CPU utilization, disk I/O, and network utilization of your managed nodes. When performance falls outside your established baseline, you might need to reconfigure or optimize the node to reduce CPU utilization, improve disk I/O, or reduce network traffic. For more information about monitoring EC2 instances, see Monitor Amazon EC2 in the Amazon EC2 User Guide.

Topics

- Monitoring tools
- Sending node logs to unified CloudWatch Logs (CloudWatch agent)
Monitoring tools

The content in this chapter provides information for using tools available for monitoring your Systems Manager and other AWS resources. For a more complete list of tools, see Logging and monitoring in AWS Systems Manager.

Sending node logs to unified CloudWatch Logs (CloudWatch agent)

You can configure and use the Amazon CloudWatch agent to collect metrics and logs from your nodes instead of using AWS Systems Manager Agent (SSM Agent) for these tasks. The CloudWatch agent allows you to gather more metrics on EC2 instances than are available using SSM Agent. In addition, you can gather metrics from on-premises servers using the CloudWatch agent.

You can also store agent configuration settings in the Systems Manager Parameter Store for use with the CloudWatch agent. Parameter Store is a capability of AWS Systems Manager.

Note

AWS Systems Manager supports migrating from SSM Agent to the unified CloudWatch agent for collecting logs and metrics on 64-bit versions of Windows only. For information about setting up the unified CloudWatch agent on other operating systems, and for complete information about using the CloudWatch agent, see Collecting metrics and logs from Amazon EC2 instances and on-premises servers with the CloudWatch agent in the Amazon CloudWatch User Guide.
You can use the CloudWatch agent on other supported operating systems, but you won’t be able to use Systems Manager to perform a tool migration.

SSM Agent writes information about executions, scheduled actions, errors, and health statuses to log files on each node. Manually connecting to a node to view log files and troubleshoot an issue with SSM Agent is time-consuming. For more efficient node monitoring, you can configure either SSM Agent itself or the CloudWatch agent to send this log data to Amazon CloudWatch Logs.

⚠️ Important

The unified CloudWatch agent has replaced SSM Agent as the tool for sending log data to Amazon CloudWatch Logs. The SSM Agent aws:cloudWatch plugin is not supported. We recommend using only the unified CloudWatch agent for your log collection processes. For more information, see the following topics:

- Sending node logs to unified CloudWatch Logs (CloudWatch agent)
- Migrate Windows Server node log collection to the CloudWatch agent
- Collecting metrics, logs, and traces with the CloudWatch agent in the Amazon CloudWatch User Guide.

Using CloudWatch Logs, you can monitor log data in real time, search and filter log data by creating one or more metric filters, and archive and retrieve historical data when you need it. For more information about CloudWatch Logs, see the Amazon CloudWatch Logs User Guide.

Configuring an agent to send log data to Amazon CloudWatch Logs provides the following benefits:

- Centralized log file storage for all SSM Agent log files.
- Quicker access to files to investigate errors.
- Indefinite log file retention (configurable).
- Logs can be maintained and accessed regardless of the status of the node.
- Access to other CloudWatch features such as metrics and alarms.

For information about monitoring Session Manager activity, see Auditing session activity and Enabling and disabling session activity logging.
If you're using SSM Agent on supported Windows Server nodes to send SSM Agent log files to Amazon CloudWatch Logs, you can use Systems Manager to migrate from SSM Agent to the CloudWatch agent as your log collection tool, and migrate your configuration settings.

The CloudWatch agent isn't supported on 32-bit versions of Windows Server.

For 64-bit EC2 instances for Windows Server, you can perform the migration to the CloudWatch agent automatically or manually. For on-premises servers and virtual machines, the process must be performed manually.

**Note**

During the migration process, the data sent to CloudWatch might be interrupted or duplicated. Your metrics and log data will be recorded accurately again in CloudWatch after the migration is completed.

We recommend testing the migration on a limited number of nodes before migrating an entire fleet to the CloudWatch agent. After migration, if you prefer log collection with SSM Agent, you can return to using it instead.

**Important**

In the following cases, you won't be able to migrate to the CloudWatch agent using the steps described in this topic:

- The existing configuration for SSM Agent specifies multiple Regions.
- The existing configuration for SSM Agent specifies multiple sets of access/secret key credentials.

In these cases, it will be necessary to turn off log collection in SSM Agent and install the CloudWatch agent without a migration process. For more information, see the following topics in the *Amazon CloudWatch User Guide*:

- [Installing the CloudWatch agent](#)
- [Installing the CloudWatch agent on on-premises servers](#)
Before you begin

Before you begin a migration to the CloudWatch agent for log collection, ensure that the nodes on which you will perform the migration meet these requirements:

- The OS is a 64-bit version of Windows Server.
- SSM Agent 2.2.93.0 or later is installed on the node.
- SSM Agent is configured for monitoring on the node.

Topics

- Automatically migrating to the CloudWatch agent
- Manually migrating to the CloudWatch agent

Automatically migrating to the CloudWatch agent

For EC2 instances for Windows Server only, you can use the AWS Systems Manager console or the AWS Command Line Interface (AWS CLI) to automatically migrate to the CloudWatch agent as your log collection tool.

ℹ️ Note

AWS Systems Manager supports migrating from SSM Agent to the unified CloudWatch agent for collecting logs and metrics on 64-bit versions of Windows only. For information about setting up the unified CloudWatch agent on other operating systems, and for complete information about using the CloudWatch agent, see Collecting metrics and logs from Amazon EC2 instances and on-premises servers with the CloudWatch agent in the Amazon CloudWatch User Guide.

You can use the CloudWatch agent on other supported operating systems, but you won't be able to use Systems Manager to perform a tool migration.

After the migration succeeds, check your results in CloudWatch to ensure you're receiving the metrics, logs, or Windows event logs you expect. If you're satisfied with the results, you can optionally Store CloudWatch agent configuration settings in Parameter Store. If the migration isn't successful or the results aren't as expected, you can try Rolling back to log collection with SSM Agent.
Note

If you want to migrate a source configuration file that includes a \{hostname\} entry, then be aware that the \{hostname\} entry can change the value of the field after the migration is complete. For example, say that the following "LogStream": "\{hostname\}" entry maps to a server named MyLogServer001.

```json
{
  "Id": "CloudWatchIISLogs",
  "FullName":
  "Parameters": {
    "AccessKey": "",
    "SecretKey": "",
    "Region": "us-east-1",
    "LogGroup": "Production-Windows-IIS",
    "LogStream": "\{hostname\}"
  }
}
```

After the migration, this entry maps to a domain, such as ip-11-1-1-11.production.ExampleCompany.com. To retain the local hostname value, specify {local_hostname} instead of {hostname}.

To automatically migrate to the CloudWatch agent (console)

2. In the navigation pane, choose Run Command, and then choose Run command.
3. In the Command document list, choose AmazonCloudWatch-MigrateCloudWatchAgent.
4. For Status, choose Enabled.
5. In the Targets section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.
Tip

If a managed node you expect to see isn't listed, see **Troubleshooting managed node availability** for troubleshooting tips.

6. For **Rate control**:

   • For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**

   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   • For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

7. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

   **Note**

   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see **Configure instance permissions required for Systems Manager** or **Create an IAM service role for a hybrid environment**. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.
8. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

   For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

9. Choose **Run**.

**To automatically migrate to the CloudWatch agent (AWS CLI)**

- Run the following command.

```bash
aws ssm send-command --document-name AmazonCloudWatch-MigrateCloudWatchAgent --targets Key=instanceids,Values=ID1,ID2,ID3
```

*ID1*, *ID2*, and *ID3* represent the IDs of nodes you want to update, such as *i-02573cafcfEXAMPLE*.

**Manually migrating to the CloudWatch agent**

For on-premises Windows Server nodes or EC2 instances for Windows Server, follow these steps to manually migrate log collection to the Amazon CloudWatch agent.

**Note**

If you want to migrate a source configuration file that includes a `{hostname}` entry, then be aware that the `{hostname}` entry can change the value of the field after the migration is complete. For example, say that the following "LogStream": "{hostname}" entry maps to a server named *MyLogServer001*.

```json
{
    "Id": "CloudWatchIISLogs",
    "Parameters": {
        "AccessKey": "",
        "SecretKey": "",
        "Region": "us-east-1",
        "LogGroup": "Production-Windows-IIS",
        "LogStream": "{hostname}"
    }
}
```
After the migration, this entry maps to a domain, such as ip-11-1-1-11.production.ExampleCompany.com. To retain the local hostname value, specify \{local\_hostname\} instead of \{hostname\}.

**One: To install the CloudWatch agent (console)**

2. In the navigation pane, choose **Run Command**, and then choose **Run command**.
3. In the **Command document** list, choose **AWS-ConfigureAWSPackage**.
4. For **Action**, choose **Install**.
5. For **Name**, enter **AmazonCloudWatchAgent**.
6. For **Version**, enter **latest** if it isn't already provided by default.
7. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

**Tip**

If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](https://console.aws.amazon.com/systems-manager/) for troubleshooting tips.

8. For **Rate control**:
   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

**Note**

If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren’t certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.
- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

```
9. Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.
```

**Note**

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

    For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

11. Choose **Run**.

Two: To update config data JSON format

- To update the JSON formatting of the existing config settings for the CloudWatch agent, use **Run Command**, a capability of AWS Systems Manager, or log in to the node directly with an RDP connection to run the following Windows PowerShell commands on the node, one at a time.

```
cd $(Env:ProgramFiles)\Amazon\AmazonCloudWatchAgent

.\amazon-cloudwatch-agent-config-wizard.exe --isNonInteractiveWindowsMigration
```

*Migrate Windows Server node log collection to the CloudWatch agent*
Three: To configure and start the CloudWatch agent (console)

2. In the navigation pane, choose Run Command, and then choose Run command.
3. In the Command document list, choose AWS-RunPowerShellScript.
4. For Commands, enter the following two commands.

   ```bash
   cd ${Env:ProgramFiles}\Amazon\AmazonCloudWatchAgent
   .\amazon-cloudwatch-agent-ctl.ps1 -a fetch-config -m ec2 -c file:config.json -s
   ```

5. In the Targets section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   Tip
   If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

6. For Rate control:

   • For Concurrency, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   Note
   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted,
then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

7. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

7. **Note**
   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/configure-instance-permissions.html) or [Create an IAM service role for a hybrid environment](https://docs.aws.amazon.com/systems-manager/latest/userguide/iam-service-roles.html). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

8. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

   For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](https://docs.aws.amazon.com/systems-manager/latest/userguide/amazon-sns-notifications.html).

9. Choose **Run**.

**Four: To turn off log collection in SSM Agent (console)**

2. In the navigation pane, choose **Run Command**, and then choose **Run command**.

3. In the **Command document** list, choose **AWS-ConfigureCloudWatch**.

4. For **Status**, choose **Disabled**.
5. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   **Tip**
   If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

6. For **Status**, choose Disabled.

7. For **Rate control**:

   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**
   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

8. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

   **Note**
   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service
role associated with the managed node has the necessary permissions to write to that bucket.

9. In the SNS notifications section, if you want notifications sent about the status of the command execution, select the Enable SNS notifications check box.

For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

After completing these steps, check your logs in CloudWatch to verify you are receiving the metrics, logs, or Windows event logs you expect. If the results are satisfactory, you can optionally Store CloudWatch agent configuration settings in Parameter Store. If the migration isn't successful or the results aren't as expected, you can Rolling back to log collection with SSM Agent.

**Store CloudWatch agent configuration settings in Parameter Store**

You can store the contents of an CloudWatch agent configuration file in Parameter Store. By maintaining this configuration data in a parameter, multiple nodes can derive their configuration settings from it, and you avoid having to create or manually update configuration files on your nodes. For example, you can use Run Command to write the contents of the parameter to configuration files on multiple nodes, or use State Manager, a capability of AWS Systems Manager, to help avoid configuration drift in the CloudWatch agent configuration settings across a fleet of nodes.

When you run the CloudWatch agent configuration wizard, you can choose to let the wizard save your configuration settings as a new parameter in Parameter Store. For information about running the CloudWatch agent configuration wizard, see Create the CloudWatch agent configuration file with the wizard in the Amazon CloudWatch User Guide.

If you ran the wizard but didn't choose the option to save the settings as a parameter, or you created the CloudWatch agent configuration file manually, you can retrieve the data to save as a parameter on your node in the following file.

```bash
$[Env:ProgramFiles]\Amazon\AmazonCloudWatchAgent\config.json
```
{Env:ProgramFiles} represents the location where the Amazon directory containing the CloudWatch agent can be found, typically C:\Program Files.

We recommend keeping a backup of the JSON in this file on a location other than the node itself.

For information about creating a parameter, see Creating Systems Manager parameters.

For more information about the CloudWatch agent, see Collecting metrics and logs from Amazon EC2 instances and on-premises servers with the CloudWatch agent in the Amazon CloudWatch User Guide.

Rolling back to log collection with SSM Agent

If you want to return to using SSM Agent for log collection, follow these steps.

One: To retrieve config data from SSM Agent

1. On the node where you want to return to collecting logs with the SSM Agent, locate the contents of the SSM Agent config file. This JSON file is typically found in the following location:

   `{Env:ProgramFiles}\Amazon\SSM\Plugins\awsCloudWatch\AWS.EC2.Windows.CloudWatch.json`

   `{Env:ProgramFiles}` represents the location where the Amazon directory can be found, typically C:\Program Files.

2. Copy this data into a text file for use in a later step.

   We recommend storing a backup of the JSON on a location other than the node itself.

Two: To uninstall the CloudWatch agent (console)

2. In the navigation pane, choose Run Command, and then choose Run command.

3. In the Command document list, choose AWS-ConfigureAWSPackage.

4. For Action, choose Uninstall.

5. For Name, enter AmazonCloudWatchAgent.
6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   **Tip**
   If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

7. For **Rate control**:

   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**
   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

8. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

   **Note**
   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service
9. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

10. Choose **Run**.

**Three: To turn log collection back on in SSM Agent (console)**

2. In the navigation pane, choose **Run Command**, and then choose **Run command**.

3. In the **Command document** list, choose AWS-ConfigureCloudWatch.

4. For **Status**, choose **Enabled**.

5. For **Properties**, paste the contents of the old config data you saved to the text file.

6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   **Tip**

   If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

7. For **Rate control**:

   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**

   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted,
then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

8. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

### Note

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

9. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

### Sending SSM Agent logs to CloudWatch Logs

AWS Systems Manager Agent (SSM Agent) is Amazon software that runs on your EC2 instances, edge devices, on-premises servers, and virtual machines (VMs) that are configured for Systems Manager. SSM Agent processes requests from the Systems Manager service in the cloud and configures your machine as specified in the request. For more information about SSM Agent, see [Working with SSM Agent](#).
In addition, using the following steps, you can configure SSM Agent to send log data to Amazon CloudWatch Logs.

**Before you begin**

Create a log group in CloudWatch Logs. For more information, see [Getting started with CloudWatch Logs](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/GettingStarted.html) in the *Amazon CloudWatch Logs User Guide*.

**To configure SSM Agent to send logs to CloudWatch**

1. Log into a node and locate the following file:

   **Linux**
   
   On most Linux node types: `/etc/amazon/ssm/seelog.xml.template`.
   

   **macOS**
   
   `/opt/aws/ssm/seelog.xml.template`

   **Windows**
   
   `%ProgramFiles%\Amazon\SSM\seelog.xml.template`

2. Change the file name from `seelog.xml.template` to `seelog.xml`

   **Note**
   
   On Ubuntu Server 20.10 STR & 20.04, 18.04, and 16.04 LTS, the file `seelog.xml` must be created in the directory `/etc/amazon/ssm/`. You can create this directory and file by running the following commands.

   ```bash
   sudo mkdir -p /etc/amazon/ssm
   sudo cp -pr /snap/amazon-ssm-agent/current/* /etc/amazon/ssm
   sudo cp -p /etc/amazon/ssm/seelog.xml.template /etc/amazon/ssm/seelog.xml
   ```
3. Open the seelog.xml file in a text editor, and locate the following section.

Linux and macOS

```xml
<outputs formatid="fmtinfo">
  <console formatid="fmtinfo"/>
  <rollingfile type="size" filename="/var/log/amazon/ssm/amazon-ssm-agent.log" maxsize="30000000" maxrolls="5"/>
  <filter levels="error,critical" formatid="fmterror">
    <rollingfile type="size" filename="/var/log/amazon/ssm/errors.log" maxsize="10000000" maxrolls="5"/>
  </filter>
</outputs>
```

Windows

```xml
<outputs formatid="fmtinfo">
  <console formatid="fmtinfo"/>
  <rollingfile type="size" maxrolls="5" maxsize="30000000" filename="{{LOCALAPPDATA}}\Amazon\SSM\Logs\amazon-ssm-agent.log"/>
  <filter formatid="fmterror" levels="error,critical">
    <rollingfile type="size" maxrolls="5" maxsize="10000000" filename="{{LOCALAPPDATA}}\Amazon\SSM\Logs\errors.log"/>
  </filter>
</outputs>
```

4. Edit the file, and add a `custom name` element after the closing `</filter>` tag. In the following example, the custom name as been specified as `cloudwatch_receiver`.

Linux and macOS

```xml
<outputs formatid="fmtinfo">
  <console formatid="fmtinfo"/>
  <rollingfile type="size" filename="/var/log/amazon/ssm/amazon-ssm-agent.log" maxsize="30000000" maxrolls="5"/>
  <filter levels="error,critical" formatid="fmterror">
    <rollingfile type="size" filename="/var/log/amazon/ssm/errors.log" maxsize="10000000" maxrolls="5"/>
  </filter>
  <custom name="cloudwatch_receiver" formatid="fmtdebug" data-log-group="your-CloudWatch-log-group-name"/>
</outputs>
```
5. Save your changes, and then restart SSM Agent or the node.

7. In the navigation pane, choose **Log groups**, and then choose the name of your log group.

Tip: The log stream for SSM Agent log file data is organized by node ID.

**Monitoring your change request events**

After turning on integration with AWS CloudTrail Lake and creating an event data store, you can view auditable details about the change requests that are run in your account or organization. This includes details such as the following:

- The identity of the user that initiated the change request
- The AWS Regions where the changes were made
- The source IP address for the request
- The AWS access key used for the request
- The API actions run for the change request
- The request parameters included for those actions
- The resources updated during the process
The following are samples of event details you can view for a change request after creating the event data store in AWS CloudTrail Lake.

Details

The following image shows the high-level information about a change request available on the Details tab. These details include information such as the time the change request operation began, the ID of the user that initiated the change request, the impacted AWS Region, and the event ID and request ID associated with the request.

![Details Tab](image)

Event record

The following image shows the structure of the JSON content provided by CloudTrail Lake for a change request event. This data is provided on the Event record tab in a change request.
Important

If you're using Change Manager for an organization, you can complete the following procedure while signed in to either the management account or the delegated administrator account for Change Manager. However, to use the delegated administrator account to complete these steps, the same delegated administrator account must be specified for both CloudTrail and Change Manager.

When you sign in to the management account for Change Manager, you can add or change the delegated administrator account for CloudTrail on the CloudTrail Settings page. This must be done before the delegated administrator account can create an event data store for use by the entire organization.

To turn on CloudTrail Lake event tracking from Change Manager

2. In the navigation pane, choose Change Manager.
3. Choose the Requests tab.
4. Choose any existing change request, and then choose the Associated events tab.
5. Choose Enable CloudTrail Lake.
6. Follow the steps in Create an event data store for CloudTrail events in the AWS CloudTrail User Guide.

To ensure that event data for your change requests is stored, make the following selections as you complete the procedure:

- For Event type, leave the defaults AWS events and CloudTrail events selected.
- If you're using Change Manager with an organization, select Enable for all accounts in my organization.
- For Management events, do not clear the Write check box.

Other options you choose when creating your event data store don't affect the storage of event data for your change requests.

### Monitoring your automations

**Metrics** are the fundamental concept in Amazon CloudWatch. A metric represents a time-ordered set of data points that are published to CloudWatch. Think of a metric as a variable to monitor and the data points as representing the values of that variable over time.

Automation is a capability of AWS Systems Manager. Systems Manager publishes metrics about Automation usage to CloudWatch. This allows you to set alarms based on those metrics.

**To view Automation metrics in the CloudWatch console**

2. In the navigation pane, choose Metrics.
3. Choose SSM.
4. On the Metrics tab, choose Usage, and then choose By AWS Resource.
5. In the search box near the list of metrics, enter SSM.

**To view Automation metrics using the AWS CLI**
Open a command prompt, and use the following command.

```
aws cloudwatch list-metrics \
   --namespace "AWS/Usage"
```

## Automation metrics

Systems Manager sends the following Automation metrics to CloudWatch.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConcurrentAutomationUsage</td>
<td>The number of automations running at the same time in the current AWS account and AWS Region.</td>
</tr>
<tr>
<td>QueuedAutomationUsage</td>
<td>The number of automations currently queued that have not started and have a status of Pending.</td>
</tr>
</tbody>
</table>

For more information about working with CloudWatch metrics, see the following topics in the *Amazon CloudWatch User Guide*:

- [Metrics](#)
- [Using Amazon CloudWatch metrics](#)
- [Using Amazon CloudWatch alarms](#)

## Monitoring Run Command metrics using Amazon CloudWatch

*Metrics* are the fundamental concept in Amazon CloudWatch. A metric represents a time-ordered set of data points that are published to CloudWatch. Think of a metric as a variable to monitor, and the data points as representing the values of that variable over time.

AWS Systems Manager publishes metrics about the status of Run Command commands to CloudWatch, allowing you to set alarms based on those metrics. Run Command is a capability of AWS Systems Manager. These statistics are recorded for an extended period so you can access historical information and gain a better perspective on the success rate of commands run in your AWS account.
The terminal status values for commands for which you can track metrics include Success, Failed, and Delivery Timed Out. For example, for an SSM Command document set to run every hour, you can configure an alarm to notify you when a status of Success isn't reported for any of those hours. For more information about command status values, see Understanding command statuses.

To view metrics in the CloudWatch console

2. In the navigation pane, choose Metrics.
3. In the Alarms by AWS service area, for Services, choose SSM-Run Command.

To view metrics using the AWS CLI

Open a command prompt, and use the following command.

```
aws cloudwatch list-metrics --namespace "AWS/SSM-RunCommand"
```

To list all available metrics, use the following command.

```
aws cloudwatch list-metrics
```

Systems Manager Run Command metrics and dimensions

Systems Manager sends Run Command command metrics to CloudWatch one time every minute.

Systems Manager sends the following command metrics to CloudWatch.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CommandsDeliveryTimedOut</td>
<td>The number of commands that have a terminal status of Delivery Timed Out.</td>
</tr>
</tbody>
</table>

Note

These metrics use Count as the unit, so Sum and SampleCount are the most useful statistics.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CommandsFailed</td>
<td>The number of commands that have a terminal status of Failed.</td>
</tr>
<tr>
<td>CommandsSucceeded</td>
<td>The number of commands that have a terminal status of Success.</td>
</tr>
</tbody>
</table>

For more information about working with CloudWatch metrics, see the following topics in the *Amazon CloudWatch User Guide*:

- Metrics
- Using Amazon CloudWatch metrics
- Using Amazon CloudWatch alarms

## Logging AWS Systems Manager API calls with AWS CloudTrail

AWS Systems Manager is integrated with [AWS CloudTrail](https://aws.amazon.com/cloudtrail/), a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures API calls for Systems Manager as events. The calls captured include calls from the Systems Manager console and code calls to the Systems Manager API operations. Using the information collected by CloudTrail, you can determine the request that was made to Systems Manager, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information that helps you determine who made the request.

- AWS account root user
- Temporary security credentials from an AWS Identity and Access Management (IAM) role or federated user.
- Long-term security credentials from an IAM user.
- Requests made on behalf of an IAM Identity Center user.
- Another AWS service.

For more information, see the [CloudTrail userIdentity Element](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/CloudTrail-userIdentity-Elements.html).
CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail Event history. The CloudTrail Event history provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see Working with CloudTrail Event history in the AWS CloudTrail User Guide. There are no CloudTrail charges for viewing the Event history.

For an ongoing record of events in your AWS account past 90 days, create a trail or a CloudTrail Lake event data store.

CloudTrail trails

A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see Creating a trail for your AWS account and Creating a trail for an organization in the AWS CloudTrail User Guide.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see AWS CloudTrail Pricing. For information about Amazon S3 pricing, see Amazon S3 Pricing.

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to Apache ORC format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into event data stores, which are immutable collections of events based on criteria that you select by applying advanced event selectors. The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see Working with AWS CloudTrail Lake in the AWS CloudTrail User Guide.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the pricing option you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.
Systems Manager data events in CloudTrail

Data events provide information about the resource operations performed on or in a resource (for example, creating or opening a control channel). These are also known as data plane operations. Data events are often high-volume activities. By default, CloudTrail doesn't log data events. The CloudTrail Event history doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

You can log data events for the Systems Manager resource types by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see Logging data events with the AWS Management Console and Logging data events with the AWS Command Line Interface in the AWS CloudTrail User Guide.

The following table lists the Systems Manager resource types for which you can log data events. The Data event type (console) column shows the value to choose from the Data event type list on the CloudTrail console. The resources.type value column shows the resources.type value, which you would specify when configuring advanced event selectors using the AWS CLI or CloudTrail APIs. The Data APIs logged to CloudTrail column shows the API calls logged to CloudTrail for the resource type.

<table>
<thead>
<tr>
<th>Data event type (console)</th>
<th>resources.type value</th>
<th>Data APIs logged to CloudTrail</th>
</tr>
</thead>
<tbody>
<tr>
<td>Systems Manager</td>
<td>AWS::SSMMessages::ControlChannel</td>
<td>• CreateControlChannel</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• OpenControlChannel</td>
</tr>
</tbody>
</table>

For more information about these operations, see Actions defined by Amazon Message Gateway Service in the Service Authorization Reference.

| Systems Manager managed node   | AWS::SSM::ManagedNode              | • RequestManagedInstanceRoleToken – This event is generated when |

Systems Manager data events in CloudTrail
You can configure advanced event selectors to filter on the eventName, readOnly, and resources.ARN fields to log only those events that are important to you. For more information about these fields, see AdvancedFieldSelector in the AWS CloudTrail API Reference.

**Systems Manager management events in CloudTrail**

Management events provide information about management operations that are performed on resources in your AWS account. These are also known as control plane operations. By default, CloudTrail logs management events.

Systems Manager logs all control plane operations to CloudTrail as management events. Systems Manager API operations are documented in the AWS Systems Manager API Reference. For example, calls to the CreateMaintenanceWindows, PutInventory, SendCommand, and StartSession actions generate entries in the CloudTrail log files. For an example of setting up CloudTrail to monitor a Systems Manager API call, see Monitoring session activity using Amazon EventBridge (console).

**Systems Manager event examples**

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

Examples:

- Management event examples
Management event examples

Example 1: DeleteDocument

The following example shows a CloudTrail event that demonstrates the DeleteDocument operation on a document named example-Document in the US East (Ohio) Region (us-east-2).

```
{
    "eventVersion": "1.04",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "AKIAI44QH8DHBEXAMPLE:203.0.113.11",
        "arn": "arn:aws:sts::123456789012:assumed-role/example-role/203.0.113.11",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "2018-03-06T20:19:16Z"
            },
            "sessionIssuer": {
                "type": "Role",
                "principalId": "AKIAI44QH8DHBEXAMPLE",
                "arn": "arn:aws:iam::123456789012:role/example-role",
                "accountId": "123456789012",
                "userName": "example-role"
            }
        }
    },
    "eventTime": "2018-03-06T20:30:12Z",
    "eventSource": "ssm.amazonaws.com",
    "eventName": "DeleteDocument",
    "awsRegion": "us-east-2",
    "sourceIPAddress": "203.0.113.11",
    "userAgent": "example-user-agent-string",
    "requestParameters": {
        "name": "example-Document"
    },
    "responseElements": null,

}
```
Example 2: StartConnection

The following example shows a CloudTrail event for a user who starts an RDP connection using Fleet Manager in the US East (Ohio) Region (us-east-2). The underlying API action is StartConnection.

```json
{
   "eventVersion": "1.08",
   "userIdentity": {
      "type": "AssumedRole",
      "principalId": "AKIAI44QH8DHBEEXAMPLE",
      "arn": "arn:aws:sts::123456789012:assumed-role/exampleRole",
      "accountId": "123456789012",
      "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
      "sessionContext": {
         "sessionIssuer": {
            "type": "Role",
            "principalId": "AKIAI44QH8DHBEEXAMPLE",
            "arn": "arn:aws:sts::123456789012:assumed-role/exampleRole",
            "accountId": "123456789012",
            "userName": "exampleRole"
         },
         "webIdFederationData": {},
         "attributes": {
            "creationDate": "2021-12-13T14:57:05Z",
            "mfaAuthenticated": "false"
         }
      }
   },
   "eventTime": "2021-12-13T16:50:41Z",
   "eventSource": "ssm-guiconnect.amazonaws.com",
   "eventName": "StartConnection",
}
Data event examples

Example 1: CreateControlChannel

The following example shows a CloudTrail event that demonstrates the CreateControlChannel operation.

```json
{
  "eventVersion": "1.08",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AKIAI44QH8DHBEXAMPLE",
    "arn": "arn:aws:sts::123456789012:assumed-role/exampleRole",
    "accountId": "123456789012",
    "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",
```

For information about CloudTrail record contents, see "CloudTrail record contents" in the AWS CloudTrail User Guide.

Logging Automation action output with CloudWatch Logs

Automation, a capability of AWS Systems Manager, integrates with Amazon CloudWatch Logs. You can send the output from `aws:executeScript` actions in your runbooks to the log group you specify. Systems Manager doesn't create a log group or any log streams for documents that don't use `aws:executeScript` actions. If the document does use `aws:executeScript`, the output sent to CloudWatch Logs only pertains to those actions. You can use the `aws:executeScript` action output stored in your CloudWatch Logs log group for debugging and troubleshooting purposes. If you choose a log group that is encrypted, the `aws:executeScript` action output is also encrypted. Logging output from `aws:executeScript` actions is an account-level setting.

To send action output to CloudWatch Logs for Amazon owned runbooks, the user or role that runs the automation must have permissions for the following operations:

- `logs:CreateLogGroup`
- `logs:CreateLogStream`
- `logs:DescribeLogGroups`
- `logs:DescribeLogStreams`
- `logs:PutLogEvents`
For runbooks that you own, the same permissions must be added to the IAM service role (or AssumeRole) you use to run the runbook.

**To send action output to CloudWatch Logs (console)**

2. In the navigation pane, choose Automation.
3. Choose the Preferences tab, and then choose Edit.
4. Select the check box next to Send output to CloudWatch Logs.
5. (Recommended) Select the check box next to Encrypt log data. With this option turned on, log data is encrypted using the server-side encryption key specified for the log group. If you don't want to encrypt the log data that is sent to CloudWatch Logs, clear the check box. Clear the check box if encryption isn't allowed on the log group.
6. For CloudWatch Logs log group, to specify the existing CloudWatch Logs log group in your AWS account that you want to send action output to, select one of the following:
   - **Send output to the default log group** – If the default log group doesn't exist (/aws/ssm/automation/executeScript), Automation creates it for you.
   - **Choose from a list of log groups** – Select a log group that has already been created in your account to store action output.
   - **Enter a log group name** – Enter the name of a log group in the text box that has already been created in your account to store action output.
7. Choose Save.

**To send action output to CloudWatch Logs (command line)**

1. Open your preferred command line tool and run the following command to update the action output destination.

   **Linux & macOS**

   ```bash
   aws ssm update-service-setting \
   --setting-value CloudWatch
   ```
Windows

```bash
aws ssm update-service-setting
customer-script-log-destination
  --setting-value CloudWatch
```

PowerShell

```powershell
Update-SSMServiceSetting
  -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/automation/
customer-script-log-destination"
  -SettingValue "CloudWatch"
```

There is no output if the command succeeds.

2. Run the following command to specify the log group you want to send action output to.

Linux & macOS

```bash
aws ssm update-service-setting
customer-script-log-group-name
  --setting-value my-log-group
```

Windows

```bash
aws ssm update-service-setting
customer-script-log-group-name
  --setting-value my-log-group
```

PowerShell

```powershell
Update-SSMServiceSetting
  -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/automation/
customer-script-log-group-name"
  -SettingValue "my-log-group"
```
There is no output if the command succeeds.

3. Run the following command to view the current service settings for Automation action logging preferences in the current AWS account and AWS Region.

**Linux & macOS**

```bash
aws ssm get-service-setting \
```

**Windows**

```bash
aws ssm get-service-setting ^\n   --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/automation/\n   customer-script-log-destination
```

**PowerShell**

```powershell
Get-SSMServiceSetting `\n   -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/automation/\n   customer-script-log-destination"
```

The command returns information like the following.

```json
{
   "ServiceSetting": {
      "Status": "Customized",

```
Configuring Amazon CloudWatch Logs for Run Command

When you send a command by using Run Command, a capability of AWS Systems Manager, you can specify where you want to send the command output. By default, Systems Manager returns only the first 24,000 characters of the command output. If you want to view the full details of the command output, you can specify an Amazon Simple Storage Service (Amazon S3) bucket. Or you can specify Amazon CloudWatch Logs. If you specify CloudWatch Logs, Run Command periodically sends all command output and error logs to CloudWatch Logs. You can monitor output logs in near real-time, search for specific phrases, values, or patterns, and create alarms based on the search.

If you configured your managed node to use the AWS Identity and Access Management (IAM) managed policies AmazonSSMManagedInstanceCore and CloudWatchAgentServerPolicy, then your node requires no additional configuration to send output to CloudWatch Logs. Choose this option if sending commands from the console, or add the cloud-watch-output-config section and CloudWatchOutputEnabled parameter if using the AWS Command Line Interface (AWS CLI), AWS Tools for Windows PowerShell, or an API operation. The cloud-watch-output-config section and CloudWatchOutputEnabled parameter are described in more detail later in this topic.

For information about adding policies to an instance profile for EC2 instances, see Configure instance permissions required for Systems Manager. For information about adding policies to a service role for on-premises servers and virtual machines that you plan to use as managed nodes, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.

If you're using a custom policy on your nodes, update the policy on each node to allow Systems Manager to send output and logs to CloudWatch Logs. Add the following policy objects to your custom policy. For more information about updating an IAM policy, see Editing IAM policies in the IAM User Guide.

```json
{
   "Effect": "Allow",
   "Action": "logs:DescribeLogGroups",
   "Resource": "*"
},
{
   "Effect": "Allow",
   "Action": [
   "logs:CreateLogGroup",
   "logs:CreateLogStream",
   "logs:PutLogEvents"
   ],
   "Resource": "*"
}
```
Specifying CloudWatch Logs when you send commands

To specify CloudWatch Logs as the output when you send a command from the AWS Management Console, choose **CloudWatch Output** in the **Output options** section. Optionally, you can specify the name of CloudWatch Logs group where you want to send command output. If you don't specify a group name, Systems Manager automatically creates a log group for you. The log group uses the following naming format: `/aws/ssm/SystemsManagerDocumentName`

If you run commands by using the AWS CLI, specify the `cloud-watch-output-config` section in your command. This section allows you to specify the `CloudWatchOutputEnabled` parameter, and optionally, the `CloudWatchLogGroupName` parameter. Here is an example.

**Linux & macOS**

```bash
aws ssm send-command \
   --instance-ids "instance ID" \
   --document-name "AWS-RunShellScript" \
   --parameters "commands=echo helloWorld" \
   --cloud-watch-output-config
   "CloudWatchOutputEnabled=true,CloudWatchLogGroupName=log group name"
```

**Windows**

```bash
aws ssm send-command ^
   --document-name "AWS-RunPowerShellScript" ^
   --parameters commands=["echo helloWorld"] ^
   --targets "Key=instanceids,Values=an instance ID" ^
   --cloud-watch-output-config '{"CloudWatchLogGroupName":"log group name","CloudWatchOutputEnabled":true}'}
```

Viewing command output in CloudWatch Logs

As soon as the command starts to run, Systems Manager sends output to CloudWatch Logs in near-real time. The output in CloudWatch Logs uses the following format:
**CommandID/InstanceID/PluginID/stdout**

**CommandID/InstanceID/PluginID/stderr**

Output from the execution is uploaded every 30 seconds or when the buffer exceeds 200 KB, whichever happens first.

⚠️ **Note**

Log streams are only created when output data is available. For example, if there is no error data for an execution, the stderr stream isn't created.

Here is an example of the command output as it is displayed in CloudWatch Logs.

```
Group - /aws/ssm/AWS-RunShellScript
Streams -
1234-567-8910/i-abcd-efg-hijk/AWS-RunPowerShellScript/stdout
24/1234-567-8910/i-abcd-efg-hijk/AWS-RunPowerShellScript/stderr
```

**Monitoring Systems Manager events with Amazon EventBridge**

Amazon EventBridge is a serverless event bus service that allows you to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, software-as-a-service (SaaS) applications, and AWS services and routes that data to targets such as AWS Lambda. You can set up routing rules to determine where to send your data to build application architectures that react in real time to all of your data sources. EventBridge allows you to build event driven architectures, which are loosely coupled and distributed.

EventBridge was formerly called Amazon CloudWatch Events. EventBridge includes new features that allow you to receive events from SaaS partners and your own applications. Existing CloudWatch Events users can access their existing default bus, rules, and events in the new EventBridge console and in the CloudWatch Events console. EventBridge uses the same CloudWatch Events API, so all of your existing CloudWatch Events API usage remains the same.

EventBridge can add events from dozens of AWS services to your rules, and targets from over 20 AWS services.

EventBridge provides support for both AWS Systems Manager events and Systems Manager targets.
Supported Systems Manager event types

Among the many types of Systems Manager events that EventBridge can detect are:

- A maintenance window being turned off.
- An Automation workflow completing successfully. Automation is a capability of AWS Systems Manager.
- A managed node being out of patch compliance.
- A parameter value being updated.

EventBridge supports events from the following AWS Systems Manager capabilities:

- Automation (Events are emitted on a best effort basis.)
- Change Calendar (Events are emitted on a best effort basis.)
- Compliance
- Inventory (Events are emitted on a best effort basis.)
- Maintenance Windows (Events are emitted on a best effort basis.)
- Parameter Store (Events are emitted on a best effort basis.)
- Run Command (Events are emitted on a best effort basis.)
- State Manager (Events are emitted on a best effort basis.)

For complete details about supported Systems Manager event types, see Reference: Amazon EventBridge event patterns and types for Systems Manager and Amazon EventBridge event examples for Systems Manager.

Supported Systems Manager target types

EventBridge supports the following three Systems Manager capabilities as targets of an event rule:

- Running an Automation workflow
- Running a Run Command Command document (Events are emitted on a best effort basis.)
- Creating an OpsCenter OpsItem

For suggested ways you might use these targets, see Sample scenarios: Systems Manager targets in Amazon EventBridge rules.
For more information about how to get started with EventBridge and set up rules, see Getting started with Amazon EventBridge in the Amazon EventBridge User Guide. For complete information about working with EventBridge, see the Amazon EventBridge User Guide.

Topics

- Configuring EventBridge for Systems Manager events
- Amazon EventBridge event examples for Systems Manager
- Sample scenarios: Systems Manager targets in Amazon EventBridge rules

Configuring EventBridge for Systems Manager events

You can use Amazon EventBridge to perform a target event when supported AWS Systems Manager status changes, state changes, or other conditions occur. You can create a rule that runs whenever there is a state or status transition, or when there is a transition to one or more states that are of interest.

The following procedure provides general steps for creating an EventBridge rule that engages when a specified event is emitted by Systems Manager. For a list of procedures in this user guide that address specific scenarios, see More info at the end of this topic.

Note

When a service in your AWS account emits an event, it always goes to your account’s default event bus. To write a rule that responds to events from AWS services in your account, associate it with the default event bus. You can create a rule on a custom event bus that looks for events from AWS services, but this rule only engages when you receive such an event from another account through cross-account event delivery. For more information, see Sending and receiving Amazon EventBridge events between AWS accounts in the Amazon EventBridge User Guide.

To configure EventBridge for Systems Manager events

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose Rules.
3. Choose Create rule.
4. Enter a name and description for the rule.
A rule can't have the same name as another rule in the same AWS Region and on the same event bus.

5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own AWS account, select **default**. When an AWS service in your account emits an event, it always goes to your account’s default event bus.

6. For **Rule type**, choose **Rule with an event pattern**.

7. Choose **Next**.

8. For **Event source**, choose **AWS events or EventBridge partner events**.

9. In the **Event pattern** section, choose **Event pattern form**.

10. For **Event source**, choose **AWS services**.

11. For **AWS service**, choose **Systems Manager**.

12. For **Event type**, do one of the following:

   - Choose **All Events**.

     If you choose **All Events**, all events emitted by Systems Manager will match the rule. Be aware that this option can result in many event target actions.

   - Choose the type of Systems Manager event to use for this rule. EventBridge supports events from the following AWS Systems Manager capabilities:

     - Automation
     - Change Calendar
     - Compliance
     - Inventory
     - Maintenance Windows
     - Parameter Store
     - Run Command
     - State Manager

**Note**

For Systems Manager actions that aren't supported by EventBridge, you can choose an AWS API call through CloudTrail to create an event rule that is based on an
13. (Optional) To make the rule more specific, add filter values. For example, if you chose State Manager and want to limit the rule to the state of a single managed instance that is targeted by an Association, for Specific type(s), choose EC2 State Manager Instance Association State Change.

For complete details about supported detail types, see Reference: Amazon EventBridge event patterns and types for Systems Manager.

Some detail types have other supported options such as status. The available options depend on the capability you selected.

15. For Target types, choose AWS service.

16. For Select a target, choose a target such as an Amazon SNS topic or AWS Lambda function. The target is triggered when an event is received that matches the event pattern defined in the rule.

17. For many target types, EventBridge needs permissions to send events to the target. In these cases, EventBridge can create the AWS Identity and Access Management (IAM) role needed for your rule to run:

   • To create an IAM role automatically, choose Create a new role for this specific resource.
   • To use an IAM role that you created earlier, choose Use existing role.

18. (Optional) Choose Add another target to add another target for this rule.

19. Choose Next.

20. (Optional) Enter one or more tags for the rule. For more information, see Amazon EventBridge tags in the Amazon EventBridge User Guide.

21. Choose Next.

22. Review the details of the rule and choose Create rule.

More info

Amazon EventBridge event examples for Systems Manager 2611
State Manager Instance Association State Change

Sample scenarios: Systems Manager targets in Amazon EventBridge rules

When you specify the target to invoke in an Amazon EventBridge rule, you can choose from over 20 target types and add up to five targets to each rule.

Of the various targets, you can choose from Automation, OpsCenter, and Run Command, which are capabilities of AWS Systems Manager, as target actions when an EventBridge event occurs.

The following are several examples of ways you can use these capabilities as the target of an EventBridge rule.

Automation examples

You can configure an EventBridge rule to start Automation workflows when events such as the following occur:

- When an Amazon CloudWatch alarm reports that a managed node has failed a status check (StatusCheckFailed_Instance=1), run the AWSSupport-ExecuteEC2Rescue Automation runbook on the node.
- When an EC2 Instance State-change Notification event occurs because a new Amazon Elastic Compute Cloud (Amazon EC2) instance is running, run the AWS-AttachEBSVolume Automation runbook on the instance.
- When an Amazon Elastic Block Store (Amazon EBS) volume is created and available, run the AWS-CreateSnapshot Automation runbook on the volume.

OpsCenter examples

You can configure an EventBridge rule to create a new OpsItem when incidents such as the following occur:

- A throttling event for Amazon DynamoDB occurs, or Amazon EBS volume performance has degraded.
• An Amazon EC2 Auto Scaling group fails to launch a node, or a Systems Manager Automation workflow fails.

• An EC2 instance changes state from Running to Stopped.

**Run Command examples**

You can configure an EventBridge rule to run a Systems Manager Command document in Run Command when events such as the following occur:

• When an Auto Scaling group is about to end, a Run Command script could capture the log files from the node before it is ended.

• When a new node is created in an Auto Scaling group, a Run Command target action could turn on the web server role or install software on the node.

• When a managed node is found to be out of compliance, a Run Command target action could update patches on the node by running the AWS-RunPatchBaseline document.

**Monitoring Systems Manager status changes using Amazon SNS notifications**

ℹ️ **Note**

Amazon Simple Notification Service FIFO topics aren't supported.

You can configure Amazon Simple Notification Service (Amazon SNS) to send notifications about the status of commands that you send using Run Command or Maintenance Windows, which are capabilities of AWS Systems Manager. Amazon SNS coordinates and manages sending and delivering notifications to clients or endpoints that are subscribed to Amazon SNS topics. You can receive a notification whenever a command changes to a new state or to a specific state, such as *Failed* or *Timed Out*. In cases where you send a command to multiple nodes, you can receive a notification for each copy of the command sent to a specific node. Each copy is called an *invocation*.

Amazon SNS can deliver notifications as HTTP or HTTPS POST, email (SMTP, either plaintext or in JSON format), or as a message posted to an Amazon Simple Queue Service (Amazon SQS) queue. For more information, see [What is Amazon SNS](https://aws.amazon.com/sns/) in the *Amazon Simple Notification Service Developer Guide*. 
For examples of the structure of the JSON data included in the Amazon SNS notification provided by Run Command and Maintenance Windows, see [Example Amazon SNS notifications for AWS Systems Manager](#).

## Configure Amazon SNS notifications for AWS Systems Manager

Run Command and Maintenance Windows tasks that are registered to a maintenance window can send Amazon SNS notifications for command tasks that enter the following statuses:

- In Progress
- Success
- Failed
- Timed Out
- Canceled

For information about the conditions that cause a command to enter one of these statuses, see [Understanding command statuses](#).

### Note

Commands sent using Run Command also report Canceling and Pending status. These statuses aren't captured by Amazon SNS notifications.

## Command summary Amazon SNS notifications

If you configure Run Command or a Run Command task in your maintenance window for Amazon SNS notifications, Amazon SNS sends summary messages that include the following information.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eventTime</td>
<td>String</td>
<td>The time that the event was initiated. The timestamp is important because Amazon SNS doesn't guarantee message delivery order.</td>
</tr>
<tr>
<td>Field</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>documentName</td>
<td>String</td>
<td>The name of the SSM document used to run this command.</td>
</tr>
<tr>
<td>commandId</td>
<td>String</td>
<td>The ID generated by Run Command after the command was sent.</td>
</tr>
<tr>
<td>expiresAfter</td>
<td>Date</td>
<td>If this time is reached and the command hasn't already started executing, it won't run.</td>
</tr>
<tr>
<td>outputS3BucketName</td>
<td>String</td>
<td>The Amazon Simple Storage Service (Amazon S3) bucket where the responses to the command execution should be stored.</td>
</tr>
<tr>
<td>outputS3KeyPrefix</td>
<td>String</td>
<td>The Amazon S3 directory path inside the bucket where the responses to the command execution should be stored.</td>
</tr>
<tr>
<td>requestedDateTime</td>
<td>String</td>
<td>The time and date that the request was sent to this specific node.</td>
</tr>
<tr>
<td>Field</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>instanceIds</td>
<td>StringList</td>
<td>The nodes that were targeted by the command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Instance IDs are only included in the summary message if the Run Command</td>
</tr>
<tr>
<td></td>
<td></td>
<td>task targeted instance IDs directly. Instance IDs aren't included in</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the summary message if the Run Command task was issued using tag-based</td>
</tr>
<tr>
<td></td>
<td></td>
<td>targeting.</td>
</tr>
<tr>
<td>status</td>
<td>String</td>
<td>Command status for the command.</td>
</tr>
</tbody>
</table>

### Invocation-based Amazon SNS notifications

If you send a command to multiple nodes, Amazon SNS can send messages about each copy or invocation of the command. The messages include the following information.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eventTime</td>
<td>String</td>
<td>The time that the event was initiated. The timestamp is important because</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Amazon SNS doesn't guarantee message delivery order. Example: 2016-04-2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>6T13:15:30Z</td>
</tr>
</tbody>
</table>
### Field | Type | Description
--- | --- | ---
documentName | String | The name of the Systems Manager document (SSM document) used to run this command.
requestedDateTime | String | The time and date that the request was sent to this specific node.
commandId | String | The ID generated by Run Command after the command was sent.
instanceId | String | The instance that was targeted by the command.
status | String | Command status for this invocation.

To set up Amazon SNS notifications when a command changes status, complete the following tasks.

**Note**

If you aren't configuring Amazon SNS notifications for your maintenance window, then you can skip Task 5 later in this topic.

### Topics

- **Task 1: Create and subscribe to an Amazon SNS topic**
- **Task 2: Create an IAM policy for Amazon SNS notifications**
- **Task 3: Create an IAM role for Amazon SNS notifications**
- **Task 4: Configure user access**
- **Task 5: Attach the iam:PassRole policy to your maintenance window role**
Task 1: Create and subscribe to an Amazon SNS topic

An Amazon SNS topic is a communication channel that Run Command and Run Command tasks that are registered to a maintenance window use to send notifications about the status of your commands. Amazon SNS supports different communication protocols, including HTTP/S, email, and other AWS services like Amazon Simple Queue Service (Amazon SQS). To get started, we recommend that you start with the email protocol. For information about how to create a topic, see Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

Note

After you create the topic, copy or make a note of the Topic ARN. You specify this ARN when you send a command that is configured to return status notifications.

After you create the topic, subscribe to it by specifying an Endpoint. If you chose the Email protocol, the endpoint is the email address where you want to receive notifications. For more information about how to subscribe to a topic, see Subscribing to an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

Amazon SNS sends a confirmation email from AWS Notifications to the email address that you specify. Open the email and choose the Confirm subscription link.

You will receive an acknowledgement message from AWS. Amazon SNS is now configured to receive notifications and send the notification as an email to the email address that you specified.

Task 2: Create an IAM policy for Amazon SNS notifications

Use the following procedure to create a custom AWS Identity and Access Management (IAM) policy that provides permissions for initiating Amazon SNS notifications.

To create a custom IAM policy for Amazon SNS notifications

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies, and then choose Create Policy. (If a Get Started button is shown, choose it, and then choose Create Policy.)
3. Choose the JSON tab.
4. Replace the default content with the following.
Task 3: Create an IAM role for Amazon SNS notifications

Use the following procedure to create an IAM role for Amazon SNS notifications. This service role is used by Systems Manager to initiate Amazon SNS notifications. In all subsequent procedures, this role is referred to as the Amazon SNS IAM role.
To create an IAM service role for Amazon SNS notifications

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
3. Choose the AWS service role type, and then choose Systems Manager.
4. Choose the Systems Manager use case. Then, choose Next.
5. On the Attach permissions policies page, select the box to the left of the name of the custom policy you created in Task 2. For example: my-sns-publish-permissions.
6. (Optional) Set a permissions boundary. This is an advanced feature that is available for service roles, but not service-linked roles.

   Expand the Permissions boundary section and choose Use a permissions boundary to control the maximum role permissions. IAM includes a list of the AWS managed and customer managed policies in your account. Select the policy to use for the permissions boundary or choose Create policy to open a new browser tab and create a new policy from scratch. For more information, see Creating IAM policies in the IAM User Guide. After you create the policy, close that tab and return to your original tab to select the policy to use for the permissions boundary.
7. Choose Next.
8. If possible, enter a role name or role name suffix to help you identify the purpose of this role. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because various entities might reference the role, you cannot edit the name of the role after it has been created.
9. (Optional) For Description, enter a description for the new role.
10. Choose Edit in the Step 1: Select trusted entities or Step 2: Select permissions sections to edit the use cases and permissions for the role.
11. (Optional) Add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM resources in the IAM User Guide.
12. Review the role and then choose Create role.
13. Choose the name of the role, and then copy or make a note of the Role ARN value. This Amazon Resource Name (ARN) for the role is used when you send a command that is configured to return Amazon SNS notifications.
Task 4: Configure user access

If an IAM entity (user, role, or group) is assigned administrator permissions, then the user or role has access to Run Command and Maintenance Windows, capabilities of AWS Systems Manager.

For entities without administrator permissions, an administrator must grant the following permissions to the IAM entity:

- The AmazonSSMFullAccess managed policy, or a policy that provides comparable permissions.
- `iam:PassRole` permissions for the role created in Task 3: Create an IAM role for Amazon SNS notifications. For example:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "iam:PassRole",
         "Resource": "arn:aws:iam::account-id:role/sns-role-name"
      }
   ]
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:
  
  Create a permission set. Follow the instructions in Create a permission set in the AWS IAM Identity Center User Guide.

- Users managed in IAM through an identity provider:
  
  Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the IAM User Guide.

- IAM users:
  
  - Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the IAM User Guide.
• (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the IAM User Guide.

To configure user access and attach the iam:PassRole policy to a user account

1. In the IAM navigation pane, choose Users, and then choose the user account that you want to configure.
2. On the Permissions tab, in the policies list, verify that either the AmazonSSMFullAccess policy is listed or that there is a comparable policy that gives the account permissions to access Systems Manager.
3. Choose Add inline policy.
4. On the Create policy page, choose the Visual editor tab.
5. Choose Choose a service, and then choose IAM.
6. For Actions, in the Filter actions text box, enter PassRole, and then select the check box next to PassRole.
7. For Resources, verify that Specific is selected, and then choose Add ARN.
8. In the Specify ARN for role field, paste the Amazon SNS IAM role ARN that you copied at the end of Task 3. The system automatically populates the Account and Role name with path fields.
11. On the Review Policy page, enter a name and then choose Create policy.

Task 5: Attach the iam:PassRole policy to your maintenance window role

When you register a Run Command task with a maintenance window, you specify a service role Amazon Resource Name (ARN). This service role is used by Systems Manager to run tasks registered to the maintenance window. To configure Amazon SNS notifications for a registered Run Command task, attach an iam:PassRole policy to the maintenance window service role specified. If you don't intend to configure the registered task for Amazon SNS notifications, then you can skip this task.

The iam:PassRole policy allows the Maintenance Windows service role to pass the Amazon SNS IAM role created in Task 3 to the Amazon SNS service. The following procedure shows how to attach the iam:PassRole policy to the Maintenance Windows service role.
Note

Use a custom service role for your maintenance window to send notifications related to the Run Command tasks registered. For information, see Setting up Maintenance Windows. If you need to create a custom service role for maintenance window tasks, see Use the console to configure permissions for maintenance windows.

To attach the `iam:PassRole` policy to your Maintenance Windows role

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles and select the Amazon SNS IAM role created in Task 3.
3. Copy or make a note of the Role ARN and return to the Roles section of the IAM console.
4. Select the custom Maintenance Windows service role you created from the Role name list.
5. On the Permissions tab, verify that either the AmazonSSMMaintenanceWindowRole policy is listed or there is a comparable policy that gives maintenance windows permission to the Systems Manager API. If it is not, choose Add permissions, Attach policies to attach it.
6. Choose Add permissions, Create inline policy.
7. Choose the Visual editor tab.
8. For Service, choose IAM.
9. For Actions, in the Filter actions text box, enter PassRole, and then select the check box next to PassRole.
10. For Resources, choose Specific, and then choose Add ARN.
11. In the Specify ARN for role box, paste the ARN of the Amazon SNS IAM role created in Task 3, and then choose Add.
13. On the Review policy page, specify a name for the PassRole policy, and then choose Create policy.

Example Amazon SNS notifications for AWS Systems Manager

You can configure Amazon Simple Notification Service (Amazon SNS) to send notifications about the status of commands that you send using Run Command or Maintenance Windows, which are capabilities of AWS Systems Manager.
Note
This guide doesn't address how to configure notifications for Run Command or Maintenance Windows. For information about configuring Run Command or Maintenance Windows to send Amazon SNS notifications about the status of commands, see Configure Amazon SNS notifications for AWS Systems Manager.

The following examples show the structure of the JSON output returned by Amazon SNS notifications when configured for Run Command or Maintenance Windows.

Sample JSON Output for Command summary messages using instance ID targeting

```json
{
    "commandId": "a8c7e76f-15f1-4c33-9052-0123456789ab",
    "documentName": "AWS-RunPowerShellScript",
    "instanceIds": [
        "i-1234567890abcdef0",
        "i-9876543210abcdef0"
    ],
    "requestedDateTime": "2019-04-25T17:57:09.17Z",
    "expiresAfter": "2019-04-25T19:07:09.17Z",
    "outputS3BucketName": "DOC-EXAMPLE-BUCKET",
    "outputS3KeyPrefix": "runcommand",
    "status": "InProgress",
    "eventTime": "2019-04-25T17:57:09.236Z"
}
```

Sample JSON Output for Command summary messages using tag-based targeting

```json
{
    "commandId": "9e92c686-ddc7-4827-b040-0123456789ab",
    "documentName": "AWS-RunPowerShellScript",
    "instanceIds": [],
    "requestedDateTime": "2019-04-25T18:01:03.888Z",
    "expiresAfter": "2019-04-25T19:01:03.888Z",
    "outputS3BucketName": "",
    "outputS3KeyPrefix": "",
    "status": "InProgress",
    "eventTime": "2019-04-25T18:01:05.825Z"
}
```
Sample JSON Output for Invocation messages

```json
{
    "commandId": "ceb96b84-16aa-4540-91e3-925a9a278b8c",
    "documentName": "AWS-RunPowerShellScript",
    "instanceId": "i-1234567890abcdef0",
    "requestedDateTime": "2019-04-25T18:06:05.032Z",
    "status": "InProgress",
    "eventTime": "2019-04-25T18:06:05.099Z"
}
```

Use Run Command to send a command that returns status notifications

The following procedures show how to use the AWS Command Line Interface (AWS CLI) or AWS Systems Manager console to send a command through Run Command, a capability of AWS Systems Manager, that is configured to return status notifications.

Sending a Run Command that returns notifications (console)

Use the following procedure to send a command through Run Command that is configured to return status notifications using the Systems Manager console.

To send a command that returns notifications (console)

2. In the navigation pane, choose Run Command.
3. Choose Run command.
4. In the Command document list, choose a Systems Manager document.
5. In the Command parameters section, specify values for required parameters.
6. In the Targets section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

Tip

If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.
7. For **Other parameters**:

   • For **Comment**, enter information about this command.

   • For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:

   • For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**

   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   • For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

   **Note**

   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-config-instance-permissions.html) or [Create an IAM service role for a hybrid environment](https://docs.aws.amazon.com/systems-manager/latest/userguide/sysman-iam-service-role.html). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS Notifications** section, choose **Enable SNS notifications**.
11. For **IAM role**, choose the Amazon SNS IAM role ARN you created in Task 3 in Monitoring Systems Manager status changes using Amazon SNS notifications.

12. For **SNS topic**, enter the Amazon SNS topic ARN to be used.

13. For **Event notifications**, choose the events for which you want to receive notifications.

14. For **Change notifications**, choose to receive notifications for the command summary only (**Command status changes**) or for each copy of a command sent to multiple nodes (**Command status on each instance changes**).

15. Choose **Run**.

16. Check your email for a message from Amazon SNS and open the email message. Amazon SNS can take several minutes to send the email message.

### Sending a Run Command that returns notifications (CLI)

Use the following procedure to send a command through Run Command that is configured to return status notifications using the AWS CLI.

**To send a command that returns notifications (CLI)**

1. Open the AWS CLI.
2. Specify parameters in the following command to target based on managed node IDs.

   ```bash
   aws ssm send-command --instance-ids "ID-1, ID-2" --document-name "Name"
   --parameters '{"commands":"input"}' --service-role "SNSRoleARN"
   --notification-config '{"NotificationArn":"SNSTopicName","NotificationEvents": ["All"],"NotificationType":"Command"}'
   
   Following is an example.
   ```

   ```bash
   aws ssm send-command --instance-ids "i-02573cafcfEXAMPLE, i-0471e04240EXAMPLE"
   
   **Alternative commands**

   Specify parameters in the following command to target managed instances using tags.

   ```bash
   Use Run Command to send a command that returns status notifications
   ```
Following is an example.

```
aws ssm send-command --targets "Key=tag:TagName,Values=TagKey" --document-name "Name" --parameters '{"commands":["input"]}' --service-role "SNSRoleARN" --notification-config '{"NotificationArn":"SNSTopicName","NotificationEvents": ["All"], "NotificationType":"Command"}'
```

3. Press **Enter**.

4. Check your email for a message from Amazon SNS and open the email message. Amazon SNS can take several minutes to send the email message.

For more information, see **send-command** in the **AWS CLI Command Reference**.

**Use a maintenance window to send a command that returns status notifications**

The following procedures show how to register a Run Command task with your maintenance window using the AWS Systems Manager console or the AWS Command Line Interface (AWS CLI). Run Command is a capability of AWS Systems Manager. The procedures also describe how to configure the Run Command task to return status notifications.

**Before you begin**

If you haven't created a maintenance window or registered targets, see **Working with maintenance windows (console)** for steps on how to create a maintenance window and register targets.

To receive notifications from the Amazon Simple Notification Service (Amazon SNS) service, attach an **iam:PassRole** policy to the Maintenance Windows service role specified in the registered task. If you haven't added **iam:PassRole** permissions to your Maintenance Windows service role, see **Task 5: Attach the iam:PassRole policy to your maintenance window role**.
Registering a Run Command task to a maintenance window that returns notifications (console)

Use the following procedure to register a Run Command task that is configured to return status notifications to your maintenance window using the Systems Manager console.

To register a Run Command task with your maintenance window that returns notifications (console)

2. In the navigation pane, choose Maintenance Windows.
3. Select the maintenance window for which you would like to register a Run Command task configured to send Amazon Simple Notification Service (Amazon SNS) notifications.
4. Choose Actions and then choose Register Run command task.
5. (Optional) In the Name field, enter a name for the task.
6. (Optional) In the Description field, enter a description.
7. For Command document, choose a Command document.
8. For Task priority, specify a priority for this task. Zero (0) is the highest priority. Tasks in a maintenance window are scheduled in priority order. Tasks that have the same priority are scheduled in parallel.
9. In the Targets section, select a registered target group or select unregistered targets.
10. For Rate control:
   - For Concurrency, specify either a number or a percentage of managed nodes on which to run the command at the same time.
   - For Error threshold, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three
errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

11. In the IAM service role area, choose the Maintenance Windows service role that has iam:PassRole permissions to the SNS role.

Note
Add iam:PassRole permissions to the Maintenance Windows role to allow Systems Manager to pass the SNS role to Amazon SNS. If you haven't added iam:PassRole permissions, see Task 5 in the topic Monitoring Systems Manager status changes using Amazon SNS notifications.

12. (Optional) For Output options, to save the command output to a file, select the Enable writing output to S3 box. Enter the bucket and prefix (folder) names in the boxes.

Note
The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

13. In the SNS notifications section, do the following:

- Choose Enable SNS Notifications.
- For IAM role, choose the Amazon SNS IAM role Amazon Resource Name (ARN) you created in Task 3 in Monitoring Systems Manager status changes using Amazon SNS notifications to initiate Amazon SNS.
- For SNS topic, enter the Amazon SNS topic ARN to be used.
- For Event type, choose the events for which you want to receive notifications.
- For Notification type, choose to receive notifications for each copy of a command sent to multiple nodes (invocations) or the command summary.
14. In the **Parameters** section, enter the required parameters based on the Command document you chose.

15. Choose **Register Run command task**.

16. After the next time your maintenance window runs, check your email for a message from Amazon SNS and open the email message. Amazon SNS can take a few minutes to send the email message.

**Registering a Run Command task to a maintenance window that returns notifications (CLI)**

Use the following procedure to register a Run Command task that is configured to return status notifications to your maintenance window using the AWS CLI.

**To register a Run Command task with your maintenance window that returns notifications (CLI)**

1. On your local machine, create a file named `RunCommandTask.json`.

2. Paste the following contents into the file.

```json
{
    "Name": "Name",
    "Description": "Description",
    "WindowId": "mw-0c50858d01EXAMPLE",
    "ServiceRoleArn": "arn:aws:iam::account-id:role/MaintenanceWindowIAMRole",
    "MaxConcurrency": "1",
    "MaxErrors": "1",
    "Priority": 3,
    "Targets": [
        {
            "Key": "WindowTargetIds",
            "Values": [
                "e32eeeb2-646c-4f4b-8ed1-205fbEXAMPLE"
            ]
        }
    ]
}
```

**Note**

To better manage your task options, this procedure uses the command option `--cli-input-json`, with option values stored in a JSON file.
3. Replace the example values with information about your own resources.

You can also restore options we've omitted from this example if you want to use them. For example, you can save command output to an S3 bucket.

For more information, see `register-task-with-maintenance-window` in the AWS CLI Command Reference.

4. Save the file.

5. In the directory on your local machine where you saved the file, run the following command.

   ```bash
   aws ssm register-task-with-maintenance-window --cli-input-json file://RunCommandTask.json
   ```

   **Important**
   Be sure to include `file://` before the file name. It's required in this command.

   If successful, the command returns information similar to the following.

   ```json
   {
     "WindowTaskId": "j218d5b5c-mw66-tk4d-r3g9-1d4d1EXAMPLE"
   }
   ```
6. After the next execution of your maintenance window, check your email for a message from Amazon SNS and open the email message. Amazon SNS can take a few minutes to send the email message.

For more information about registering tasks for a maintenance window from the command line, see [Register tasks with the maintenance window](#).
Product and service integrations with Systems Manager

By default, AWS Systems Manager integrates with AWS services and other products and services. The following information can help you configure Systems Manager to integrate with the products and services you use.

- Integration with AWS services
- Integration with other products and services

Integration with AWS services

Through the use of Systems Manager Command documents (SSM documents) and Automation runbooks, you can use AWS Systems Manager to integrate with AWS services. For more information about these resources, see AWS Systems Manager Documents.

Systems Manager is integrated with the following AWS services.

Compute

Amazon Elastic Compute Cloud (Amazon EC2)

Amazon EC2 provides scalable computing capacity in the AWS Cloud. Using Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage.

Systems Manager allows you to perform several tasks on EC2 instances. For example you can launch, configure, manage, maintain, troubleshoot, and securely connect to your EC2 instances. You can also use Systems Manager to deploy software, determine compliance status, and gather inventory from your EC2 instances.
Amazon EC2 Auto Scaling

Auto Scaling helps you ensure that you have the correct number of EC2 instances available to handle the load for your application. You create collections of EC2 instances, called Auto Scaling groups.

Systems Manager allows you to automate common procedures like patching the Amazon Machine Image (AMI) used in your Auto Scaling template for your Auto Scaling group.

Learn more

 Updating AMIs for Auto Scaling groups
### Amazon Elastic Container Service (Amazon ECS)

Amazon ECS is a highly scalable, fast, container management service that allows you to run, stop, and manage Docker containers on a cluster.

Systems Manager allows you to manage container instances remotely and inject sensitive data into your containers by storing your sensitive data in parameters in Parameter Store, a capability of Systems Manager, and then referencing them in your container definition.

**Learn more**

- [Manage container instances remotely using AWS Systems Manager](#)
- [Specifying sensitive data using Systems Manager Parameter Store](#)
**AWS Lambda**

Lambda is a compute service that allows you to run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

Systems Manager allows you to use Lambda functions within Automation runbook content by using the `aws:invokeLambdaFunction` action.

To use parameters from Parameter Store in AWS Lambda functions, you can use the AWS Parameters and Secrets Lambda Extension to retrieve parameter values and cache them for future use.

**Learn more**

- [Update a golden AMI using Automation, AWS Lambda, and Parameter Store](#)
- [Using Parameter Store parameters in AWS Lambda functions](#)

---

**Internet of Things (IoT)**

**AWS IoT Greengrass core devices**

AWS IoT Greengrass is an open source IoT edge runtime and cloud service that helps you build, deploy and manage IoT applications on your devices. Systems Manager offers native support for AWS IoT Greengrass core devices.

**Learn more**

- [Managing edge devices with Systems Manager](#)
AWS IoT core devices

AWS IoT provides the cloud services that connect your IoT devices to other devices and AWS cloud services. AWS IoT provides device software that can help you integrate your IoT devices into AWS IoT-based solutions. If your devices can connect to AWS IoT, AWS IoT can connect them to the cloud services that AWS provides. Systems Manager supports AWS IoT core devices as long as those devices are configured as managed nodes in a hybrid and multicloud environment.

Learn more

Using Systems Manager in hybrid and multicloud environments

### Storage

Amazon Simple Storage Service (Amazon S3)

Amazon S3 is storage for the Internet. It's designed to make web-scale computing easier for developers. Amazon S3 has a simple web services interface that you can use to store and retrieve any amount of data, at any time, from anywhere on the web.

Systems Manager allows you to run remote scripts and SSM documents that are stored in Amazon S3. Distributor, a capability of AWS Systems Manager, uses Amazon S3 to store packages. You can also send output to Amazon S3 for Run Command and Session Manager, capabilities of AWS Systems Manager.
Learn more

- Running scripts from Amazon S3
- Running documents from remote locations
- AWS Systems Manager Distributor
- Logging session data using Amazon S3 (console)

Developer Tools

AWS CodeBuild

**CodeBuild** is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy. CodeBuild eliminates the need to provision, manage, and scale your own build servers.

Parameter Store allows you to store sensitive information for your build specifications and projects.

Learn more

- Build specification reference for CodeBuild
- Create a build project in AWS CodeBuild

AWS CDK

The AWS Cloud Development Kit (AWS CDK) is a framework for defining cloud infrastructure as code, with programming languages, and deploying it through AWS CloudFormation.

Application Manager allows you to view your CDK constructs grouped as applications, view the application structure including the underlying resources, view alerts, investigate
and remediate operational issues, and track costs in the Application Manager console.

**Learn more**

- [Viewing overview information about an application](#)
- [Viewing application resources](#)

## Security, Identity, and Compliance

| AWS Identity and Access Management (IAM) | **IAM** is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources. Systems Manager allows you to control access to services using IAM. **Learn more**
| | - [How AWS Systems Manager works with IAM](#)
| | - [Actions, resources, and condition keys for AWS Systems Manager](#)
| | - [Configure instance permissions required for Systems Manager](#)

<table>

### AWS Security Hub

*Security Hub* gives you a comprehensive view of your high-priority security alerts and compliance status across AWS accounts. Security Hub aggregates, organizes, and prioritizes your security alerts, or findings, from multiple AWS services.

When you turn on integration between Security Hub and Patch Manager, a capability of AWS Systems Manager, Security Hub monitors the patching status of your fleets from a security standpoint. Patch compliance details are automatically exported to Security Hub. This allows you to use a single view to centrally monitor your patch compliance status and to track other security findings. You can receive alerts when nodes in your fleet go out of patch compliance and review patch compliance findings in the Security Hub console.

You can also integrate Security Hub with Explorer and OpsCenter, capabilities of AWS Systems Manager. Integration with Security Hub allows you to receive findings from Security Hub in Explorer and OpsCenter. Security Hub findings provide security information that you can use in Explorer and OpsCenter to aggregate and take action on your security, performance, and operational issues in AWS Systems Manager.

There is a charge to use Security Hub. For more information, see [Security Hub pricing](https://aws.amazon.com/securityhub/pricing/).
Learn more

- Receiving findings from AWS Security Hub in Explorer
- AWS Security Hub
- Integrating Patch Manager with AWS Security Hub

Cryptography and PKI

AWS Key Management Service (AWS KMS)

AWS KMS is a managed service that allows you to create and control customer managed keys, the encryption keys used to encrypt your data.

Systems Manager allows you to use AWS KMS to create SecureString parameters and encrypt Session Manager session data.

Learn more

- How AWS Systems Manager Parameter Store uses AWS KMS
- Turn on KMS key encryption of session data (console)

Management and Governance

AWS CloudFormation

AWS CloudFormation is a service that helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.

Parameter Store is a source for dynamic references. Dynamic references provide a
compact, powerful way for you to specify external values that are stored and managed in other services in your AWS CloudFormation stack templates.

**Learn more**

**Using dynamic references to specify template values**

<table>
<thead>
<tr>
<th>AWS CloudTrail</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CloudTrail</strong> is an AWS service that helps you authorize governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail. Events include actions taken in the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDKs and APIs. Systems Manager integrates with CloudTrail which captures most Systems Manager API calls as events. These include API calls initiated from the Systems Manager console and calls made to the Systems Manager APIs.</td>

</tbody>
</table>
| Amazon CloudWatch Logs | Amazon CloudWatch Logs allows you to centralize the logs from all of your systems, applications, and AWS services that you use. You can then view them, search them for specific error codes or patterns, filter them based on specific fields, or archive them securely for future analysis.

Systems Manager supports sending logs for the SSM Agent, Run Command, and Session Manager to CloudWatch Logs.

**Learn more**

- [Sending node logs to unified CloudWatch Logs (CloudWatch agent)](https://aws.amazon.com)
- [Configuring Amazon CloudWatch Logs for Run Command](https://aws.amazon.com)
- [Logging session data using Amazon CloudWatch Logs (console)](https://aws.amazon.com) |
| Amazon EventBridge | EventBridge delivers a near real-time stream of system events that describes changes in Amazon Web Services resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. EventBridge becomes aware of operational changes as they occur. EventBridge responds to these operational changes and takes corrective action as necessary. These actions include sending messages to respond to the environment, activating functions, and capturing state information.

Systems Manager has multiple events that are supported by EventBridge allowing you to take actions based on the content of those events.

Learn more

Monitoring Systems Manager events with Amazon EventBridge

Note
Amazon EventBridge is the preferred way to manage your events. CloudWatch Events and EventBridge are the same underlying service and API, but EventBridge provides more features. Changes you make in either CloudWatch or EventBridge are reflected in each console. For more information, see the Amazon EventBridge User Guide. |
<table>
<thead>
<tr>
<th>AWS Config</th>
<th><strong>AWS Config</strong> provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured. This allows you to see how the configurations and relationships change over time. Systems Manager is integrated with AWS Config, providing multiple rules that help you gain visibility into your EC2 instances. These rules help you identify which EC2 instances are managed by Systems Manager, operating system configurations, system-level updates, installed applications, network configurations, and more.  <strong>Learn more</strong>  - <a href="#">AWS Config supported resource types</a>  - <a href="#">Recording software configuration for managed instances</a>  - <a href="#">Viewing inventory history and change tracking</a></th>
</tr>

<tbody>
<tr>
<td>AWS Trusted Advisor</td>
<td><strong>Trusted Advisor</strong> is an online tool that provides real-time guidance to help you provision your resources following AWS best practices. Systems Manager hosts Trusted Advisor and you can view Trusted Advisor data in Explorer.  <strong>Learn more</strong>  - <a href="#">AWS Systems Manager Explorer</a>  - <a href="#">Getting started with AWS Trusted Advisor</a></td>
</tr>
</tbody>
</table>
AWS Organizations

Organizations is an account management service that allows you to consolidate multiple AWS accounts into an organization that you create and centrally manage. Organizations includes account management and consolidated billing capabilities that allow you to better meet the budgetary, security, and compliance needs of your business.

Integration between Change Manager, a capability of AWS Systems Manager, with Organizations makes it possible to use a delegated administrator account to manage change requests, change templates, and approvals for your entire organization through this single account.

Organizations integration with Inventory, a capability of AWS Systems Manager, and Explorer allows you to aggregate inventory and operations data (OpsData) from multiple AWS Regions and AWS accounts.

Integration between Quick Setup, a capability of AWS Systems Manager, and Organizations automates common service setup tasks, and deploys service configurations based on best practices across your organizational units (OUs).

Networking and Content Delivery

AWS PrivateLink

AWS PrivateLink allows you to privately connect your virtual private cloud (VPC) to supported AWS services and VPC endpoint services without requiring an internet
gateway, NAT device, VPN connection, or AWS Direct Connect connection.

Systems Manager supports managed nodes connecting to Systems Manager APIs using AWS PrivateLink. This improves the security posture of your managed nodes because AWS PrivateLink restricts all network traffic between your managed nodes, Systems Manager, and Amazon EC2 to the Amazon network. This means that managed nodes aren't required to have access to the internet.

Learn more

Improve the security of EC2 instances by using VPC endpoints for Systems Manager

Analytics

Amazon Athena

Athena is an interactive query service that allows you to analyze data directly in Amazon Simple Storage Service (Amazon S3) using standard SQL. With a few actions in the AWS Management Console, you can point Athena at your data stored in Amazon S3 and begin using standard SQL to run one-time queries and get results in seconds.

Systems Manager Inventory integrates with Athena to help you query inventory data from multiple AWS Regions and AWS accounts. Athena integration uses resource data sync so that you can view inventory data from all managed nodes on the Detailed View page in the Systems Manager Inventory console.
AWS Glue

AWS Glue is a fully managed ETL (extract, transform, and load) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.

Systems Manager uses AWS Glue to crawl the Inventory data in your S3 bucket.

Learn more

Amazon QuickSight

Amazon QuickSight is a business analytics service you can use to build visualizations, perform one-time analysis, and get business insights from your data. It can automatically discover AWS data sources and also works with your data sources.

Systems Manager resource data sync sends inventory data collected from all of your managed nodes to a single S3 bucket. You can use Amazon QuickSight to query and analyze the aggregated data.

Learn more

- Querying inventory data from multiple Regions and accounts
- Walkthrough: Use resource data sync to aggregate inventory data

- Configuring resource data sync for Inventory
- Walkthrough: Use resource data sync to aggregate inventory data
Application Integration

Amazon Simple Notification Service (Amazon SNS)

Amazon SNS is a web service that coordinates and manages the delivery or sending of messages to subscribing endpoints or clients.

Systems Manager generates statuses for multiple services that can be captured by Amazon SNS notifications.

Learn more

- Monitoring Systems Manager status changes using Amazon SNS notifications
- Setting up notifications or trigger actions based on Parameter Store events

AWS Management Console

AWS Resource Groups

Resource Groups organize your AWS resources. Resource groups make it easier to manage, monitor, and automate tasks on large numbers of resources at one time.

Systems Manager resource types like managed nodes, SSM documents, maintenance windows, Parameter Store parameters, and patch baselines can be added to resource groups.

Learn more

What are AWS Resource Groups?

Topics

- Running scripts from Amazon S3
Running scripts from Amazon S3

This section describes how to download and run scripts from Amazon Simple Storage Service (Amazon S3). The following topic includes information and terminology relating to Amazon S3. To learn more about Amazon S3, see What is Amazon S3? You can run different types of scripts, including Ansible Playbooks, Python, Ruby, Shell, and PowerShell.

You can also download a directory that includes multiple scripts. When you run the primary script in the directory, AWS Systems Manager also runs any referenced scripts that are included in the directory.

Note the following important details about running scripts from Amazon S3:

- Systems Manager doesn't verify that your script is capable of running on an node. Before you download and run the script, verify that the required software is installed on the node. Or, you can create a composite document that installs the software by using either Run Command or State Manager, capabilities of AWS Systems Manager, and then downloads and runs the script.

- Verify that your user, role, or group has been granted the AWS Identity and Access Management (IAM) permissions needed to read from the S3 bucket.

- Ensure that the instance profile on your Amazon Elastic Compute Cloud (Amazon EC2) instances has s3:ListBucket and s3:GetObject permissions. If the instance profile doesn't have these permissions, the system fails to download your script from the S3 bucket. For more information, see Using instance profiles in the IAM User Guide.

Run shell scripts from Amazon S3

This following information includes procedures to help you run scripts from Amazon Simple Storage Service (Amazon S3) by using either the AWS Systems Manager console or the AWS Command Line Interface (AWS CLI). Though shell scripts are used in the examples, other types of scripts can be substituted.
Run a shell script from Amazon S3 (console)

Run a shell script from Amazon S3

2. In the navigation pane, choose Run Command.
3. Choose Run command.
5. In Command parameters, do the following:
   - In Source Type, select S3.
   - In the Source Info text box, enter the required information to access the source in the following format. Replace each example resource placeholder with your own information.

   ```json
   {"path":"https://s3.aws-api-domain/path to script"}
   ```

   The following is an example.

   ```json
   ```

   - In the Command Line field, enter parameters for the script execution. Here is an example.

     ```bash
     helloworld.sh argument-1 argument-2
     ```

   - (Optional) In the Working Directory field, enter the name of a directory on the node where you want to download and run the script.
   - (Optional) In Execution Timeout, specify the number of seconds for the system to wait before failing the script command execution.
6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   **Tip**
   If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

7. For **Other parameters:**
   - For **Comment**, enter information about this command.
   - For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:
   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**
   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

   **Note**
   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more
information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the SNS notifications section, if you want notifications sent about the status of the command execution, select the Enable SNS notifications check box.

For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

Run a shell script from Amazon S3 (command line)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command. Replace each example resource placeholder with your own information.

   ```bash
   aws ssm send-command
   --document-name "AWS-RunRemoteScript"
   --output-s3-bucket-name "bucket-name"
   --output-s3-key-prefix "key-prefix"
   --targets "Key=InstanceIds,Values=instance-id"
   --parameters "{"sourceType":["S3"],"sourceInfo":{"path":":https://s3.aws-api-domain/script path"},"commandLine":["script name and arguments"]}""
   ```

   **Note**
   Replace https://s3.aws-api-domain with the URL for your bucket. You can copy your bucket URL in Amazon S3 on the Objects tab.

   **Linux & macOS**

   ```bash
   aws ssm send-command
   --document-name "AWS-RunRemoteScript"
   --output-s3-bucket-name "bucket-name"
   --output-s3-key-prefix "key-prefix"
   --targets "Key=InstanceIds,Values=instance-id"
   --parameters "{"sourceType":["S3"],"sourceInfo":{"path":":https://s3.aws-api-domain/script path"},"commandLine":["script name and arguments"]}""
Referencing AWS Secrets Manager secrets from Parameter Store parameters

AWS Secrets Manager helps you organize and manage important configuration data such as credentials, passwords, and license keys. Parameter Store, a capability of AWS Systems Manager, is integrated with Secrets Manager so that you can retrieve Secrets Manager secrets when using other AWS services that already support references to Parameter Store parameters. These services include Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic Container Service (Amazon ECS), AWS Lambda, AWS CloudFormation, AWS CodeBuild, AWS CodeDeploy, and other Systems Manager capabilities. By using Parameter Store to reference Secrets Manager secrets, you create a consistent and secure process for calling and using secrets and reference data in your code and configuration scripts.

For more information about Secrets Manager, see What Is AWS Secrets Manager? in the AWS Secrets Manager User Guide.
Restrictions

Note the following restrictions when using Parameter Store to reference Secrets Manager secrets:

- You can only retrieve Secrets Manager secrets by using the GetParameter and GetParameters API operations. Modification operations and advance querying API operations, such as DescribeParameters and GetParametersByPath, aren't supported for Secrets Manager.
- You can use the AWS Command Line Interface (AWS CLI), AWS Tools for Windows PowerShell, and the SDKs to retrieve a secret by using Parameter Store.
- When you retrieve a Secrets Manager secret from Parameter Store, the name must begin with the following reserved path: /aws/reference/secretsmanager/secret-_ID.
  
  Here is an example: /aws/reference/secretsmanager/CFCreds1
- Parameter Store honors AWS Identity and Access Management (IAM) policies attached to Secrets Manager secrets. For example, if User 1 doesn't have access to Secret A, then User 1 can't retrieve Secret A by using Parameter Store.
- Parameters that reference Secrets Manager secrets can't use the Parameter Store versioning or history features.
- Parameter Store honors Secrets Manager version stages. If you reference a version stage, it uses letters, numbers, a period (.), a hyphen (-), or an underscore (_). All other symbols specified in the version stage cause the reference to fail.

How to reference a Secrets Manager secret by using Parameter Store

The following procedure describes how to reference a Secrets Manager secret by using Parameter Store APIs. The procedure references other procedures in the AWS Secrets Manager User Guide.

⚠️ Note

Before you begin, verify that you have permission to reference Secrets Manager secrets in Parameter Store parameters. If you have administrator permissions in Secrets Manager and Systems Manager, then you can reference or retrieve secrets by using Parameter Store APIs. If you reference a Secrets Manager secret in a Parameter Store parameter, and you don't have permission to access that secret, then the reference fails. For more information, see Authentication and access control for AWS Secrets Manager in the AWS Secrets Manager User Guide.
Important

Parameter Store functions as a pass-through service for references to Secrets Manager secrets. Parameter Store doesn't retain data or metadata about secrets. The reference is stateless.

To reference a Secrets Manager secret by using Parameter Store

1. Create a secret in Secrets Manager. For more information, see Create and manage secrets with AWS Secrets Manager.

2. Reference a secret by using the AWS CLI, AWS Tools for Windows PowerShell, or the SDK. When you reference a Secrets Manager secret, the name must begin with the following reserved path: /aws/reference/secretsmanager/. By specifying this path, Systems Manager knows to retrieve the secret from Secrets Manager instead of Parameter Store. Here are some example names that correctly reference the Secrets Manager secrets, CFCreds1 and DBPass, using Parameter Store.

- /aws/reference/secretsmanager/CFCreds1
- /aws/reference/secretsmanager/DBPass

Here is a Java code example that references an access key and a secret key that are stored in Secrets Manager. This code example sets up an Amazon DynamoDB client. The code retrieves configuration data and credentials from Parameter Store. The configuration data is stored as a string parameter in Parameter Store and the credentials are stored in Secrets Manager. Even though the configuration data and credentials are stored in separate services, both sets of data can be accessed from Parameter Store by using the GetParameter API.

```java
/**
 * Initialize Systems Manager client with default credentials
 */
AWSSimpleSystemsManagement ssm =
    AWSSimpleSystemsManagementClientBuilder.defaultClient();
...

/**
 * Example method to launch DynamoDB client with credentials different from default
```
//Getting AWS credentials from Secrets Manager using GetParameter
BasicAWSCredentials differentAWSCreds = new BasicAWSCredentials(
    getParameter("/aws/reference/secretsmanager/access-key"),
    getParameter("/aws/reference/secretsmanager/secret-key"));

//Initialize the DynamoDB client with different credentials
final AmazonDynamoDB client = AmazonDynamoDBClient.builder()
    .withCredentials(new AWSStaticCredentialsProvider(differentAWSCreds))
    .withRegion(getParameter("region")) //Getting configuration from Parameter Store
    .build();
return client;

/**
* Helper method to retrieve parameter value
* @param parameterName identifier of the parameter
* @return decrypted parameter value
*/
public GetParameterResult getParameter(String parameterName) {
    GetParameterRequest request = new GetParameterRequest();
    request.setName(parameterName);
    request.setWithDecryption(true);
    return ssm.newGetParameterCall().call(request).getParameter().getValue();
}

Here are some AWS CLI examples. Use the `aws secretsmanager list-secrets` command to find the names of your secrets.

**AWS CLI Example 1: Reference by using the name of the secret**

**Linux & macOS**

```
aws ssm get-parameter \
  --name /aws/reference/secretsmanager/s1-secret \
  --with-decryption
```
The command returns information like the following.

```json
{
    "Parameter": {
        "Name": "/aws/reference/secretsmanager/s1-secret",
        "Type": "SecureString",
        "Value": "Fl*MEishm!al875",
        "Version": 0,
        "SourceResult": {
            "CreatedDate": 1526334434.743,
            "Name": "s1-secret",
            "VersionId": "aaabbbccc-1111-222-333-123456789",
            "SecretString": "Fl*MEishm!al875",
            "VersionStages": ["AWSCURRENT"],
            "ARN": "arn:aws:secretsmanager:us-east-2:123456789012:secret:s1-secret-E18LRP"
        }
    }
}
```

**AWS CLI Example 2: Reference that includes the version ID**

**Linux & macOS**

```bash
aws ssm get-parameter
  --name /aws/reference/secretsmanager/s1-secret:11111-aaa-bbb-ccc-123456789
  --with-decryption
```
Windows

```
aws ssm get-parameter ^
  --name /aws/reference/secretsmanager/s1-secret:11111-aaa-bbb-ccc-123456789 ^
  --with-decryption
```

The command returns information like the following.

```
{
  "Parameter": {
    "Name": "/aws/reference/secretsmanager/s1-secret",
    "Type": "SecureString",
    "Value": "Fl*MEishm!al875",
    "Version": 0,
    "SourceResult": {
      "CreatedDate": 1526334434.743,
      "Name": "s1-secret",
      "VersionId": "11111-aaa-bbb-ccc-123456789",
      "SecretString": "Fl*MEishm!al875",
      "VersionStages": ["AWSCURRENT"],
      "ARN": "arn:aws:secretsmanager:us-east-2:123456789012:secret:s1-secret-E18LRP"
    }
    "Selector": ":11111-aaa-bbb-ccc-123456789"
  }
  "LastModifiedDate": 2018-05-14T21:47:14.743Z,
}
```

**AWS CLI Example 3: Reference that includes the version stage**

Linux & macOS

```
aws ssm get-parameter \
  --name /aws/reference/secretsmanager/s1-secret:AWSCURRENT \
  --with-decryption
```
Using Parameter Store parameters in AWS Lambda functions

Parameter Store, a capability of AWS Systems Manager, provides secure, hierarchical storage for configuration data management and secrets management. You can store data such as passwords, database strings, Amazon Machine Image (AMI) IDs, and license codes as parameter values.

To use parameters from Parameter Store in AWS Lambda functions without using an SDK, you can use the AWS Parameters and Secrets Lambda Extension. This extension retrieves parameter values
and caches them for future use. Using the Lambda extension can reduce your costs by reducing the number of API calls to Parameter Store. Using the extension can also improve latency because retrieving a cached parameter is faster than retrieving it from Parameter Store.

A Lambda extension is a companion process that augments the capabilities of a Lambda function. An extension is like a client that runs in parallel to a Lambda invocation. This parallel client can interface with your function at any point during its lifecycle. For more information about Lambda extensions, see Lambda Extensions API in the AWS Lambda Developer Guide.

The AWS Parameters and Secrets Lambda Extension works for both Parameter Store and AWS Secrets Manager. To learn how to use the Lambda extension with secrets from Secrets Manager, see Use AWS Secrets Manager secrets in AWS Lambda functions in the AWS Secrets Manager User Guide.

Related info

Using the AWS Parameter and Secrets Lambda extension to cache parameters and secrets (AWS Compute Blog)

How the extension works

To use parameters in a Lambda function without the Lambda extension, you must configure your Lambda function to receive configuration updates by integrating with the GetParameter API action for Parameter Store.

When you use the AWS Parameters and Secrets Lambda Extension, the extension retrieves the parameter value from Parameter Store and stores it in the local cache. Then, the cached value is used for further invocations until it expires. Cached values expire after they pass their time-to-live (TTL). You can configure the TTL value using the SSM_PARAMETER_STORE_TTL environment variable, as explained later in this topic.

If the configured cache TTL has not expired, the cached parameter value is used. If the time has expired, the cached value is invalidated and the parameter value is retrieved from Parameter Store.

Also, the system detects parameter values that are used frequently and maintains them in the cache while clearing those that are expired or unused.

Implementation details

Use the following details to help you configure the AWS Parameters and Secrets Lambda Extension.
Authentication

To authorize and authenticate Parameter Store requests, the extension uses the same credentials as those used to run the Lambda function itself. Therefore, the AWS Identity and Access Management (IAM) role used to run the function must have the following permissions to interact with Parameter Store:

- **ssm:GetParameter** – Required to retrieve parameters from Parameter Store
- **kms:Decrypt** – Required if you are retrieving SecureString parameters from Parameter Store

For more information, see [AWS Lambda execution role](https://docs.aws.amazon.com/lambda/latest/dg/configuration-role.html) in the *AWS Lambda Developer Guide*.

Instantiation

Lambda instantiates separate instances corresponding to the concurrency level that your function requires. Each instance is isolated and maintains its own local cache of your configuration data. For more information about Lambda instances and concurrency, see [Configuring reserved concurrency](https://docs.aws.amazon.com/lambda/latest/dg/configuration-concurrency.html) in the *AWS Lambda Developer Guide*.

No SDK dependence

The AWS Parameters and Secrets Lambda Extension works independently of any AWS SDK language library. An AWS SDK is not required to make GET requests to Parameter Store.

Localhost port

Use `localhost` in your GET requests. The extension makes requests to localhost port 2773. You do not need to specify an external or internal endpoint to use the extension. You can configure the port by setting the environment variable `PARAMETERS_SECRETS_EXTENSION_HTTP_PORT`.

For example, in Python, your GET URL might look something like the following example.

```python
parameter_url = ('http://localhost:' + port + '/systemsmanager/parameters/get/?name=' + ssm_parameter_path)
```

Changes to a parameter value before TTL expires

The extension doesn't detect changes to the parameter value and doesn't perform an auto-refresh before the TTL expires. If you change a parameter value, operations that use the cached
parameter value might fail until the cache is next refreshed. If you expect frequent changes to a parameter value, we recommend setting a shorter TTL value.

Header requirement

To retrieve parameters from the extension cache, the header of your GET request must include an X-Aws-Parameters-Secrets-Token reference. Set the token to AWS_SESSION_TOKEN, which is provided by Lambda for all running functions. Using this header indicates that the caller is within the Lambda environment.

Example

The following example in Python demonstrates a basic request to retrieve the value of a cached parameter.

```python
import urllib.request
import os
import json

aws_session_token = os.environ.get('AWS_SESSION_TOKEN')

def lambda_handler(event, context):
    # Retrieve /my/parameter from Parameter Store using extension cache
    req = urllib.request.Request('http://localhost:2773/systemsmanager/parameters/get?name=%2Fmy%2Fparameter')
    req.add_header('X-Aws-Parameters-Secrets-Token', aws_session_token)
    config = urllib.request.urlopen(req).read()

    return json.loads(config)
```

ARM support

The extension doesn't support the ARM architecture in all the same AWS Regions where the x86_64 and x86 architectures are supported.

For complete lists of extension ARNs, see [AWS Parameters and Secrets Lambda Extension ARNs](#).

Logging

Lambda logs execution information about the extension along with the function by using Amazon CloudWatch Logs. By default, the extension logs a minimal amount of information to CloudWatch. To log more details, set the environment variable PARAMETERS_SECRETS_EXTENSION_LOG_LEVEL to DEBUG.
Adding the extension to a Lambda function

To use the AWS Parameters and Secrets Lambda Extension, you add the extension to your Lambda function as a layer.

Use one of the following methods to add the extension to your function.

AWS Management Console (Add layer option)

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose your function. In the Layers area, choose Add a layer.
3. In the Choose a layer area, choose the AWS layers option.
4. For AWS layers, choose AWS-Parameters-and-Secrets-Lambda-Extension, choose a version, and then choose Add.

AWS Management Console (Specify ARN option)

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose your function. In the Layers area, choose Add a layer.
3. In the Choose a layer area, choose the Specify an ARN option.
4. For Specify an ARN, enter the extension ARN for your AWS Region and architecture, and then choose Add.

AWS Command Line Interface

Run the following command in the AWS CLI. Replace each example resource placeholder with your own information.

```
aws lambda update-function-configuration \
  --function-name function-name \n  --layers layer-ARN
```

Sample commands for using the AWS Systems Manager Parameter Store and AWS Secrets Manager Extension

The examples in this section demonstrate API actions for use with the AWS Systems Manager Parameter Store and AWS Secrets Manager extension.

**Sample commands for Parameter Store**

The Lambda extension uses read-only access to the `GetParameter` API action.

To call this action, make an HTTP GET call similar to the following.
GET http://localhost:port/systemsmanager/parameters/get?name=parameter-path&version=version&label=label&withDecryption={true|false}

In this example, `parameter-path` represents the full parameter name. `version` and `label` are the selectors available for use with the GetParameter action. This command format provides access to parameters in the standard parameter tier.

**Note**

When using GET calls, parameter values must be encoded for HTTP to preserve special characters. For example, instead of formatting a hierarchical path like `/a/b/c`, encode characters that could be interpreted as part of the URL, such as `%2Fa%2Fb%2Fc`.

GET http://localhost:port/systemsmanager/parameters/get/?name=MyParameter&version=5

To call a parameter in a hierarchy, make an HTTP GET call similar to the following.

To call a public (global) parameter, make an HTTP GET call similar to the following.

GET http://localhost:port/systemsmanager/parameters/get/?name=%2Faws%2Fservice%20list%2F...

To make an HTTP GET call to a Secrets Manager secret by using Parameter Store references, make an HTTP GET call similar to the following.

To make a call using the Amazon Resource Name (ARN) for a parameter, make an HTTP GET call similar to the following.

To make a call that accesses a SecureString parameter with decryption, make an HTTP GET call similar to the following.

```
GET http://localhost:port/systemsmanager/parameters/get?
name=MyParameter&withDecryption=true
```

You can specify that parameters aren't decrypted by omitting `withDecryption` or explicitly setting it to `false`. You can also specify either a version or a label, but not both. If you do, only the first of these that is placed after question mark (?) in the URL is used.

**AWS Parameters and Secrets Lambda Extension ARNs**

- [Running scripts from GitHub](#)

### Jenkins

Jenkins is an open-source automation server that allows developers to reliably build, test, and deploy their software.

Automation, a capability of Systems Manager, can be used as a post-build step to pre-install application releases into Amazon Machine Images (AMIs).

**Learn more**

[Updating AMIs using Automation and Jenkins](#)
| ServiceNow | ServiceNow is an enterprise service management system that allows you to manage your IT services and operations. Automation, Change Manager, Incident Manager, and OpsCenter, all capabilities of Systems Manager, integrate with ServiceNow by using the AWS Service Management Connector. With this integration, you can view, create, update, add correspondence, and resolve AWS Support cases from ServiceNow. | Learn more |

**Topics**

- Running scripts from GitHub
- Using Chef InSpec profiles with Systems Manager Compliance
- Integrating with ServiceNow

### Running scripts from GitHub

This topic describes how to use the pre-defined Systems Manager document (SSM document) `AWS-RunRemoteScript` to download scripts from GitHub, including Ansible Playbooks, Python, Ruby, and PowerShell scripts. By using this SSM document, you no longer need to manually port scripts into Amazon Elastic Compute Cloud (Amazon EC2) or wrap them in SSM documents. AWS Systems Manager integration with GitHub promotes *infrastructure as code*, which reduces the time it takes to manage nodes while standardizing configurations across your fleet.

You can also create custom SSM documents that allow you to download and run scripts or other SSM documents from remote locations. For more information, see [Creating composite documents](#).

You can also download a directory that includes multiple scripts. When you run the primary script in the directory, Systems Manager also runs any referenced scripts that are included in the directory.
Note the following important details about running scripts from GitHub.

- Systems Manager doesn't verify that your script is capable of running on a node. Before you download and run the script, verify that the required software is installed on the node. Or, you can create a composite document that installs the software by using either Run Command or State Manager, capabilities of AWS Systems Manager, and then downloads and runs the script.

- You're responsible for ensuring that all GitHub requirements are met. This includes refreshing your access token, as needed. Ensure that you don't surpass the number of authenticated or unauthenticated requests. For more information, see the GitHub documentation.

- GitHub Enterprise repositories are not supported.

Topics

- Run Ansible Playbooks from GitHub
- Run Python scripts from GitHub

Run Ansible Playbooks from GitHub

This section includes procedures to help you run Ansible Playbooks from GitHub by using either the console or the AWS Command Line Interface (AWS CLI).

Before you begin

If you plan to run a script stored in a private GitHub repository, create an AWS Systems Manager SecureString parameter for your GitHub security access token. You can't access a script in a private GitHub repository by manually passing your token over SSH. The access token must be passed as a Systems Manager SecureString parameter. For more information about creating a SecureString parameter, see Creating Systems Manager parameters.

Run an Ansible Playbook from GitHub (console)

Run an Ansible Playbook from GitHub

2. In the navigation pane, choose Run Command.
3. Choose Run command.
5. In **Command parameters**, do the following:

- In **Source Type**, select **GitHub**.
- In the **Source Info** box, enter the required information to access the source in the following format.

```json
{
   "owner": "owner_name",
   "repository": "repository_name",
   "getOptions": "branch:branch_name",
   "path": "path_to_scripts_or_directory",
   "tokenInfo": "{{ssm-secure:SecureString_parameter_name}}"
}
```

This example downloads a file named `webserver.yml`.

```json
{
   "owner": "TestUser1",
   "repository": "GitHubPrivateTest",
   "getOptions": "branch:myBranch",
   "path": "scripts/webserver.yml",
   "tokenInfo": "{{ssm-secure:mySecureStringParameter}}"
}
```

**Note**

"branch" is required only if your SSM document is stored in a branch other than master.

To use the version of your scripts that are in a particular commit in your repository, use `commitID` with `getOptions` instead of `branch`. For example:

```
"getOptions": "commitID:bbc1ddb94...b76d3bEXAMPLE"
```

- In the **Command Line** field, enter parameters for the script execution. Here is an example.

  `ansible-playbook -i "localhost," --check -c local webserver.yml`

- (Optional) In the **Working Directory** field, enter the name of a directory on the node where you want to download and run the script.

- (Optional) In **Execution Timeout**, specify the number of seconds for the system to wait before failing the script command execution.
6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   **Tip**
   If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

7. For **Other parameters**:
   - For **Comment**, enter information about this command.
   - For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:
   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**
   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

   **Note**
   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more
In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

    For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

11. Choose **Run**.

### Run an Ansible Playbook from GitHub by using the AWS CLI

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven’t already.

    For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to download and run a script from GitHub.

    ```bash
    aws ssm send-command \
        --document-name "AWS-RunRemoteScript" \
        --instance-ids "instance-IDs"\n        --parameters '{"sourceType":"GitHub","sourceInfo":{"owner":"owner_name","repository":"repository_name","path":"path_to_file_or_directory","tokenInfo":"{{ssm-secure:name_of_your_SecureString_parameter}}" },"commandLine": ["commands_to_run"]}'
    ```

    Here is an example command to run on a local Linux machine.

    ```bash
    aws ssm send-command \
        --document-name "AWS-RunRemoteScript" \
        --instance-ids "i-02573cafceEXAMPLE" \
        --parameters '{"sourceType":"GitHub","sourceInfo":{"owner":"TestUser1","repository":"GitHubPrivateTest","path":"scripts/webserver.yml","tokenInfo":"{{ssm-secure:mySecureStringParameter}}" },"commandLine": ["ansible-playbook -i "localhost," --check -c local webserver.yml"]}'
    ```
Run Python scripts from GitHub

This section includes procedures to help you run Python scripts from GitHub by using either the AWS Systems Manager console or the AWS Command Line Interface (AWS CLI).

Run a Python script from GitHub (console)

Run a Python script from GitHub

2. In the navigation pane, choose Run Command.
3. Choose Run command.
5. For Command parameters, do the following:

   - In Source Type, select GitHub.
   - In the Source Info box, enter the required information to access the source in the following format:

   ```json
   {
       "owner": "owner_name",
       "repository": "repository_name",
       "getOptions": "branch:branch_name",
       "path": "path_to_document",
       "tokenInfo": "{{ssm-secure:SecureString_parameter_name}}"
   }
   
   The following example downloads a directory of scripts named complex-script.

   ```json
   {
       "owner": "TestUser1",
       "repository": "SSMTestDocsRepo",
       "getOptions": "branch:myBranch",
       "path": "scripts/python/complex-script",
       "tokenInfo": "{{ssm-secure:myAccessTokenParam}}"
   }
   ```
Note
"branch" is required only if your scripts are stored in a branch other than master. To use the version of your scripts that are in a particular commit in your repository, use commitID with getOptions instead of branch. For example: "getOptions": "commitID: bbc1ddb94...b76d3bEXAMPLE",

- For **Command Line**, enter parameters for the script execution. Here is an example.

```
mainFile.py argument-1 argument-2
```

This example runs `mainFile.py`, which can then run other scripts in the complex-script directory.

- (Optional) For **Working Directory**, enter the name of a directory on the node where you want to download and run the script.

- (Optional) For **Execution Timeout**, specify the number of seconds for the system to wait before failing the script command execution.

6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

Tip
If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

7. For **Other parameters**:

- For **Comment**, enter information about this command.

- For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

8. For **Rate control**:

- For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.
### Note
If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

#### Note
The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

    For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

11. Choose **Run**.

---

### Run a Python script from GitHub by using the AWS CLI

1. Install and configure the **AWS Command Line Interface (AWS CLI)**, if you haven't already.
For information, see Installing or updating the latest version of the AWS CLI.

2. Run the following command to download and run a script from GitHub.

```bash/aws ssm send-command --document-name "AWS-RunRemoteScript" --instance-ids "instance-IDs" --parameters '{"sourceType": "GitHub","sourceInfo": [{"owner": "owner_name", "repository": "repository_name", "path": "path_to_script_or_directory"}], "commandLine": ["commands_to_run"]}'
```

Here is an example.

```bash/aws ssm send-command --document-name "AWS-RunRemoteScript" --instance-ids "i-02573cafcfEXAMPLE" --parameters '{"sourceType": "GitHub","sourceInfo": [{"owner": "TestUser1", "repository": "GitHubTestPublic", "path": "scripts/python/complex-script"}], "commandLine": ["mainFile.py argument-1 argument-2"]}'
```

This example downloads a directory of scripts called complex-script. The commandLine entry runs mainFile.py, which can then run other scripts in the complex-script directory.

### Using Chef InSpec profiles with Systems Manager Compliance

AWS Systems Manager integrates with Chef InSpec. Chef InSpec is an open-source testing framework that allows you to create human-readable profiles to store in GitHub or Amazon Simple Storage Service (Amazon S3). Then you can use Systems Manager to run compliance scans and view compliant and noncompliant nodes. A profile is a security, compliance, or policy requirement for your computing environment. For example, you can create profiles that perform the following checks when you scan your nodes with Compliance, a capability of AWS Systems Manager:

- Check if specific ports are open or closed.
- Check if specific applications are running.
- Check if certain packages are installed.
- Check Windows Registry keys for specific properties.

You can create InSpec profiles for Amazon Elastic Compute Cloud (Amazon EC2) instances and on-premises servers or virtual machines (VMs) that you manage with Systems Manager. The following sample Chef InSpec profile checks if port 22 is open.
control 'Scan Port' do
  impact 10.0
  title 'Server: Configure the service port'
  desc 'Always specify which port the SSH server should listen to. Prevent unexpected settings.'
  describe sshd_config do
    its('Port') { should eq('22') }
  end
end

InSpec includes a collection of resources that help you quickly write checks and auditing controls. InSpec uses the InSpec Domain-specific Language (DSL) for writing these controls in Ruby. You can also use profiles created by a large community of InSpec users. For example, the DevSec chef-os-hardening project on GitHub includes dozens of profiles to help you secure your nodes. You can author and store profiles in GitHub or Amazon S3.

**How it works**

Here is how the process of using InSpec profiles with Compliance works:

1. Either identify predefined InSpec profiles that you want to use, or create your own. You can use predefined profiles on GitHub to get started. For information about how to create your own InSpec profiles, see [ChefChef InSpec Profiles](#).
2. Store profiles in either a public or private GitHub repository, or in an S3 bucket.
3. Run Compliance with your InSpec profiles by using the Systems Manager document (SSM document) AWS-RunInspecChecks. You can begin a Compliance scan by using Run Command, a capability of AWS Systems Manager, for on-demand scans, or you can schedule regular Compliance scans by using State Manager, a capability of AWS Systems Manager.
4. Identify noncompliant nodes by using the Compliance API or the Compliance console.

**Note**

Note the following information.

- Chef uses a client on your nodes to process the profile. You don't need to install the client. When Systems Manager runs the SSM document AWS-RunInspecChecks, the system checks if the client is installed. If not, Systems Manager installs the Chef client during the scan, and then uninstalls the client after the scan is completed.
Running the SSM document AWS-RunInspecChecks, as described in this topic, assigns a compliance entry of type Custom:Inspec to each targeted node. To assign this compliance type, the document calls the `PutComplianceItems` API operation.

### Running an InSpec compliance scan

This section includes information about how to run an InSpec compliance scan by using the Systems Manager console and the AWS Command Line Interface (AWS CLI). The console procedure shows how to configure State Manager to run the scan. The AWS CLI procedure shows how to configure Run Command to run the scan.

### Running an InSpec compliance scan with State Manager (console)

To run an InSpec compliance scan with State Manager by using the AWS Systems Manager console

2. In the navigation pane, choose State Manager.
3. Choose Create association.
4. In the Provide association details section, enter a name.
5. In the Document list, choose AWS-RunInspecChecks.
6. In the Document version list, choose Latest at runtime.
7. In the Parameters section, in the Source Type list, choose either GitHub or S3.

If you choose GitHub, then enter the path to an InSpec profile in either a public or private GitHub repository in the Source Info field. Here is an example path to a public profile provided by the Systems Manager team from the following location: [https://github.com/awslabs/amazon-ssm/tree/master/Compliance/InSpec/PortCheck](https://github.com/awslabs/amazon-ssm/tree/master/Compliance/InSpec/PortCheck).

```json
{"owner":"awslabs","repository":"amazon-ssm","path":"Compliance/InSpec/PortCheck","getOptions":"branch:master"}
```

If you choose S3, then enter a valid URL to an InSpec profile in an S3 bucket in the Source Info field.
For more information about how Systems Manager integrates with GitHub and Amazon S3, see Running scripts from GitHub.

8. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   **Tip**
   If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

9. In the **Specify schedule** section, use the schedule builder options to create a schedule that specifies when you want the Compliance scan to run.

10. For **Rate control**:

    - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

   **Note**
   If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

    - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

11. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

   **Note**
   The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more
information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

12. Choose Create Association. The system creates the association and automatically runs the Compliance scan.

13. Wait several minutes for the scan to complete, and then choose Compliance in the navigation pane.

14. In Corresponding managed instances, locate nodes where the Compliance Type column is Custom:Inspec.

15. Choose a node ID to view the details of noncompliant statuses.

Running an InSpec compliance scan with Run Command (AWS CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

   For information, see Installing or updating the latest version of the AWS CLI.

2. Run one of the following commands to run an InSpec profile from either GitHub or Amazon S3.

   The command takes the following parameters:

   - **sourceType**: GitHub or Amazon S3
   - **sourceInfo**: URL to the InSpec profile folder either in GitHub or an S3 bucket. The folder must contain the base InSpec file (*.yml) and all related controls (*.rb).

   **GitHub**

   ```bash
   aws ssm send-command --document-name "AWS-RunInspecChecks" --targets '[["Key":"tag:tag_name","Values":["tag_value"]]]' --parameters '{"sourceType": ["GitHub"], "sourceInfo": ["\"owner\":\"owner_name\", \"repository\": \"repository_name\", \"path\": \"Inspec.yml_file\"]}'
   
   Here is an example.
   ```
Integrating with ServiceNow

ServiceNow provides a cloud-based service management system to create and manage organization-level workflows, such as for IT services, ticketing systems, and support. The AWS Service Management Connector integrates ServiceNow with Systems Manager to provision, manage, and operate AWS resources from ServiceNow. You can use the AWS Service Management Connector to integrate ServiceNow with Automation, Change Manager, Incident Manager, and OpsCenter, all capabilities of AWS Systems Manager.
You can perform the following tasks using ServiceNow:

- Run automation playbooks from Systems Manager.
- View, update, and resolve incidents from Systems Manager OpsItems.
- View and manage operational items, such as incidents, through Systems Manager OpsCenter.
- View and run Systems Manager change requests from a curated list of pre-approved change templates.
- Manage and resolve incidents involving AWS hosted applications by integrating with Incident Manager.

**Note**

For information about how to integrate with ServiceNow, see Configuring AWS service integrations in the AWS Service Management Connector Administrator Guide.
Tagging Systems Manager resources

A tag is a label that you assign to an AWS resource. Each tag consists of a key and a value, both of which you define.

Tags allow you to categorize your AWS resources in different ways, such as by purpose, owner, or environment. For example, if you want to organize and manage your resources according to whether they’re used for development or production, you might tag some of them with the key Environment and the value Production. You can then perform various types of queries for resources tagged "Key=Environment,Values=Production". For example, you could define a set of tags for your account's managed nodes that help you track or target nodes by operating system and environment, such as your SUSE Linux Enterprise Server grouped as development, staging, and production. You can also perform operations on resources by specifying this key-value pair in your commands, such as running an update script on all nodes in the group or reviewing the status of those nodes.

You can use the tags applied to your AWS Systems Manager resources in various operations. For example, you can target only managed nodes that are tagged with a specified tag key-value pair when you run a command or assign targets to a maintenance window. You can also restrict access to your resources based on the tags applied to them.

Going further, you can create resource groups by specifying the same tags for AWS resources of various types, not only the same type. After that, you can use Resource Groups to view information about which resources in a group are compliant and working correctly and which resources require action. The information you view pertains to all types of AWS resources that can be added to a resource group, not only supported Systems Manager resource types. For more information, see What are AWS Resource Groups? in the AWS Resource Groups User Guide.

The remainder of this chapter describes how to add and remove tags from Systems Manager resources.

Topics

- Systems Manager resources you can tag
- Tagging Systems Manager associations
- Tagging automations
- Tagging Systems Manager documents
- Tagging maintenance windows
• Tagging managed nodes
• Tagging OpsItems
• Tagging Systems Manager parameters
• Tagging patch baselines

Systems Manager resources you can tag

You can apply tags to the following AWS Systems Manager resources:

• Associations
• Automations
• Documents
• Maintenance windows
• Managed nodes
• OpsItems
• OpsMetadata
• Parameters
• Patch baselines

You can add each of these types, except OpsItems and OpsMetadata, to a resource group.

Depending on the resource type, you can use tags to identify which resources should be included in an operation. For example, you can tag a group of managed nodes and then run a maintenance window task that targets only nodes with that key-value pair.

You can also restrict user access to these resource types by creating AWS Identity and Access Management (IAM) policies that specify the tags that a user can access and attaching the policy to IAM entities (users, roles, or groups). The following are several examples of restricting resource access using tags.

• You can apply a tag to a set of custom Systems Manager documents (SSM documents) and then create and apply an IAM policy that grants access to documents with that tag but no others (or that prohibits access to only those documents).
• You can assign tags to OpsItems and then create IAM policies that limit which users or groups have access to view or update those resources. For example, organization directors could be
granted full access to all OpsItems, but software developers and support engineers could be
granted access only to the projects or client segments they're responsible for.

- You can apply a common tag to resources of all six supported types and create an IAM policy
  that grants access to only those resources, such as Key=Project, Value=ProjectA or
  Key=Environment, Value=Development. You can even grant access to only resources to
  which both tag pairs have been assigned. This makes it possible, for example, to restrict users to
  working only with resources for ProjectA in the Development environment.

You can use the Systems Manager Resource Groups console, the console for the supported resource
types (for example, the Maintenance Windows console or OpsCenter console), the AWS Command
Line Interface (AWS CLI), and the AWS Tools for PowerShell. You can add tags when you create or
update a resource. For example, you can use the AWS CLI add-tags-to-resource command to add
tags to any of the supported Systems Manager resource types after they have been created. You
can use the remove-tags-from-resource command to remove them.

Tagging Systems Manager associations

The topics in this section describe how to work with tags on State Manager associations. State
Manager is a component of AWS Systems Manager.

Topics
- Creating associations with tags
- Adding tags to an existing association
- Removing tags from an association

Creating associations with tags

You can add tags to a State Manager association when you create it by using the AWS CLI. Adding
tags to an association when you create it by using the Systems Manager console isn't supported.
For information, see Create an association (command line).

Adding tags to an existing association

Use the following procedures add tags to an existing State Manager association by using the
command line.

Topics
Adding tags to an existing association (AWS CLI)

1. Using the AWS CLI, run the following command to list associations that you can tag.

   ```bash
   aws ssm list-associations
   ```

   Note the name of an association that you want to tag.

2. Run the following command to tag an association. Replace each example resource placeholder with your own information.

   ```bash
   aws ssm add-tags-to-resource \
   --resource-type "Association" \
   --resource-id "association-ID" \
   --tags "Key=tag-key,Value=tag-value"
   ```

   If successful, the command has no output.

3. Run the following command to verify the association tags.

   ```bash
   aws ssm list-tags-for-resource --resource-type "Association" --resource-id "association-ID"
   ```

Adding tags to an existing association (AWS Tools for PowerShell)

1. Run the following command to list associations that you can tag.

   ```powershell
   Get-SSMAssociationList
   ```

2. Run the following commands to tag a parameter. Replace each example resource placeholder with your own information.

   ```powershell
   $tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
   $tag.Key = "tag-key"
   ```
$tag.Value = "tag-value"

Add-SSMResourceTag ' -ResourceType "Association" ' -ResourceId "association-ID" ' -Tag $tag ' -Force

3. Run the following command to verify the association tags.

Get-SSMResourceTag ' -ResourceType "Association" ' -ResourceId "association-ID"

Removing tags from an association

You can use the command line to remove tags from a State Manager association.

Removing tags from an association (command line)

1. Using your preferred command line tool, run the following command to list the associations in your account.

   Linux & macOS
   
   `aws ssm list-associations`

   Windows
   
   `aws ssm list-associations`

   PowerShell
   
   `Get-SSMAssociationList`

   Note the name of the association from which you want to remove tags.
2. Run the following command to remove tags from an association. Replace each example resource placeholder with your own information.

**Linux & macOS**

```bash
aws ssm remove-tags-from-resource \
--resource-type "Association" \
--resource-id "association-ID" \
--tag-key "tag-key"
```

**Windows**

```bash
aws ssm remove-tags-from-resource ^
--resource-type "Association" ^
--resource-id "association-ID" ^
--tag-key "tag-key"
```

**PowerShell**

```powershell
Remove-SSMResourceTag
    -ResourceId "association-ID"
    -ResourceType "Association"
    -TagKey "tag-key"
```

If successful, the command has no output.

3. Run the following command to verify the association tags.

**Linux & macOS**

```bash
aws ssm list-tags-for-resource \
--resource-type "Association" \
--resource-id "association-ID"
```

**Windows**

```bash
aws ssm list-tags-for-resource ^
--resource-type "Association" ^
--resource-id "association-ID"
```
Tagging automations

The topics in this section describe how to work with tags on automations. You can add a maximum of five tags to AWS Systems Manager automations. You can add tags to automations at the time you initiate them from either the console or the command line, or after they've run by using the command line.

Adding tags to automations (console)

2. In the navigation pane, choose Automation.
3. Choose the Automation runbook you want to run.
4. Select Execute automation.
5. In the Tags section, choose Edit, and then add one or more key-value tag pairs.
6. Choose Save.

Adding tags to automations (command line)

Using your preferred command line tool, run the following command to add tags to an automation when it starts. Replace each example resource placeholder with your own information.

Linux & macOS

```bash
aws ssm start-automation-execution \   --document-name DocumentName \   --parameters ParametersRequiredByDocument \   --tags "Key=ExampleKey,Value=ExampleValue"
```
Windows

```bash
aws ssm start-automation-execution ^
   --document-name DocumentName ^
   --parameters ParametersRequiredByDocument ^
   --tags "Key=ExampleKey,Value=ExampleValue"
```

PowerShell

```powershell
$exampleTag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
$exampleTag.Key = "ExampleKey"
$exampleTag.Value = "ExampleValue"

Start-SSMAutomationExecution `  
   -DocumentName DocumentName `  
   -Parameter ParametersRequiredByDocument 
   -Tag $exampleTag
```

1. You can also tag automations after they run by using your preferred command line tool. Run the following command to add tags to an automation. Replace each `example resource placeholder` with your own information.

Linux & macOS

```bash
aws ssm add-tags-to-resource \
   --resource-type "Automation" \
   --resource-id "automation-execution-id" \
   --tags "Key=ExampleKey,Value=ExampleValue"
```

Windows

```bash
aws ssm add-tags-to-resource ^
   --resource-type "Automation" ^
   --resource-id "automation-execution-id" ^
   --tags "Key=ExampleKey,Value=ExampleValue"
```

PowerShell

```powershell
$exampleTag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
$exampleTag.Key = "ExampleKey"
```

Adding tags to automations (command line)
If successful, the command has no output.

2. Run the following command to verify the automation's tags.

Linux & macOS

```bash
aws ssm list-tags-for-resource
--resource-type "Automation"
--resource-id "automation-execution-id"
```

Windows

```bash
aws ssm list-tags-for-resource
--resource-type "Automation"
--resource-id "automation-execution-id"
```

PowerShell

```powershell
Get-SSMResourceTag
-ResourceType "Automation"
-ResourceId "automation-execution-id"
```

Removing tags from automations

You can use a command line tool to remove tags from an automation.

Removing tags from automations (command line)

1. Using your preferred command line tool, run the following command to remove a tag from an automation. Replace each example resource placeholder with your own information.
### Removing tags from automations

**Linux & macOS**

```bash
aws ssm remove-tags-from-resource
    --resource-type "Automation"
    --resource-id "automation-execution-id"
    --tag-key "tag-key"
```

**Windows**

```bash
aws ssm remove-tags-from-resource
    --resource-type "Automation"
    --resource-id "automation-execution-id"
    --tag-key "tag-key"
```

**PowerShell**

```powershell
Remove-SSMResourceTag
    -ResourceId "automation-execution-id"
    -ResourceType "Automation"
    -TagKey "tag-key"
    -Force
```

2. Run the following command to verify the automation's tags.

**Linux & macOS**

```bash
aws ssm list-tags-for-resource
    --resource-type "Automation"
    --resource-id "automation-execution-id"
```

**Windows**

```bash
aws ssm list-tags-for-resource
    --resource-type "Automation"
    --resource-id "automation-execution-id"
```

**PowerShell**

```powershell
Get-SSMResourceTag
    -ResourceType "Automation"
```
Tagging Systems Manager documents

The topics in this section describe how to work with tags on Systems Manager documents (SSM documents).

Topics

- Creating documents with tags
- Adding tags to existing documents
- Removing tags from SSM documents

Creating documents with tags

You can add tags to custom SSM documents at the time you create them.

For information, see the following topics:

- Create an SSM document (console)
- Create an SSM document (command line)

Adding tags to existing documents

You can add tags to custom SSM documents that you own by using the Systems Manager console or the command line.

Topics

- Adding tags to an existing SSM document (console)
- Adding tags to an existing SSM document (command line)

Adding tags to an existing SSM document (console)

2. In the navigation pane, choose Documents.
3. Choose the **Owned by me** tab.

4. Choose the name of the document to add tags to, and then choose the **Details** tab.

5. In the **Tags** section, choose **Edit**, and then add one or more key-value tag pairs.

6. Choose **Save**.

**Adding tags to an existing SSM document (command line)**

To add tags to an existing SSM document (command line)

1. Using your preferred command line tool, run the following command to view the list of documents that you can tag.

   **Linux & macOS**
   ```bash
daemon ssm list-documents
   ```

   **Windows**
   ```bash
daemon ssm list-documents
   ```

   **PowerShell**
   ```bash
   Get-SSMDocumentList
   ```

   Note the name of a document that you want to tag.

2. Run the following command to tag a document. Replace each *example resource placeholder* with your own information.

   **Linux & macOS**
   ```bash
   aws ssm add-tags-to-resource
   --resource-type "Document" \
   --resource-id "document-name" \
   --tags "Key=tag-key,Value=tag-value"
   ```
Adding tags to existing documents

Windows

```bash
aws ssm add-tags-to-resource
  --resource-type "Document"
  --resource-id "document-name"
  --tags "Key=tag-key,Value=tag-value"
```

PowerShell

```powershell
$tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
$tag.Key = "tag-key"
$tag.Value = "tag-value"
Add-SSMResourceTag
  -ResourceType "Document"
  -ResourceId "document-name"
  -Tag $tag
  -Force
```

If successful, the command has no output.

3. Run the following command to verify the document tags.

Linux & macOS

```bash
aws ssm list-tags-for-resource
  --resource-type "Document"
  --resource-id "document-name"
```

Windows

```bash
aws ssm list-tags-for-resource
  --resource-type "Document"
  --resource-id "document-name"
```
Removing tags from SSM documents

You can use the Systems Manager console or the command line to remove tags from SSM documents.

### Topics
- Removing tags from SSM documents (console)
- Removing tags from SSM documents (command line)

### Removing tags from SSM documents (console)

2. In the navigation pane, choose Documents.
3. Choose the Owned by me tab.
4. Choose the name of the document to remove tags from, and then choose the Details tab.
5. In the Tags section, choose Edit, and then choose Remove next to the tag pair you no longer need.
6. Choose Save.

### Removing tags from SSM documents (command line)

1. Using your preferred command line tool, run the following command to list the documents in your account.

   Linux & macOS
   ```bash
   aws ssm list-documents
   ```
Note the name of a document from which you want to remove tags.

2. Run the following command to remove tags from a document. Replace each example resource placeholder with your own information.

Linux & macOS

```
aws ssm remove-tags-from-resource \
  --resource-type "Document" \
  --resource-id "document-name" \
  --tag-key "tag-key"
```

Windows

```
aws ssm remove-tags-from-resource ^
  --resource-type "Document" ^
  --resource-id "document-name" ^
  --tag-key "tag-key"
```

PowerShell

```
Remove-SSMResourceTag `'
  -ResourceId "document-name" `'
  -ResourceType "Document" `'
  -TagKey "tag-key" `'
  -Force
```

If successful, the command has no output.

3. Run the following command to verify the document tags.
Tagging maintenance windows

The topics in this section describe how to work with tags on maintenance windows.

Topics

- Creating maintenance windows with tags
- Adding tags to existing maintenance windows
- Removing tags from maintenance windows

Creating maintenance windows with tags

You can add tags to maintenance windows at the time you create them.

For information, see the following topics:

- Create a maintenance window (console)
- Tutorial: Create and configure a maintenance window (AWS CLI)
Adding tags to existing maintenance windows

You can add tags to maintenance windows that you own by using the AWS Systems Manager console or the command line.

Topics

- Adding tags to an existing maintenance window (console)
- Adding tags to an existing maintenance window (AWS CLI)
- Tag a maintenance window (AWS Tools for PowerShell)

Adding tags to an existing maintenance window (console)

2. In the navigation pane, choose Maintenance Windows.
3. Choose the name of a maintenance window you have already created, and then choose the Tags tabs.
4. Choose Edit tags, and then choose Add tag.
5. For Key, enter a key for the tag, such as Environment.
6. For Value, enter a value for the tag, such as Test.
7. Choose Save changes.

Adding tags to an existing maintenance window (AWS CLI)

1. Using your preferred command line tool, run the following command to view the list of maintenance windows that you can tag.

   ```bash
   aws ssm describe-maintenance-windows
   ```

   Note the ID of a maintenance window that you want to tag.
2. Run the following command to tag a maintenance window. Replace each example resource placeholder with your own information.
### Linux & macOS

/aws ssm add-tags-to-resource
  --resource-type "MaintenanceWindow"
  --resource-id "window-id"
  --tags "Key=tag-key,Value=tag-value"

### Windows

/aws ssm add-tags-to-resource
  --resource-type "MaintenanceWindow"
  --resource-id "window-id"
  --tags "Key=tag-key,Value=tag-value"

If successful, the command has no output.

3. Run the following command to verify the maintenance window tags.

### Linux & macOS

/aws ssm list-tags-for-resource
  --resource-type "MaintenanceWindow"
  --resource-id "window-id"

### Windows

/aws ssm list-tags-for-resource
  --resource-type "MaintenanceWindow"
  --resource-id "window-id"

---

### Tag a maintenance window (AWS Tools for PowerShell)

1. Run the following command to list maintenance windows that you can tag.

   ```powershell
   Get-SSMMaintenanceWindow
   ```

2. Run the following commands to tag a maintenance window.
$tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag

$tag.Key = "tag-key"

$tag.Value = "tag-value"

Add-SSMResourceTag `-ResourceType "MaintenanceWindow" `-ResourceId "window-id" `-Tag $tag

*window-id* the ID of the maintenance window you want to tag.

*tag-key* is the name of a custom key you supply. For example, *Environment* or *Project*.

*tag-value* is the custom content for the value you want to supply for that key. For example, *Production* or *Q321*.

3. Run the following command to verify the maintenance window tags.

Get-SSMResourceTag `-ResourceType "MaintenanceWindow" `-ResourceId "window-id"

**Removing tags from maintenance windows**

You can use the Systems Manager console or the command line to remove tags from maintenance windows.

**Topics**

- Removing tags from maintenance windows (console)
- Removing tags from maintenance windows (command line)
Removing tags from maintenance windows (console)

2. In the navigation pane, choose Maintenance Windows.
3. Choose the name of the maintenance window to remove tags from, and then choose Tags tab.
4. Choose Edit tags, and then choose Remove tag next to the tag pair you no longer need.
5. Choose Save changes.

Removing tags from maintenance windows (command line)

1. Using your preferred command line tool, run the following command to list the maintenance windows in your account.

   Linux & macOS
   
   ```bash
   aws ssm describe-maintenance-windows
   ```

   Windows
   
   ```bash
   aws ssm describe-maintenance-windows
   ```

   PowerShell
   
   ```powershell
   Get-SSMMaintenanceWindows
   ```

   Note the ID of a maintenance window from which you want to remove tags.
2. Run the following command to remove tags from a maintenance window. Replace each example resource placeholder with your own information.

   Linux & macOS
   
   ```bash
   aws ssm remove-tags-from-resource
   --resource-type "MaintenanceWindow"
   --resource-id "window-id"
   --tag-key "tag-key"
   ```
Removing tags from maintenance windows

2. Run the following command to remove tags from a maintenance window:

`aws ssm remove-tags-from-resource --resource-type "MaintenanceWindow" --resource-id "window-id" --tag-key "tag-key"`

PowerShell

```
Remove-SSMResourceTag -ResourceType "MaintenanceWindow" -ResourceId "window-id" -TagKey "tag-key"
```

If successful, the command has no output.

3. Run the following command to verify the maintenance window tags:

Linux & macOS

```
aws ssm list-tags-for-resource --resource-type "MaintenanceWindow" --resource-id "window-id"
```

Windows

```
aws ssm list-tags-for-resource --resource-type "MaintenanceWindow" --resource-id "window-id"
```

PowerShell

```
Get-SSMResourceTag -ResourceType "MaintenanceWindow" -ResourceId "window-id"
```
Tagging managed nodes

The topics in this section describe how to work with tags on managed nodes.

A managed node is any machine configured for AWS Systems Manager. This includes Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 machines in a hybrid and multicloud environment that are configured for Systems Manager.

The instructions in this topic are applicable to any machine that is managed using Systems Manager.

Topics

• Creating or activating managed nodes with tags
• Adding tags to existing managed nodes
• Removing tags from managed nodes

Creating or activating managed nodes with tags

You can add tags to EC2 instances at the time you create them. You can add tags to on-premises servers and virtual machines (VMs) at the time you activate them.

For information, see the following topics:

• For EC2 instances, see Tag your Amazon EC2 resources in the Amazon EC2 User Guide. (Content applies to both EC2 instances for Linux and for Windows)
• For on-premises servers and VMs, see Create a hybrid activation to register nodes with Systems Manager.

Adding tags to existing managed nodes

You can add tags to managed nodes by using the Systems Manager console or the command line.

Topics

• Adding tags to an existing managed node (console)
• Adding tags to an existing managed node (command line)
Adding tags to an existing managed node (console)

2. In the navigation pane, choose Fleet Manager.
3. Choose the ID of the managed node to add tags to, and then choose the Tags tab.

⚠️ Note

If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

4. In the Tags section, choose Edit, and then add one or more key-value tag pairs.
5. Choose Save.

Adding tags to an existing managed node (command line)

To add tags to an existing managed node (command line)

1. Using your preferred command line tool, run the following command to view the list of managed nodes that you can tag.

   Linux & macOS

   ```
   aws ssm describe-instance-information
   ```

   Windows

   ```
   aws ssm describe-instance-information
   ```

   PowerShell

   ```
   Get-SSMInstanceInformation
   ```

   Note the ID of a managed node that you want to tag.
Non-EC2 machines that have been registered for use with Systems Manager in a hybrid and multicloud environment begin with mi-, such as mi-0471e04240EXAMPLE. EC2 instances have IDs that begin with i-, such as i-02573cacfEXAMPLE.

2. Run the following command to tag a managed node. Replace each example resource placeholder with your own information.

Linux & macOS

```bash
aws ssm add-tags-to-resource
  --resource-type "ManagedInstance"
  --resource-id "instance-id"
  --tags Key=tag-key,Value=tag-value
```

Windows

```bash
aws ssm add-tags-to-resource
  --resource-type "ManagedInstance"
  --resource-id "instance-id"
  --tags "Key=tag-key,Value=tag-value"
```

PowerShell

```powershell
$tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag

$tag.Key = "tag-key"

$tag.Value = "tag-value"

Add-SSMResourceTag
  -ResourceType "ManagedInstance"
  -ResourceId "instance-id"
  -Tag $tag
  -Force
```
If successful, the command has no output.

3. Run the following command to verify the managed node tags.

**Linux & macOS**

```
aws ssm list-tags-for-resource
   --resource-type "ManagedInstance"
   --resource-id "instance-id"
```

**Windows**

```
aws ssm list-tags-for-resource
   --resource-type "ManagedInstance"
   --resource-id "instance-id"
```

**PowerShell**

```
Get-SSMResourceTag
   -ResourceType "ManagedInstance"
   -ResourceId "instance-id"
```

### Removing tags from managed nodes

You can use the Systems Manager console or the command line to remove tags from managed nodes.

**Topics**

- [Removing tags from managed nodes (console)](#)
- [Removing tags from managed nodes (command line)](#)

### Removing tags from managed nodes (console)

2. In the navigation pane, choose **Fleet Manager**.
3. Choose the name of the managed node to remove tags from, and then choose the **Tags** tab.

4. In the **Tags** section, choose **Edit**, and then choose **Remove** next to the tag pair you no longer need.

5. Choose **Save**.

### Removing tags from managed nodes (command line)

1. Using your preferred command line tool, run the following command to list the managed nodes in your account.

   **Linux & macOS**
   ```bash
   aws ssm describe-instance-information
   ```

   **Windows**
   ```bash
   aws ssm describe-instance-information
   ```

   **PowerShell**
   ```bash
   Get-SSMInstanceInformation
   ```

   Note the name of a managed node from which you want to remove tags.

2. Run the following command to remove tags from a managed node. Replace each *example resource placeholder* with your own information.

   **Linux & macOS**
   ```bash
   aws ssm remove-tags-from-resource \
   --resource-type "ManagedInstance" \
   --resource-id "instance-id" \
   --tag-key "tag-key"
   ```

   **Windows**
   ```bash
   aws ssm remove-tags-from-resource ^
   --resource-type "ManagedInstance" ^
   ```
PowerShell

Remove-SSMResourceTag ` 
  -ResourceId "instance-id" ` 
  -ResourceType "ManagedInstance" ` 
  -TagKey "tag-key" ` 
  -Force

If successful, the command has no output.

3. Run the following command to verify the managed node tags.

Linux & macOS

aws ssm list-tags-for-resource \
  --resource-type "ManagedInstance" \
  --resource-id "instance-id"

Windows

aws ssm list-tags-for-resource ^ 
  --resource-type "ManagedInstance" ^ 
  --resource-id "instance-id"

PowerShell

Get-SSMResourceTag ` 
  -ResourceType "ManagedInstance" ` 
  -ResourceId "instance-id"

Tagging OpsItems

The topics in this section describe how to work with tags on OpsItems.

Topics

• Creating OpsItems with tags
• Adding tags to existing OpsItems
• Removing tags from Systems Manager OpsItems

Creating OpsItems with tags

You can add tags to custom AWS Systems Manager OpsItems at the time you create them if you use a command line tool.

For information, see the following topic:

Adding tags to existing OpsItems

You can add tags to OpsItems by using a command line tool.

Topics

• Adding tags to an existing OpsItem (command line)

Adding tags to an existing OpsItem (command line)

To add tags to an existing OpsItem (command line)

1. Using your preferred command line tool, run the following command to view the list of OpsItem that you can tag.

   Linux & macOS
   
   ```
   aws ssm describe-ops-items
   ```

   Windows
   
   ```
   aws ssm describe-ops-items
   ```

   PowerShell
   
   ```
   Get-SSMOpsItemSummary
   ```

   Note the ID of an OpsItem that you want to tag.
2. Run the following command to tag an OpsItem. Replace each *example resource placeholder* with your own information.

**Linux & macOS**

```bash/aws ssm add-tags-to-resource
    --resource-type "OpsItem"
    --resource-id "ops-item-id"
    --tags "Key=tag-key,Value=tag-value"
```

**Windows**

```bash
/aws ssm add-tags-to-resource
    --resource-type "OpsItem"
    --resource-id "ops-item-id"
    --tags "Key=tag-key,Value=tag-value"
```

**PowerShell**

```powershell
$tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
$tag.Key = "tag-key"
$tag.Value = "tag-value"
Add-SSMResourceTag
    -ResourceType "OpsItem"
    -ResourceId "ops-item-id"
    -Tag $tag
    -Force
```

If successful, the command has no output.

3. Run the following command to verify the OpsItem tags.

**Linux & macOS**

```bash
/aws ssm list-tags-for-resource
    --resource-type "OpsItem"
```
Removing tags from Systems Manager OpsItems

You can use a command line tool to remove tags from Systems Manager OpsItems.

Topics

- Removing tags from OpsItems (command line)

Removing tags from OpsItems (command line)

1. Using your preferred command line tool, run the following command to list the OpsItems in your account.

   Linux & macOS

   ```bash
   aws ssm describe-ops-items
   ```

   Windows

   ```bash
   aws ssm describe-ops-items
   ```

   PowerShell

   ```bash
   Get-SSMOpsItemSummary
   ```
Note the name of an OpsItem from which you want to remove tags.

2. Run the following command to remove tags from an OpsItem. Replace each example resource placeholder with your own information.

**Linux & macOS**

```
aws ssm remove-tags-from-resource
--resource-type "OpsItem"
--resource-id "ops-item-id"
--tag-key "tag-key"
```

**Windows**

```
aws ssm remove-tags-from-resource
--resource-type "OpsItem"
--resource-id "ops-item-id"
--tag-key "tag-key"
```

**PowerShell**

```
Remove-SSMResourceTag
-ResourceId "ops-item-id"
-ResourceType "OpsItem"
-TagKey "tag-key"
-Force
```

If successful, the command has no output.

3. Run the following command to verify the OpsItem tags.

**Linux & macOS**

```
aws ssm list-tags-for-resource
--resource-type "OpsItem"
--resource-id "ops-item-id"
```
Tagging Systems Manager parameters

The topics in this section describe how to work with tags on AWS Systems Manager parameters (SSM parameters).

Topics
- Creating parameters with tags
- Adding tags to existing parameters
- Removing tags from SSM parameters

Creating parameters with tags

You can add tags to SSM parameters at the time you create them.

For information, see the following topics:
- Create a Systems Manager parameter (console)
- Create a Systems Manager parameter (AWS CLI)
- Create a Systems Manager parameter (Tools for Windows PowerShell)

Adding tags to existing parameters

You can add tags to custom SSM parameters that you own by using the Systems Manager console or the command line.
Adding tags to an existing parameter (console)

2. In the navigation pane, choose Parameter Store.
3. Choose the name of a parameter you have already created, and then choose the Tags tab.
4. In the first box, enter a key for the tag, such as Environment.
5. In the second box, enter a value for the tag, such as Test.
6. Choose Save.

Adding tags to an existing parameter (AWS CLI)

1. Using your preferred command line tool, run the following command to view the list of parameters that you can tag.

   ```bash
   aws ssm describe-parameters
   ```

   Note the name of a parameter that you want to tag.

2. Run the following command to tag a parameter. Replace each example resource placeholder with your own information.

   ```bash
   aws ssm add-tags-to-resource \
   --resource-type "Parameter" \
   --resource-id "parameter-name" \
   --tags "Key=tag-key,Value=tag-value"
   ```

   If successful, the command has no output.

3. Run the following command to verify the parameter tags.
Adding tags to an existing parameter (AWS Tools for PowerShell)

1. Run the following command to list parameters that you can tag.

   ```powershell
   Get-SSMParameterList
   ```

2. Run the following commands to tag a parameter. Replace each example resource placeholder with your own information.

   ```powershell
   $tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
   $tag.Key = "tag-key"
   $tag.Value = "tag-value"
   Add-SSMResourceTag -ResourceType "Parameter" -ResourceId "parameter-name" -Tag $tag -Force
   ```

3. Run the following command to verify the parameter tags.

   ```powershell
   Get-SSMResourceTag -ResourceType "Parameter" -ResourceId "parameter-name"
   ```

Removing tags from SSM parameters

You can use the Systems Manager console or the command line to remove tags from SSM parameters.

Topics
Removing tags from SSM parameters (console)

2. In the navigation pane, choose Parameter Store.
3. Choose the name of the parameter to remove tags from, and then choose the Tags tab.
4. Choose Remove next to the tag pair you no longer need.
5. Choose Save.

Removing tags from SSM parameters (command line)

1. Using your preferred command line tool, run the following command to list the parameters in your account.
   
   **Linux & macOS**
   ```
   aws ssm describe-parameters
   ```
   
   **Windows**
   ```
   aws ssm describe-parameters
   ```
   
   **PowerShell**
   ```
   Get-SSMParameterList
   ```
   
   Note the name of a parameter from which you want to remove tags.
2. Run the following command to remove tags from a parameter. Replace each example resource placeholder with your own information.
Removing tags from SSM parameters

**Linux & macOS**

```bash
aws ssm remove-tags-from-resource \
   --resource-type "Parameter" \
   --resource-id "parameter-name" \
   --tag-key "tag-key"
```

**Windows**

```bash
aws ssm remove-tags-from-resource ^
   --resource-type "Parameter" ^
   --resource-id "parameter-name" ^
   --tag-key "tag-key"
```

**PowerShell**

```powershell
Remove-SSMResourceTag
   -ResourceId "parameter-name"
   -ResourceType "Parameter"
   -TagKey "tag-key"
```

If successful, the command has no output.

3. Run the following command to verify the document tags.

**Linux & macOS**

```bash
aws ssm list-tags-for-resource \
   --resource-type "Parameter" \
   --resource-id "parameter-name"
```

**Windows**

```bash
aws ssm list-tags-for-resource ^
   --resource-type "Parameter" ^
   --resource-id "parameter-name"
```
## Tagging patch baselines

The topics in this section describe how to work with tags on patch baselines.

### Topics

- Creating patch baselines with tags
- Adding tags to existing patch baselines
- Removing tags from patch baselines

## Creating patch baselines with tags

You can add tags to AWS Systems Manager patch baselines at the time you create them.

For information, see the following topics:

- Working with custom patch baselines
- Create a patch baseline
- Create a patch baseline with custom repositories for different OS versions

## Adding tags to existing patch baselines

You can add tags to patch baselines that you own by using the Systems Manager console or the command line.

### Topics

- Adding tags to an existing patch baseline (console)
- Adding tags to an existing patch baseline (AWS CLI)
- Tag a patch baseline (AWS Tools for PowerShell)
Adding tags to an existing patch baseline (console)

2. In the navigation pane, choose **Patch Manager**.
3. Choose the name of a custom patch baseline you have already created, scroll down to the **Tags table** section, and then choose **Edit tags**.
4. Choose **Add tag**.
5. For **Key**, enter a key for the tag, such as **Environment**.
6. For **Value**, enter a value for the tag, such as **Test**.
7. Choose **Save changes**.

Adding tags to an existing patch baseline (AWS CLI)

1. Using your preferred command line tool, run the following command to view the list of patch baselines that you can tag.

   ```bash
   aws ssm describe-patch-baselines --filters "Key=OWNER,Values=[Self]"
   ```

   Note the ID of a patch baseline that you want to tag.

2. Run the following command to tag a patch baseline. Replace each *example resource placeholder* with your own information.

   **Linux & macOS**
   ```bash
   aws ssm add-tags-to-resource
   --resource-type "PatchBaseline"
   --resource-id "baseline-id"
   --tags "Key=tag-key,Value=tag-value"
   ```

   **Windows**
   ```bash
   aws ssm add-tags-to-resource
   --resource-type "PatchBaseline"
   --resource-id "baseline-id"
   --tags "Key=tag-key,Value=tag-value"
   ```
If successful, the command has no output.

3. Run the following command to verify the patch baseline tags.

**Linux & macOS**

```bash
aws ssm list-tags-for-resource
   --resource-type "PatchBaseline"
   --resource-id "baseline-id"
```

**Windows**

```bash
aws ssm list-tags-for-resource ^
   --resource-type "PatchBaseline" ^
   --resource-id "patchbaseline-id"
```

---

**Tag a patch baseline (AWS Tools for PowerShell)**

1. Run the following command to list patch baseline that you can tag.

   ```powershell
   Get-SSMPatchBaseline
   ```

2. Run the following commands to tag a patch baseline. Replace each *example resource placeholder* with your own information.

   ```powershell
   $tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
   $tag.Key = "tag-key"
   $tag.Value = "tag-value"
   Add-SSMResourceTag
      -ResourceType "PatchBaseline" 
      -ResourceId "baseline-id"
      -Tag $tag 
      -Force
   ```
3. Run the following command to verify the patch baseline tags.

```bash
Get-SSMResourceTag -ResourceType "PatchBaseline" -ResourceId "baseline-id"
```

Removing tags from patch baselines

You can use the Systems Manager console or the command line to remove tags from a patch baseline.

Topics

- Removing tags from patch baseline (console)
- Removing tags from patch baselines (command line)

Removing tags from patch baseline (console)

2. In the navigation pane, choose Patch Manager.
3. Choose the name of the patch baseline to remove tags from, scroll down to the Tags table section, and then choose Edit tags tab.
4. Choose Remove tag next to the tag pair you no longer need.
5. Choose Save changes.

Removing tags from patch baselines (command line)

1. Using your preferred command line tool, run the following command to list the patch baselines in your account.

   Linux & macOS

   ```bash
   aws ssm describe-patch-baselines
   ```
Note the ID of a patch baseline from which you want to remove tags.

2. Run the following command to remove tags from a patch baseline. Replace each *example resource placeholder* with your own information.

**Linux & macOS**

```bash
aws ssm remove-tags-from-resource \
  --resource-type "PatchBaseline" \
  --resource-id "baseline-id" \
  --tag-key "tag-key"
```

**Windows**

```bash
aws ssm remove-tags-from-resource ^
  --resource-type "PatchBaseline" ^
  --resource-id "baseline-id" ^
  --tag-key "tag-key"
```

**PowerShell**

```powershell
Remove-SSMResourceTag `  
  -ResourceType "PatchBaseline" `  
  -ResourceId "baseline-id" `  
  -TagKey "tag-key"
```

If successful, the command has no output.

3. Run the following command to verify the patch baseline tags.
Removing tags from patch baselines
AWS Systems Manager reference

The following information and topics can help you better implement AWS Systems Manager solutions.

**Principal**

In AWS Identity and Access Management (IAM), you can grant or deny a service access to resources using the Principal policy element. The Principal policy element value for Systems Manager is `ssm.amazonaws.com`.

**Supported AWS Regions and endpoints**

See [Systems Manager service endpoints](https://docs.aws.amazon.com/AmazonSSM/latest/UserGuide/systems-manager-service-endpoints.html) in the *Amazon Web Services General Reference*.

**Service Quotas**

See [Systems Manager service quotas](https://docs.aws.amazon.com/AmazonSSM/latest/UserGuide/systems-manager-service-quotas.html) in the *Amazon Web Services General Reference*.

**API Reference**

See [AWS Systems Manager API Reference](https://docs.aws.amazon.com/AmazonSSM/latest/APIReference/)

**AWS CLI Command Reference**

**Ask a Question**

Systems Manager issues in [AWS re:Post](https://aws.amazon.com/solutions/repost/)

**AWS News Blog**

[Management Tools](https://aws.amazon.com/about-aws/leaders-management)

**More reference topics**

Using Amazon EventBridge, you can create rules that match incoming events and route them to targets for processing.

An event indicates a change in an environment in your own applications, software as a service (SaaS) applications, or an AWS service. Events are produced on a best effort basis. After an event type that is specified in a rule is detected, EventBridge routes it to a specified target for processing. Targets can include Amazon Elastic Compute Cloud (Amazon EC2) instances, AWS Lambda functions, Amazon Kinesis streams, Amazon Elastic Container Service (Amazon ECS) tasks, AWS Step Functions state machines, Amazon Simple Notification Service (Amazon SNS) topics, Amazon Simple Queue Service (Amazon SQS) queues, built-in targets and many more.

For information about creating EventBridge rules, see the following topics:

- Monitoring Systems Manager events with Amazon EventBridge
- Amazon EventBridge event examples for Systems Manager
- Getting started with Amazon EventBridge in the Amazon EventBridge User Guide

The remainder of this topic describes the types of Systems Manager events that you can include in your EventBridge rules.
## Event type: Automation

<table>
<thead>
<tr>
<th>Event type name</th>
<th>Description of events you can add to a rule</th>
</tr>
</thead>
</table>
| EC2 Automation Execution Status-change Notification | The overall status of an Automation workflow changes. You can add one or more of the following status changes to an event rule:  
  - Approved  
  - Canceled  
  - Failed  
  - PendingApproval  
  - PendingChangeCalendarOverride  
  - Rejected  
  - Scheduled  
  - Success  
  - TimedOut                                                |
| EC2 Automation Step Status-change Notification       | The status of a specific step in an Automation workflow changes. You can add one or more of the following status changes to an event rule:  
  - Canceled  
  - Failed  
  - Success  
  - TimedOut                                                |
### Event type: Change Calendar

<table>
<thead>
<tr>
<th>Event type name</th>
<th>Description of events you can add to a rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calendar State Change</td>
<td>The state of a Change Calendar changes. You can add one or both of the following state changes to an event rule:</td>
</tr>
<tr>
<td></td>
<td>• OPEN</td>
</tr>
<tr>
<td></td>
<td>• CLOSED</td>
</tr>
<tr>
<td></td>
<td>State changes for calendars shared from other AWS accounts aren't supported.</td>
</tr>
</tbody>
</table>

### Event type: Change Manager

<table>
<thead>
<tr>
<th>Event type name</th>
<th>Description of events you can add to a rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Request Status Update</td>
<td>The state of a Change Manager change request. You can use the following states in an event rule:</td>
</tr>
<tr>
<td></td>
<td>• Approved</td>
</tr>
<tr>
<td></td>
<td>• Rejected</td>
</tr>
<tr>
<td></td>
<td>• InProgress</td>
</tr>
</tbody>
</table>

### Event type: Configuration Compliance

<table>
<thead>
<tr>
<th>Event type name</th>
<th>Description of events you can add to a rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration Compliance State Change</td>
<td>The state of a managed node changes, for either association compliance or patch compliance. You can add one or more of the following state changes to an event rule:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## Event type: Inventory

<table>
<thead>
<tr>
<th>Event type name</th>
<th>Description of events you can add to a rule</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• compliant</td>
</tr>
<tr>
<td></td>
<td>• non_compliant</td>
</tr>
</tbody>
</table>

### Inventory Resource State Change

The deletion of custom inventory and a `PutInventory` call that uses an old schema version. You can add one or more of the following state changes to an event rule:

- Custom inventory type deleted event on a specific node. EventBridge sends one event per node per custom `InventoryType`.
- Custom inventory type deleted event for all nodes.
- `PutInventory` call with old schema version event. EventBridge sends this event when the schema version is less than the current schema. This event applies to all inventory types.

For more information, see [About EventBridge monitoring of Inventory events](#).
# Event type: Maintenance Window

<table>
<thead>
<tr>
<th>Event type name</th>
<th>Description of events you can add to a rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maintenance Window Status-change Notification</td>
<td>The overall status of one or more maintenance windows changes. You can add one or more of the following state changes to an event rule:</td>
</tr>
<tr>
<td></td>
<td>• DISABLED</td>
</tr>
<tr>
<td></td>

**Reference: Cron and rate expressions for Systems Manager**

When you create a State Manager association or a maintenance window in AWS Systems Manager, you specify a schedule for when the window or the association should run. You can specify a schedule as either a time-based entry, called a *cron expression*, or a frequency-based entry, called a *rate expression*.

**General information about cron and rate expressions**

The following information applies to cron and rate expressions for both maintenance windows and associations.

**Single-run schedules**

When you create an association or a maintenance window, you can specify a timestamp in Coordinated Universal Time (UTC) format so that it runs once at the specified time. For example: "at(2020-07-07T15:55:00)"

**Schedule offsets**

Associations and maintenance windows support *schedule offsets* for cron expressions only. A schedule offset is the number of days to wait after the date and time specified by a cron expression before running the association or maintenance window.

Maintenance window example

In the following command, the cron expression schedules a maintenance window to run the third Tuesday of every month at 11:30 PM. However, because the schedule offset is 2, the maintenance window won't run until 11:30 PM two days later.

```
aws ssm create-maintenance-window \
```
Association example

In the following command, the cron expression schedules an association to run the second Thursday of each month. However, because the schedule offset is 3, the association won't run until the next Sunday, three days later.

```
aws ssm create-association \
--name "AWS-UpdateSSMAgent" \
--targets "Key=instanceids,Values=i-0cb2b964d3e14fd9f" \
--schedule-expression "cron(0 0 ? * THU#2 *)" \
--schedule-offset 3 \
--apply-only-at-cron-interval
```

**Note**

To use an offset with an association, you must specify the `--apply-only-at-cron-interval` option. This option tells the system not to run an association immediately after you create it.

If you create an association or a maintenance window with a cron expression that targets a day that has already passed in the current period, but add a schedule offset date that falls in the future, the association or maintenance window won't run in the period. It will go into effect in the following period. For example, if you specify a cron expression that would have run a maintenance window yesterday and add a schedule offset of two days, the maintenance window won't run tomorrow.

**Required fields**

Cron expressions for maintenance windows have six required fields. Cron expressions for associations have five. (State Manager doesn't currently support specifying months in cron expressions for associations.) An additional field, the Seconds field (the first in a cron expression), is optional. Fields are separated by a space.

General information about cron and rate expressions

<td>*</td>
<td>Run at 8:00 AM (UTC) every 1st day of the month</td>
</tr>
</tbody>
</table>

### Supported values

The following table shows supported values for required cron entries.

### Supported values for cron expressions

<table>
<thead>
<tr>
<th>Field</th>
<th>Values</th>
<th>Wildcards</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minutes</td>
<td>0-59</td>
<td>, - * /</td>
</tr>
</tbody>
</table>
### Field Values Wildcards

<table>
<thead>
<tr>
<th>Field</th>
<th>Values</th>
<th>Wildcards</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hours</td>
<td>0-23</td>
<td>, - * /</td>
</tr>
<tr>
<td>Day-of-month</td>
<td>1-31</td>
<td>, - * ? / L W</td>
</tr>
<tr>
<td>Month (maintenance windows only)</td>
<td>1-12 or JAN-DEC</td>
<td>, - * /</td>
</tr>
<tr>
<td>Day-of-week</td>
<td>1-7 or SUN-SAT</td>
<td>, - * ? / L #</td>
</tr>
<tr>
<td>Year</td>
<td>1970-2199</td>
<td>, - * /</td>
</tr>
</tbody>
</table>

#### Note
You can't specify a value in the day-of-month and in the day-of-week fields in the same cron expression. If you specify a value in one of the fields, use a ? (question mark) in the other field.

#### Wildcards for cron expressions

The following table shows the wildcard values that cron expressions support.

#### Note
Cron expressions that lead to rates faster than five (5) minute aren't supported. Support for specifying both a day-of-week and a day-of-month value isn't complete. Use the question mark (?) character in one of these fields.

#### Supported wildcards for cron expressions

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>,</td>
<td>The , (comma) wildcard includes additional values. In the Month field, JAN,FEB,MAR would include January, February, and March.</td>
</tr>
<tr>
<td>Wildcard</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>-</td>
<td>The - (dash) wildcard specifies ranges. In the Day field, 1-15 would include days 1 through 15 of the specified month.</td>
</tr>
<tr>
<td>*</td>
<td>The * (asterisk) wildcard includes all values in the field. In the Hours field, * would include every hour.</td>
</tr>
<tr>
<td>/</td>
<td>The / (forward slash) wildcard specifies increments. In the Minutes field, you could enter 1/10 to specify every tenth minute, starting from the first minute of the hour. So 1/10 specifies the first, 11th, 21st, and 31st minute, and so on.</td>
</tr>
<tr>
<td>?</td>
<td>The ? (question mark) wildcard specifies one or another. In the Day-of-month field you could enter 7 and if you didn't care what day of the week the 7th was, you could enter ? in the Day-of-week field.</td>
</tr>
<tr>
<td>L</td>
<td>The L wildcard in the Day-of-month or Day-of-week fields specifies the last day of the month or week.</td>
</tr>
<tr>
<td>W</td>
<td>The W wildcard in the Day-of-month field specifies a weekday. In the Day-of-month field, 3W specifies the day closest to the third weekday of the month.</td>
</tr>
<tr>
<td>#</td>
<td>The # wildcard in the day-of-week field followed by a number between one and five specifies a given day of the month. 5#3 specifies the 3rd Thursday of the month.</td>
</tr>
</tbody>
</table>
Rate expressions

Rate expressions have the following two required fields. Fields are separated by spaces.

Required fields for rate expressions

<table>
<thead>
<tr>
<th>Field</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value</td>
<td>positive number, such as 1 or 15</td>
</tr>
<tr>
<td>Unit</td>
<td>minute</td>
</tr>
<tr>
<td></td>
<td>minutes</td>
</tr>
<tr>
<td></td>
<td>hour</td>
</tr>
<tr>
<td></td>
<td>hours</td>
</tr>
<tr>
<td></td>
<td>day</td>
</tr>
<tr>
<td></td>
<td>days</td>
</tr>
</tbody>
</table>

If the value is equal to 1, then the unit must be singular. Similarly, for values greater than 1, the unit must be plural. For example, rate(1 hours) and rate(5 hour) aren't valid, but rate(1 hour) and rate(5 hours) are valid.

Topics

- Cron and rate expressions for associations
- Cron and rate expressions for maintenance windows

Cron and rate expressions for associations

This section includes examples of cron and rate expressions for State Manager associations. Before you create one of these expressions, be aware of the following information:

- Associations support the following cron expressions: Every 1/2, 1, 2, 4, 8, or 12 hours; every day, every week, or every specified day and time of the week; a specific day in a specific week of the month, or the last x day of the month at a specific time.
• Associations support the following rate expressions: intervals of 30 minutes or greater and less than 31 days.

• If you specify the optional Seconds field, its value can be 0 (zero). For example: `cron(0 */30 * * * ? *)`

• For an association that collects metadata for Inventory, a capability of AWS Systems Manager, we recommend using a rate expression.

• State Manager doesn't currently support specifying months in cron expressions for associations.

Associations support cron expressions that include a day of the week and the number sign (#) to designate the n-th day of a month to run an association. Here is an example that runs a cron schedule on the third Tuesday of every month at 23:30 UTC:

`cron(30 23 ? * TUE#3 *)`

Here is an example that runs on the second Thursday of every month at midnight UTC:

`cron(0 0 ? * THU#2 *)`

Associations also support the (L) sign to indicate the last X day of the month. Here is an example that runs a cron schedule on the last Tuesday of every month at midnight UTC:

`cron(0 0 ? * 3L *)`

To further control when an association runs, for example if you want to run an association two days after patch Tuesday, you can specify an offset. An offset defines how many days to wait after the scheduled day to run an association. For example, if you specified a cron schedule of `cron(0 0 ? * THU#2 *)`, you could specify the number 3 in the Schedule offset field to run the association each Sunday after the second Thursday of the month.

To use offsets, you must either choose the Apply association only at the next specified Cron interval option in the console or you must specify the use `--apply-only-at-cron-interval` parameter from the command line. This option tells State Manager not to run an association immediately after you create it.

The following table presents cron examples for associations.
Cron examples for associations

<table>
<thead>
<tr>
<th>Example</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron(0/30 * * * ? *)</td>
<td>Every 30 minutes</td>
</tr>
<tr>
<td>cron(0 0/1 * * ? *)</td>
<td>Every hour</td>
</tr>
<tr>
<td>cron(0 0/2 * * ? *)</td>
<td>Every 2 hours</td>
</tr>
<tr>
<td>cron(0 0/4 * * ? *)</td>
<td>Every 4 hours</td>
</tr>
<tr>
<td>cron(0 0/8 * * ? *)</td>
<td>Every 8 hours</td>
</tr>
<tr>
<td>cron(0 0/12 * * ? *)</td>
<td>Every 12 hours</td>
</tr>
<tr>
<td>cron(15 13 ? * * *)</td>
<td>Every day at 1:15 PM</td>
</tr>
<tr>
<td>cron(15 13 ? * MON *)</td>
<td>Every Monday at 1:15 PM</td>
</tr>
<tr>
<td>cron(30 23 ? TUE#3 *)</td>
<td>The third Tuesday of every month at 11:30 PM</td>
</tr>
</tbody>
</table>

Here are some rate examples for associations.

Rate examples for associations

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>rate(30 minutes)</td>
<td>Every 30 minutes</td>
</tr>
<tr>
<td>rate(1 hour)</td>
<td>Every hour</td>
</tr>
<tr>
<td>rate(5 hours)</td>
<td>Every 5 hours</td>
</tr>
<tr>
<td>rate(15 days)</td>
<td>Every 15 days</td>
</tr>
</tbody>
</table>

AWS CLI examples for associations

To create State Manager associations using the AWS CLI, you include the `--schedule-expression` parameter with a cron or rate expression. The following examples use the AWS CLI on a local Linux machine.
**Note**

By default, when you create a new association, the system runs it immediately after it's created and then according to the schedule you specified. Specify `--apply-only-at-cron-interval` so that the association doesn't run immediately after you create it. This parameter isn't supported for rate expressions.

```
aws ssm create-association \
  --association-name "My-Cron-Association" \
  --schedule-expression "cron(0 2 ? * SUN *)" \
  --targets Key=tag:ServerRole,Values=WebServer \
  --name AWS-UpdateSSMAgent
```

```
aws ssm create-association \
  --association-name "My-Rate-Association" \
  --schedule-expression "rate(7 days)" \
  --targets Key=tag:ServerRole,Values=WebServer \
  --name AWS-UpdateSSMAgent
```

```
aws ssm create-association \
  --association-name "My-Rate-Association" \
  --schedule-expression "at(2020-07-07T15:55:00)" \
  --targets Key=tag:ServerRole,Values=WebServer \
  --name AWS-UpdateSSMAgent \
  --apply-only-at-cron-interval
```

**Cron and rate expressions for maintenance windows**

This section includes examples of cron and rate expressions for maintenance windows.

Unlike State Manager associations, maintenance windows support all cron and rate expressions. This includes support for values in the seconds field.

For example, the following 6-field cron expression runs a maintenance window at 9:30 AM every day.

```
cron(30 09 ? * *)
```
By adding a value to the Seconds field, the following 7-field cron expression runs a maintenance window at 9:30:24 AM every day.

cron(24 30 09 ? * *)

The following table provides additional 6-field cron examples for maintenance windows.

### Cron examples for maintenance windows

<table>
<thead>
<tr>
<th>Example</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron(0 2 ? * THU#3 *)</td>
<td>02:00 AM the third Thursday of every month</td>
</tr>
<tr>
<td>cron(15 10 ? ** *)</td>
<td>10:15 AM every day</td>
</tr>
<tr>
<td>cron(15 10 ? * MON-FRI *)</td>
<td>10:15 AM every Monday, Tuesday, Wednesday, Thursday and Friday</td>
</tr>
<tr>
<td>cron(0 2 L * ? *)</td>
<td>02:00 AM on the last day of every month</td>
</tr>
<tr>
<td>cron(15 10 ? * 6L *)</td>
<td>10:15 AM on the last Friday of every month</td>
</tr>
</tbody>
</table>

The following table provides rate examples for maintenance windows.

### Rate examples for maintenance windows

<table>
<thead>
<tr>

<td>Every 5 hours</td>
</tr>
<tr>
<td>rate(25 days)</td>
<td>Every 25 days</td>
</tr>
</tbody>
</table>

AWS CLI examples for maintenance windows

Cron and rate expressions for maintenance windows
To create maintenance windows using the AWS CLI, you include the `--schedule` parameter with a cron or rate expression or a timestamp. The following examples use the AWS CLI on a local Linux machine.

```bash
aws ssm create-maintenance-window \
    --name "My-Cron-Maintenance-Window" \
    --allow-unassociated-targets \
    --schedule "cron(0 16 ? * TUE *)" \
    --schedule-timezone "America/Los_Angeles" \
    --start-date 2021-01-01T00:00:00-08:00 \n    --end-date 2021-06-30T00:00:00-08:00 \n    --duration 4 \n    --cutoff 1
```

```bash
aws ssm create-maintenance-window \
    --name "My-Rate-Maintenance-Window" \
    --allow-unassociated-targets \
    --schedule "rate(7 days)" \
    --duration 4 \n    --schedule-timezone "America/Los_Angeles" \
    --cutoff 1
```

```bash
aws ssm create-maintenance-window \
    --name "My-TimeStamp-Maintenance-Window" \
    --allow-unassociated-targets \
    --schedule "at(2021-07-07T13:15:30)" \
    --duration 4 \n    --schedule-timezone "America/Los_Angeles" \
    --cutoff 1
```

More info

[CRON expression](https://en.wikipedia.org/wiki/Cron) at the [Wikipedia website](https://en.wikipedia.org)

Reference: `ec2messages`, `ssmmessages`, and other API operations

If you monitor API operations, you might see calls to the following operations:
These are special operations used by AWS Systems Manager, as described in the rest of this topic.

Agent-related API operations (**ssmmessages** and **ec2messages** endpoints)

**ssmmessages** API operations

Systems Manager uses the ssmmessages endpoint for the following two types of API operations:
• Operations from SSM Agent to Session Manager, a capability of AWS Systems Manager, in the cloud. This endpoint is required to create and delete session channels with the Session Manager service in the cloud. Additionally, if connectivity is allowed, SSM Agent receives Command documents through this Amazon Message Gateway Service. If connectivity is not allowed, SSM Agent receives Command documents through the Amazon Message Delivery Service. For more information, see Actions, resources, and condition keys for Amazon Session Manager Message Gateway Service.

• Operations from Systems Manager Agent (SSM Agent) to the Systems Manager service in the cloud.

**ec2messages API operations**

ec2messages:* API operations are made to the Amazon Message Delivery Service endpoint. Systems Manager uses this endpoint for API operations from Systems Manager Agent (SSM Agent) to the Systems Manager service in the cloud.

⚠️ **Important**

ec2messages:* API operations are supported only in AWS Regions that launched before 2024. In Regions launched in 2024 and later, only ssmmessages:* API operations are supported.

**Endpoint connection precedence**

Beginning with version 3.3.40.0 of SSM Agent, Systems Manager began using the ssmmessages:* endpoint (Amazon Message Gateway Service) whenever available instead of the ec2messages:* endpoint (Amazon Message Delivery Service).

If you provide access to ssmmessages:* in your AWS Identity and Access Management (IAM) permission policies, SSM Agent connects to the ssmmessages:* endpoint, even if your IAM instance profile is configured to allow both endpoints. This includes policies for IAM instance profiles and IAM service roles you have created yourself, and for IAM instance profiles created by the Quick Setup Host management configuration and Default Host Management Configuration.

If you have provided permissions for both endpoints and monitor API operations using, for example, CloudWatch Metrics, you will see no calls to ec2messages:*.
For AWS Regions launched before 2024: You can safely remove ec2messages:* permissions from your policies at this time.

**Endpoint connection failover**

For AWS Regions launched before 2024 only: If your IAM instance profile does not provide permissions for ssmmessages:* at the time the agent starts, but only ec2messages:*, SSM Agent connects to the ec2messages:* endpoint. If you have both ssmmessages:* and ec2messages:* at the time SSM Agent starts, but remove ssmmessages:* after the agent starts, SSM Agent soon switches the connection to the ec2messages:* endpoint. For Regions launched in 2024 and later, only the ssmmessages:* endpoint is supported.

For more information about the ssmmessages and ec2messages:* endpoints, see the following topics in the *AWS Service Authorization Reference*.

- [Actions, resources, and condition keys for Amazon Message Gateway Service](#) (ssmmessages).
- [Actions, resources, and condition keys for Amazon Message Delivery Service](#) (ec2messages:*)

**ssm:* namespace instance-related API operations**

**DescribeDocumentParameters**

Systems Manager runs this API operation to render specific nodes in the Amazon EC2 console. Results of the DescribeDocumentParameters operation are displayed in the Documents node.

**DescribeInstanceProperties**

Systems Manager runs this API operations to render specific nodes in the Amazon EC2 console. Results of the DescribeInstanceProperties operation are displayed in the Fleet Manager node.

**GetCalendar**

Systems Manager runs this API operation to render Change Calendar type documents in the Change Calendar console.

**GetManifest**

SSM Agent runs this API operation to determine system requirements for installing or updating a specified version of an [AWS Systems Manager Distributor](#) package. This is a legacy API operation and not available in AWS Regions launched after 2017.
ListInstanceAssociations

SSM Agent runs this API operation to see if a new State Manager association is available. This API operation is required for State Manager to function.

PutCalendar

Systems Manager runs this API operation to update Change Calendar type documents in the Change Calendar console.

PutConfigurePackageResult

SSM Agent runs this API operation to publish installation error and latency metrics for public Distributor packages to the package owner’s account.

RegisterManagedInstance

SSM Agent runs this API operation for the following scenarios:

- To register an on-premises server or virtual machine (VM) with Systems Manager as a managed instance using an activation code and ID.
- To register AWS IoT Greengrass Version 2 credentials.

This operation is also called by Amazon EC2 instances running SSM Agent version 3.1.x or later.

RequestManagedInstanceRoleToken

SSM Agent runs this API operation to retrieve temporary credentials to access the managed node.

UpdateInstanceAssociationStatus

SSM Agent runs this API operation to update an association. This API operation is required for State Manager, a capability of AWS Systems Manager, to function.

UpdateInstanceInformation

SSM Agent calls the Systems Manager service in the cloud every 5 minutes to provide heartbeat information. This call is necessary to maintain a heartbeat with the agent so that the service knows the agent is functioning as expected.

UpdateManagedInstancePublicKey

SSM Agent runs this API operation to provide the public key after rotating the key pair on the managed node. The public key is used to authenticate the requests, signed with the private key, to get temporary credentials from Systems Manager.
Reference: Creating formatted date and time strings for Systems Manager

AWS Systems Manager API operations accept filters to limit the number of results returned by a request. Some of these API operations accept filters that require a formatted string to represent a specific date and time. For example, the DescribeSessions API operation accepts the InvokedAfter and InvokedBefore keys as some valid values for a SessionFilter object. Another example is the DescribeAutomationExecutions API operation, which accepts the StartTimeBefore and StartTimeAfter keys as some valid values for an AutomationExecutionFilter object. The values you provide for these keys when filtering your requests must match the ISO 8601 standard. For information about ISO 8601, see ISO 8601.

These formatted date and time strings aren't limited to filters. There are also API operations that require an ISO 8601 formatted string to represent a specific date and time when providing a value for a request parameter. For example, the AtTime request parameter for the GetCalendarState operation. These strings are difficult to create. Use the examples in this topic to create formatted date and time strings to use with Systems Manager API operations.

Formatting date and time strings for Systems Manager

The following is an example of an ISO 8601 formatted date and time string.

```
2020-05-08T15:16:43Z
```

This represents May 8, 2020 at 15:16 Coordinated Universal Time (UTC). The calendar date portion of the string is represented by a four-digit year, two-digit month, and two-digit day separated by hyphens. This can be represented in the following format.

```
YYYY-MM-DD
```

The time portion of the string begins with the letter "T" as a delimiter, and then is represented by a two-digit hour, two-digit minute, and two-digit second separated by colons. This can be represented in the following format.

```
hh:mm:ss
```

The time portion of the string ends with the letter "Z", denoting the UTC standard.
Creating custom date and time strings for Systems Manager

You can create custom date and time strings from your local machine using your preferred command line tool. The syntax you use to create an ISO 8601 formatted date and time string differs depending on your local machine's operating system. The following are examples of how you can use `date` from GNU's coreutils on Linux, or PowerShell on Windows to create an ISO 8601 formatted date and time string.

**coreutils**

```
date '+%Y-%m-%dT%H:%M:%SZ'
```

**PowerShell**

```
(Get-Date).ToString("yyyy-MM-ddTH:mm:ssZ")
```

When working with Systems Manager API operations, you might need to create historical date and time strings for reporting or troubleshooting purposes. The following are examples of how you can create and use custom historical ISO 8601 formatted date and time strings for the AWS Tools for PowerShell and AWS Command Line Interface (AWS CLI).

**AWS CLI**

- Retrieve the last week of command history for an SSM document.

```
lastWeekStamp=$(date '+%Y-%m-%dT%H:%M:%SZ' -d '7 days ago')
docFilter='{"key":"DocumentName","value":"AWS-RunPatchBaseline"}'
timeFilter='{"key":"InvokedAfter","value":"\"$lastWeekStamp\"'}'
commandFilters=[$docFilter,$timeFilter]

aws ssm list-commands
   --filters $commandFilters
```

- Retrieve the last week of automation execution history.

```
lastWeekStamp=$(date '+%Y-%m-%dT%H:%M:%SZ' -d '7 days ago')
aws ssm describe-automation-executions
```
• Retrieve the last month of session history.

```
lastWeekStamp=$(date '+%Y-%m-%dT%H:%M:%SZ' -d '30 days ago')

aws ssm describe-sessions \\
--state History \\
--filters key=InvokedAfter,value=$lastWeekStamp
```

AWS Tools for PowerShell

• Retrieve the last week of command history for an SSM document.

```
$lastWeekStamp = (Get-Date).AddDays(-7).ToString("yyyy-MM-ddTH:mm:ssZ")
$docFilter = @{
    Key="DocumentName"
    Value="AWS-InstallWindowsUpdates"
}
$timeFilter = @{
    Key="InvokedAfter"
    Value=$lastWeekStamp
}
$commandFilters = $docFilter,$timeFilter

Get-SSMCommand ` \
-Filters $commandFilters
```

• Retrieve the last week of automation execution history.

```
$lastWeekStamp = (Get-Date).AddDays(-7).ToString("yyyy-MM-ddTH:mm:ssZ")

Get-SSMAutomationExecutionList ` \
-Filters @{Key="StartTimeAfter";Values=$lastWeekStamp}
```

• Retrieve the last month of session history.

```
$lastWeekStamp = (Get-Date).AddDays(-30).ToString("yyyy-MM-ddTH:mm:ssZ")

Get-SSMSession ` 
```
- State History ` 
- Filters @{Key="InvokedAfter";Value=$lastWeekStamp}
Use cases and best practices

This topic lists common use cases and best practices for AWS Systems Manager capabilities. If available, this topic also includes links to relevant blog posts and technical documentation.

⚠️ Note

The title of each section here is an active link to the corresponding section in the technical documentation.

Automation

- Create self-service Automation runbooks for infrastructure.
- Use Automation, a capability of AWS Systems Manager, to simplify creating Amazon Machine Images (AMIs) from the AWS Marketplace or custom AMIs, using public Systems Manager documents (SSM documents) or by authoring your own workflows.
- **Build and maintain AMIs** using the AWS-UpdateLinuxAmi and AWS-UpdateWindowsAmi Automation runbooks, or using custom Automation runbooks that you create.

Inventory

- Use Inventory, a capability of AWS Systems Manager, with AWS Config to audit your application configurations over time.

Maintenance Windows

- Define a schedule to perform potentially disruptive actions on your nodes such as operating system (OS) patching, driver updates, or software installations.
- For information about the differences between State Manager and Maintenance Windows, capabilities of AWS Systems Manager, see [Choosing between State Manager and Maintenance Windows](#).
Parameter Store

- Use Parameter Store, a capability of AWS Systems Manager, to centrally manage global configuration settings.

- How AWS Systems Manager Parameter Store uses AWS KMS.

- Reference AWS Secrets Manager secrets from Parameter Store parameters.

Patch Manager

- Use Patch Manager, a capability of AWS Systems Manager, to roll out patches at scale and increase fleet compliance visibility across your nodes.

  - Integrate Patch Manager with AWS Security Hub to receive alerts when nodes in your fleet go out of compliance and monitor the patching status of your fleets from a security point of view. There is a charge to use Security Hub. For more information, see Pricing.

- Use only one method at a time for scanning managed nodes for patch compliance to avoid unintentionally overwriting compliance data.

Run Command

- Manage Instances at Scale without SSH Access Using EC2 Run Command.

- Audit all API calls made by or on behalf of Run Command, a capability of AWS Systems Manager, using AWS CloudTrail.

- When you send a command using Run Command, don't include sensitive information formatted as plaintext, such as passwords, configuration data, or other secrets. All Systems Manager API activity in your account is logged in an S3 bucket for AWS CloudTrail logs. This means that any user with access to S3 bucket can view the plaintext values of those secrets. For this reason, we recommend creating and using SecureString parameters to encrypt sensitive data you use in your Systems Manager operations.

  For more information, see Restricting access to Systems Manager parameters using IAM policies.

Note

- By default, the log files delivered by CloudTrail to your bucket are encrypted by Amazon server-side encryption with Amazon S3-managed encryption keys (SSE-S3). To provide
a security layer that is directly manageable, you can instead use server-side encryption with AWS KMS–managed keys (SSE-KMS) for your CloudTrail log files.

For more information, see Encrypting CloudTrail log files with AWS KMS–managed keys (SSE-KMS) in the AWS CloudTrail User Guide.

• Use the targets and rate control features in Run Command to perform a staged command operation.

• Use fine-grained access permissions for Run Command (and all Systems Manager capabilities) by using AWS Identity and Access Management (IAM) policies.

Session Manager

• Audit session activity in your AWS account using AWS CloudTrail.

• Log session data in your AWS account using Amazon CloudWatch Logs or Amazon S3.

• Control user session access to instances.

• Restrict access to commands in a session.

• Turn off or turn on ssm-user account administrative permissions.

State Manager

• Update SSM Agent at least once a month using the pre-configured AWS-UpdateSSMAgent document.

• (Windows) Upload the PowerShell or DSC module to Amazon Simple Storage Service (Amazon S3), and use AWS-InstallPowerShellModule.

• Use tags to create application groups for your nodes. And then target nodes using the Targets parameter instead of specifying individual node IDs.

• Automatically remediate findings generated by Amazon Inspector by using Systems Manager.

• Use a centralized configuration repository for your SSM documents, and share documents across your organization.

• For information about the differences between State Manager and Maintenance Windows, see Choosing between State Manager and Maintenance Windows.
Managed nodes

- Systems Manager requires accurate time references to perform its operations. If your node's date and time aren't set correctly, they might not match the signature date of your API requests. This might lead to errors or incomplete functionality. For example, nodes with incorrect time settings won't be included in your lists of managed nodes.

For information about setting the time on your nodes, see [Set the time for your Amazon EC2 instance](#).

- On Linux managed nodes, [verify the signature of SSM Agent](#).

More info

- [Security best practices for Systems Manager](#)

Deleting Systems Manager resources and artifacts

As a best practice, we recommend that you delete Systems Manager resources and artifacts if you no longer need to view data about those resources or use the artifacts in any way. The following table lists each Systems Manager capability or artifact and a link to more information about deleting the resources or artifacts created by Systems Manager.

<table>
<thead>
<tr>
<th>Capability or artifact</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application Manager</td>
<td>You can't delete an application in Application Manager, but you can remove an application from the service by deleting the underlying tags, Resource Groups, or AWS CloudFormation stacks.</td>
</tr>
<tr>
<td>Automation</td>
<td>If you create AWS resources by using Systems Manager Automation, you must manually delete those resources by using the corresponding AWS Management Console. If you created a custom runbook, you can delete the underlying SSM document. For more information, see <a href="#">Deleting custom SSM documents</a>.</td>
</tr>
<tr>
<td>Capability or artifact</td>
<td>Details</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Change Calendar</td>
<td>You can delete a change calendar and a change calendar event. For more information, see <a href="#">Deleting a change calendar</a> and <a href="#">Deleting a Change Calendar event</a>.</td>
</tr>
<tr>
<td>Change Manager</td>
<td>You can delete a change template. For more information, see <a href="#">Deleting change templates</a>.</td>
</tr>
<tr>
<td>Compliance</td>
<td>Systems Manager Compliance automatically displays compliance data about Patch Manager patching and State Manager associations. You can't delete this data. If you configured a resource data sync to centralize compliance data in an S3 bucket, you can delete the sync. For more information, see <a href="#">Deleting a resource data sync for Compliance</a>.</td>
</tr>
<tr>
<td>Distributor</td>
<td>You can delete packages in Distributor. For more information, see <a href="#">Delete a package</a>.</td>
</tr>
<tr>
<td>Explorer</td>
<td>You can disconnect from the sources from which Explorer collects OpsData. For more information, see <a href="#">Editing Systems Manager Explorer data sources</a>. You can also delete a resource data sync used by Explorer to aggregate OpsData and OpsItems from multiple AWS Regions and accounts to a single Amazon Simple Storage Service (Amazon S3) bucket. For more information, see <a href="#">Deleting a Systems Manager Explorer resource data sync</a>. For information about deleting an S3 bucket, see <a href="#">Deleting a bucket</a> in the <a href="#">Amazon Simple Email Service Developer Guide</a>.</td>
</tr>
<tr>
<td>Capability or artifact</td>
<td>Details</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Fleet Manager</td>
<td>You can't delete a managed node by using Fleet Manager. You must use Amazon Elastic Compute Cloud (Amazon EC2). For more information, see <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/terminate-instance-linux.html">Terminate your instance (Linux)</a> and <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/terminate-instance-windows.html">Terminate your instance (Windows)</a>.</td>
</tr>
<tr>
<td>Inventory</td>
<td>You can stop Inventory data collection by deleting the State Manager associations that define the schedule and the resources from which to collect metadata. For more information, see <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/stop-data-collection.html">Stopping data collection and deleting inventory data</a>. If you no longer want to use AWS Systems Manager Inventory to view metadata about your AWS resources, then we also recommend deleting resource data syncs used for inventory data collection. For more information, see <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/delete-data-sync.html">Deleting an Inventory resource data sync</a>.</td>
</tr>
<tr>
<td>Maintenance Windows</td>
<td>You can delete a maintenance window, a maintenance window target, and a maintenance window task. For more information, see <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/update-delete-window.html">Updating or deleting maintenance window resources (console)</a>.</td>
</tr>
<tr>
<td>OpsCenter</td>
<td>You can delete an individual OpsItem by calling the <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/reference-api-opscenter.html">DeleteOpsItem</a> API operation using the AWS Command Line Interface or the AWS SDK. You can't delete an OpsItem in the AWS Management Console. For more information, see <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/reference-api-opscenter.html">Delete OpsItems</a>.</td>
</tr>
<tr>
<td>Capability or artifact</td>
<td>Details</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Parameter Store</td>
<td>You can delete a parameter that you have created. For more information, see Deleting Systems Manager parameters.</td>
</tr>
<tr>
<td>Patch Manager</td>
<td>You can delete a custom patch baseline. For more information, see Updating or deleting a custom patch baseline.</td>
</tr>
<tr>
<td>Quick Setup</td>
<td>You can delete associations created by Quick Setup. The associations are stored and processed by State Manager. For more information, see Deleting associations.</td>
</tr>
<tr>
<td>Run Command</td>
<td>After a command finishes processing, information about it is stored in the Command history tab. You can't delete information from the Command history tab.</td>
</tr>
<tr>
<td>Service-linked role</td>
<td>Systems Manager automatically creates service-linked roles for some capabilities. You can delete these roles. For more information, see Deleting the AWSServiceRoleForAmazonSSM service-linked role for Systems Manager.</td>
</tr>
<tr>
<td>Session Manager</td>
<td>Session Manager doesn't retain data about your resources after you terminate a session. To terminate a session, see End a session.</td>
</tr>
</tbody>
</table>

| SSM Agent                              | You can manually uninstall SSM Agent from your nodes. For more information, see the following topics.  
  - Linux: [Manually installing and uninstalling SSM Agent on EC2 instances for Linux](#)  
  - macOS: [Manually installing and uninstalling SSM Agent on EC2 instances for macOS](#)  
  - Windows Server: Open **Control panel** and then choose **Add/remove programs**. |
| State Manager                          | You can delete an association. For more information, see [Deleting associations](#).                                                    |
| Systems Manager document service       | You can't delete runbooks provided by AWS or AWS Support, but you can delete custom runbooks. For more information, see [Deleting custom SSM documents](#). |

### Choosing between State Manager and Maintenance Windows

State Manager and Maintenance Windows, both capabilities of AWS Systems Manager, can perform some similar types of updates on your managed nodes. Which one you choose depends on whether you need to automate system compliance or perform high-priority, time-sensitive tasks during periods you specify.

### State Manager and Maintenance Windows: Key use cases

State Manager, a capability of AWS Systems Manager, sets and maintains the targeted state configuration for managed nodes and AWS resources within your AWS account. You can define combinations of configurations and targets as association objects. State Manager is the recommended capability if you want to maintain all managed nodes in your account in a consistent state, use Amazon EC2 Auto Scaling to generate new nodes, or have strict compliance reporting requirements for the managed nodes in your account.
The main use cases for State Manager are as follows:

- **Auto Scaling scenarios:** State Manager can monitor all new nodes launched within an account either manually or through Auto Scaling groups. If there are any associations in the account targeting that new node (through tags or all nodes), then that particular association is automatically applied to the new node.

- **Compliance reporting:** State Manager can drive compliance reporting of required states for resources in your account.

- **Supporting all nodes:** State Manager can target all nodes within a given account.

A **maintenance window** takes one or more actions on AWS resources within a given time window. You can define a single maintenance window with start and end times. You can specify multiple tasks to run within this maintenance window. Use Maintenance Windows, a capability of AWS Systems Manager, if your high priority operations include patching your managed nodes, running multiple types of tasks on your nodes during an update period, or controlling when update operations can be run on your nodes.

The main use cases for Maintenance Windows are as follows:

- **Running multiple documents:** Maintenance windows can run multiple tasks. Each task can use a different document type. As a result, you can build complex workflows using different tasks within a single maintenance window.

- **Patching:** A maintenance window can provide patching support for all managed nodes in a single Region that are tagged with a specific tag or resource group. Because patching usually involves bringing down nodes (for example, removing nodes from a load balancer), patching, and post processing (putting nodes back into production), patching can be achieved as a series of tasks within a given patch time window.

⚠️ **Note**

Using a maintenance window, your patching operation is limited to a single Region in a single account. Using a patch policy created in Quick Setup, a capability of Systems Manager, you can instead configure patching for some or all accounts and Regions in an organization created in AWS Organizations. For more information, see [Using Quick Setup patch policies](#).
• **Window actions:** Maintenance windows can make one or more sets of actions start within a specific time window. Maintenance windows won't start outside of that window. Actions already started continue until finished, even if they finish outside of the time window.

The following table compares the main features of State Manager and Maintenance Windows.

<table>
<thead>
<tr>
<th>Feature</th>
<th>State Manager</th>
<th>Maintenance Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS CloudFormation integration</strong></td>
<td>AWS CloudFormation templates support State Manager associations.</td>
<td>AWS CloudFormation templates support maintenance windows, window targets, and window tasks.</td>
</tr>
<tr>
<td><strong>Compliance</strong></td>
<td>Every State Manager association reports compliance with respect to the required state of the targeted resource. You can use the Compliance Dashboard to aggregate and view the reported compliance.</td>
<td>Not applicable.</td>
</tr>
<tr>
<td><strong>Configuration Management integration</strong></td>
<td>State Manager supports external targeted state solutions such as Microsoft PowerShell Desired State Configuration (DSC), Ansible playbooks, and Chef recipes. You can use State Manager associations to test that the Configuration Management solutions work and to apply their configuration changes to your nodes when you're ready.</td>
<td>Not applicable.</td>
</tr>
<tr>
<td>Feature</td>
<td>State Manager</td>
<td>Maintenance Windows</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Documents</td>
<td>State Manager configurations can be defined as Policy documents (for gathering inventory information), Automation runbooks, for AWS resources such as Amazon Simple Storage Service (Amazon S3) buckets, or Systems Manager Command documents (SSM documents) for managed nodes.</td>
<td>Maintenance Windows configurations can be defined as automation documents (multi-step actions with optional approval workflows) or SSM documents (required state for managed nodes).</td>
</tr>
<tr>
<td>Monitoring</td>
<td>State Manager monitors changes in the configuration, association, or state of a node (for example, new nodes coming online). When State Manager detects these changes, the given association is re-applied to the nodes originally targeted with that association.</td>
<td>Not applicable.</td>
</tr>
<tr>
<td>Feature</td>
<td>State Manager</td>
<td>Maintenance Windows</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Priorities within tasks</strong></td>
<td>Not applicable.</td>
<td>Tasks within a maintenance window can be assigned a priority. All tasks with the same priority are run in parallel. Tasks with lower priorities are run after tasks with higher priorities reach a final state. There is no way to conditionally run tasks. After a higher priority task reaches its final state, the next priority task runs, regardless of the state of the previous task.</td>
</tr>
<tr>
<td><strong>Safety controls</strong></td>
<td>State Manager supports two safety controls when deploying configurations across a large fleet. You can use maximum concurrency to define how many concurrent nodes or resources should have the configuration applied. You can define a maximum error rate which can be used to pause the State Manager association if a certain number or percentage of errors occur across the fleet.</td>
<td>Maintenance windows support two safety controls when deploying configurations across a large fleet. You can use maximum concurrency to define how many concurrent nodes or resources should have the configuration applied. You can define a maximum error rate which can be used to pause the actions in a maintenance window if a certain number or percentage of errors occur across the fleet.</td>
</tr>
<tr>
<td>Feature</td>
<td>State Manager</td>
<td>Maintenance Windows</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Scheduling</td>
<td>You can run State Manager associations on demand, at a particular cron interval, at a given rate, or after they're created. This is useful if you want to maintain the required state of your resources in a consistent and timely manner.</td>
<td>Maintenance windows support several scheduling options including at expressions (for example, &quot;at(2021-07-07T13:15:30)&quot;), cron and rate expressions, cron with offsets, and start and end times for when maintenance windows should run, and cutoff times to specify when to stop scheduling within a given time window.</td>
</tr>
</tbody>
</table>

**Important**

Cron expressions for State Manager associations do not support the months field, such as 03 or MAR for the month of March. If you require monthly or quarterly configuration updates, a maintenance window can best meet your needs. For more information, see [Reference: Cron and rate expressions for Systems Manager](#).
<table>
<thead>
<tr>
<th>Feature</th>
<th>State Manager</th>
<th>Maintenance Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Targeting</strong></td>
<td>State Manager associations can target one or more nodes by using node ID, tag, or resource group. State Manager can target all managed nodes within a given account.</td>
<td>Maintenance windows can target one or more nodes using node IDs, tags, or resource groups.</td>
</tr>
</tbody>
</table>
| **Tasks within maintenance windows** | Not applicable.                                                               | Maintenance windows can support one or more tasks where each task targets a specific Automation runbook or Command document action. All tasks within a maintenance window run in parallel unless different priorities are set for different tasks. Overall, maintenance windows support four task types:  
  - AWS Systems Manager Run Command commands  
  - AWS Systems Manager Automation workflows  
  - AWS Lambda functions  
  - AWS Step Functions tasks |

<td><strong>Launch a Mac instance</strong> in the Amazon EC2 User Guide</td>
<td></td>
</tr>
</tbody>
</table>
• **Amazon EC2 Mac instances**
  in the *Amazon EC2 User Guide*

• **Use AWS Systems Manager parameters instead of AMI IDs in launch templates**
  in the *Amazon EC2 Auto Scaling User Guide*

**Update: Regional availability of the /aws/service/global-infrast ructure parameter path**

We have clarified which **commercial Regions** the /aws/service/globa l-infrastructure public parameter path can be queried from, and how to run a query for the path if you are working in a different commercial AWS Region.

For information, see [Calling public parameters for AWS services, Regions, endpoints, Availability Zones, local zones, and Wavelength Zones](#).

**New: Code examples chapter**

A new chapter, **Code examples for Systems Manager using AWS SDKs**, provides examples in different SDK languages for how to work with the Systems Manager service.
**Changes to ec2messages:* endpoint support**

For AWS Regions launching in 2024 or later, the ec2messages:* endpoints are not supported by SSM Agent for sending status and execution information back to the Systems Manager service. Accounts in these Regions must use ssmmessages:*.

In Regions launched before 2024, both ssmmessages:* and ec2messages:* are still supported, but we recommend using only the ssmmessages:* endpoint (Amazon Message Gateway Service) now. You can safely remove ec2messages:* permissions from your policies at this time. For more information, see [Working with SSM Agent](#) and [Agent-related API operations (ssmmessages and ec2messages endpoints)](#).

**Additional runtimes available for running scripts in Automation runbooks**

The `aws:executeScript` action now supports the Python 3.9, 3.10, and 3.11 runtimes. For more information about how to use this action, see [aws:executeScript](#).

---

*May 3, 2024*

*April 23, 2024*
Support for 8.8 and 8.9 versions: AlmaLinux, Oracle Linux, and Rocky Linux

Systems Manager now supports versions 8.8 and 8.9 of AlmaLinux, Oracle Linux, and Rocky Linux, in addition to earlier 8.x versions. For complete lists of supported OSs and versions, see Supported operating systems for Systems Manager.

Patch Manager: Change to patching status 'INSTALLED_PENDING_REBOOT'

Previously, only patches installed by Patch Manager could be marked as INSTALLED_PENDING_REBOOT. Patches installed outside of Patch Manager were never given this status. Now, INSTALLED_PENDING_REBOOT can apply to any patch that has been applied to a managed node since it was last rebooted. This includes patches installed by Patch Manager with the NoReboot option selected, and to patches installed outside of Patch Manager after the node's most recent reboot. For descriptions of all Patch Manager patching status values, see Understanding patch compliance state values.
Support for RHEL 8.9 and 9.3

Systems Manager, including Patch Manager, now supports Red Hat Enterprise Linux (RHEL) versions 8.9 and 9.3, in addition to earlier 8.x and 9.x versions.

March 26, 2024

Topic update: AWS managed policies for AWS Systems Manager

The topic AWS managed policies for AWS Systems Manager has provided information about the four managed policies for Systems Manager that have been introduced or updated since March 12, 2021. We have added a section to this topic with information about the 12 other managed policies for use with Systems Manager that were created or last updated before that date. For details, see Additional managed policies for Systems Manager.

March 1, 2024
Parameter Store now supports cross-account sharing

You can now share advanced parameters securely and efficiently across AWS accounts or within your AWS Organization by setting up resource sharing. Resource sharing allows you to centralize application configuration management and reduce the operational overhead of sharing the parameters with every single account you own. Parameters can be shared across accounts using the Parameter Store console, the AWS RAM console, or the AWS CLI. For more information, see Working with shared parameters.

Automation action enhancement

You can now use the `onFailure` and `isCritical` properties with the `aws:approve` action. For more information about the `aws:approve` action, see `aws:approve – Pause an automation for manual approval`.

| **Configure automated SSM Agent updates using the Application Manager console** | You can now use the Application Manager console to automate SSM Agent updates for your application instances. For more information, see Working with your application instances. | December 21, 2023 |

| **Updated process for registering non Amazon EC2 machines in hybrid and multicloud environments** | Systems Manager now provides the `ssm-setup-cli` to help you register non Amazon Elastic Compute Cloud (Amazon EC2) machines in hybrid and multicloud environments. For more information, see How to install the SSM Agent on hybrid Linux nodes and How to install the SSM Agent on hybrid Windows nodes. | December 20, 2023 |
Manage Amazon EBS volumes using Fleet Manager

You can now use Fleet Manager, a capability of AWS Systems Manager, to manage Amazon Elastic Block Store volumes on your managed instances. For example, you can initialize an EBS volume, format a partition, and mount the volume to make it available for use. For more information, see EBS volume management.

Session Manager plugin enhancement

Added support for passing a StartSession API response as an environment variable to session-manager-plugin.

New visual design experience for Automation runbooks

You can now create and edit runbooks using a new visual design experience developed by Systems Manager Automation. The visual design experience provides a low-code, drag-and-drop interface so you can create and edit runbooks more easily. For more information, see Visual design experience for Automation runbooks.

December 14, 2023

December 4, 2023

November 26, 2023
New Systems Manager Automation actions, data element, and functional enhancements for runbooks

You can now loop over multiple actions in a runbook using the `aws:loop` action. This new action supports `do while` and `for each` style loops. Additionally, using the new `variables` data element, you can define, reference and update values dynamically within the context of a runbook. To update the value of a variable in your runbook, use the new `aws:updateVariable` action. Automation has also added support for dynamic data type conversions for outputs. This means that if the value of an output doesn't match the data type you've specified, Automation tries to convert the data type. For example, if the value returned is an `Integer`, but the `Type` specified is `String`, the final output value is a `String` value.

Lastly, Automation now supports JSONPath filter expressions for selectors. For more information, see the following topics:

- `aws:loop` – Iterate over steps in an automation
• **aws:updateVariable** – Updates a value for a runbook variable

• **Data elements and parameters** – Top-level data elements

• **Using action outputs as inputs.**

• **Using JSONPath in runbooks.**

---

**Updated Region support for Remote Desktop Protocol (RDP) connections**

**Fleet Manager Remote Desktop**, which is powered by NICE DCV, provides you with secure connectivity to your Windows Server instances directly from the Systems Manager console. The following three additional Regions have been enabled for Fleet Manager Remote Desktop connections:

• Africa (Cape Town) (af-south-1)

• Asia Pacific (Jakarta) (ap-southeast-3)

• Israel (Tel Aviv) (il-central-1)

---

November 15, 2023
Patch Manager: Expanded OS version support for RHEL and macOS

Patch Manager now supports the following additional operating system versions:

- Red Hat Enterprise Linux: version 8.8
- macOS: 11.5–11.7 (Big Sur)
- macOS: 12.0–12.6 (Monterey)
- macOS: 13.0–13.5 (Ventura)

New OpsCenter API - DeleteOpsItem

OpsCenter now offers the DeleteOpsItem API for deleting individual OpsItems. For more information, see DeleteOpsItem in the AWS Systems Manager API Reference.

New Quick Setup configuration type: SSM Agent updates for entire organization

The new configuration type Default Host Management Configuration makes it possible for an organization administrator, as defined in AWS Organizations, to prompt automatic check and updates of SSM Agent on all EC2 instances in the organization's accounts and Regions. For more information, see Default Host Management for an organization.

| **Support for multiple display resolutions in Fleet Manager RDP connections** | When you connect to Windows Server managed nodes using the Remote Desktop protocol (RDP) option in Fleet Manager, you can now choose the display resolution. Previously, all connections used a fixed 720P (1366 x 768) resolution. You can now choose from the following for each connection:  
  - **Adapt Automatically** (determines optimum resolution based on your detected screen size)  
  - **1920 x 1080**  
  - **1400 x 900**  
  - **1366 x 768**  
  - **800 x 600**  
For information, see Connect to a managed node using Remote Desktop. | September 22, 2023  |
We have added content to describe how Quick Setup patch policies use the BaselineOverride parameter in the AWS-RunPatchBaseline SSM Command document to generate random IDs for patch baselines each time a patch policy operation is run. For information, see Random patch baseline IDs in patch policy operations.

OpsCenter now includes an operational insight called Resources generating the most OpsItems. An insight of this type is generated when an AWS resource has more than 10 open OpsItems. Use this insight to locate problematic resources. Use the AWS-BulkResolveOpsItems runbook from within an insight to quickly resolve OpsItems associated with a resource. For more information, see Analyzing operational insights to reduce OpsItems.

A new public key has been created to verify the signature of SSM Agent. For more information, see Verifying the signature of SSM Agent.
Support added for additional versions of AlmaLinux, Oracle Linux, RHEL, and Rocky Linux

The lists of supported operating systems for AWS Systems Manager and Patch Manager have been updated to reflect support the following additional OS versions:

- AlmaLinux: 9.2
- Oracle Linux: 8.7 and 9.2
- Red Hat Enterprise Linux (RHEL): 8.7, 9.1, and 9.2
- Rocky Linux: 8.6 and 8.7, 9.0–9.2

August 30, 2023

OpsCenter added support for Markdown formatting in the OpsItem description field.

OpsCenter now supports Markdown formatting in the OpsItem description field. The following types of Markdown formatting are supported:

- Paragraphs
- Line spacing
- Horizontal Lines
- Headings
- Text Formatting
- Links
- Lists

For more information, see Using Markdown in the Console in the Getting Started with the AWS Management Console Getting Started Guide.

August 18, 2023
New versions of the AWS Parameters and Secrets Lambda Extension are now available. In addition, extension support has been added for the Asia Pacific (Melbourne) (ap-southeast-4) and Israel (Tel Aviv) (il-central-1) Regions (x86_64 and x86 architectures only.) For more information, see Using Parameter Store parameters in AWS Lambda functions.

August 16, 2023
Update: Added information about required permissions for Quick Setup patch policy buckets

When you create a patch policy, Quick Setup creates an Amazon S3 bucket that contains a file named baseline_overrides.json. This file stores information about the patch baselines that you specified for your patch policy. When configuring the patch policy, you have the option of selecting an Add required IAM policies to existing instance profiles attached to your instances check box. If you choose not to select this option, then you must manually provide certain resources with permissions to access this bucket or your policy operations might fail. For more information, see the following topics:

- Permissions for the patch policy S3 bucket
- Issue: "Invoke-PatchBaselineOperation : Access Denied" error or "Unable to download file from S3" error for baseline_overrides.json
Use Quick Setup to configure OpsCenter for multi-account OpsItem management

Quick Setup for OpsCenter helps you complete the following tasks for managing OpsItems across accounts:

- Specifying the delegated administrator account
- Creating required AWS Identity and Access Management (IAM) policies and roles
- Specifying an AWS Organizations organization, or a subset of member accounts, where a delegated administrator can manage OpsItems across accounts

For more information, see (Optional) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup.

Update Amazon EC2 launch agents using Quick Setup

You can now allow Systems Manager to check every 30 days for a new version of the launch agent installed on your instance. If a new version is available, Systems Manager updates the agent on your instance. For more information, see Quick Setup Host Management.

June 19, 2023
Patch Manager now supports Ubuntu Server 22.04 LTS

You can now use Patch Manager to patch Ubuntu Server 22.04 LTS nodes. Like other supported versions of Ubuntu Server, version 22.04 LTS, uses the AWS managed AWS-UbuntuDefaultPatchBaseline patch baseline.

May 15, 2023

Systems Manager now supports AlmaLinux, including Patch Manager

You can now use Systems Manager to manage AlmaLinux 8.3-8.7; 9.0-9.1 nodes. Many of the rules that apply to RHEL 8 for patching also apply to AlmaLinux. AlmaLinux uses the new AWS-DefaultAlmaLinuxPatchBaseline. For more information, see the following topics:

- [Manually install SSM Agent on AlmaLinux instances](#)
- [How security patches are selected](#)
- [How patches are installed](#)
- [How patch baseline rules work on AlmaLinux, RHEL, and Rocky Linux](#)

May 8, 2023
Deploy the EC2Launch v2 agent using Quick Setup

You can now deploy the EC2Launch v2 agent using Quick Setup. For more information, see Deploy Distributor packages with Quick Setup.

April 13, 2023

Systems Manager now supports Amazon Linux 2023

Systems Manager now supports the new Amazon Linux 2023 (AL2023) EC2 instance type, including support for Patch Manager operations. Many of the rules for patching that apply to Amazon Linux 2 also apply to Amazon Linux 2023. (Patch Manager also continues to support the preview release Amazon Linux 2022.) For more information, see the following topics:

- How security patches are selected
- How patches are installed
- How patch baseline rules work on Amazon Linux 1, Amazon Linux 2, Amazon Linux 2022, and Amazon Linux 2023

<td><strong>New Change Manager approval workflow</strong></td>
<td>The Change Manager approval workflow now supports <em>per-level</em> approvals instead of <em>per-line approvals</em>. Previously, every approver you added to an approval level had to approve a change request. Otherwise, the level was not approved. Now, you specify how many approvals are required for the level and can add that many or more approvers. For example, you can require three approvals for a level but specify up to five approvers. Approvals from any three of those approvers are sufficient to approve the level. For more information, see About approvals in your change templates.</td>
<td>January 23, 2023</td>
</tr>
</tbody>
</table>
New: Configure patching for an entire organization using a patch policy in Quick Setup

With Quick Setup, a capability of Systems Manager, you can now create patch policies powered by Patch Manager. A patch policy defines the schedule and patch baseline to use when automatically patching your managed nodes. Using a single patch policy configuration, you can define patching for all accounts in all Regions in your organization, for only the accounts and Regions you choose, or for a single account-Region pair. For more information, see the following topics.

- Using Quick Setup patch policies
- Automate organization-wide patching using a Quick Setup patch policy
Application Manager integrates with Amazon EC2 to display information about your instances in the context of an application.

Application Manager displays instance state, status, and Amazon EC2 Auto Scaling health for a selected application in a graphical format. The **Instances** tab also includes a table with the following information for each instance in your application.

- Instance state (Pending, Stopping, Running, Stopped)
- Ping status for SSM Agent
- Status and name of the last Systems Manager Automation runbook processed on the instance
- A count of Amazon CloudWatch Logs alarms per state.
  - **ALARM** – The metric or expression is outside of the defined threshold.
  - **OK** – The metric or expression is within the defined threshold.
  - **INSUFFICIENT_DATA** – The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.
• Auto Scaling group health for the parent and individual autoscaling groups

Schedule the starting and stopping of your Amazon EC2 instances using Quick Setup

You can now deploy the Resource Scheduler solution to automate the starting and stopping of your Amazon EC2 instances using Quick Setup. For more information, see Resource Scheduler.
OpsCenter supports working with OpsItems from a management account (either an AWS Organizations management account or a Systems Manager delegated administrator account) and a member account during a session. Once configured, users can perform the following types of actions:

- Create, view, and update OpsItems in a member account
- View detailed information about AWS resources specified in OpsItems in a member account
- Start Systems Manager Automation runbooks to remediate issues with AWS resources in a member account

For more information, see Setting up OpsCenter to work with OpsItems across accounts.
You can now use an event data store in AWS CloudTrail Lake to capture and review details about the change requests that are run in Change Manager for your organization or account. This information includes auditable details about the user identity that created the change request, the IP address from which the request was made, the AWS Regions in which the changes were made, the targeted resources, and more. For information, see Monitoring your change request events and Reviewing change request details, tasks, and timelines.
<table>
<thead>
<tr>
<th><strong>Additional Systems Manager Automation task controls using CloudWatch alarms</strong></th>
<th>You can now implement additional control when running automations across multiple accounts and Regions by using CloudWatch alarms. By applying a metric or composite CloudWatch alarm to an automation, you can control when an automation stops based on the metrics you define. </thead>
<tbody>
<tr>
<td><strong>Updated: 'Using Parameter Store parameters in AWS Lambda functions'</strong></td>
<td>We have provided additional information to help you use the AWS Parameters and Secrets Lambda Extension to retrieve parameter values and cache them for future use in Lambda functions. Using the Lambda extension can reduce your costs by reducing the number of API calls to Parameter Store. For information, see Using Parameter Store parameters in AWS Lambda functions.</td>
<td>October 25, 2022</td>
</tr>
</tbody>
</table>
You can now implement additional control when running automations and commands by using CloudWatch alarms. A CloudWatch alarm can also be added to an automation or command when it is registered with a State Manager association or maintenance window task. By applying a composite CloudWatch alarm to an automation or command, you can control when an automation or command stops based on the metric you define. For more information about applying a CloudWatch alarm to an automation or command see the following procedures:

- [How security patches are selected](#)
- [How patches are installed](#)
- [How patch baseline rules work on Amazon Linux 1, Amazon Linux 2, and Amazon Linux 2022](#).
**Additional Systems Manager task controls using CloudWatch alarms**

You can now implement additional control when running automations and commands by using CloudWatch alarms. A CloudWatch alarm can also be added to an automation or command when it is registered with a State Manager association or maintenance window task. By applying a composite CloudWatch alarm to an automation or command, you can control when an automation or command stops based on the metric you define. For more information about applying a CloudWatch alarm to an automation or command see the following procedures:

- [Running a simple automation](#)
- [Running commands from the console](#)
- [Create an association](#)
- [Assign tasks to a maintenance window](#)

**Clarifying advanced-instances tier requirements**

Based on customer feedback, we have clarified the scenarios that require you to activate the advanced-instances tier in [Configuring instance tiers](#).
**Deploy the Amazon CloudWatch Agent using Quick Setup**

You can now deploy the Amazon CloudWatch agent using Quick Setup. For more information, see [Deploy Distributor packages with Quick Setup](#).

**'PatchGroup' key now supported for patch groups when EC2 instance metadata is allowed**

When you allow tags in EC2 instance metadata, the tag keys you create must not contain any spaces. Previously, this prevented customers from adding some of their EC2 instances to patch groups in Patch Manager because the tag key `Patch Group` had to be applied to the instances. Patch Manager now supports both `Patch Group` (with a space) and `PatchGroup` (without a space) as the tag key for identifying instances for a patch group. EC2 instances where tags are allowed in instance metadata can now be added to patch groups in Patch Manager. For information, see [About patch groups](#).
New topic: "How package release dates and update dates are calculated"

In patch baselines managed by AWS, new patches are auto-approved 7 days after they are released or updated. In custom patch baselines you create, you can optionally specify how many days to wait after they are released or updated to auto-approve their installation. For Amazon Linux 1 and Amazon Linux 2, various factors influence how the latest release dates and update dates are calculated. To help you avoid unexpected results when choosing auto-approval delays, these factors are explained in the topic How package release dates and update dates are calculated.

Updated content: Patch an AMI and update an Auto Scaling group

We have updated the Updating AMIs for Auto Scaling groups walkthrough to use launch templates instead of launch configurations. Additionally, we've implemented the latest Automation actions and runtimes in the runbook content.

August 24, 2022

June 22, 2022
**Change Manager: Prevent users from creating auto-approvable requests**

You can configure change templates in Change Manager to support automatic approvals, meaning that users with the necessary IAM permissions can choose to start the change request without requiring additional approval. Now, you can also restrict individual users, groups, or IAM roles from submitting auto-approval requests, even if a change template supports them. This is achieved through the use of a new IAM condition key, `ssm:AutoApprove`. For more information, see [Controlling access to auto-approval runbook workflows](#)
<table>

</tr>
<tr>
<td>Port forwarding to remote hosts support for Session Manager</td>
<td>Session Manager now supports port forwarding sessions to remote hosts. The remote host isn't required to be managed by Systems Manager. For more information, see <a href="#">Starting a session (port forwarding to remote host)</a>.</td>
<td>May 25, 2022</td>
</tr>
</tbody>
</table>
Updated content: Instructions for manually installing SSM Agent on Amazon EC2 Linux instances

In response to customer feedback, we have overhauled the topics that provide instructions for manually installing SSM Agent on Amazon EC2 instances. These topics now provide commands using globally available files that you can copy and paste for quick installation on EC2 instances in any AWS Region. These topics also provide information to help you creating installation commands that use files available in your own working Region. The latter approach is recommended when you are installing the agent on multiple instances using a script or template.

For more information, see the instructions for your Linux operating system in the section Manually installing SSM Agent on EC2 instances for Linux.
New topic: Amazon Machine Images (AMIs) with SSM Agent preinstalled

In response to customer feedback, we have centralized information about which AWS managed AMIs include SSM Agent preinstalled. This topic also provides instructions for how to verify that an Amazon EC2 instance created from these AMIs was successfully installed and is running. For rare cases where the agent might not install successfully, or install but not start, we also provide information about starting or manually installing the agent on these instances. For details, see Amazon Machine Images (AMIs) with SSM Agent preinstalled.

New State Manager section

Added a new section that describes the details of when State Manager runs associations. For more information, see About association scheduling.

May 8, 2022

April 27, 2022
Patch Manager now supports Rocky Linux

You can now use Patch Manager to patch Rocky Linux nodes. Many of the rules that apply to RHEL 8 for patching also apply to Rocky Linux. Rocky Linux 8 uses the new AWS-DefaultRockyLinuxPatchBaseline. For more information, see the following topics:

- [How security patches are selected](#)
- How patches are installed
- [How patch baseline rules work on RHEL, CentOS Stream, and Rocky Linux](#)
Patch Manager now supports CentOS Stream 8

You can now use Patch Manager to patch CentOS Stream 8 instances and Red Hat Enterprise Linux (RHEL) 4.4-4.5 instances. Many of the rules that apply to RHEL 8 for patching also apply CentOS Stream 8. CentOS Stream 8 uses the AWS-DefaultCentOSPatchBaseline. For more information, see the following topics:

- [How security patches are selected](#)
- [How patches are installed](#)
- [How patch baseline rules work on RHEL and CentOS Stream](#)

Support for Rocky Linux and Windows Server 2022 managed nodes

Systems Manager supports Rocky Linux and Windows Server 2022 managed nodes, including edge devices and hybrid machines located on-premises or with other cloud providers. To use Systems Manager with these operating systems, you must complete all required Systems Manager set up procedures, including procedures for hybrid environments or edge devices, if applicable. For more information, see Setting up Systems Manager.

For Rocky Linux machines, you must also manually install SSM Agent. For more information, see Manually install SSM Agent on Rocky Linux instances. For Windows Server 2022 Amazon Elastic Compute Cloud (Amazon EC2) instances, SSM Agent is installed by default.

March 1, 2022
| Allow Automation to adapt to your concurrency needs and view Automation usage metrics | You can now allow Automation to automatically adjust your concurrent automation quota, and view Automation usage metrics that are published to CloudWatch. For more information about adaptive concurrency, see **Allowing Automation to adapt to your concurrency needs.** For more information about how to view Automation usage metrics, see **Monitoring Automation metrics using Amazon CloudWatch.** | January 27, 2022 |

View resource cost details for an application

Application Manager is integrated with AWS Billing and Cost Management through the **Cost Explorer** widget. After you enable Cost Explorer in the Billing and Cost Management console, the Cost Explorer widget in Application Manager shows cost data for a specific non-container application or application component. You can use filters in the widget to view cost data according to different time periods, granularities, and cost types in either a bar or line chart. For more information, see [Viewing overview information about an application](#).

Manage processes using Fleet Manager

You can now use Fleet Manager to manage processes on your nodes. For more information, see [Working with processes](#).
Terminology change: managed instances are now managed nodes

With support for AWS IoT Greengrass core devices, the phrase *managed instance* has been changed to *managed node* in most of the Systems Manager documentation. The Systems Manager console, API calls, error messages, and SSM documents still use the term instance.
Support for edge devices

Systems Manager supports the following edge device configurations.

- **AWS IoT Greengrass:** Systems Manager now supports any device that is configured for AWS IoT Greengrass and runs the AWS IoT Greengrass Core software. To onboard your AWS IoT Greengrass core devices, you must create an AWS Identity and Access Management (IAM) service role. You must also use the AWS IoT Greengrass console to deploy SSM Agent as a AWS IoT Greengrass component on your devices. For more information, see [Setting up AWS Systems Manager for edge devices](#).

- **Edge devices in a hybrid environment:** Systems Manager also supports AWS IoT Core devices and non-AWS IoT devices after you configure them as on-premises machines. To onboard your devices, you must create an IAM service role, create a managed-node activation for a hybrid environment, and manually
install SSM Agent on your devices. For more information, see Setting up AWS Systems Manager for hybrid environments.

**Connect to managed instances using Remote Desktop**

You can now use Fleet Manager to connect to managed Windows instances using the Remote Desktop Protocol (RDP). These Remote Desktop sessions powered by NICE DCV provide secure connections to your instances directly from your browser. For more information, see Connect using Remote Desktop.

**Specify a maximum session duration and provide reasons for sessions**

You can now specify a maximum session duration for all Session Manager sessions in an AWS Region in your AWS account. When a session reaches the duration you specify, it's terminated. You can now also optionally add a reason when starting a session. For more information, see Specify maximum session duration.

November 23, 2021

November 16, 2021
Patch Manager now supports the Raspberry Pi OS operating system

You can now use Patch Manager to patch Raspberry Pi OS instances. Patch Manager supports patching Raspberry Pi OS 9 (Stretch) and 10 (Buster). Because the Raspberry Pi OS is Debian-based OS, many of the same patching rules apply to it as to Debian Server. For more information, see the following topics:

- [How security patches are selected](#)
- [How patches are installed](#)
- [How patch baseline rules work on Debian Server and Raspberry Pi OS](#)

Access the Red Hat Knowledgebase portal

Use Fleet Manager to access the RHEL Knowledgebase portal to find solutions, articles, documentation, and videos about using Red Hat products. For more information, see [Accessing the Red Hat Knowledgebase portal](#).

Patch Manager support for macOS 11.3.1 and 11.4 (Big Sur)

Amazon Elastic Compute Cloud (Amazon EC2) instances for macOS 11.3.1 and 11.4 (Big Sur) can now be patched using Patch Manager. This is in addition to existing support for macOS 10.14.x (Mojave) and 10.15.x (Catalina). For information about working with Patch Manager, see AWS Systems Manager Patch Manager.

October 1, 2021
Application Manager integrates with Amazon CloudWatch Application Insights. Application Insights identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. Application Insights continually monitors metrics and logs to detect and correlate anomalies and errors. When the system detects errors or anomalies, Application Insights generates CloudWatch Events that you can use to set up notifications or take actions. You can enable and view Application Insights on the Overview and Monitoring tabs in Application Manager. For more information about Application Insights, see What is Amazon CloudWatch Application Insights in the Amazon CloudWatch User Guide.
Import events from other calendars into Change Calendar

You can now import the events from a third-party calendar into a calendar in Change Calendar. Previously, each event had to be entered manually into a calendar. After you export a calendar from a supported third-party calendar provider to an iCalendar (.ics) file, import it into Change Calendar, and its events are included in the rules for your open or closed calendar in Systems Manager. Supported providers include iCloud Calendar, Google Calendar, and Microsoft Outlook. For more information, see Importing and managing events from third-party calendars.

September 8, 2021
| New tagging and runbook features in Application Manager | Tagging enhancements include the ability to add tags to or delete tags from a specific resource or all resources in an Application Manager application. Runbook enhancements include the ability to view a filtered list of runbooks for a specific resource type or initiate a runbook on all resources of the same type. For more information, see Working with tags in Application Manager and Working with runbooks in Application Manager. | August 31, 2021 |
| New example: Create a change request using the AWS CLI | An example of creating a change request with the AWS CLI has been added to the Change Manager chapter. The example uses the sample AWS-HelloWorldChangeTemplate change template and AWS-HelloWorld runbook:

### New section: Use parameters in Amazon EKS

A new section has been added to the Parameter Store chapter. This topic is a walkthrough on how to use your parameters in Amazon EKS clusters. For more information, see [Use Parameter Store parameters in Amazon Elastic Kubernetes Service](#).

*August 19, 2021*

### Updated Patch Manager lifecycle hooks

Patch Manager now provides a lifecycle hook—the ability to run a Systems Manager Command document—for an additional point during a **Patch now** patching operation. If you schedule instance reboots after running **Patch now**, you can specify a lifecycle hook to run after the reboot is complete. For more information, see [Using 'Patch now' lifecycle hooks](#) and [About the AWS-RunPatchBaselineWithHooks SSM document](#).

*August 9, 2021*
Auto-approvals now supported for Change Manager requests

You can now configure change templates in Change Manager to support automatic approvals, meaning that users with the necessary IAM permissions can choose to start the change request without requiring additional approval. Users who have access to auto-approval templates can still choose to specify approvers if they choose. To help you control your Change Manager processes, approvals are still required for all requests during change freeze periods. For more information, see the following topics:

- [Creating change templates](#)
- [Creating change requests](#)
- [Try out the AWS managed Hello World change template](#)

Application Manager helps you provision and manage resources for your applications by integrating with CloudFormation. You can create, edit, and delete AWS CloudFormation templates and stacks in Application Manager. Application Manager also includes a template library where you can clone, create, and store templates. Application Manager and CloudFormation display the same information about the current status of a stack. Templates and template updates are stored in Systems Manager until you provision the stack, at which time the changes are also displayed in CloudFormation. For more information, see Working with AWS CloudFormation Stacks in Application Manager.

A new topic, Setting up private key auto rotation, provides instructions on how to strengthen your security posture by configuring SSM Agent to rotate the hybrid environment private key automatically.

**Improved support for maintenance window tasks that don't require specified targets (console)**

You can now create maintenance window tasks in the console without having to specify a target in the task if one isn't required. Previously, this option was available only when using the AWS CLI or API. This option applies to Automation, AWS Lambda, and AWS Step Functions task types. For example, if you create an Automation task and the resources to update are specified in the Automation document parameters, you no longer need to specify a target in the task itself.

For more information, see [Registering maintenance window tasks without targets](#), [Assign tasks to a maintenance window (console)](#), and [Schedule automations with maintenance windows](#).

| **State Manager supports Change Calendar** | You can now specify Change Calendar names or Amazon Resource Names (ARNs) when you create or update a State Manager association. State Manager applies associations only when the change calendar is open, not when it's closed. For more information, see [Creating associations](#) and [Editing and creating a new version of an association](#). | May 6, 2021 |
| **Clone Systems Manager documents** | Using the Systems Manager Documents console, you can now copy content from an existing document to a new document that you can modify. To learn more, see [Cloning an SSM document](#). | May 4, 2021 |
Integrate Security Hub with Explorer and OpsCenter

You can now integrate Explorer and OpsCenter with AWS Security Hub. Security Hub provides a comprehensive view of your security state in AWS and helps you check your environment against security industry standards and best practices. When integrated with Explorer, you can view security findings in the Security Hub widget on the Explorer dashboard. When integrated with OpsCenter, you can create OpsItems for Security Hub findings. For more information, see Receiving findings from AWS Security Hub in Explorer and Receiving findings from AWS Security Hub in OpsCenter.

New topic: Document conventions

We've added a new topic to help users understand the common typographical conventions for the AWS Systems Manager User Guide. For more information, see Document conventions.
<table>
<thead>
<tr>
<th>Updated topic: About patching applications released by Microsoft on Windows Server</th>
<th>The topic <a href="https://aws.amazon.com/">About patching applications released by Microsoft on Windows Server</a> now clarifies that, in order for Patch Manager to be able to patch applications released by Microsoft on your Windows Server managed instances, the Windows update option <a href="https://aws.amazon.com/">Give me updates for other Microsoft products when I update Windows</a> must be allowed on the instance.</th>

Patch Manager: Generate .csv patch compliance reports

Patch Manager now supports the ability to generate patch compliance reports for your instances and save the report in an S3 bucket of your choice, in .csv format. Then, using a tool like Amazon QuickSight, you can analyze the patch compliance report data. You can generate a patch compliance report for a single instance, or for all instances in your AWS account. You can generate a one-time report on demand, or set up a schedule for reports to be created automatically. You can also specify an Amazon Simple Notification Service topic to provide notifications when a report is generated. For more information, see Generating CSV patch compliance reports.

Delete Parameter Store parameter labels

You can now delete Parameter Store parameter labels by using either the Systems Manager console or the AWS CLI. For more information, see Working with parameter labels.

Fleet Manager, a capability of AWS Systems Manager, is a unified user interface (UI) experience that helps you remotely manage your server fleet running on AWS, or on-premises. With Fleet Manager, you can view the health and performance status of your entire server fleet from one console. You can also gather data from individual instances to perform common troubleshooting and management tasks from the console. For information, see AWS Systems Manager Fleet Manager.
Amazon Web Services has released Change Manager, an enterprise change management framework for requesting, approving, implementing, and reporting on operational changes to your application configuration and infrastructure. From a single *delegated administrator account*, if you use AWS Organizations, you can manage changes across multiple AWS accounts in multiple AWS Regions. Alternatively, using a *local account*, you can manage changes for a single AWS account. Use Change Manager for managing changes to both AWS resources and on-premises resources. For information, see AWS Systems Manager Change Manager.
| New capability: Application Manager | Application Manager helps you investigate and remediate issues with your AWS resources in the context of your applications. Application Manager aggregates operations information from multiple AWS services and Systems Manager capabilities to a single AWS Management Console. For information, see [AWS Systems Manager Application Manager](#). | December 15, 2020 |
In tandem with the release of Amazon Elastic Compute Cloud (Amazon EC2) support for macOS instances, Systems Manager now supports many operations on EC2 instances for macOS. Supported versions include macOS 10.14.x (Mojave) and 10.15.x (Catalina). For more information, see the following topics.

- For information about installing SSM Agent on EC2 instances for macOS, see Installing and configuring SSM Agent on EC2 instances for macOS.

- For information about patching EC2 instances for macOS, see How patches are installed, and Creating a custom patch baseline (macOS).

- For general information about support for EC2 instances for macOS, see Amazon EC2 Mac instances in the Amazon EC2 User Guide.

Patch compliance results now report which CVEs are resolved by which patches

For most supported Linux systems, when you view patch compliance results for your managed instances, the details you can view now report which Common Vulnerabilities and Exposure (CVE) bulletin issues are resolved by which available patches. This information can help you determine how urgently you need to install a missing or failed patch. For more information, see Viewing patch compliance results.

October 20, 2020
Expanded support for Linux patch metadata

You can now view many details about available Linux patches in Patch Manager. You can choose to view patch data such as architecture, epoch, version, CVE ID, Advisory ID, Bugzilla ID, repository, and more. In addition, the DescribeAvailablePatches API operation has been updated to support Linux operating systems and filtering according to these newly available patch metadata types. For more information, see the following topics:

- Viewing available patches
- DescribeAvailablePatches and Patch in the AWS Systems Manager API Reference
- describe-available-patches in the AWS Systems Manager section of the AWS CLI Command Reference

Session Manager plugin for the AWS CLI version 1.2.7.0

A new version of the Session Manager plugin for the AWS CLI has been released. For more information, see Session Manager plugin latest version and release history.
The new topic **Session document schema** describes the schema elements for a Session document. This information can help you create custom Session documents where you specify preferences for the types of sessions you use with Session Manager.

The search box on the Systems Manager **Documents** page now supports free text search. Free text search compares the search term or terms that you enter against the document name in each SSM document. For more information, see **Using free text search**.

The new topic **Troubleshooting Amazon EC2 managed instance availability** helps you investigate why an Amazon EC2 instance that you have confirmed is running isn't available in lists of available managed instances in Systems Manager.
Parameter Store chapter reorganization

To help you find the information you need more efficiently, we reorganized content in the Parameter Store chapter of the *AWS Systems Manager User Guide*. Most content is now organized in the sections **Setting up Parameter Store** and **Working with Parameter Store**. In addition, the topic **AWS Systems Manager Parameter Store** has been expanded to include the following sections:

- How can Parameter Store benefit my organization?
- Who should use Parameter Store?
- What are the features of Parameter Store?
- What is a parameter?
New patch compliance-related topics

The following topics have been added to help you identify managed instances that are out of patch compliance, understand the different types of patch compliance scans, and take the appropriate steps to bring your instances into compliance.

- Identifying noncompliant instances
- Patching noncompliant instances
- Viewing patch compliance results

SSM Agent version 3.0

Systems Manager launched a new version of SSM Agent.

September 24, 2020
September 21, 2020
New and updated topics:
Amazon EventBridge replaces CloudWatch Events for event management

CloudWatch Events and EventBridge are the same underlying service and API, but EventBridge provides more features and is now the preferred way to manage your events in AWS. (Changes you make in either CloudWatch or EventBridge are reflected in each console.) References to CloudWatch Events and existing procedures throughout the AWS Systems Manager User Guide have been updated to reflect EventBridge support. In addition, the following new topics have been added.

- Monitoring Systems Manager events
- Configuring EventBridge for Systems Manager events
- Systems Manager target type examples
- Reference: Amazon EventBridge event patterns and types for Systems Manager
You can now integrate Patch Manager with AWS Security Hub. Security Hub provides a comprehensive view of your security state in AWS and helps you check your environment against security industry standards and best practices. When integrated with Patch Manager, Security Hub monitors the patching status of your fleets from a security point of view. For more information, see Integrating Patch Manager with AWS Security Hub.
When you register a maintenance window task, you use the `--task-inocation-parameter` option to specify the parameters that are unique to each of the four task types. You can also reference certain values using *pseudo parameter* syntax, such as `{{TARGET_ID}}` and `{{RESOURCE_ID}}`.

When the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. Two additional resource types are now available for use with the pseudo parameters `{{TARGET_ID}}` and `{{RESOURCE_ID}}`. You can now use the resources types `AWS::RDS::DBInstance` and `AWS::SSM::ManagedInstance` with both these pseudo parameters. For information about maintenance window pseudo parameters, see [Using pseudo parameters when registering maintenance window tasks](#).
Patch instances on demand with new 'Patch now' option

You can now use the Systems Manager console to patch instances, or scan for missing patches, at any time. You can do this without having to create or modify a schedule, or specify full patching configuration options to accommodate an immediate patching need. You need only specify whether to scan or install patches and identify the target instances for the operation. Patch Manager automatically applies the current default patch baseline for your instance types and applies best practice options for how many instances are patched at once, and how many errors are permitted before the operation fails. For more information, see Patching instances on demand.

September 9, 2020

New topic: Checking SSM Agent status and starting the agent

The new topic Checking SSM Agent status and starting the agent provides commands to check whether SSM Agent is running on each supporting operating system. It also provides the commands to start the agent if it isn't running.

New data source in Explorer: AWS Support cases

Explorer now displays information about AWS Support cases. You must have either an Enterprise or Business account set up with AWS Support. For more information, see Editing Systems Manager Explorer data sources.

Distributor now provides a third-party package from Trend Micro.

Distributor now includes a third-party package from Trend Micro. You can use Distributor to install the Trend Micro Cloud One agent on your managed instances. Trend Micro Cloud One helps you secure your workloads in the cloud. For more information, see AWSDistributor.

The aws:configurePackage document plugin now includes the additionalArguments parameter.

The Systems Manager Command document plugin aws:configurePackage now supports providing additional parameters to your scripts (install, uninstall, and update) with the new additionalArguments parameter. For more information, see the topic aws:configurePackage.

</tr>
<tr>
<td>New Systems Manager Command document to turn on and turn off Kernel Live Patching</td>
<td>The document AWS-ConfigureKernelLivePatching is now available to use with Run Command when you want to turn on or turn off Kernel Live Patching on Amazon Linux 2 instances. This document replaces the need for creating your own custom Command documents for these tasks. For more information, see Use Kernel Live Patching on Amazon Linux 2 instances.</td>
</tr>
<tr>
<td>Updated Automation quotas</td>
<td>Service quotas for Automation have been updated including a separate queue for rate control automations. For more information, see AWS Systems Manager Automation.</td>
</tr>
</tbody>
</table>
Specify the number of schedule offset days for a maintenance window using the console

Using the Systems Manager console, you can now specify a number of days to wait after the date and time specified by a CRON expression before running a maintenance window. (Previously, this option was available only when using an AWS SDK or a command line tool.) For example, if your CRON expression schedules a maintenance window to run on the third Tuesday of every month at 11:30 PM – `cron(0 30 23 ? * TUE#3 *)` – and you specify a schedule offset of 2, the window won't run until two days later at 11:30 PM. For more information, see Cron and rate expressions for Systems Manager and Specify the number of schedule offset days for a maintenance window.

Update PowerShell using Run Command

To help you update PowerShell to version 5.1 on your Windows Server 2012 and 2012 R2 instances, we added a walkthrough to the AWS Systems Manager User Guide. For more information, see Update PowerShell using Run Command.
Patch Manager now supports CentOS 8.0 and 8.1

You can now use Patch Manager to patch CentOS 8.0 and 8.1 instances. For more information, see the following topics:

- [How security patches are selected](#)
- [How patches are installed](#)
- [How patch baseline rules work on CentOS](#)
- [Manually install SSM Agent on CentOS instances](#)
- [How to install the SSM Agent on hybrid Linux nodes](#)
AppConfig integrates with AWS CodePipeline

AppConfig is an integrated deploy action for AWS CodePipeline (CodePipeline). CodePipeline is a fully managed continual delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deploy phases of your release process every time there is a code change, based on the release model you define. The integration of AppConfig with CodePipeline offers the following benefits. For more information, see AppConfig integration with CodePipeline.

- Customers who use CodePipeline to manage orchestration now have a lightweight means of deploying configuration changes to their applications without having to deploy their entire codebase.
- Customers who want to use AppConfig to manage configuration deployments but are limited because AppConfig doesn't support their current code or
configuration store, now have additional options. CodePipeline supports AWS CodeCommit, GitHub, and BitBucket (to name a few).

**New chapter: Product and service integrations**

To help you understand how Systems Manager integrates with AWS services and other products and services, a new chapter has been added to the AWS Systems Manager User Guide. For more information, see [Product and service integrations with Systems Manager](#).

**Automation chapter reorganization**

To help you find what you need, we reorganized topics in the Automation chapter of the *AWS Systems Manager User Guide*. For example, the Automation actions and Automation runbooks references are now top-level sections in the chapter. For more information, see [AWS Systems Manager Automation](#).

Patch Manager now supports Red Hat Enterprise Linux (RHEL) 7.8-8.2

You can now use Patch Manager to patch RHEL 7.8–8.2 instances. For more information, see the following topics:

- How security patches are selected
- How patches are installed
- How patch baseline rules work on RHEL
- Manually install SSM Agent on Red Hat Enterprise Linux instances
- How to install the SSM Agent on hybrid Linux nodes
Explorer supports delegated administration

If you aggregate Explorer data from multiple AWS Regions and AWS accounts by using resource data sync with AWS Organizations, then we suggest that you configure a delegated administrator for Explorer. A delegated administrator improves Explorer security by limiting the number of Explorer administrators who can create or delete multi-account and Region resource data syncs to only one individual. You also no longer need to be logged into the AWS Organizations management account to administer resource data syncs in Explorer. For more information, see Configuring a Delegated Administrator.

Apply State Manager association only at the next specified Cron interval

If you don't want a State Manager association to run immediately after you create it, you can choose the Apply association only at the next specified Cron interval option in the Systems Manager console. For more information, see Creating associations.
New data source in Explorer:
AWS Compute Optimizer

Explorer now displays data from AWS Compute Optimizer. This includes a count of Under provisioned and Over provisioned EC2 instances, optimization findings, on-demand pricing details, and recommendations for instance type and price. For more information, see the details for setting up AWS Compute Optimizer in Setting up related services.

New chapter: Tagging Systems Manager Resources

The new chapter Tagging Systems Manager resources provides an overview of how you can use tags with the six taggable resource types in Systems Manager. The chapter also provides comprehensive instructions for adding and removing tags from these resource types:

- Documents
- Maintenance windows
- Managed instances
- OpsItems
- Parameters
- Patch baselines

Create State Manager associations that target AWS Resource Groups

In addition to targeting tags, individual instances, and all instances in your AWS account, you can now create State Manager associations that target instances in AWS Resource Groups. For more information, see About targets and rate controls in State Manager associations.

May 7, 2020
**New aws:ec2:image data type in Parameter Store to validate AMI IDs**

When you create a String parameter, you can now specify a *data type* as `aws:ec2:image` to ensure that the parameter value you enter is a valid Amazon Machine Image (AMI) ID format. Support for AMI ID formats means you don’t have to update all your scripts and templates with a new ID each time the AMI that you want to use in your processes changes. You can create a parameter with the data type `aws:ec2:image`, and for its value, enter the ID of an AMI. This is the AMI from which you want new instances to be created. You then reference this parameter in your templates, commands. When you’re ready to use a different AMI, update the parameter value. Parameter Store validates the new AMI ID, and you don’t need to update your scripts and templates. For more information, see [Native parameter support for Amazon Machine Image IDs](#).
Managing exit codes in Run Command commands

Run Command enables you to define how exit codes are handled in your scripts. By default, the exit code of the last command run in a script is reported as the exit code for the entire script. However, you can include a shell conditional statement to exit the script if any command before the final one fails using the following approach. For examples, see the new topic Managing exit codes in Run Command commands.

New public parameters released for availability zones and local zones

Public parameters have been released to make information about AWS availability zones and local zones available programmatically. These are in addition to existing global infrastructure public parameters for AWS services and AWS Regions. For more information, see Calling public parameters for AWS services, Regions, endpoints, Availability Zones, local zones, and Wavelength Zones.
New data source in Explorer: AWS Trusted Advisor

Explorer now displays data from AWS Trusted Advisor. This includes the status of best practice checks and recommendations in the following areas: cost optimization, security, fault tolerance, performance, and service quotas. For more information, see the details for setting up Trusted Advisor in Setting up related services.
Create State Manager associations that run Chef recipes

You can create State Manager associations that run Chef cookbooks and recipes by using the AWS-Apply ChefRecipes document. This document offers the following benefits for running Chef recipes:

- Supports multiple releases of Chef (Chef 11 through Chef 14).
- Automatically installs the Chef client software on target instances.
- Optionally runs Systems Manager compliance checks on target instances, and stores the results of compliance checks in an S3 bucket.
- Runs multiple cookbooks and recipes in a single run of the document.
- Optionally runs recipes in why-run mode, to show which recipes will change on target instances without making changes.
- Optionally applies custom JSON attributes to chef-client runs.
Synchronize inventory data from multiple AWS accounts to a central Amazon S3 bucket

You can synchronize Systems Manager Inventory data from multiple AWS accounts to a central S3 bucket. The accounts must be defined in AWS Organizations. For more information, see Creating an Inventory resource data sync for multiple accounts defined in AWS Organizations.

March 16, 2020

Store AppConfig configurations in Amazon S3

Previously, AppConfig only supported application configurations that were stored in Systems Manager (SSM) documents or Parameter Store parameters. In addition to these options, AppConfig now supports storing configurations in Amazon S3. For more information, see About configurations stored in Amazon S3.

March 13, 2020

SSM Agent installed by default on Amazon ECS-optimized AMIs

SSM Agent is now installed by default on Amazon ECS-Optimized AMIs. For more information, see Working with SSM Agent.

February 25, 2020
Create AppConfig configurations in the console

AppConfig now allows you to create an application configuration in the console at the time you create a configuration profile. For more information, see Creating a configuration and a configuration profile.

Auto-approve only patches released up to a specified date

In addition to the option for automatically approving patches for installation a specified number of days after they're released, Patch Manager now supports the ability to auto-approve only patches released on or before a date that you specify. For example, if you specify July 7, 2020, as the cutoff date in your patch baseline, no patches released on or after July 8, 2020, are installed automatically. For more information, see About custom baselines and Working with custom patch baselines (console).
Use the `{{RESOURCE_ID}}` pseudo parameter in maintenance window tasks

When you register a maintenance window task, you specify the parameters that are unique to the task type. You can reference certain values using pseudo parameter syntax, such as `{{TARGET_ID}}`, `{{TARGET_TYPE}}`, `{{WINDOW_TARGET_ID}}`. When the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. To support resources that are part of a resource group as a target, you can use the `{{RESOURCE_ID}}` pseudo parameter to pass values for resources such as DynamoDB tables, S3 buckets, and other supported types. For more information, see the following topics in Tutorial: Create and configure a maintenance window (AWS CLI):

- Using pseudo parameters when registering maintenance window tasks
- Examples: Register tasks with a maintenance window
Quickly rerun commands

Systems Manager includes two options to help you rerun a command from the Run Command page in the AWS Systems Manager console.

Rerun: This button allows you to run the same command without making changes to it. Copy to new: This button copies the settings of one command to a new command and gives you the option to edit those settings before you run it. For more information, see Rerunning commands.
Reverting from the advanced-instances tier to the standard-instances tier

If you previously configured all on-premises instances running in your hybrid environment to use the advanced-instances tier, you can now quickly configure those instances to use the standard-instance tier. Reverting to the standard-instances tier applies to all hybrid instances in an AWS account and a single AWS Region. Reverting to the standard-instances tier impacts the availability of some Systems Manager capabilities. For more information, see Reverting from the advanced-instances tier to the standard-instances tier.

New "Security" chapter outlines practices for securing Systems Manager resources

A new Security chapter in the AWS Systems Manager User Guide helps you understand how to apply the shared responsibility model when using Systems Manager. Topics in the chapter show you how to configure Systems Manager to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Systems Manager resources.

Note

As part of this update, the user guide chapter "Authentication and Access Control" has been replaced by a new, simpler section, Identity and access management for AWS Systems Manager.

December 24, 2019
New sample custom Automation runbooks

A set of sample custom Automation runbooks has been added to the user guide. These samples show how to use various Automation actions to simplify deployment, troubleshooting, and maintenance tasks, and are intended to help you write your own custom Automation runbooks.

For more information, see Custom Automation runbook samples. You can also view Amazon managed Automation runbook content in the Systems Manager console.

For more information, see Systems Manager Automation runbook reference.

December 23, 2019

Support for the Oracle Linux

Systems Manager now supports Oracle Linux 7.5 and 7.7. For information about manually installing SSM Agent on EC2 instances for Oracle Linux instances, see Oracle Linux. For information about installing SSM Agent on Oracle Linux servers in a hybrid environment, see How to install the SSM Agent on hybrid Linux nodes.

December 19, 2019
You can now start Session Manager sessions from the Amazon Elastic Compute Cloud (Amazon EC2) console. Working with session-related tasks from the Amazon EC2 console requires different IAM permissions for both users and administrators. You can provide permissions for using the Session Manager console and AWS CLI only, for using the Amazon EC2 console only, or for using all three tools. For more information, see the following topics.

- Quickstart default IAM policies for Session Manager
- Starting a session (Amazon EC2 console)
<table>
<thead>

<tbody>
<tr>
<td><strong>CloudWatch support for Run Command metrics and alarms</strong></td>
<td>AWS Systems Manager now publishes metrics about the status of Run Command commands to CloudWatch, allowing you to set alarms based on those metrics. The terminal status values for commands for which you can track metrics include Success, Failed, and Delivery Timed Out. For more information, see <a href="#">Monitoring Run Command metrics using Amazon CloudWatch</a>.</td>
<td>December 17, 2019</td>
</tr>
<tr>
<td><strong>New Systems Manager capability: Change Calendar</strong></td>
<td>Use Systems Manager Change Calendar to specify periods of time (events) during which you want to limit or prevent code changes (such as from Systems Manager Automation runbooks or AWS Lambda functions) to resources. A change calendar is a new Systems Manager document type that stores iCalendar 2.0 data in plaintext format. For more information, see <a href="#">AWS Systems Manager Change Calendar</a>.</td>
<td>December 11, 2019</td>
</tr>
</tbody>
</table>
Use AppConfig to create, manage, and quickly deploy application configurations. AppConfig supports controlled deployments to applications of any size. You can use AppConfig with applications hosted on EC2 instances, AWS Lambda, containers, mobile applications, or IoT devices. To prevent errors when deploying application configurations, AppConfig includes validators. A validator provides a syntactic or semantic check to ensure that the configuration you want to deploy works as intended. During a configuration deployment, AppConfig monitors the application to ensure that the deployment is successful. If the system encounters an error or if the deployment starts an alarm, AppConfig rolls back the change to minimize impact for your application users. For more information, see AWSAppConfig.
New Systems Manager capability: Systems Manager Explorer

AWS Systems Manager Explorer is a customizable operations dashboard that reports information about your AWS resources. Explorer displays an aggregated view of operations data (OpsData) for your AWS accounts and across AWS Regions. In Explorer, OpsData includes metadata about your EC2 instances, patch compliance details, and operational work items (OpsItems). Explorer provides context about how OpsItems are distributed across your business units or applications, how they trend over time, and how they vary by category. You can group and filter information in Explorer to focus on items that are relevant to you and that require action. When you identify high priority issues, you can use Systems Manager OpsCenter to run Automation runbooks and quickly resolve those issues. For information see, AWS Systems Manager Explorer.

Note
Set up for Systems Manager OpsCenter is integrated with
set up for Explorer. If you already set up OpsCenter, you still need to complete Integrated Setup to verify settings and options. If you haven't set up OpsCenter, then you can use Integrated Setup to get started with both capabilities. For more information, see Getting started with Explorer and OpsCenter.

Improved parameter search capabilities

The tools for searching for parameters now make it easier to find parameters when you have a large number of them in your account or when you don't remember the exact name of a parameter. With the search tool, you can filter by contains. Previously, the search tools supported searching for parameter names only by equals and begins-with. For more information, see Searching for Systems Manager parameters.

November 15, 2019
New console-based Document Builder for Automation | Support for running scripts in Automation steps

You can now use Systems Manager Automation to build and share standardized operational playbooks to ensure consistency across users, AWS accounts, and AWS Regions. With this ability to run scripts and add inline documentation to your Automation runbooks using Markdown, you can reduce errors and eliminate manual steps such as navigating written procedures in wikis and running terminal commands.

For more information, see the following topics.

- Walkthrough: Using Document Builder to create a custom Automation runbook
- `aws:executeScript` (Automation actions reference)
- Creating Automation runbooks using Document Builder
- New Automation Features In Systems Manager on the AWS News Blog
Perform an in-place package update using Distributor

Previously, when you wanted to install an update to a package using Distributor, your only choice was to uninstall the entire package and reinstall the new version. Now you can choose to perform an in-place update instead. During an in-place update, Distributor installs only files that are new or changed since the last installation, according to the update script you include in your package. With this option, your package application can remain available and not be taken offline during the update. For more information, see the following topics.

- Create a package
- Install or update packages

New SSM Agent auto update feature

With one click, you can configure all instances in your AWS account to automatically check for and download new versions of SSM Agent. To do this, choose Agent auto update on the Managed instances page in the AWS Systems Manager console. For information, see Automate updates to SSM Agent.
Restrict Session Manager access using AWS-supplied tags

A second method for controlling user access to session actions is now available. With this new method, you create IAM access policies using AWS-supplied session tags instead of using the `{aws:username}` variable. Using these AWS-supplied session tags makes it possible for organizations that use federated IDs to control user access to sessions. For information, see Allow a user to terminate only sessions they started.
New SSM Command
document to apply Ansible Playbooks

You can create State Manager associations that run Ansible Playbooks by using the AWS-ApplyAnsiblePlaybooks document. This document offers the following benefits for running Playbooks:

- Support for running complex Playbooks
- Support for downloading Playbooks from GitHub and Amazon Simple Storage Service (Amazon S3)
- Support for compressed Playbook structure
- Enhanced logging
- Ability to specify which Playbook to run when Playbooks are bundled

For more information, see Creating associations that run Ansible playbooks
### Port forwarding support for Session Manager

Session Manager now supports port forwarding sessions. Port forwarding allows you to securely create tunnels between your instances deployed in private subnets, without the need to start the SSH service on the server, to open the SSH port in the security group, or to use a bastion host. Similar to SSH tunnels, port forwarding allows you to forward traffic between your laptop to open ports on your instance. Once port forwarding is configured, you can connect to the local port and access the server application running inside the instance. For more information, see the following topics:

Specify a default parameter tier or automate tier selection

You can now specify a default parameter tier to use for requests to create or update a parameter that don't specify a tier. You can set the default tier to standard parameters, advanced parameters, or a new option, Intelligent-Tiering. Intelligent-Tiering evaluates each PutParameter request and creates an advanced parameter only when required. (Advanced parameters are required if the size of the parameter value is more than 4 KB, a parameter policy is associated with the parameter, or the maximum 10,000 parameters supported for the standard tier are already created.) For more information about specifying a default tier and using Intelligent-Tiering, see Specifying a default parameter tier.

Working with associations section updated with CLI and PowerShell procedures

The Working with Associations section has been updated to include procedural documentation for managing associations using the AWS CLI or AWS Tools for PowerShell. For information see, Working with associations in Systems Manager.

August 27, 2019

August 26, 2019
Working with Automation executions section updated with CLI and PowerShell procedures

The Working with Automation Executions section has been updated to include procedural documentation for running Automation workflows using the AWS CLI or AWS Tools for PowerShell. For information see, Working with Automation executions.

OpsCenter integrates with application insights

OpsCenter integrates with Amazon CloudWatch Application Insights for .NET and SQL Server. This means you can automatically create OpsItems for problems detected in your applications. For information about how to configure Application Insights to create OpsItems, see Set up, configure, and manage your application for monitoring in the Amazon CloudWatch User Guide.

August 20, 2019
August 7, 2019
Quick Setup is a new feature in the Systems Manager console that helps you quickly configure several Systems Manager components on your EC2 instances. Specifically, Quick Setup helps you configure the following components on the instances you choose or target by using tags:

- An AWS Identity and Access Management (IAM) instance profile role for Systems Manager.
- A scheduled, bi-monthly update of SSM Agent.
- A scheduled collection of Inventory metadata every 30 minutes.
- A daily scan of your instances to identify missing patches.
- A one-time installation and configuration of the Amazon CloudWatch agent.
- A scheduled, monthly update of the CloudWatch agent.

For more information, see [AWS Systems Manager Quick Setup](#).
Register a resource group as a maintenance window target

In addition to registering managed instances as the target of a maintenance window, you can now register a resource group as a maintenance window target. Maintenance Windows supports all the AWS resource types that are supported by AWS Resource Groups including `AWS::EC2::Instance`, `AWS::DynamoDB::Table`, `AWS::OpsWorks::Instance`, `AWS::Redshift::Cluster`, and more. With this release you can also send commands to a resource group, for example by using the Run Command console or the AWS CLI `send-command` command. For more information, see the following topics:

- [Assign targets to a maintenance window (console)](#)
- [Examples: Register targets with a maintenance window](#)
- [Using targets and rate controls to send commands to a fleet](#)

Verify user permissions to access the default Session Manager configuration document

When a user in your account uses the AWS CLI to start a Session Manager session and doesn't specify a configuration document in the command, Systems Manager uses the default configuration document SSM-SessionManagerRunShell. You can now verify that the user has been granted permission to access this document by adding a condition element for ssm:SessionDocumentAccessCheck to the policy for the AWS Identity and Access Management (IAM) entity (user, group, or role). For information, see Enforce document permission check for default CLI scenario.

July 9, 2019

Support for starting Session Manager sessions using operating system user credentials

By default, Session Manager sessions are launched using the credentials of a system-generated ssm-user account that is created on a managed instance. On Linux machines, you can now instead launch sessions using the credentials of an operating system account. For information, see Turn on Run As support for Linux instances.

July 9, 2019
Support for starting Session Manager sessions using SSH

You can now use the AWS CLI to start an SSH session on a managed instance using Session Manager. For information about allowing SSH sessions with Session Manager, see (Optional) Turn on SSH Session Manager sessions. For information about starting an SSH session using Session Manager, see Starting a session (SSH).

Support for changing passwords on managed instances

You can now reset passwords on machines that you manage using Systems Manager (managed instances). You can reset the password using the Systems Manager console or the AWS CLI. For information, see Resetting passwords on managed instances.

Revisions to "What is AWS Systems Manager?"

The introductory content in What is AWS Systems Manager? has been expanded to provide a broader introduction to the service and reflect Systems Manager capabilities that have been released recently. In addition, other content in the section has been moved into individual topics for better discoverability.
New Systems Manager capability: OpsCenter

OpsCenter provides a central location where operations engineers and IT professionals can view, investigate, and resolve operational work items (OpsItems) related to AWS resources. OpsCenter is designed to reduce mean time to resolution for issues impacting AWS resources. This Systems Manager capability aggregates and standardizes OpsItems across services while providing contextual investigation data about each OpsItem, related OpsItems, and related resources. OpsCenter also provides Systems Manager Automation runbooks that you can use to quickly resolve issues. You can specify searchable, custom data for each OpsItem. You can also view automatically-generated summary reports about OpsItems by status and source. For more information, see AWS Systems Manager OpsCenter.
Changes to Systems Manager
left navigation pane in the
AWS Management Console

The Systems Manager left navigation pane in the AWS Management Console includes new headings, including a new heading for Ops Center, that provide a more logical grouping of Systems Manager capabilities.

June 6, 2019
Revised tutorial for creating and configuring a maintenance window using the AWS CLI

Tutorial: Create and configure a maintenance window (AWS CLI) has been overhauled to provide a simple path through the practice steps. You create a single maintenance window, identify a single target, and set up a simple task for the maintenance window to run. Along the way, we provide information and examples you can use to create your own task registration commands, including information for using pseudo parameters such as `{{{TARGET_ID}}}`. For additional information and examples, see the following topics:

- [Examples: Register targets with a maintenance window](#)
- [Examples: Register tasks with a maintenance window](#)
- [About register-task-with-maintenance-windows options](#)
- [Using pseudo parameters when registering maintenance window tasks](#)

Notifications about SSM Agent updates

To be notified about SSM Agent updates, subscribe to the [SSM Agent Release Notes](#) page on GitHub.

May 31, 2019

May 24, 2019
The topic Set up notifications or trigger actions based on Parameter Store events now helps you set up Amazon EventBridge rules to respond to changes in Parameter Store. You can receive notifications or trigger other actions when any of the following occur:

- A parameter is created, updated, or deleted.
- A parameter label version is created, updated, or deleted.
- A parameter expires, is going to expire, or hasn't changed in a specified period of time.
We have expanded and reorganized the *Setting Up* and *Getting Started* content in the *AWS Systems Manager User Guide*. *Setting Up* content has been divided into two sections. One section focuses on tasks for setting up Systems Manager to configure and manage your EC2 instances. The other focuses on tasks for setting up Systems Manager to configure and manage your on-premises servers and virtual machines (VMs) in a hybrid environment. Both sections now present all setup topics as major numbered steps, in the recommended order of completion. A new *Getting Started* chapter focuses on helping end-users get started with Systems Manager after account and service configuration tasks have been completed.

- [Setting up AWS Systems Manager](#)
- [Setting up AWS Systems Manager for hybrid environments](#)
- [Getting started with AWS Systems Manager](#)
Patch Manager now supports patch updates for applications released by Microsoft on Windows Server instances. Previously, only patches for the Windows Server operating system were supported.

Patch Manager provides two predefined patch baselines for Windows Server instances. The patch baseline AWS-WindowsPredefinedPatchBaseline-OS applies to operating system patches only. AWS-WindowsPredefinedPatchBaseline-OS-Applications applies to both the Windows Server operating system and applications released by Microsoft on Windows. For information about creating a custom patch baseline that includes patches for applications released by Microsoft, see the first procedure in Create a custom patch baseline.

Also, as part of this update, the names of AWS-provided predefined patch baselines are being changed. For more information, see Predefined baselines.
The new topic Examples: Register targets with a maintenance window provides three sample commands to demonstrate different ways you can specify the targets for a maintenance window when you use the AWS CLI. The topic also explains the best use case for each of the sample commands.

The topic About patch groups has been updated to include a section on how managed instances determine the appropriate patch baseline to use during patching operations. Additionally, instructions have been added for using the AWS CLI or Systems Manager console to add Patch Group or PatchGroup tags to your managed instances, and how to add a Patch Group or PatchGroup to a patch baseline. (You must use PatchGroup, without a space, if you have allowed tags in EC2 instance metadata.) For more information see Create a patch group and Add a patch group to a patch baseline.

May 3, 2019

May 1, 2019
New Parameter Store features

Parameter Store offers the following new features:

- **Advanced parameters**: Parameter Store now allows you to individually configure parameters to use either a standard-parameter tier (the default tier) or an advanced-parameter tier. Advanced parameters offer a larger size quota for the parameter value, a higher quota for the number of parameters you can create per AWS account and AWS Region, and the ability to use parameter policies. For more information about advanced parameters, see [About Systems Manager advanced parameters](#).

- **Parameter policies**: Parameter policies help you manage a growing set of parameters by allowing you to assign specific criteria to a parameter, such as an expiration date or **time to live**. Parameter policies are especially helpful in forcing you to update or delete passwords and configuration data stored in Parameter Store. Parameter
policies are only available for parameters that use the advanced-parameter tier. For more information, see Working with parameter policies.

- **Higher throughput:** You can now increase the Parameter Store throughput quota to a maximum of 1,000 transactions per second. For more information, see Increasing Parameter Store throughput.

**Updates to the Automation section**

The Automation section has been updated for improved discoverability. In addition, three new topics have been added to the Automation section:

- Run an automation manually
- Run an automation with approvers
- Scheduling automations

April 17, 2019
Encrypt session data using an AWS KMS key

By default, Session Manager uses TLS 1.2 to encrypt session data transmitted between the local machines of users in your account and your EC2 instances. Now you can choose to further encrypt that data using an AWS KMS key that has been created in AWS Key Management Service. You can use a KMS key that has been created in your AWS account or one that has been shared with you from another account. For information about specifying a KMS key to encrypt session data, see Turn on AWS KMS key encryption of session data (console), Create Session Manager preferences (AWS CLI), or Update Session Manager preferences (AWS CLI).

Configuring Amazon SNS notifications for AWS Systems Manager

Added instructions for using the AWS CLI or Systems Manager console to configure Amazon SNS notifications for Run Command and Run Command tasks registered to a maintenance window. For more information see Configuring Amazon SNS notifications for AWS Systems Manager.
AWS Systems Manager offers a standard-instances tier and an advanced-instances tier for servers and VMs in your hybrid environment. The standard-instances tier allows you to register a maximum of 1,000 servers or VMs per AWS account per AWS Region. If you need to register more than 1,000 servers or VMs in a single account and Region, then use the advanced-instances tier. You can create as many instances as you like in the advanced-instances tier, but all instances configured for Systems Manager are available on a pay-per-use basis. Advanced instances also allow you to connect to your hybrid machines by using AWS Systems Manager Session Manager. Session Manager provides interactive shell access to your instances. For more information about allowing advanced instances, see Using the advanced-instances tier.

<td>The new topic <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/monitor-sm-events-eventbridge.html">Monitoring Systems Manager events with Amazon EventBridge</a> provides a summary of the various events emitted by Systems Manager for which you can set up event monitoring rules in EventBridge.</td>
<td>February 25, 2019</td>
</tr>
</tbody>
</table>
Add tags when you create Systems Manager resources

Systems Manager now supports the ability to add tags to certain resource types when you create them. The resources you can tag when you create them with the AWS CLI or an SDK include maintenance windows, patch baselines, Parameter Store parameters, and SSM documents. You can also assign tags to a managed instance when you create an activation for it. When you use the Systems Manager console, you can add tags to maintenance windows, patch baselines, and parameters.
Automatic IAM role creation for Systems Manager Inventory

Previously you had to create an AWS Identity and Access Management (IAM) role and attach separate policies to this role to view inventory data on the Inventory Detail View page in the console. You no longer need to create this role or attach policies to it. When you choose a Remote Data Sync on the Inventory Detail View page, Systems Manager automatically creates the Amazon-GlueServicePolicyForSSM role and assigns the Amazon-GlueServicePolicyForSSM-\{S3 bucket name\} policy and the AWSGlueServiceRole policy to it. For more information, see Querying inventory data from multiple Regions and accounts.

February 14, 2019

Maintenance Windows walkthroughs to update SSM Agent

Added two new walkthroughs to the Maintenance Windows documentation. The walkthroughs detail how to use the Systems Manager console or the AWS CLI to create a maintenance window that keeps SSM Agent up-to-date automatically. For more information, see Maintenance Windows walkthroughs.

| Turn on SSM Agent debug logging | You can turn on SSM Agent debug logging by editing the seelog.xml.template file on the managed instance. For more information, see [Turn on SSM Agent debug logging](https://docs.aws.amazon.com/systems-manager/latest/userguide/turn-on-ssm-agent-debug-logging.html). | November 30, 2018 |
Support for ARM64 processor architectures

AWS Systems Manager now supports ARM64 versions of the Amazon Linux 2, Red Hat Enterprise Linux 7.6, and Ubuntu Server (18.04 LTS and 16.04 LTS) operating systems. For more information, see the instructions for installing Amazon Linux 2, RHEL, and Ubuntu Server 18.04 and 16.04 LTS with Snap packages. For more information about the A1 instance type, see General purpose instances in the Amazon EC2 User Guide.

November 26, 2018
Create and deploy packages by using AWS Systems Manager Distributor

Using AWS Systems Manager Distributor, you package your own software—or find AWS-provided agent software packages, such as AmazonCloudWatchAgent—to install on AWS Systems Manager managed instances. Distributor publishes resources, such as software packages, to AWS Systems Manager managed instances. Publishing a package advertises specific versions of the package's document—a Systems Manager document that you create when you add the package in Distributor—to managed instances that you identify by managed instance IDs, AWS account IDs, tags, or an AWS Region. For more information, see AWS Systems Manager Distributor.

Create State Manager associations that run MOF files

You can run Managed Object Format (MOF) files to enforce a targeted state on Windows Server managed instances with State Manager by using the AWS-ApplyDSCMofs SSM document. The AWS-ApplyDSCMofs document has two execution modes. With the first mode, you can configure the association to scan and report if the managed instances are currently in the targeted state defined in the specified MOF files. In the second mode, you can run the MOF files and change the configuration of your instances based on the resources and their values defined in the MOF files. The AWS-ApplyDSCMofs document allows you to download and run MOF configuration files from Amazon Simple Storage Service (Amazon S3), a local share, or from a secure web site with an HTTPS domain. For more information, see Creating associations that run MOF files.

<td>October 9, 2018</td>
</tr>
</tbody>
</table>
Maintain a custom list of patches for your patch baseline in an S3 bucket

With the new 'InstallOverrideList' parameter in the SSM command document AWS-RunPatchBaseline, you can specify an https URL or an Amazon Simple Storage Service (Amazon S3) path-style URL to a list of patches to be installed. This patch installation list, which you maintain in an S3 bucket in YAML format, overrides the patches specified by the default patch baseline. For more information, see Parameter name: InstallOverrideList.

Expanded control over whether patch dependencies are installed

Previously, if a patch in your Rejected patches list was identified as a dependency of another patch, it would still be installed. Now you can choose whether to install these dependencies or block them from being installed. For more information, see Create a patch baseline.

Manage instances without opening inbound ports or maintaining bastion hosts using Session Manager

Using Session Manager, a fully managed capability of AWS Systems Manager, you can manage your EC2 instances through an interactive one-click browser-based shell or through the AWS CLI. Session Manager provides secure and auditable instance management without the need to open inbound ports, maintain bastion hosts, or manage SSH keys. Session Manager also allows you to comply with corporate policies that require controlled access to instances, strict security practices, and fully auditable logs with instance access details, while still providing end users with simple one-click cross-platform access to your EC2 instances. For more information, see Learn more about Session Manager.

</tr>
<tr>
<td>Aggregate inventory data with groups to see which instances are and aren't configured to collect an inventory type</td>
<td>Groups allow you to quickly see a count of which managed instances are and aren't configured to collect one or more Inventory types. With groups, you specify one or more Inventory types and a filter that uses the exists operator. For more information, see Aggregating Inventory data.</td>
<td>August 16, 2018</td>
</tr>
</tbody>
</table>
You can now view history and change tracking for Inventory collected from your managed instances. You can also viewing history and changing tracking for Patch Manager patching and State Manager associations reported by Configuration Compliance. For more information, see Viewing Inventory history and change tracking.
Parameter Store integrates with Secrets Manager

Parameter Store is now integrated with AWS Secrets Manager so that you can retrieve Secrets Manager secrets when using other AWS services that already support references to Parameter Store parameters. These services include Amazon EC2, Amazon Elastic Container Service, AWS Lambda, AWS CloudFormation, AWS CodeBuild, AWS CodeDeploy, and other Systems Manager capabilities. By using Parameter Store to reference Secrets Manager secrets, you create a consistent and secure process for calling and using secrets and reference data in your code and configuration scripts. For information, see Referencing AWS Secrets Manager secrets from Parameter Store parameters.
**Attach labels to Parameter**

A parameter label is a user-defined alias to help you manage different versions of a parameter. When you modify a parameter, Systems Manager automatically saves a new version and increments the version number by one. A label can help you remember the purpose of a parameter version when there are multiple versions. For information, see Labeling parameters.

**Create dynamic Automation workflows**

By default, the steps (or actions) that you define in the mainSteps section of an Automation runbook run in sequential order. After one action is complete, the next action specified in the mainSteps section begins. With this release, you can now create Automation workflows that perform *conditional branching*. This means that you can create Automation workflows that dynamically respond to condition changes and jump to a specified step. For information, see Using conditional statements in runbooks.
SSM Agent now pre-installed on Ubuntu Server 16.04 AMIs using Snap

Beginning with instances created from Ubuntu Server 16.04 AMIs identified with 20180627, the SSM Agent is pre-installed using Snap packages. On instances created from earlier AMIs, you should continue using deb installer packages. For information, see About SSM Agent installations on 64-bit Ubuntu Server 16.04 instances.

Review minimum S3 permissions required by SSM Agent

The new topic Minimum S3 bucket permissions for SSM Agent provides information about the Amazon Simple Storage Service (Amazon S3) buckets that resources might need to access to perform Systems Manager operations. You can specify these buckets in a custom policy if you want to limit S3 bucket access for an instance profile or VPC endpoint to the minimum required to use Systems Manager.

View complete execution history for a specific State Manager association ID

The new topic Viewing association histories describes how to view all executions for a specific association ID and then view execution details for one or more resources.

New and updated topics

You can now use Patch Manager to install patches that are in a different source repository than the default one configured on the instance. This is useful for patching instances with updates not related to security; with the content of Personal Package Archives (PPA) for Ubuntu Server; with updates for internal corporate applications; and so on. You specify alternative patch source repositories when you create a custom patch baseline. For more information, see the following topics:

- How to specify an alternative patch source repository (Linux)
- Working with custom patch baselines
- Create a patch baseline with custom repositories for different OS versions

In addition, you can now use Patch Manager to patch SUSE Linux Enterprise Server instances. Patch Manager supports patching SLES 12.* versions (64-bit only). For more information, see the SLES-specific information in the following topics:

- How security patches are selected
- How patches are installed
- How patch baseline rules work on SUSE Linux Enterprise Server

New topic

The new topic About SSM documents for patching managed nodes describes the seven SSM documents available to help you keep your managed instances patched with the latest security-related updates.
## Important updates regarding Linux support

Updated various topics with the following information:

- SSM Agent is installed, by default, on Amazon Linux 1 *base* AMIs dated 2017.09 and later.
- Manually install SSM Agent on other versions of Linux, including non-base images like *Amazon ECS-Optimized AMIs*.

### Release date

January 9, 2018

## New topic

A new topic, *[About the AWS-RunPatchBaseline SSM document](#)*, provides details of how this SSM document operates on both Windows and Linux systems. It also provides information about the two available parameters in the *AWS-RunPatchBaseline document*, Operation and Snapshot ID.

### Release date

January 5, 2018

## New topics

A new section, *[How Patch Manager operations work](#)*, provides technical details that explain how Patch Manager determines which security patches to install and how it installs them on each supported operating system. It also provides information about how patch baseline rules work on different distributions of the Linux operating system.

### Release date

January 2, 2018

## Retitled and moved the Systems Manager Automation Actions Reference

Based on customer feedback, the Automation actions reference is now called the Systems Manager Automation runbook reference. Furthermore, we moved the reference into the Shared Resources > Documents node so it is closer to the *Command document plugin reference*. For more information, see *[Systems Manager Automation actions reference](#)*.

### Release date

December 20, 2017

---

<tr>
<td>Using Run Command to Take VSS-Enabled Snapshots of EBS Volumes</td>
<td>Using Run Command, you can take application-consistent snapshots of all Amazon Elastic Block Store (Amazon EBS) volumes attached to your Amazon EC2 Windows instances. The snapshot process uses the Windows Volume Shadow Copy Service (VSS) to take image-level backups of VSS-aware applications, including data from pending transactions between these applications and the disk. Furthermore, you don't need to shut down your instances or disconnect them when you need to back up all attached volumes. For more information, see Take Microsoft VSS-Enabled Snapshots Using AWS Systems Manager in the Amazon EC2 User Guide.</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Enhanced Systems Manager Security Available By Using VPC Endpoints</td>
<td>You can improve the security posture of your managed instances (including managed instances in your hybrid environment) by configuring Systems Manager to use an interface VPC endpoint. Interface endpoints are powered by PrivateLink, a technology that allows you to privately access Amazon EC2 and Systems Manager APIs by using private IP addresses. PrivateLink restricts all network traffic between your managed instances, Systems Manager, and EC2 to the Amazon network (managed instances don't have access to the Internet). Also, you don't need an Internet gateway, a NAT device, or a virtual private gateway. For more information, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.</td>

</table>
| Inventory Support for Files, Services, Windows Roles, and the Windows Registry | SSM Inventory now supports gathering the following information from your managed instances.  
- **Files**: Name, size, version, installed date, modification and last accessed times, and so on.  
- **Services**: Name, display name, status, dependent services, service type, start type, and so on.  
- **Windows Registry**: Registry key path, value name, value type, and value.  
- **Windows roles**: Name, display name, path, feature type, installed state, and so on. | November 6, 2017        |
<p>| <strong>Updates to Automation documentation</strong>                               | Fixed several issues in the information about setting up and configuring access for Systems Manager Automation. For more information, see <a href="#">Setting up Automation</a>. | October 31, 2017      |</p>

<th>Change</th>
<th>Description</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>GitHub and Amazon S3 Integration</td>
<td><strong>Run remote scripts</strong>: Systems Manager now supports downloading and running scripts from a private or public GitHub repository, and from Amazon S3. Using either the AWS-RunRemoteScript pre-defined SSM document or the <code>aws:downloadContent</code> plugin in a custom SSM document, you can run Ansible Playbooks and scripts in Python, Ruby, or PowerShell, to name a few. These changes further enhance <em>infrastructure as code</em> when you use Systems Manager to automate configuration and deployment of EC2 instances and on-premises managed instances in your hybrid environment. For more information, see <a href="#">Running scripts from GitHub</a> and <a href="#">Running scripts from Amazon S3</a>.</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td></td>
<td><strong>Create composite SSM documents</strong>: Systems Manager now supports running one or more secondary SSM documents from a primary SSM document. These primary documents that run other documents are called <em>composite</em> documents. Composite documents allow you to create and share a standard set of secondary SSM documents across AWS accounts for common tasks such as boot-strapping anti-virus software or domain-joining instances. You can run composite and secondary documents stored in Systems Manager, GitHub, or Amazon S3. After you create a composite document, you can run it by using the AWS-RunDocument pre-defined SSM document. For more information, see <a href="#">Creating composite documents</a> and <a href="#">Running documents from remote locations</a>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>SSM document plugin reference</strong>: For easier access, we moved the SSM Plugin Reference for SSM documents out of the Systems Manager API Reference and into the User Guide. For more information, see <a href="#">Command document plugin reference</a>.</td>
<td></td>

<td>Release date</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Support for Parameter Versions in Parameter Store</td>
<td>When you edit a parameter, Parameter Store now automatically iterates the version number by 1. You can specify a parameter name and a specific version number in API calls and SSM documents. If you don't specify a version number, the system automatically uses the latest version. Parameter versions provide a layer of protection in the event that a parameter is accidentally changed. You can view the values of all versions, and reference older versions if necessary. You can also use parameter versions to see how many times a parameter changed over a period of time. For more information, see <a href="#">Working with parameter versions</a>.</td>
<td>October 24, 2017</td>
</tr>
<tr>
<td>Support for Tagging Systems Manager Documents</td>
<td>You can now use the AddTagsToResource API, the AWS CLI, or the AWS Tools for PowerShell to tag Systems Manager documents with key-value pairs. Tagging helps you quickly identify specific resources based on the tags you've assigned to them. This is in addition to existing tagging support for managed instances, maintenance windows, Parameter Store parameters, and patch baselines. For information, see <a href="#">Tagging Systems Manager documents</a>.</td>

</table>
| Various Documentation Updates to Fix Errors or Update Content Based on Feedback | • Updated [Using Systems Manager in hybrid and multicloud environments](https://docs.aws.amazon.com/systems-manager/latest/userguide/ssm-basics.html) with information for Raspbian Linux.  
• Updated [Using Systems Manager with EC2 instances](https://docs.aws.amazon.com/systems-manager/latest/userguide/ssm-basics.html) with new requirement for Windows Server instances. SSM Agent requires Windows PowerShell 3.0 or later to run certain SSM Documents on Windows Server instances (for example, the legacy AWS-Apply PatchBaseline SSM document). Verify that your Windows Server instances are running Windows Management Framework 3.0 or later. The framework includes PowerShell. For more information, see [Windows Management Framework 3.0](https://docs.microsoft.com/en-us/windows-server/administration/windows-essentials-framework/). | October 2, 2017       |
<p>| Troubleshoot Unreachable Windows Instances by Using the EC2Rescue Automation Workflow | EC2Rescue can help you diagnose and troubleshoot problems on Amazon EC2 Windows Server instances. You can run the tool as a Systems Manager Automation workflow by using the <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/awssupport-ec2rescue.html">AWSSupport-ExecuteEC2Rescue</a> document. The <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/awssupport-ec2rescue.html">AWSSupport-ExecuteEC2Rescue</a> document is designed to perform a combination of Systems Manager actions, AWS CloudFormation actions, and Lambda functions that automate the steps normally required to use EC2Rescue. For more information, see <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/awssupport-ec2rescue.html">Run the EC2Rescue tool on unreachable instances</a>. | September 29, 2017    |
| SSM Agent Installed By Default on Amazon Linux                      | SSM Agent is installed, by default, on Amazon Linux AMIs dated 2017.09 and later. Manually install SSM Agent on other versions of Linux, as described in <a href="https://docs.aws.amazon.com/systems-manager/latest/userguide/working-with-ssm-agent-on-ec2.html">Working with SSM Agent on EC2 instances for Linux</a>.                   | September 27, 2017    |</p>
<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Release date</th>
</tr>
</thead>
</table>
| Run Command Enhancements | Run Command includes the following enhancements.  
  • You can restrict command execution to specific instances by creating and assigning an IAM policy that includes a condition that the user can only run commands on instances that are tagged with specific Amazon EC2 tags. For more information, see [Restricting Run Command access based on tags](#).  
  • You have more options for targeting instances by using Amazon EC2 tags. You can now specify multiple tag keys and multiple tag values when sending commands. For more information, see [Run commands at scale](#). | September 12, 2017 |
<p>| Systems Manager Supported on Raspbian | Systems Manager can now run on Raspbian Jessie and Raspbian Stretch devices, including Raspberry Pi (32-Bit). | September 7, 2017 |
| Automatically Send SSM Agent Logs to Amazon CloudWatch Logs | You can now make a simple configuration change on your instances to have SSM Agent send log files to CloudWatch. For more information, see <a href="#">Sending SSM Agent logs to CloudWatch Logs</a>. | September 7, 2017 |
| Encrypt resource data sync | With Systems Manager resource data sync, you can aggregate Inventory data collected on dozens or hundreds of managed instance in a central S3 bucket. You can now encrypt resource data sync by using an AWS Key Management Service key. For more information, see <a href="#">Walkthrough: Use resource data sync to aggregate inventory data</a>. | September 1, 2017 |</p>
<table>
<thead>
<tr>
<th>Change</th>

<th>Release date</th>
</tr>
</thead>
</table>
| New State Manager Walkthroughs | Added two new walkthroughs to the State Manager documentation:  
- **Walkthrough: Automatically update SSM Agent (CLI)**  
- **Walkthrough: Automatically update PV drivers on EC2 instances for Windows Server (console)** | August 31, 2017 |
<p>| Systems Manager Configuration Compliance | Use Configuration Compliance to scan your fleet of managed instances for patch compliance and configuration inconsistencies. You can collect and aggregate data from multiple AWS accounts and AWS Regions, and then drill down into specific resources that aren’t compliant. By default, Configuration Compliance displays compliance data about Patch Manager patching and State Manager associations. You can also customize the service and create your own compliance types based on your IT or business requirements. For more information, see <a href="#">AWS Systems Manager Compliance</a>. | August 28, 2017 |
| New Automation Action: <code>aws:executeAutomation</code> | Runs a secondary Automation workflow by calling a secondary Automation runbook. With this action, you can create Automation runbooks for your most common workflows, and reference those documents during an Automation execution. This action can simplify your Automation runbooks by removing the need to duplicate steps across similar runbooks. For more information, see <a href="#">aws:executeAutomation – Run another automation</a>. | August 22, 2017 |
| Automation as the Target of a CloudWatch Event | You can start an Automation workflow by specifying an Automation runbook as the target of an Amazon CloudWatch event. You can start workflows according to a schedule, or when a specific AWS system event occurs. For more information, see <a href="#">Run automations based on events</a>. | August 21, 2017 |</p>
<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>State Manager Association Versioning and General Updates</td>
<td>You can now create different State Manager association versions. There is a quota of 1,000 versions for each association. You can also specify names for your associations. Also, the State Manager documentation has been updated to address outdated information and inconsistencies. For more information, see <a href="https://aws.amazon.com">AWS Systems Manager State Manager</a>.</td>
<td>August 21, 2017</td>
</tr>
<tr>
<td>Changes to Maintenance Windows</td>
<td>Maintenance Windows include the following changes or enhancements:</td>
<td>August 16, 2017</td>
</tr>
<tr>
<td></td>
<td>• Previously, Maintenance Windows could only perform tasks by using Run Command. You can now perform tasks by using Systems Manager Automation, AWS Lambda, and AWS Step Functions.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• You can edit the targets of a maintenance window, specify a target name, description, and owner.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• You can edit tasks in a maintenance window, including specifying a new SSM document for Run Command and Automation tasks.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• All Run Command parameters are now supported, including DocumentHash, DocumentHashType, TimeoutSeconds, Comment, and NotificationConfig.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• You can now use a safe flag when you attempt to deregister a target. If turned on, the system returns an error if the target is referenced by any task.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="https://aws.amazon.com">AWS Systems Manager Maintenance Windows</a>.</td>
<td></td>
</tr>

<tr>
<td>---------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>New Automation Action: <code>aws:approve</code></td>
<td>This new action for Automation runbooks temporarily pauses an Automation execution until designated principals either approve or reject the action. After the required number of approvals is reached, the Automation execution resumes.</td>
<td>August 10, 2017</td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="#">Systems Manager Automation actions reference</a>.</td>
<td></td>
</tr>
<tr>
<td>Automation assume role no longer required</td>
<td>Automation previously required that you specify a service role (or <em>assume role</em>) so that the service had permission to perform actions on your behalf. Automation no longer requires this role because the service now operates by using the context of the user who invoked the execution.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>However, the following situations still require that you specify a service role for Automation:</td>
<td>August 3, 2017</td>
</tr>
<tr>
<td></td>
<td>• When you want to restrict a user's permissions on a resource, but you want the user to run an Automation workflow that requires elevated permissions. In this scenario, you can create a service role with elevated permissions and allow the user to run the workflow.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Operations that you expect to run longer than 12 hours require a service role.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="#">Setting up Automation</a>.</td>
<td></td>
</tr>
<tr>
<td>Change</td>

<td>--------------</td>
</tr>
<tr>
<td>Configuration Compliance</td>
<td>Use Amazon EC2 Systems Manager Configuration Compliance to scan your fleet of managed instances for patch compliance and configuration inconsistencies. You can collect and aggregate data from multiple AWS accounts and AWS Regions, and then drill down into specific resources that aren’t compliant. For more information, see <a href="https://docs.aws.amazon.com/systems-manager/latest/adminguide/config-compliance.html">AWS Systems Manager Compliance</a>.</td>
<td>August 8, 2017</td>
</tr>
</tbody>
</table>
| SSM Document Enhancements  | SSM Command and Policy documents now offer cross-platform support. This means that a single SSM document can process plugins for Windows and Linux operating systems. Cross-platform support allows you to consolidate the number of documents you manage. Cross-platform support is offered in SSM documents that use schema version 2.2 or later.  

SSM Command documents that use schema version 2.0 or later can now include multiple plugins of the same type. For example, you can create a Command document that calls the `aws:runShellScript` plugin multiple times.

For more information about schema version 2.2 changes, see [AWS Systems Manager documents](https://docs.aws.amazon.com/systems-manager/latest/adminguide/schemas.html). For more information about SSM plugins, see [Command document plugin reference](https://docs.aws.amazon.com/systems-manager/latest/adminguide/plugin-ref-command.html). | July 12, 2017 |

</thead>
<tbody>
<tr>
<td>Resource data sync</td>
<td>You can use Systems Manager resource data sync to send Inventory data collected from all of your managed instances to a single Amazon S3 bucket. Resource data sync then automatically updates the centralized data when new Inventory data is collected. With all Inventory data stored in a target S3 bucket, you can use services like Amazon Athena and Amazon QuickSight to query and analyze the aggregated data. For more information, see <a href="#">Configuring resource data sync for Inventory</a>. For an example of how to work with resource data sync, see <a href="#">Walkthrough: Use resource data sync to aggregate inventory data</a>.</td>
<td>June 29, 2017</td>
</tr>
</tbody>
</table>
| Systems Manager Parameter Hierarchies | Managing dozens or hundreds of Systems Manager parameters as a flat list is time-consuming and prone to errors. You can use parameter hierarchies to help you organize and manage Systems Manager parameters. A hierarchy is a parameter name that includes a path that you define by using forward slashes. Here is an example that uses three hierarchy levels in the name to identify the following:  

/Environment/Type of computer/Application/Data  

/Dev/DBServer/MySQL/db-string13  

For more information, see [Working with parameter hierarchies](#). For an example of how to work with parameter hierarchies, see [Working with parameter hierarchies](#). | June 22, 2017 |
| SSM Agent Support for SUSE Linux Enterprise Server | You can install SSM Agent on 64-bit SUSE Linux Enterprise Server (SLES). For more information, see [Working with SSM Agent on EC2 instances for Linux](#). | June 14, 2017 |
Document conventions

The following are common typographical conventions for the *AWS Systems Manager User Guide*.

**Differentiated examples for local operating systems or command line languages**

We use tabs to present different examples of commands based on a user's local operating system type. For Linux and macOS examples, we use the backslash (\) character to break long commands into multiple lines. For Windows Server examples, we use the caret (^) character to break commands into multiple lines.

Example:

**Linux & macOS**

```bash
aws ssm update-service-setting
   --setting-value advanced
```

**Windows**

```bash
aws ssm update-service-setting ^
   --setting-value advanced
```

**Elements in the user interface**

Formatting: Text in bold

Example: Choose **File, Properties**.

**User input (text that a user types)**

Formatting: Text in a monospace font

Example: For the name, type **my-new-resource**.

**Placeholder text for a required value**

Formatting: Text in *italics*
Example:

```bash
aws ec2 register-image --image-location DOC-EXAMPLE-BUCKET/image.manifest.xml
```
AWS Glossary

For the latest AWS terminology, see the AWS glossary in the AWS Glossary Reference.
