What is Amazon VPC?

Amazon Virtual Private Cloud (Amazon VPC) enables you to launch AWS resources into a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Features

The following features help you configure a VPC to provide the connectivity that your applications need:

Virtual private clouds (VPC)

A VPC (p. 13) is a virtual network that closely resembles a traditional network that you'd operate in your own data center. After you create a VPC, you can add subnets.

Subnets

A subnet (p. 56) is a range of IP addresses in your VPC. A subnet must reside in a single Availability Zone. After you add subnets, you can deploy AWS resources in your VPC.

IP addressing

You can assign IPv4 addresses and IPv6 addresses to your VPCs and subnets. You can also bring your public IPv4 and IPv6 GUA addresses to AWS and allocate them to resources in your VPC, such as EC2 instances, NAT gateways, and Network Load Balancers.

Routing

Use route tables (p. 74) to determine where network traffic from your subnet or gateway is directed.

Gateways and endpoints

A gateway (p. 128) connects your VPC to another network. For example, use an internet gateway (p. 128) to connect your VPC to the internet. Use a VPC endpoint to connect to AWS services privately, without the use of an internet gateway or NAT device.

Peering connections

Use a VPC peering connection to route traffic between the resources in two VPCs.

Traffic Mirroring

Copy network traffic from network interfaces and send it to security and monitoring appliances for deep packet inspection.

Transit gateways

Use a transit gateway (p. 177), which acts as a central hub, to route traffic between your VPCs, VPN connections, and AWS Direct Connect connections.

VPC Flow Logs

A flow log (p. 180) captures information about the IP traffic going to and from network interfaces in your VPC.

VPN connections

Connect your VPCs to your on-premises networks using AWS Virtual Private Network (AWS VPN) (p. 177).
Getting started with Amazon VPC

Your AWS account includes a default VPC (p. 25) in each AWS Region. Your default VPCs are configured such that you can immediately start launching and connecting to EC2 instances. For more information, see Get started (p. 10).

You can choose to create additional VPCs with the subnets, IP addresses, gateways and routing that you need. For more information, see the section called “Create a VPC” (p. 18).

Working with Amazon VPC

You can create and manage your VPCs using any of the following interfaces:

- **AWS Management Console** — Provides a web interface that you can use to access your VPCs.
- **AWS Command Line Interface (AWS CLI)** — Provides commands for a broad set of AWS services, including Amazon VPC, and is supported on Windows, Mac, and Linux. For more information, see AWS Command Line Interface.
- **AWS SDKs** — Provides language-specific APIs and takes care of many of the connection details, such as calculating signatures, handling request retries, and error handling. For more information, see AWS SDKs.
- **Query API** — Provides low-level API actions that you call using HTTPS requests. Using the Query API is the most direct way to access Amazon VPC, but it requires that your application handle low-level details such as generating the hash to sign the request, and error handling. For more information, see Amazon VPC actions in the Amazon EC2 API Reference.

Pricing for Amazon VPC

There's no additional charge for using a VPC. There are charges for some VPC components, such as NAT gateways, Reachability Analyzer, and traffic mirroring. For more information, see Amazon VPC Pricing.
How Amazon VPC works

Amazon Virtual Private Cloud (Amazon VPC) enables you to launch AWS resources into a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Concepts
- VPCs and subnets (p. 3)
- Default and nondefault VPCs (p. 3)
- IP addressing (p. 4)
- Route tables (p. 7)
- Access the internet (p. 7)
- Access a corporate or home network (p. 8)
- Connect VPCs and networks (p. 8)
- AWS private global network considerations (p. 8)

VPCs and subnets

A virtual private cloud (VPC) is a virtual network dedicated to your AWS account. It is logically isolated from other virtual networks in the AWS Cloud. You can specify an IP address range for the VPC, add subnets, add gateways, and associate security groups.

A subnet is a range of IP addresses in your VPC. You launch AWS resources, such as Amazon EC2 instances, into your subnets. You can connect a subnet to the internet, other VPCs, and your own data centers, and route traffic to and from your subnets using route tables.

Learn more
- VPC basics (p. 13)
- Subnet basics (p. 56)
- Internetwork traffic privacy in Amazon VPC (p. 224)
- IP addressing (p. 4)

Default and nondefault VPCs

If your account was created after 2013-12-04, it comes with a default VPC in each Region. A default VPC is configured and ready for you to use. For example, it has a default subnet in each Availability Zone in the Region, an attached internet gateway, a route in the main route table that sends all traffic to the internet gateway, and DNS settings that provide EC2 instances with public IP addresses and DNS hostnames. Therefore, an EC2 instance that is launched in a default subnet automatically has access to the internet. If you have a default VPC in a Region and you don’t specify a subnet when you launch an EC2 instance into that Region, we choose one of the default subnets and launch the instance into that subnet.

You can also create your own VPC, and configure it as you need. This is known as a nondefault VPC. Subnets that you create in your nondefault VPC and additional subnets that you create in your default VPC are called nondefault subnets.

Learn more
- Default VPCs (p. 25)
IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet.

Classless Inter-Domain Routing (CIDR) notation is a way of representing an IP address and its network mask. The format of these addresses is as follows:

- An individual IPv4 address is 32 bits, with 4 groups of up to 3 decimal digits. For example, 10.0.1.0.
- An IPv4 CIDR block has four groups of up to three decimal digits, 0-255, separated by periods, followed by a slash and a number from 0 to 32. For example, 10.0.0.0/16.
- An individual IPv6 address is 128 bits, with 8 groups of 4 hexadecimal digits. For example, 2001:0db8:85a3:0000:0000:8a2e:0370:7334.
- An IPv6 CIDR block has four groups of up to four hexadecimal digits, separated by colons, followed by a double colon, followed by a slash and a number from 1 to 128. For example, 2001:db8:1234:1a00::/56.

For more information, see Classless Inter-Domain Routing in Wikipedia.

When you create a VPC, you assign it an IPv4 CIDR block (a range of private IPv4 addresses), an IPv6 CIDR block, or both IPv4 and IPv6 CIDR blocks (dual-stack).

Private IPv4 addresses are not reachable over the internet. IPv6 addresses are globally unique and can be configured to remain private or be reachable over the internet.

Your VPC can operate in dual-stack mode. This means that your resources can communicate over IPv4, IPv6, or both IPv4 and IPv6. IPv4 and IPv6 addresses are independent of each other; you must add separate routes and security group rules for IPv4 and IPv6.

Contents

- Compare IPv4 and IPv6 (p. 4)
- Private IPv4 addresses (p. 5)
- Public IPv4 addresses (p. 5)
- IPv6 addresses (p. 6)
- Use your own IP addresses (p. 7)

Compare IPv4 and IPv6

The following table summarizes the differences between IPv4 and IPv6 in Amazon EC2 and Amazon VPC.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>IPv4</th>
<th>IPv6</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC size</td>
<td>Up to 5 CIDRs from /16 to /28. This quota (p. 353) is adjustable.</td>
<td>Up to 5 CIDRs fixed at /56. This quota is not adjustable.</td>
</tr>
<tr>
<td>Subnet size</td>
<td>From /16 to /28</td>
<td>Fixed at /64</td>
</tr>
<tr>
<td>Address selection</td>
<td>You can choose the IPv4 CIDR block for your VPC or you can allocate a CIDR block from Amazon VPC IP Address</td>
<td>You can bring your own IPv6 CIDR block to AWS for your VPC, choose an Amazon-provided IPv6 CIDR block, or</td>
</tr>
</tbody>
</table>
### Private IPv4 addresses

Private IPv4 addresses (also referred to as *private IP addresses* in this topic) are not reachable over the internet, and can be used for communication between the instances in your VPC. When you launch an instance into a VPC, a primary private IP address from the IPv4 address range of the subnet is assigned to the default network interface (eth0) of the instance. Each instance is also given a private (internal) DNS hostname that resolves to the private IP address of the instance. The hostname can be of two types: resource-based or IP-based. For more information, see [EC2 instance naming](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EC2-instance-naming.html). If you don't specify a primary private IP address, we select an available IP address in the subnet range for you. For more information about network interfaces, see [Elastic Network Interfaces](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/elastic-network-interfaces.html) in the *Amazon EC2 User Guide for Linux Instances*.

You can assign additional private IP addresses, known as secondary private IP addresses, to instances that are running in a VPC. Unlike a primary private IP address, you can reassign a secondary private IP address from one network interface to another. A private IP address remains associated with the network interface when the instance is stopped and restarted, and is released when the instance is terminated. For more information about primary and secondary IP addresses, see [Multiple IP Addresses](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/using-secondary-ips.html) in the *Amazon EC2 User Guide for Linux Instances*.

We refer to private IP addresses as the IP addresses that are within the IPv4 CIDR range of the VPC. Most VPC IP address ranges fall within the private (non-publicly routable) IP address ranges specified in RFC 1918; however, you can use publicly routable CIDR blocks for your VPC. Regardless of the IP address range of your VPC, we do not support direct access to the internet from your VPC's CIDR block, including a publicly-routable CIDR block. You must set up internet access through a gateway; for example, an internet gateway, virtual private gateway, a AWS Site-to-Site VPN connection, or AWS Direct Connect.

### Public IPv4 addresses

All subnets have an attribute that determines whether a network interface created in the subnet automatically receives a public IPv4 address (also referred to as a *public IP address* in this topic). Therefore, when you launch an instance into a subnet that has this attribute enabled, a public IP address...
is assigned to the primary network interface (eth0) that’s created for the instance. A public IP address is mapped to the primary private IP address through network address translation (NAT).

You can control whether your instance receives a public IP address by doing the following:

- Modifying the public IP addressing attribute of your subnet. For more information, see Modify the public IPv4 addressing attribute for your subnet (p. 61).
- Enabling or disabling the public IP addressing feature during instance launch, which overrides the subnet's public IP addressing attribute.

A public IP address is assigned from Amazon's pool of public IP addresses; it's not associated with your account. When a public IP address is disassociated from your instance, it's released back into the pool, and is no longer available for you to use. You cannot manually associate or disassociate a public IP address. Instead, in certain cases, we release the public IP address from your instance, or assign it a new one. For more information, see Public IP addresses in the Amazon EC2 User Guide for Linux Instances.

If you require a persistent public IP address allocated to your account that can be assigned to and removed from instances as you require, use an Elastic IP address instead. For more information, see Associate Elastic IP addresses with resources in your VPC (p. 134).

If your VPC is enabled to support DNS hostnames, each instance that receives a public IP address or an Elastic IP address is also given a public DNS hostname. We resolve a public DNS hostname to the public IP address of the instance outside the instance network, and to the private IP address of the instance from within the instance network. For more information, see DNS attributes for your VPC (p. 37).

IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets. For more information, see Associate an IPv6 CIDR block with your subnet (p. 61).

Your instance in a VPC receives an IPv6 address if an IPv6 CIDR block is associated with your VPC and your subnet, and if one of the following is true:

- Your subnet is configured to automatically assign an IPv6 address to the primary network interface of an instance during launch.
- You manually assign an IPv6 address to your instance during launch.
- You assign an IPv6 address to your instance after launch.
- You assign an IPv6 address to a network interface in the same subnet, and attach the network interface to your instance after launch.

When your instance receives an IPv6 address during launch, the address is associated with the primary network interface (eth0) of the instance. You can disassociate the IPv6 address from the primary network interface. We do not support IPv6 DNS hostnames for your instance.

An IPv6 address persists when you stop and start your instance, and is released when you terminate your instance. You cannot reassign an IPv6 address while it's assigned to another network interface—you must first unassign it.

You can assign additional IPv6 addresses to your instance by assigning them to a network interface attached to your instance. The number of IPv6 addresses you can assign to a network interface, and the number of network interfaces you can attach to an instance varies per instance type. For more information, see IP Addresses Per Network Interface Per Instance Type in the Amazon EC2 User Guide.

IPv6 addresses are globally unique and can be configured to remain private or reachable over the Internet. You can control whether instances are reachable via their IPv6 addresses by controlling the
Use your own IP addresses

You can bring part or all of your own public IPv4 address range or IPv6 address range to your AWS account. You continue to own the address range, but AWS advertises it on the internet by default. After you bring the address range to AWS, it appears in your account as an address pool. You can create an Elastic IP address from your IPv4 address pool, and you can associate an IPv6 CIDR block from your IPv6 address pool with a VPC.

For more information, see Bring your own IP addresses (BYOIP) in the Amazon EC2 User Guide for Linux Instances.

Route tables

A route table contains a set of rules, called routes, that are used to determine where network traffic from your VPC is directed. You can explicitly associate a subnet with a particular route table. Otherwise, the subnet is implicitly associated with the main route table.

Each route in a route table specifies the range of IP addresses where you want the traffic to go (the destination) and the gateway, network interface, or connection through which to send the traffic (the target).

Learn more
• Configure route tables (p. 74)

Access the internet

You control how the instances that you launch into a VPC access resources outside the VPC.

A default VPC includes an internet gateway, and each default subnet is a public subnet. Each instance that you launch into a default subnet has a private IPv4 address and a public IPv4 address. These instances can communicate with the internet through the internet gateway. An internet gateway enables your instances to connect to the internet through the Amazon EC2 network edge.

By default, each instance that you launch into a nondefault subnet has a private IPv4 address, but no public IPv4 address, unless you specifically assign one at launch, or you modify the subnet’s public IP address attribute. These instances can communicate with each other, but can’t access the internet.

You can enable internet access for an instance launched into a nondefault subnet by attaching an internet gateway to its VPC (if its VPC is not a default VPC) and associating an Elastic IP address with the instance.

Alternatively, to allow an instance in your VPC to initiate outbound connections to the internet but prevent unsolicited inbound connections from the internet, you can use a network address translation (NAT) device. NAT maps multiple private IPv4 addresses to a single public IPv4 address. You can configure the NAT device with an Elastic IP address and connect it to the internet through an internet gateway. This makes it possible for an instance in a private subnet to connect to the internet through the NAT device, routing traffic from the instance to the internet gateway and any responses to the instance.
If you associate an IPv6 CIDR block with your VPC and assign IPv6 addresses to your instances, instances can connect to the internet over IPv6 through an internet gateway. Alternatively, instances can initiate outbound connections to the internet over IPv6 using an egress-only internet gateway. IPv6 traffic is separate from IPv4 traffic; your route tables must include separate routes for IPv6 traffic.

Learn more
- Connect to the internet using an internet gateway (p. 128)
- Enable outbound IPv6 traffic using an egress-only internet gateway (p. 139)
- Connect to the internet or other networks using NAT devices (p. 142)

Access a corporate or home network

You can optionally connect your VPC to your own corporate data center using an IPsec AWS Site-to-Site VPN connection, making the WSCLoud an extension of your data center.

A Site-to-Site VPN connection consists of two VPN tunnels between a virtual private gateway or transit gateway on the AWS side, and a customer gateway device located in your data center. A customer gateway device is a physical device or software appliance that you configure on your side of the Site-to-Site VPN connection.

Learn more
- AWS Site-to-Site VPN User Guide
- Transit Gateways

Connect VPCs and networks

You can create a VPC peering connection between two VPCs that enables you to route traffic between them privately. Instances in either VPC can communicate with each other as if they are within the same network.

You can also create a transit gateway and use it to interconnect your VPCs and on-premises networks. The transit gateway acts as a Regional virtual router for traffic flowing between its attachments, which can include VPCs, VPN connections, AWS Direct Connect gateways, and transit gateway peering connections.

Learn more
- VPC Peering Guide
- Transit Gateways

AWS private global network considerations

AWS provides a high-performance, and low-latency private global network that delivers a secure cloud computing environment to support your networking needs. AWS Regions are connected to multiple Internet Service Providers (ISPs) as well as to a private global network backbone, which provides improved network performance for cross-Region traffic sent by customers.

The following considerations apply:
• Traffic that is in an Availability Zone, or between Availability Zones in all Regions, routes over the AWS private global network.
• Traffic that is between Regions always routes over the AWS private global network, except for China Regions.

Network packet loss can be caused by a number of factors, including network flow collisions, lower level (Layer 2) errors, and other network failures. We engineer and operate our networks to minimize packet loss. We measure packet-loss rate (PLR) across the global backbone that connects the AWS Regions. We operate our backbone network to target a p99 of the hourly PLR of less than 0.0001%.
Get started with Amazon VPC

You can create AWS resources in the subnets of your virtual private cloud (VPC). For example, to get started with Amazon EC2 quickly, you can launch an EC2 instance into the default subnets of a default VPC. For more information, see the section called “Default VPCs” (p. 25).

Alternatively, you can create subnets in a custom VPC for your AWS resources. For more information, see Create a VPC (p. 18).

Note
In this tutorial, you'll launch an EC2 instance into a default subnet, connect to the instance, and then terminate the instance. If you are within the AWS Free Tier, there is no charge for launching an On-Demand instance. For more information, see Amazon EC2 Pricing.

Contents
- Prerequisites (p. 10)
- Step 1: Get to know your default VPC (p. 10)
- Step 2: Launch an instance into your VPC (p. 11)
- Step 3: Connect to an EC2 instance in your public subnet (p. 12)
- Step 4: Clean up (p. 12)
- Next steps (p. 12)

Prerequisites

If this is your first time using AWS, you must sign up for an account. When you sign up, your AWS account is automatically signed up for all services in AWS, including Amazon VPC. If you haven't created an AWS account already, use the following procedure to create one.

To create an AWS account

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

   When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

Before you can use Amazon VPC, you must have the required permissions. For more information, see Identity and access management for Amazon VPC (p. 228) and Amazon VPC policy examples (p. 235).

Step 1: Get to know your default VPC

If you are new to Amazon VPC, use the following procedure to view the configuration of your default VPC, including its default subnets, main route table, and internet gateway. All default subnets use the
main route table, which has a route to the internet gateway. This means that the resources that you launch into a default subnet have access to the internet.

To view the configuration of your default VPC

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs. For the default VPC, the Default VPC column is Yes. If you've created other VPCs, Default VPC is No.
3. Each VPC has a main route table. The default subnets use the main route table, as they are not associated with another route table. To view the main route table, select the checkbox for the default VPC and choose the ID under Route table. Alternatively, choose Route tables from the navigation pane and find the route table where the Main column is Yes and the VPC column displays the ID of the VPC followed by the name, default.

On the Routes tab, there is a local route that allows the resources in the VPC to communicate with each other and another route that allows all other traffic to reach the internet through the internet gateway.

4. In the navigation pane, choose Subnets. For the default VPC, there is one subnet per Availability Zone. For these default subnets, the Default subnet column is Yes. If you select each subnet, you can view information such as its CIDR block, the routes for the route table, and the rules for the default network ACL.
5. In the navigation pane, choose Internet gateways. For the internet gateway attached to the default VPC, the VPC ID column displays the ID of the VPC followed by the name, default.

Step 2: Launch an instance into your VPC

The Amazon EC2 console provides default values for your instance configuration, which makes it easy to get started quickly. For example, after you choose an AWS Region, we automatically choose the default VPC for this Region.

To launch an instance in a default subnet

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the dashboard, choose Launch instance.
3. From the navigation bar at the top of the screen, select a Region in which to launch the instance.
4. (Optional) Under Name and tags, enter a descriptive name for your instance.
5. Under Application and OS Images (Amazon Machine Image), choose Quick Start, and then choose an operating system (OS) for your instance.
6. Under Instance type, keep the default value, t2.micro, which is free tier eligible.
7. Under Key pair (login), choose an existing key pair, create a new key pair, or choose Proceed without a key pair if you do not intend to connect to the new instance that you create as part of this exercise.
8. Under Network settings, notice that we've selected the default VPC for the Region that you selected, we will select a default subnet for you, and we will assign your instance a public IP address. You can keep these settings. We also create a default security group with a rule that allows SSH traffic (Linux instances) or RDP traffic (Windows instances) to your instance from anywhere.

Important
Rules that allow SSH or RDP traffic to your instance from anywhere are acceptable if you are launching a test instance and plan to stop or terminate it after completing this exercise. In a production environment, you should authorize only specific address ranges for SSH or RDP traffic.

9. In the Summary panel, choose Launch instance.
Step 3: Connect to an EC2 instance in your public subnet

The EC2 instance in your default public subnet is accessible from the internet. You can connect to your instance using SSH or Remote Desktop from your home network.

- For more information about how to connect to a Linux instance in your public subnet, see Connecting to your Linux instance in the Amazon EC2 User Guide for Linux Instances.
- For more information about how to connect to a Windows instance in your public subnet, see Connect to your Windows instance in the Amazon EC2 User Guide for Windows Instances.

Step 4: Clean up

When you are finished, you can terminate an instance. As soon as the instance state changes, you stop incurring any charges for that instance. After the instance is terminated, it remains visible in the console for a short while.

Do not delete your default VPC.

To terminate an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, and choose Instance state, Terminate instance.
4. When prompted for confirmation, choose Terminate.

For more information, see Terminate an instance in the Amazon EC2 User Guide for Linux Instances.

Next steps

Now that you've worked with your default VPC and the default public subnets, you might want to do the following:

- Learn more about VPCs: Virtual private clouds (VPC) (p. 13).
- Add a private subnet to your VPC: Create a subnet in your VPC (p. 59).
- Enable IPv6 support for your VPC and subnets: Associate an IPv6 CIDR block with your subnet (p. 61).
- Enable instances in a private subnet to access the internet: Connect to the internet or other networks using NAT devices (p. 142).
Virtual private clouds (VPC)

A virtual private cloud (VPC) is a virtual network dedicated to your AWS account. It is logically isolated from other virtual networks in the AWS Cloud. You can launch your AWS resources, such as Amazon EC2 instances, into your VPC.

Contents
- VPC basics (p. 13)
- VPC CIDR blocks (p. 14)
- Work with VPCs (p. 18)
- Default VPCs (p. 25)
- DHCP option sets in Amazon VPC (p. 30)
- DNS attributes for your VPC (p. 37)
- Network Address Usage for your VPC (p. 42)
- Share your VPC with other accounts (p. 44)
- Extend a VPC to a Local Zone, Wavelength Zone, or Outpost (p. 49)

VPC basics

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a Classless Inter-Domain Routing (CIDR) block. For example, 10.0.0.0/16. This is the primary CIDR block for your VPC. For more information, see the section called "IP addressing" (p. 4).

A VPC spans all of the Availability Zones in the Region. The following diagram shows a new VPC. After you create a VPC, you can add one or more subnets in each Availability Zone. For more information, see Subnets (p. 56).
VPC CIDR blocks

Amazon VPC supports IPv4 and IPv6 addressing. A VPC must have an IPv4 CIDR block associated with it. You can optionally associate multiple IPv4 CIDR blocks and multiple IPv6 CIDR blocks to your VPC. For more information about IP addressing, see IP addressing (p. 4).

Contents

- IPv4 VPC CIDR blocks (p. 14)
- Manage IPv4 CIDR blocks for a VPC (p. 15)
- IPv4 CIDR block association restrictions (p. 17)
- IPv6 VPC CIDR blocks (p. 18)

IPv4 VPC CIDR blocks

When you create a VPC, you must specify an IPv4 CIDR block for the VPC. The allowed block size is between a /16 netmask (65,536 IP addresses) and /28 netmask (16 IP addresses). After you've created your VPC, you can associate additional IPv4 CIDR blocks with the VPC. For more information, see Associate additional IPv4 CIDR blocks with your VPC (p. 22).

When you create a VPC, we recommend that you specify a CIDR block from the private IPv4 address ranges as specified in RFC 1918.
RFC 1918 range | Example CIDR block
--- | ---
10.0.0.0 - 10.255.255.255 (10/8 prefix) | 10.0.0.0/16
172.16.0.0 - 172.31.255.255 (172.16/12 prefix) | 172.31.0.0/16
192.168.0.0 - 192.168.255.255 (192.168/16 prefix) | 192.168.0.0/20

You can create a VPC with a publicly routable CIDR block that falls outside of the private IPv4 address ranges specified in RFC 1918. However, for the purposes of this documentation, we refer to private IP addresses as the IPv4 addresses that are within the CIDR range of your VPC.

When you create a VPC for use with an AWS service, check the service documentation to verify if there are specific requirements for its configuration.

If you create a VPC using a command line tool or the Amazon EC2 API, the CIDR block is automatically modified to its canonical form. For example, if you specify 100.68.0.18/18 for the CIDR block, we create a CIDR block of 100.68.0.0/18.

### Manage IPv4 CIDR blocks for a VPC

You can associate secondary IPv4 CIDR blocks with your VPC. When you associate a CIDR block with your VPC, a route is automatically added to your VPC route tables to enable routing within the VPC (the destination is the CIDR block and the target is local).

In the following example, the VPC has both a primary and a secondary CIDR block. The CIDR blocks for Subnet A and Subnet B are from the primary VPC CIDR block. The CIDR block for Subnet C is from the secondary VPC CIDR block.

The following route table shows the local routes for the VPC.
To add a CIDR block to your VPC, the following rules apply:

- The allowed block size is between a /28 netmask and /16 netmask.
- The CIDR block must not overlap with any existing CIDR block that's associated with the VPC.
- There are restrictions on the ranges of IPv4 addresses you can use. For more information, see IPv4 CIDR block association restrictions (p. 17).
- You cannot increase or decrease the size of an existing CIDR block.
- You have a quota on the number of CIDR blocks you can associate with a VPC and the number of routes you can add to a route table. You cannot associate a CIDR block if this results in you exceeding your quotas. For more information, see Amazon VPC quotas (p. 353).
- The CIDR block must not be the same or larger than a destination CIDR range in a route in any of the VPC route tables. For example, in a VPC where the primary CIDR block is 10.2.0.0/16, you have an existing route in a route table with a destination of 10.0.0.0/24 to a virtual private gateway. You want to associate a secondary CIDR block in the 10.0.0.0/16 range. Because of the existing route, you cannot associate a CIDR block of 10.0.0.0/24 or larger. However, you can associate a secondary CIDR block of 10.0.0.0/25 or smaller.
- If you’ve enabled your VPC for ClassicLink, you can associate CIDR blocks from the 10.0.0.0/16 and 10.1.0.0/16 ranges, but you cannot associate any other CIDR block from the 10.0.0.0/8 range.
- The following rules apply when you add IPv4 CIDR blocks to a VPC that’s part of a VPC peering connection:
  - If the VPC peering connection is active, you can add CIDR blocks to a VPC provided they do not overlap with a CIDR block of the peer VPC.
  - If the VPC peering connection is pending-acceptance, the owner of the requester VPC cannot add any CIDR block to the VPC, regardless of whether it overlaps with the CIDR block of the accepter VPC. Either the owner of the accepter VPC must accept the peering connection, or the owner of the requester VPC must delete the VPC peering connection request, add the CIDR block, and then request a new VPC peering connection.
  - If the VPC peering connection is pending-acceptance, the owner of the accepter VPC can add CIDR blocks to the VPC. If a secondary CIDR block overlaps with a CIDR block of the requester VPC, the VPC peering connection request fails and cannot be accepted.
  - If you’re using AWS Direct Connect to connect to multiple VPCs through a Direct Connect gateway, the VPCs that are associated with the Direct Connect gateway must not have overlapping CIDR blocks. If you add a CIDR block to one of the VPCs that’s associated with the Direct Connect gateway, ensure that the new CIDR block does not overlap with an existing CIDR block of any other associated VPC. For more information, see Direct Connect gateways in the AWS Direct Connect User Guide.
  - When you add or remove a CIDR block, it can go through various states: associating | associated | disassociating | disassociated | failing | failed. The CIDR block is ready for you to use when it's in the associated state.

You can disassociate a CIDR block that you've associated with your VPC; however, you cannot disassociate the CIDR block with which you originally created the VPC (the primary CIDR block). To view the primary CIDR for your VPC in the Amazon VPC console, choose Your VPCs, select the checkbox for your VPC, and choose the CIDRs tab. To view the primary CIDR using the AWS CLI, use the describe-vpcs command as follows. The primary CIDR is returned in the top-level CidrBlock element.
The following is example output.

```
[  
  "10.0.0.0/16",  
]
```

**IPv4 CIDR block association restrictions**

The following table provides an overview of permitted and restricted VPC CIDR block associations.

<table>
<thead>
<tr>
<th>IP address range</th>
<th>Restricted associations</th>
<th>Permitted associations</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/8</td>
<td>CIDR blocks from other RFC 1918* ranges (172.16.0.0/12 and 192.168.0.0/16).&lt;br&gt; If any of the CIDR blocks associated with the VPC are from the 10.0.0.0/15 range (10.0.0.0 to 10.1.255.255), you cannot add a CIDR block from the 10.0.0.0/16 range (10.0.0.0 to 10.0.255.255).&lt;br&gt; CIDR blocks from the 198.19.0.0/16 range.</td>
<td>Any other CIDR block from the 10.0.0.0/8 range that's not restricted.&lt;br&gt; Any publicly routable IPv4 CIDR block (non-RFC 1918), or a CIDR block from the 100.64.0.0/10 range.</td>
</tr>
<tr>
<td>172.16.0.0/12</td>
<td>CIDR blocks from other RFC 1918* ranges (10.0.0.0/8 and 192.168.0.0/16).&lt;br&gt; CIDR blocks from the 172.31.0.0/16 range.&lt;br&gt; CIDR blocks from the 198.19.0.0/16 range.</td>
<td>Any other CIDR block from the 172.16.0.0/12 range that’s not restricted.&lt;br&gt; Any publicly routable IPv4 CIDR block (non-RFC 1918), or a CIDR block from the 100.64.0.0/10 range.</td>
</tr>
<tr>
<td>192.168.0.0/16</td>
<td>CIDR blocks from other RFC 1918* ranges (10.0.0.0/8 and 172.16.0.0/12).&lt;br&gt; CIDR blocks from the 198.19.0.0/16 range.</td>
<td>Any other CIDR block from the 192.168.0.0/16 range.&lt;br&gt; Any publicly routable IPv4 CIDR block (non-RFC 1918), or a CIDR block from the 100.64.0.0/10 range.</td>
</tr>
<tr>
<td>198.19.0.0/16</td>
<td>CIDR blocks from the RFC 1918* ranges.</td>
<td>Any publicly routable IPv4 CIDR block (non-RFC 1918), or a CIDR block from the 100.64.0.0/10 range.</td>
</tr>
<tr>
<td>Publicly routable CIDR block (non-RFC 1918), or a CIDR block from the 100.64.0.0/10 range</td>
<td>CIDR blocks from the RFC 1918* ranges.&lt;br&gt; CIDR blocks from the 198.19.0.0/16 range.</td>
<td>Any other publicly routable IPv4 CIDR block (non-RFC 1918), or a CIDR block from the 100.64.0.0/10 range.</td>
</tr>
</tbody>
</table>
IPv6 VPC CIDR blocks

You can associate a single IPv6 CIDR block when you create a new VPC with an existing VPC in your account or you can associate up to five by modifying an existing VPC. The CIDR block is a fixed prefix length of /56. You can request an IPv6 CIDR block from Amazon's pool of IPv6 addresses. For more information, see Associate IPv6 CIDR blocks with your VPC (p. 22).

If you've associated an IPv6 CIDR block with your VPC, you can associate an IPv6 CIDR block with an existing subnet in your VPC or when you create a new subnet. For more information, see the section called “Subnet sizing for IPv6” (p. 58).

For example, you create a VPC and specify that you want to associate an Amazon-provided IPv6 CIDR block with the VPC. Amazon assigns the following IPv6 CIDR block to your VPC: 2001:db8:1234:1a00::/56. You cannot choose the range of IP addresses yourself. You can create a subnet and associate an IPv6 CIDR block from this range; for example, 2001:db8:1234:1a00::/64.

You can disassociate an IPv6 CIDR block from a VPC. After you've disassociated an IPv6 CIDR block from a VPC, you cannot expect to receive the same CIDR if you associate an IPv6 CIDR block with your VPC again later.
Create a VPC, subnets, and other VPC resources

In this step, you create a VPC, subnets, Availability Zones, NAT gateways, and VPC endpoints.

To create a VPC, subnets, and other VPC resources

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs, Create VPC.
3. Under Resources to create, choose VPC and more.
4. Modify the options as needed:
   - **Name tag auto-generation**: Choose the Name tag that will be applied to the resources you create. The tag can either be automatically generated for you or you can define the value. The defined value will be used to generate the Name tag in all resources as "name-resource". For example if you enter "Preproduction", each subnet will be tagged with a "Preproduction-" Name tag.
   - **IPv4 CIDR block**: Choose an IPv4 CIDR for the VPC. This option is required.
   - **IPv6 CIDR block**: Choose an IPv6 CIDR for the VPC.
   - **Tenancy**: Choose the tenancy option for this VPC.
     - Select **Default** to ensure that EC2 instances launched in this VPC use the EC2 instance tenancy attribute specified when the EC2 instance is launched.
     - Select **Dedicated** to ensure that EC2 instances launched in this VPC are run on dedicated tenancy instances regardless of the tenancy attribute specified at launch.
   - **Number of Availability Zones (AZs)**: Choose the number of AZs in which you want to create subnets. An AZ is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. AZs give you the ability to operate production applications and databases that are more highly available, fault tolerant, and scalable than would be possible from a single data center. If you partition your applications running in subnets across AZs, you are better isolated and protected from issues such as power outages, lightning strikes, tornadoes, earthquakes, and more.
   - **Number of public subnets**: Choose the number of subnets you would like to be considered "public" subnets. A "public" subnet is a subnet that has a route table entry that points to an internet gateway. This enables EC2 instances running in the subnet to be publicly accessible over the internet.
   - **Number of private subnets**: Choose the number of subnets you would like to be considered "private" subnets. A "private" subnet is a subnet that does not have a route table entry that points to an internet gateway. Use private subnets to secure backend resources that do not need to be publicly accessible over the internet.
   - **Customize subnets CIDR blocks**: Choose the CIDR blocks for the public and or private subnets.
   - **NAT gateways**: Choose the number of AZs in which to create Network Address Translation (NAT) gateways. A NAT gateway is an AWS-managed service that enables EC2 instances in private subnets to send outbound traffic to the internet. Resources on the internet, however, cannot establish a connection with the instances. Note that there is cost associated with NAT gateways. For more information, see NAT gateways (p. 143).
   - **VPC endpoints**: Choose whether to create a VPC endpoint for Amazon S3. A VPC endpoint enables you to privately connect your VPC to supported AWS services and VPC endpoint services powered
Create a VPC by PrivateLink without requiring an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC do not require public IP addresses to communicate with resources in the service. For more information, see Gateway VPC endpoints in the AWS PrivateLink Guide.

- **DNS options**: Choose the domain name resolution options for the EC2 instances launched into this VPC.

  - **Enable DNS hostnames**: Enables hostnames to be provisioned for EC2 instance public IPv4 addresses.

  - **Enable DNS resolution**: Enables hostnames to be provisioned for EC2 instance public IPv4 addresses and enables domain name resolution of the hostnames.

  **Note**
  If you want to provision public IPv4 DNS hostnames to the EC2 instances launched into the subnets you are creating, you must enable both Enable DNS hostnames and Enable DNS resolution on the VPC. If you only enable Enable DNS hostnames, the Public IPv4 DNS hostname does not get provisioned.

5. In the Preview pane, you can see the planned VPC, subnet, route tables, and network interfaces that will be created.

6. Choose Create VPC.

**Create a VPC only**

Follow the steps in this section to create only a VPC and no additional resources.

**To create a VPC only**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

2. In the navigation pane, choose Your VPCs, Create VPC.

3. Under Resources to create, choose VPC only.

4. Specify the following VPC details as needed.

  - **Name tag**: Optionally provide a name for your VPC. Doing so creates a tag with a key of Name and the value that you specify.

  - **IPv4 CIDR block**: Specify an IPv4 CIDR block (or IP address range) for your VPC. Choose one of the following options:

    - **IPv4 CIDR manual input**: Manually input an IPv4 CIDR. The CIDR block size must have a size between /16 and /28. We recommend that you specify a CIDR block from the private (non-publicly routable) IP address ranges as specified in RFC 1918; for example, 10.0.0.0/16, or 192.168.0.0/16.

      You can specify a range of publicly routable IPv4 addresses. However, we currently do not support direct access to the internet from publicly routable CIDR blocks in a VPC. Windows instances cannot boot correctly if launched into a VPC with ranges from 224.0.0.0 to 255.255.255.255 (Class D and Class E IP address ranges).

    - **IPAM-allocated IPv4 CIDR block**: If there is an Amazon VPC IP Address Manager (IPAM) IPv4 address pool available in this Region, you can get a CIDR from an IPAM pool. If you select an IPAM pool, the size of the CIDR is limited by the allocation rules on the IPAM pool (allowed minimum, allowed maximum, and default). For more information about IPAM, see What is IPAM? in the Amazon VPC IPAM User Guide.

    - **IPv6 CIDR block**: Optionally associate an IPv6 CIDR block with your VPC. Choose one of the following options, and then choose Select CIDR:

      - **No IPv6 CIDR block**: No IPv6 CIDR will be provisioned for this VPC.
• **IPAM-allocated IPv6 CIDR block**: If there is an Amazon VPC IP Address Manager (IPAM) IPv6 address pool available in this Region, you can get a CIDR from an IPAM pool. If you select an IPAM pool, the size of the CIDR is limited by the allocation rules on the IPAM pool (allowed minimum, allowed maximum, and default). For more information about IPAM, see What is IPAM? in the Amazon VPC IPAM User Guide.

• **Amazon-provided IPv6 CIDR block**: Requests an IPv6 CIDR block from an Amazon pool of IPv6 addresses. For Network Border Group, select the group from which AWS advertises IP addresses. Amazon provides a fixed IPv6 CIDR block size of /56. You cannot configure the size of the IPv6 CIDR that Amazon provides.

• **IPv6 CIDR owned by me: (BYOIP)** Allocates an IPv6 CIDR block from your IPv6 address pool. For Pool, choose the IPv6 address pool from which to allocate the IPv6 CIDR block.

• **Tenancy**: Choose the tenancy option for this VPC.
  - Select Default to ensure that EC2 instances launched in this VPC use the EC2 instance tenancy attribute specified when the EC2 instance is launched.
  - Select Dedicated to ensure that EC2 instances launched in this VPC are run on dedicated tenancy instances regardless of the tenancy attribute specified at launch.

For more information about tenancy see Configuring instance tenancy with a launch configuration in the Amazon EC2 Auto Scaling User Guide.

**Note**
If your AWS Outposts require private connectivity, you must select Default. For more information about AWS Outposts, see What is AWS Outposts? in the AWS Outposts User Guide.

• **Tags**: Add optional tags on the VPC. A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value. You can use tags to search and filter your resources or track your AWS costs.

5. Choose Create VPC.

Alternatively, you can use a command line tool.

**To create a VPC using a command line tool**

- `create-vpc` (AWS CLI)
- `New-EC2Vpc` (AWS Tools for Windows PowerShell)

**To describe a VPC using a command line tool**

- `describe-vpcs` (AWS CLI)
- `Get-EC2Vpc` (AWS Tools for Windows PowerShell)

For more information about IP addresses, see IP addressing (p. 4).

After you have created a VPC, you can create subnets. For more information, see Create a subnet in your VPC (p. 59).

**View your VPCs**

Use the following steps to view the details about your VPCs.

**To view VPC details using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **VPCs**.
3. Select the VPC, and then choose **View Details**.

**To describe a VPC using a command line tool**

- `describe-vpcs` (AWS CLI)
- `Get-EC2Vpc` (AWS Tools for Windows PowerShell)

**To view all of your VPCs across Regions**

Open the Amazon EC2 Global View console at [https://console.aws.amazon.com/ec2globalview/home](https://console.aws.amazon.com/ec2globalview/home).

For more information about using Amazon EC2 Global View, see List and filter resources using the Amazon EC2 Global View in the Amazon EC2 User Guide for Linux Instances.

**Associate additional IPv4 CIDR blocks with your VPC**

You can add up to five IPv4 CIDR blocks to your VPC by default, but the limit is adjustable. For more information, see [Amazon VPC quotas](#). For information about restrictions on IPv4 CIDR blocks associated with a VPC, see [VPC CIDR blocks](#).

After you associate an IPv4 CIDR block with the VPC, the status changes to associating. The CIDR block is ready to use when it's in the associated state. After you've added the CIDR blocks that you need, you can create subnets that use the new CIDR blocks. For more information, see [Create a subnet in your VPC](#).

**To associate an IPv4 CIDR block with a VPC using the console**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Your VPCs**.
3. Select the VPC, and then choose **Actions, Edit CIDRs**.
4. Choose **Add new IPv4 CIDR**.
5. For **IPv4 CIDR block**, do one of the following:
   - Choose **IPv4 CIDR manual input** and enter an IPv4 CIDR block.
   - Choose **IPAM-allocated IPv4 CIDR** and select a CIDR from an IPv4 IPAM pool.

**To add a CIDR block using a command line tool**

- `associate-vpc-cidr-block` (AWS CLI)
- `Register-EC2VpcCidrBlock` (AWS Tools for Windows PowerShell)

After you've added the IPv4 CIDR blocks that you need, you can create subnets. For more information, see [Create a subnet in your VPC](#).

**Associate IPv6 CIDR blocks with your VPC**

You can associate up to five IPv6 CIDR blocks with any existing VPC. The limit is not adjustable. For more information, see [Amazon VPC quotas](#). For information about restrictions on IPv6 CIDR blocks associated with a VPC, see [VPC CIDR blocks](#).

**To associate an IPv6 CIDR block with a VPC using the console**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose Your VPCs.
3. Select the VPC, and then choose Actions, Edit CIDRs.
4. Choose Add new IPv6 CIDR.
5. The CIDR block options when you add a CIDR are the same as when you create a VPC. For complete information about what your CIDR block options are, see Create a VPC (p. 18).
6. Choose Select CIDR.
7. Choose Close.

To associate an IPv4 CIDR block with a VPC using the command line
- associate-vpc-cidr-block (AWS CLI)
- Register-EC2VpcCidrBlock (AWS Tools for Windows PowerShell)

Disassociate an IPv4 CIDR block from your VPC

If your VPC has more than one IPv4 CIDR block associated with it, you can disassociate an IPv4 CIDR block from the VPC. You cannot disassociate the primary IPv4 CIDR block. You can only disassociate an entire CIDR block; you cannot disassociate a subset of a CIDR block or a merged range of CIDR blocks. You must first delete all subnets in the CIDR block.

To remove a CIDR block from a VPC using the console
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Select the VPC, and choose Actions, Edit CIDRs.
4. Under VPC IPv4 CIDRs, choose the delete button (a cross) for the CIDR block to remove.
5. Choose Close.

Alternatively, you can use a command line tool.

To remove an IPv4 CIDR block from a VPC using a command line tool
- disassociate-vpc-cidr-block (AWS CLI)
- Unregister-EC2VpcCidrBlock (AWS Tools for Windows PowerShell)

Disassociate an IPv6 CIDR block from your VPC

If you no longer want IPv6 support in your VPC, but you want to continue using your VPC to create and communicate with IPv4 resources, you can disassociate the IPv6 CIDR block.

To disassociate an IPv6 CIDR block, you must first unassign any IPv6 addresses that are assigned to any instances in your subnet.

To disassociate an IPv6 CIDR block from a VPC using the console
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Select your VPC, choose Actions, Edit CIDRs.
4. Remove the IPv6 CIDR block by choosing the cross icon.
5. Choose Close.
**Delete your VPC**

When you are finished with a VPC, you can delete it. If you delete a VPC using the VPC console, we also delete the following VPC components for you:

- DHCP options
- Egress-only internet gateways
- Gateway endpoints
- Internet gateways
- Network ACLs
- Route tables
- Security groups
- Subnets

If you have a AWS Site-to-Site VPN connection, you don't need to delete it or the other components related to the VPN (such as the customer gateway and virtual private gateway). If you plan to use the customer gateway with another VPC, we recommend that you keep the Site-to-Site VPN connection and the gateways. Otherwise, you must configure your customer gateway device again after you create a new Site-to-Site VPN connection.

**Requirement**

Before you can delete a VPC, you must first terminate or delete any resources that created a requester-managed network interface in the VPC. For example, you must terminate your EC2 instances and delete your load balancers, NAT gateways, transit gateways, and interface VPC endpoints.

**To delete your VPC using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Terminate all instances in the VPC. For more information, see Terminate Your Instance in the Amazon EC2 User Guide for Linux Instances.
3. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
4. In the navigation pane, choose Your VPCs.
5. Select the VPC to delete and choose Actions, Delete VPC.
6. If you have a Site-to-Site VPN connection, select the option to delete it; otherwise, leave it unselected. Choose Delete VPC.

Alternatively, you can use a command line tool. Before you can delete a VPC using the command line, you must terminate or delete any resources that created a requester-managed network interface in the VPC.
VPC, plus you must delete or detach all associated resources, such as subnets, custom security groups, custom network ACLs, custom route tables, internet gateways, and egress-only internet gateways.

To delete a VPC using the command line

- `delete-vpc` (AWS CLI)
- `Remove-EC2Vpc` (AWS Tools for Windows PowerShell)

Default VPCs

When you start using Amazon VPC, you have a default VPC in each AWS Region. A default VPC comes with a public subnet in each Availability Zone, an internet gateway, and settings to enable DNS resolution. Therefore, you can immediately start launching Amazon EC2 instances into a default VPC. You can also use services such as Elastic Load Balancing, Amazon RDS, and Amazon EMR in your default VPC.

A default VPC is suitable for getting started quickly and for launching public instances such as a blog or simple website. You can modify the components of your default VPC as needed.

You can add subnets to your default VPC. For more information, see the section called “Create a subnet in your VPC” (p. 59).

Contents
- Default VPC components (p. 25)
- Default subnets (p. 27)
- View your default VPC and default subnets (p. 27)
- Create a default VPC (p. 28)
- Create a default subnet (p. 28)
- Delete your default subnets and default VPC (p. 29)

Default VPC components

When we create a default VPC, we do the following to set it up for you:

- Create a VPC with a size /16 IPv4 CIDR block (172.31.0.0/16). This provides up to 65,536 private IPv4 addresses.
- Create a size /20 default subnet in each Availability Zone. This provides up to 4,096 addresses per subnet, a few of which are reserved for our use.
- Create an internet gateway (p. 128) and connect it to your default VPC.
- Add a route to the main route table that points all traffic (0.0.0.0/0) to the internet gateway.
- Create a default security group and associate it with your default VPC.
- Create a default network access control list (ACL) and associate it with your default VPC.
- Associate the default DHCP options set for your AWS account with your default VPC.

Note
Amazon creates the above resources on your behalf. IAM policies do not apply to these actions because you do not perform these actions. For example, if you have an IAM policy that denies the ability to call CreateInternetGateway, and then you call CreateDefaultVpc, the internet gateway in the default VPC is still created.

The following figure illustrates the key components that we set up for a default VPC.
The following table shows the routes in the main route table for the default VPC.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.31.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>internet_gateway_id</td>
</tr>
</tbody>
</table>

You can use a default VPC as you would use any other VPC:

- Add additional nondefault subnets.
- Modify the main route table.
- Add additional route tables.
- Associate additional security groups.
- Update the rules of the default security group.
- Add AWS Site-to-Site VPN connections.
• Add more IPv4 CIDR blocks.
• Access VPCs in a remote Region by using a Direct Connect gateway. For information about Direct Connect gateway options, see Direct Connect gateways in the AWS Direct Connect User Guide.

You can use a default subnet as you would use any other subnet; add custom route tables and set network ACLs. You can also specify a specific default subnet when you launch an EC2 instance.

You can optionally associate an IPv6 CIDR block with your default VPC. For more information, Work with VPCs (p. 18).

Default subnets

By default, a default subnet is a public subnet, because the main route table sends the subnet's traffic that is destined for the internet to the internet gateway. You can make a default subnet into a private subnet by removing the route from the destination 0.0.0.0/0 to the internet gateway. However, if you do this, no EC2 instance running in that subnet can access the internet.

Instances that you launch into a default subnet receive both a public IPv4 address and a private IPv4 address, and both public and private DNS hostnames. Instances that you launch into a nondefault subnet in a default VPC don't receive a public IPv4 address or a DNS hostname. You can change your subnet's default public IP addressing behavior. For more information, see Modify the public IPv4 addressing attribute for your subnet (p. 61).

From time to time, AWS may add a new Availability Zone to a Region. In most cases, we automatically create a new default subnet in this Availability Zone for your default VPC within a few days. However, if you made any modifications to your default VPC, we do not add a new default subnet. If you want a default subnet for the new Availability Zone, you can create one yourself. For more information, see Create a default subnet (p. 28).

View your default VPC and default subnets

You can view your default VPC and subnets using the Amazon VPC console or the command line.

To view your default VPC and subnets using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. In the Default VPC column, look for a value of Yes. Take note of the ID of the default VPC.
4. In the navigation pane, choose Subnets.
5. In the search bar, type the ID of the default VPC. The returned subnets are subnets in your default VPC.
6. To verify which subnets are default subnets, look for a value of Yes in the Default Subnet column.

To describe your default VPC using the command line

• Use the describe-vpcs (AWS CLI)
• Use the Get-EC2Vpc (AWS Tools for Windows PowerShell)

Use the commands with the isDefault filter and set the filter value to true.

To describe your default subnets using the command line

• Use the describe-subnets (AWS CLI)
• Use the Get-EC2Subnet (AWS Tools for Windows PowerShell)
Create a default VPC

If you delete your default VPC, you can create a new one. You cannot restore a previous default VPC that you deleted, and you cannot mark an existing nondefault VPC as a default VPC. If your account supports EC2-Classic, you cannot use these procedures to create a default VPC in a Region that supports EC2-Classic.

When you create a default VPC, it is created with the standard components (p. 25) of a default VPC, including a default subnet in each Availability Zone. You cannot specify your own components. The subnet CIDR blocks of your new default VPC may not map to the same Availability Zones as your previous default VPC. For example, if the subnet with CIDR block 172.31.0.0/20 was created in us-east-2a in your previous default VPC, it may be created in us-east-2b in your new default VPC.

If you already have a default VPC in the Region, you cannot create another one.

To create a default VPC using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Choose Actions, Create Default VPC.

To create a default VPC using the command line

You can use the create-default-vpc AWS CLI command. This command does not have any input parameters.

```
aws ec2 create-default-vpc
```

The following is example output.

```
{
    "Vpc": {
        "VpcId": "vpc-3f139646",
        "InstanceTenancy": "default",
        "Tags": [],
        "Ipv6CidrBlockAssociationSet": [],
        "State": "pending",
        "DhcpOptionsId": "dopt-61079b07",
        "CidrBlock": "172.31.0.0/16",
        "IsDefault": true
    }
}
```

Alternatively, you can use the New-EC2DefaultVpc Tools for Windows PowerShell command or the CreateDefaultVpc Amazon EC2 API action.

Create a default subnet

You can create a default subnet in an Availability Zone that does not have one. For example, you might want to create a default subnet if you have deleted a default subnet, or if AWS has added a new Availability Zone and did not automatically create a default subnet for that zone in your default VPC.
When you create a default subnet, it is created with a size /20 IPv4 CIDR block in the next available contiguous space in your default VPC. The following rules apply:

- You cannot specify the CIDR block yourself.
- You cannot restore a previous default subnet that you deleted.
- You can have only one default subnet per Availability Zone.
- You cannot create a default subnet in a nondefault VPC.

If there is not enough address space in your default VPC to create a size /20 CIDR block, the request fails. If you need more address space, you can add an IPv4 CIDR block to your VPC.

If you've associated an IPv6 CIDR block with your default VPC, the new default subnet does not automatically receive an IPv6 CIDR block. Instead, you can associate an IPv6 CIDR block with the default subnet after you create it. For more information, see Associate an IPv6 CIDR block with your subnet.

You cannot create a default subnet using the AWS Management Console.

**To create a default subnet using the AWS CLI**

Use the `create-default-subnet` AWS CLI command and specify the Availability Zone in which to create the subnet.

```bash
aws ec2 create-default-subnet --availability-zone us-east-2a
```

The following is example output.

```json
{
  "Subnet": {
    "AvailabilityZone": "us-east-2a",
    "Tags": [],
    "AvailableIpAddressCount": 4091,
    "DefaultForAz": true,
    "Ipv6CidrBlockAssociationSet": [],
    "VpcId": "vpc-1a2b3c4d",
    "State": "available",
    "MapPublicIpOnLaunch": true,
    "SubnetId": "subnet-1122aabb",
    "CidrBlock": "172.31.32.0/20",
    "AssignIpv6AddressOnCreation": false
  }
}
```

For more information about setting up the AWS CLI, see the AWS Command Line Interface User Guide.

Alternatively, you can use the `New-EC2DefaultSubnet` Tools for Windows PowerShell command or the `CreateDefaultSubnet` Amazon EC2 API action.

**Delete your default subnets and default VPC**

You can delete a default subnet or default VPC just as you can delete any other subnet or VPC. For more information, see Work with VPCs (p. 18). However, if you delete your default subnets or default VPC, you must explicitly specify a subnet in another VPC in which to launch your instance, because you can't launch instances into EC2-Classic. If you do not have another VPC, you must create a nondefault VPC and nondefault subnet. For more information, see Create a VPC (p. 18).

If you delete your default VPC, you can create a new one. For more information, see Create a default VPC (p. 28).
If you delete a default subnet, you can create a new one. For more information, see Create a default subnet (p. 28). To ensure that your new default subnet behaves as expected, modify the subnet attribute to assign public IP addresses to instances that are launched in that subnet. For more information, see Modify the public IPv4 addressing attribute for your subnet (p. 61). You can only have one default subnet per Availability Zone. You cannot create a default subnet in a nondefault VPC.

DHCP option sets in Amazon VPC

This section explains how network devices in your VPC use Dynamic Host Configuration Protocol (DHCP). It also explains the network communication parameters that are stored in DHCP option sets, and tells you how to customize the option sets used by devices in your VPC.

DHCP option sets give you control over the following aspects of routing in your virtual network:

- You can control the DNS servers, domain names, or Network Time Protocol (NTP) servers used by the devices in your VPC.
- You can disable DNS resolution completely in your VPC.

Contents

- What is DHCP? (p. 30)
- DHCP option set concepts (p. 31)
- Work with DHCP option sets (p. 33)

What is DHCP?

Every device on a TCP/IP network requires an IP address to communicate over the network. In the past, IP addresses had to be assigned to each device in your network manually. Today, IP addresses are assigned dynamically by DHCP servers using the Dynamic Host Configuration Protocol (DHCP).

Applications running on EC2 instances in subnets can communicate with Amazon DHCP servers as needed to retrieve their IP address lease or other network configuration information (such as the IP address of an Amazon DNS server or the IP address of the router in your VPC).

Amazon VPC enables you to specify the network configurations that are provided by Amazon DHCP servers by using DHCP option sets.

Note

If you have a VPC configuration that requires your applications to make direct requests to the Amazon IPv6 DHCP server, note the following limitation:

- An EC2 instance in a dual-stack subnet can only retrieve its IPv6 address from the IPv6 DHCP server. It cannot retrieve any additional network configurations from the IPv6 DHCP server, such as DNS server names or domain names.
- An EC2 instance in a IPv6-only subnet can retrieve its IPv6 address from the IPv6 DHCP server and can retrieve additional networking configuration information, such as DNS server names and domain names.

The Amazon DHCP servers can also provide an entire IPv4 or IPv6 prefix to an elastic network interface in your VPC using prefix delegation (see Assigning prefixes to Amazon EC2 network interfaces in the Amazon EC2 User Guide for Linux Instances). IPv4 prefix delegation is not provided in DHCP responses. IPv4 prefixes assigned to the interface can be retrieved using IMDS (see Instance metadata categories in the Amazon EC2 User Guide for Linux Instances).
What's next?

- DHCP option set concepts (p. 31)
- Work with DHCP option sets (p. 33)

DHCP option set concepts

A DHCP option set is a group of network configurations used by EC2 instances in your VPC to communicate over your virtual network.

Each VPC in a Region uses the same default DHCP option set unless you choose to create a custom DHCP option set, or if you disassociate all option sets from your VPC.

Contents

- Default DHCP option set (p. 31)
- Custom DHCP option set (p. 32)

Default DHCP option set

Each VPC in a Region uses the same default DHCP option set, which contains the following network configurations:

- **Domain name**: The domain name that a client should use when resolving hostnames via the Domain Name System.
- **Domain name servers**: The DNS servers that your network interfaces will use for domain name resolution.

If you use the default option set, the Amazon DHCP server uses the network configurations stored in the default option set. When you launch an instance into your VPC, the instance interacts with the DHCP server(1), interact with the Amazon DNS server (2), and connect to other devices in the network through your VPC's router (3). The instances can interact with the Amazon DHCP server at any time to get their IP address lease and additional network configurations.
Custom DHCP option set

You can create your own DHCP option set in Amazon VPC. This enables you to configure the following network configurations:

- **Domain name**: The domain name that a client should use when resolving hostnames via the Domain Name System.
- **Domain name servers**: The DNS servers that your network interfaces will use for domain name resolution.
- **NTP servers**: The NTP servers that will provide the time to the instances in your network.
- **NetBIOS name servers**: For EC2 instances running a Windows OS, the NetBIOS computer name is a friendly name assigned to the instance to identify it on the network. A NetBIOS name server maintains a list of mappings between NetBIOS computer names and network addresses for networks that use NetBIOS as their naming service.
- **NetBIOS node type**: For EC2 instances running a Windows OS, the method that the instances use to resolve NetBIOS names to IP addresses.

If you use a custom option set, instances launched into your VPC use the network configurations in the custom DHCP option set (1), interact with non Amazon DNS, NTP, and NetBIOS servers (2), and then connect to other devices in the network through your VPC’s router (3).
Work with DHCP option sets

This section shows you how to view and work with DHCP option sets.

EC2 instances launched into VPC subnets automatically use the default DHCP options unless you create a new DHCP option set or you disassociate the default option set from your VPC. A custom DHCP option set enables you to customize your VPC with your own DNS server, domain name, and more. Disassociating the default option set from your VPC enables you to disable domain name resolution in your VPC.

Contents

- View your default option set (p. 33)
- Create a DHCP option set (p. 34)
- Change the option set associated with a VPC (p. 36)
- Delete a DHCP option set (p. 36)

View your default option set

To View the default DHCP option set

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose DHCP option sets.
3. Choose the option set that’s available.
4. View the configurations in the default option set:
• **Domain name servers**: The DNS servers that will be used to resolve the IP address of the host. In the default option set, the only value is `AmazonProvidedDNS`. The string `AmazonProvidedDNS` maps to Amazon’s DNS server. For more information about this server, see Amazon DNS server (p. 37).

• **Domain name**: The domain name that a client should use when resolving hostnames via the Domain Name System.

In the default option set, for VPCs in AWS Region `us-east-1`, the value is `ec2.internal`. For VPCs in other Regions, the value is `region.compute.internal` (for example, `ap-northeast-1.compute.internal`).

• **NTP servers**: The NTP servers that provide the time to your network. In the default option set, there is no value for NTP servers. Your default DHCP option set does not include an NTP server because EC2 instances use the Amazon Time Sync Service by default to retrieve the time.

• **NetBIOS name servers**: For EC2 instances running a Windows OS, the NetBIOS computer name is a friendly name assigned to the instance to identify it on the network. The NetBIOS name server maintains a list of mappings between NetBIOS computer names and network addresses for networks that use NetBIOS as their naming service. In the default option set, there are no NetBIOS name servers defined.

• **NetBIOS node type**: For EC2 instances running a Windows OS, this is the method that the instances use to resolve NetBIOS names to IP addresses. In the default option set, there are no NetBIOS node types set.

**Describe one or more sets of DHCP options using the AWS CLI or API**

For more information about the command line interfaces and a list of available APIs, see Working with Amazon VPC (p. 2).

- `describe-dhcp-options` (AWS CLI)
- `Get-EC2DhcpOption` (AWS Tools for Windows PowerShell)

**Create a DHCP option set**

A custom DHCP option set enables you to customize your VPC with your own DNS server, domain name, and more. You can create as many additional DHCP option sets as you want. However, you can only associate a VPC with one set of DHCP options at a time.

**Note**

After you create a DHCP option set, you can't modify it. If you need your VPC to use a different set of DHCP options, you must create a new option set and then associate it with your VPC. Alternatively, you can specify that your VPC should use the default option set or no DHCP options.

**To create a DHCP options set**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **DHCP option sets**.
3. Choose **Create DHCP options set**.
4. For **Tag settings**, optionally enter a name for the DHCP option set. If you enter a value, it automatically creates a Name tag for the DHCP option set.
5. For **DHCP options**, provide the configuration parameters that you need.

   • **Domain name** (optional): Enter the domain name that a client should use when resolving hostnames via the Domain Name System. If you are not using AmazonProvidedDNS, your custom
domain name servers must resolve the hostname as appropriate. If you use an Amazon Route 53 private hosted zone, you can use AmazonProvidedDNS. For more information, see DNS attributes for your VPC (p. 37).

Some Linux operating systems accept multiple domain names separated by spaces. However, other Linux operating systems and Windows treat the value as a single domain, which results in unexpected behavior. If your DHCP option set is associated with a VPC that contains instances that are not all running the same operating systems, specify only one domain name.

- **Domain name servers** (optional): Enter the DNS servers that will be used to resolve the IP address of a host from the host's name.

You can enter either AmazonProvidedDNS or custom domain name servers. Using both might cause unexpected behavior. You can enter the IP addresses of up to four IPv4 domain name servers (or up to three IPv4 domain name servers and AmazonProvidedDNS) and four IPv6 domain name servers separated by commas. Although you can specify up to eight domain name servers, some operating systems might impose lower limits. For more information about AmazonProvidedDNS and the Amazon DNS server, see Amazon DNS server (p. 37).

**Important**

If your VPC has an internet gateway, make sure to specify your own DNS server or an Amazon DNS server (AmazonProvidedDNS) for the Domain name servers value. Otherwise, the instances that need to communicate with the internet won't have access to DNS.

- **NTP servers** (optional): Enter the IP addresses of up to eight Network Time Protocol (NTP) servers (four IPv4 addresses and four IPv6 addresses).

NTP servers provide the time to your network. You can specify the Amazon Time Sync Service at IPv4 address 169.254.169.123 or IPv6 address fd00:ec2::123. Instances communicate with the Amazon Time Sync Service by default. Note that the IPv6 address is only accessible on EC2 instances built on the Nitro System.

For more information about the NTP servers option, see RFC 2132. For more information about the Amazon Time Sync Service, see Set the time for your instance in the Amazon EC2 User Guide for Linux Instances.

- **NetBIOS name servers** (optional): Enter the IP addresses of up to four NetBIOS name servers.

For EC2 instances running a Windows OS, the NetBIOS computer name is a friendly name assigned to the instance to identify it on the network. The NetBIOS name server maintains a list of mappings between NetBIOS computer names and network addresses for networks that use NetBIOS as their naming service.

- **NetBIOS node type** (optional): Enter 1, 2, 4, or 8. We recommend that you specify 2 (point-to-point or P-node). Broadcast and multicast are not currently supported. For more information about these node types, see section 8.7 of RFC 2132 and section 10 of RFC1001.

For EC2 instances running a Windows OS, this is the method that the instances use to resolve NetBIOS names to IP addresses. In the default options set, there is no value for NetBIOS node type.

6. Add Tags.
7. Choose Create DHCP options set.
8. Note the ID of the new set of DHCP options (dopt-xxxxxxxx). You will need this ID in the next step.
9. Configure your VPC to use the new option set. For more information, see Change the option set associated with a VPC (p. 36).

**Note**

After you create a DHCP option set, you can't modify it. If you need your VPC to use a different set of DHCP options, you must create a new option set and then associate it with your VPC.
Alternatively, you can specify that your VPC should use the default option set or no DHCP options.

Create a set of DHCP options for your VPC using the AWS CLI or API

For more information about the command line interfaces and a list of available APIs, see Working with Amazon VPC (p. 2).

- create-dhcp-options (AWS CLI)
- New-EC2DhcpOption (AWS Tools for Windows PowerShell)

Change the option set associated with a VPC

Follow the steps in this section to change which set of DHCP options your VPC uses. You can assign a new DHCP option set to the VPC, or you can disassociate a DHCP option set from your VPC. You might want to disassociate any option sets to disable domain name resolution in your VPC.

Note

- The following procedure assumes that you've already created the DHCP option set. Otherwise, create the option set as described in the previous section.
- If you associate a new set of DHCP options with the VPC, any existing instances and all new instances that you launch in that VPC use the new options. You don't need to restart or relaunch your instances. Instances automatically pick up the changes within a few hours, depending on how frequently they renew their DHCP leases. If you prefer, you can explicitly renew the lease using the operating system on the instance.
- You can have multiple sets of DHCP options, but you can associate only one set of DHCP options with a VPC at a time. If you delete a VPC, the DHCP option set that is associated with the VPC is disassociated from the VPC.

To change the DHCP option set associated with a VPC

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Select the check box for the VPC, and then choose Actions, Edit VPC settings.
4. For DHCP options set, choose a new DHCP option set. Alternatively, choose No DHCP options set to not use a DHCP option set in your VPC.
5. Choose Save changes.

Associate a set of DHCP options with the specified VPC or no DHCP options using the AWS CLI or API

For more information about the command line interfaces and a list of available APIs, see Working with Amazon VPC (p. 2).

- associate-dhcp-options (AWS CLI)
- Register-EC2DhcpOption (AWS Tools for Windows PowerShell)

Delete a DHCP option set

When you no longer need a DHCP option set, use the following procedure to delete it. Make sure that you change the VPCs that use these options to another option set or to no option set before you delete the option set. You cannot delete an option set if it’s associated with a VPC. For more information, see the section called “Change the option set associated with a VPC” (p. 36).
To delete a DHCP option set

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **DHCP option sets**.
3. Select the radio button for the DHCP option set, and then choose **Actions, Delete DHCP options set**.
4. When prompted for confirmation, enter **delete**, and then choose **Delete DHCP options set**.

Delete a DHCP option set using the AWS CLI or API

For more information about the command line interfaces and a list of available APIs, see Working with Amazon VPC (p. 2).

- delete-dhcp-options (AWS CLI)
- Remove-EC2DhcpOption (AWS Tools for Windows PowerShell)

DNS attributes for your VPC

Domain Name System (DNS) is a standard by which names used on the internet are resolved to their corresponding IP addresses. A DNS hostname is a name that uniquely and absolutely names a computer; it's composed of a host name and a domain name. DNS servers resolve DNS hostnames to their corresponding IP addresses.

Public IPv4 addresses enable communication over the internet, while private IPv4 addresses enable communication within the network of the instance. For more information, see IP addressing (p. 4).

Amazon provides a DNS server (the Amazon Route 53 Resolver (p. 37)) for your VPC. To use your own DNS server instead, create a new set of DHCP options for your VPC. For more information, see DHCP option sets in Amazon VPC (p. 30).

Contents

- Amazon DNS server (p. 37)
- DNS hostnames (p. 38)
- DNS attributes in your VPC (p. 39)
- DNS quotas (p. 39)
- View DNS hostnames for your EC2 instance (p. 40)
- View and update DNS attributes for your VPC (p. 41)
- Private hosted zones (p. 41)

Amazon DNS server

The Amazon DNS server is an Amazon Route 53 Resolver server. This server enables DNS for instances that need to communicate over the VPC's internet gateway.

The Amazon DNS server does not reside within a specific subnet or Availability Zone in a VPC. It's located at the address 169.254.169.253 (and the reserved IP address at the base of the VPC IPv4 network range, plus two) and fd00:ec2::253. For example, the Amazon DNS Server on a 10.0.0.0/16 network is located at 10.0.0.2. For VPCs with multiple IPv4 CIDR blocks, the DNS server IP address is located in the primary CIDR block.

When you launch an instance into a VPC, we provide the instance with a private DNS hostname. We also provide a public DNS hostname if the instance is configured with a public IPv4 address and the VPC DNS attributes are enabled.
The format of the private DNS hostname depends on how you configure the EC2 instance when you launch it. For more information on the types of private DNS hostnames, see EC2 instance naming.

The Amazon DNS server in your VPC is used to resolve the DNS domain names that you specify in a private hosted zone in Route 53. For more information about private hosted zones, see Working with private hosted zones in the Amazon Route 53 Developer Guide.

Rules and considerations

When using the Amazon DNS server, the following rules and considerations apply.

- You cannot filter traffic to or from the Amazon DNS server using network ACLs or security groups.
- Services that use the Hadoop framework, such as Amazon EMR, require instances to resolve their own fully qualified domain names (FQDN). In such cases, DNS resolution can fail if the domain-name-servers option is set to a custom value. To ensure proper DNS resolution, consider adding a conditional forwarder on your DNS server to forward queries for the domain region-name.compute.internal to the Amazon DNS server. For more information, see Setting up a VPC to host clusters in the Amazon EMR Management Guide.
- Windows Server 2008 disallows the use of a DNS server located in the link-local address range (169.254.0.0/16).
- The Amazon Route 53 Resolver only supports recursive DNS queries.

DNS hostnames

When you launch an instance, it always receives a private IPv4 address and a private DNS hostname that corresponds to its private IPv4 address. If your instance has a public IPv4 address, the DNS attributes for its VPC determines whether it receives a public DNS hostname that corresponds to the public IPv4 address. For more information, see DNS attributes in your VPC (p. 39).

With the Amazon provided DNS server enabled, DNS hostnames are assigned and resolved as follows.

Private IP DNS name (IPv4 only)

You can use the Private IP DNS name (IPv4 only) hostname for communication between instances in the same VPC. You can resolve the Private IP DNS name (IPv4 only) hostnames of other instances in other VPCs as long as the instances are in the same AWS Region and the hostname of the other instance is in the private address space range defined by RFC 1918: 10.0.0.0 - 10.255.255.255 (10/8 prefix), 172.16.0.0 - 172.31.255.255 (172.16/12 prefix), and 192.168.0.0 - 192.168.255.255 (192.168/16 prefix).

Private resource DNS name

The RBN-based DNS name that can resolve to the A and AAAA DNS records selected for this instance. This DNS hostname is visible in the instance details for instances in dual-stack and IPv6-only subnets. For more information about RBN, see EC2 instance hostname types.

Public IPv4 DNS

A public (external) IPv4 DNS hostname takes the form ec2-public-ipv4-address.compute-1.amazonaws.com for the us-east-1 Region, and ec2-public-ipv4-address.region.compute.amazonaws.com for other Regions. The Amazon DNS server resolves a public DNS hostname to the public IPv4 address of the instance outside the network of the instance, and to the private IPv4 address of the instance from within the network of the instance. For more information, see Public IPv4 addresses and external DNS hostnames in the Amazon EC2 User Guide for Linux Instances.
DNS attributes in your VPC

The following VPC attributes determine the DNS support provided for your VPC. If both attributes are enabled, an instance launched into the VPC receives a public DNS hostname if it is assigned a public IPv4 address or an Elastic IP address at creation. If you enable both attributes for a VPC that didn’t previously have them both enabled, instances that were already launched into that VPC receive public DNS hostnames if they have a public IPv4 address or an Elastic IP address.

To check whether these attributes are enabled for your VPC, see View and update DNS attributes for your VPC (p. 41).

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableDnsHostnames</td>
<td>Determines whether the VPC supports assigning public DNS hostnames to instances with public IP addresses. The default for this attribute is false unless the VPC is a default VPC.</td>
</tr>
<tr>
<td>enableDnsSupport</td>
<td>Determines whether the VPC supports DNS resolution through the Amazon provided DNS server. If this attribute is true, queries to the Amazon provided DNS server succeed. For more information, see Amazon DNS server (p. 37). The default for this attribute is true.</td>
</tr>
</tbody>
</table>

Rules and considerations

The following rules apply:

- If both attributes are set to true, the following occurs:
  - Instances with public IP addresses receive corresponding public DNS hostnames.
  - The Amazon Route 53 Resolver server can resolve Amazon-provided private DNS hostnames.
- If at least one of the attributes is set to false, the following occurs:
  - Instances with public IP addresses do not receive corresponding public DNS hostnames.
  - The Amazon Route 53 Resolver cannot resolve Amazon-provided private DNS hostnames.
  - Instances receive custom private DNS hostnames if there is a custom domain name in the DHCP options set (p. 30). If you are not using the Amazon Route 53 Resolver server, your custom domain name servers must resolve the hostname as appropriate.
- If you use custom DNS domain names defined in a private hosted zone in Amazon Route 53, or use private DNS with interface VPC endpoints (AWS PrivateLink), you must set both the enableDnsHostnames and enableDnsSupport attributes to true.
- The Amazon Route 53 Resolver can resolve private DNS hostnames to private IPv4 addresses for all address spaces, including where the IPv4 address range of your VPC falls outside of the private IPv4 addresses ranges specified by RFC 1918. However, if you created your VPC before October 2016, the Amazon Route 53 Resolver does not resolve private DNS hostnames if your VPC’s IPv4 address range falls outside of these ranges. To enable support for this, contact AWS Support.

DNS quotas

Each EC2 instance can send 1024 packets per second per network interface to Route 53 Resolver (specifically the .2 address, such as 10.0.0.2 and 169.254.169.253). This quota cannot be increased. The
number of DNS queries per second supported by Route 53 Resolver varies by the type of query, the size of the response, and the protocol in use. For more information and recommendations for a scalable DNS architecture, see the AWS Hybrid DNS with Active Directory Technical Guide.

If you reach the quota, the Route 53 Resolver rejects traffic. Some of the causes for reaching the quota might be a DNS throttling issue, or instance metadata queries that use the Route 53 Resolver network interface. For information about how to solve VPC DNS throttling issues, see How can I determine whether my DNS queries to the Amazon provided DNS server are failing due to VPC DNS throttling. For information about instance metadata retrieval, see Retrieve instance metadata in the Amazon EC2 User Guide for Linux Instances.

View DNS hostnames for your EC2 instance

You can view the DNS hostnames for a running instance or a network interface using the Amazon EC2 console or the command line.

The Public DNS (IPv4) and Private DNS fields are available when the DNS options are enabled for the VPC that is associated with the instance. For more information, see the section called “DNS attributes in your VPC” (p. 39).

Instance

To view DNS hostnames for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance from the list.
4. In the details pane, the Public DNS (IPv4) and Private DNS fields display the DNS hostnames, if applicable.

To view DNS hostnames for an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Working with Amazon VPC (p. 2).

- describe-instances (AWS CLI)
- Get-EC2Instance (AWS Tools for Windows PowerShell)

Network interface

To view the private DNS hostname for a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface from the list.
4. In the details pane, the Private DNS (IPv4) field displays the private DNS hostname.

To view DNS hostnames for a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Working with Amazon VPC (p. 2).

- describe-network-interfaces (AWS CLI)
View and update DNS attributes for your VPC

You can view and update the DNS support attributes for your VPC using the Amazon VPC console.

To describe and update DNS support for a VPC using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Select the checkbox for the VPC.
4. Review the information in Details. In this example, both DNS hostnames and DNS resolution are enabled.

5. To update these settings, choose Actions and then choose Edit VPC settings. Select or clear Enable on the appropriate DNS attribute and choose Save changes.

To describe DNS support for a VPC using the command line

You can use one of the following commands. For more information about these command line interfaces, see Working with Amazon VPC (p. 2).

- describe-vpc-attribute (AWS CLI)
- Get-EC2VpcAttribute (AWS Tools for Windows PowerShell)

To update DNS support for a VPC using the command line

You can use one of the following commands. For more information about these command line interfaces, see Working with Amazon VPC (p. 2).

- modify-vpc-attribute (AWS CLI)
- Edit-EC2VpcAttribute (AWS Tools for Windows PowerShell)

Private hosted zones

To access the resources in your VPC using custom DNS domain names, such as example.com, instead of using private IPv4 addresses or AWS-provided private DNS hostnames, you can create a private hosted zone in Route 53. A private hosted zone is a container that holds information about how you want to route traffic for a domain and its subdomains within one or more VPCs without exposing your resources to the internet. You can then create Route 53 resource record sets, which determine how Route 53 responds to queries for your domain and subdomains. For example, if you want browser requests for example.com to be routed to a web server in your VPC, you'll create an A record in your private hosted...
zone and specify the IP address of that web server. For more information about creating a private hosted zone, see Working with private hosted zones in the Amazon Route 53 Developer Guide.

To access resources using custom DNS domain names, you must be connected to an instance within your VPC. From your instance, you can test that your resource in your private hosted zone is accessible from its custom DNS name by using the ping command; for example, ping mywebserver.example.com. (You must ensure that your instance's security group rules allow inbound ICMP traffic for the ping command to work.)

Private hosted zones do not support transitive relationships outside of the VPC; for example, you cannot access your resources using their custom private DNS names from the other side of a VPN connection.

**Important**
If you use custom DNS domain names defined in a private hosted zone in Amazon Route 53, you must set both the `enableDnsHostnames` and `enableDnsSupport` attributes to `true`.

### Network Address Usage for your VPC

Network Address Usage (NAU) is a metric applied to resources in your virtual network to help you plan for and monitor the size of your VPC. Each NAU unit contributes to a total that represents the size of your VPC.

It's important to understand the total number of units that make up the NAU of your VPC because the following VPC quotas limit the size of a VPC:

- **Network Address Usage (p. 358)** – The maximum number of NAU units that a single VPC can have. Each VPC can have up to 64,000 NAU units by default. You can request a quota increase up to 256,000.

- **Peered Network Address Usage (p. 358)** – The maximum number of NAU units for a VPC and all of its peered VPCs. If a VPC is peered with other VPCs in the same Region, the VPCs combined can have up to 128,000 NAU units by default. You can request a quota increase up to 512,000. VPCs that are peered across different Regions do not contribute to this limit.

You can use the NAU in the following ways:

- Before you create your virtual network, calculate the NAU units to help you decide if you should spread workloads across multiple VPCs.
- After you've created your VPC, use Amazon CloudWatch to monitor the NAU usage of the VPC so that it doesn't grow beyond the NAU quota limits. For more information, see the section called “CloudWatch metrics” (p. 219).

### How NAU is calculated

If you understand how NAU is calculated, it can help you plan for the scaling of your VPCs.

The following table explains which resources make up the NAU count in a VPC and how many NAU units each resource uses. Some AWS resources are represented as single NAU units and some resources are represented as multiple NAU units. You can use the table to learn how NAU is calculated.

<table>
<thead>
<tr>
<th>Resource</th>
<th>NAU units</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4 or IPv6 address assigned to a network interface for an EC2 instance in the VPC</td>
<td>1</td>
</tr>
<tr>
<td>Resource</td>
<td>NAU units</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>Additional network interfaces attached to an EC2 instance</td>
<td>1</td>
</tr>
<tr>
<td>Prefix assigned to a network interface</td>
<td>1</td>
</tr>
<tr>
<td>Network Load Balancer per AZ</td>
<td>6</td>
</tr>
<tr>
<td>VPC endpoint per AZ</td>
<td>6</td>
</tr>
<tr>
<td>Transit gateway attachment</td>
<td>6</td>
</tr>
<tr>
<td>Lambda function</td>
<td>6</td>
</tr>
<tr>
<td>NAT gateway</td>
<td>6</td>
</tr>
<tr>
<td>EFS attached to an EC2 instance</td>
<td>6</td>
</tr>
</tbody>
</table>

**NAU examples**

The following examples show how to calculate NAU.

**Example 1 - Two VPCs connected using VPC peering**

Peered VPCs in the same Region contribute to a combined NAU quota.

- **VPC 1**
  - 50 Network Load Balancers in 2 zones - 600 NAU units
  - 5,000 instances in 2 zones with both IPv4 and IPv6 addresses assigned (1 NAU per IP address associated with each instance network interface) - 20,000 NAU units
  - 100 Lambda functions - 600 NAU units

- **VPC 2**
  - 50 Network Load Balancers in 2 zones - 600 NAU units
  - 5,000 instances in 2 zones with both IPv4 and IPv6 addresses assigned (1 NAU per IP address associated with each instance network interface) - 20,000 NAU units
  - 100 Lambda functions - 600 NAU units
  - Total peering NAU count: 42,400 units
  - Default peering NAU quota: 128,000 units

**Example 2 - Two VPCs connected using a transit gateway**

VPCs that are connected using a transit gateway do not contribute to a combined NAU quota as they do for peered VPCs.

- **VPC 1**
  - 50 Network Load Balancers in 2 zones - 600 NAU units
  - 5,000 instances in 2 zones with both IPv4 and IPv6 addresses assigned (1 NAU per IP address associated with each instance network interface) - 20,000 NAU units
  - 100 Lambda functions - 600 NAU units

- **VPC 2**
  - 50 Network Load Balancers in 2 zones - 600 NAU units
Share your VPC with other accounts

VPC sharing allows multiple AWS accounts to create their application resources, such as Amazon EC2 instances, Amazon Relational Database Service (RDS) databases, Amazon Redshift clusters, and AWS Lambda functions, into shared, centrally-managed virtual private clouds (VPCs). In this model, the account that owns the VPC (owner) shares one or more subnets with other accounts (participants) that belong to the same organization from AWS Organizations. After a subnet is shared, the participants can view, create, modify, and delete their application resources in the subnets shared with them. Participants cannot view, modify, or delete resources that belong to other participants or the VPC owner.

You can share your VPCs to leverage the implicit routing within a VPC for applications that require a high degree of interconnectivity and are within the same trust boundaries. This reduces the number of VPCs that you create and manage, while using separate accounts for billing and access control. You can simplify network topologies by interconnecting shared Amazon VPCs using connectivity features, such as AWS PrivateLink, transit gateways, and VPC peering. For more information about the benefits of VPC sharing, see VPC sharing: A new approach to multiple accounts and VPC management.

Contents
- Shared VPCs prerequisites (p. 44)
- Share a subnet (p. 44)
- Unshare a shared subnet (p. 45)
- Identify the owner of a shared subnet (p. 46)
- Manage VPC resources (p. 46)
- Billing and metering for the owner and participants (p. 47)
- Limitations (p. 47)
- Example of sharing public subnets and private subnets (p. 48)

Shared VPCs prerequisites

You must enable resource sharing from the management account for your organization. For information about enabling resource sharing, see Enable sharing with AWS Organizations in the AWS RAM User Guide.

Share a subnet

You can share non-default subnets with other accounts within your organization. To share subnets, you must first create a Resource Share with the subnets to be shared and the AWS accounts, organizational units, or an entire organization that you want to share the subnets with. For information about creating a Resource Share, see Creating a resource share in the AWS RAM User Guide.

To share a subnet using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select your subnet and choose **Actions, Share subnet**.
4. Select your resource share and choose **Share subnet**.

**To share a subnet using the AWS CLI**

Use the `create-resource-share` and `associate-resource-share` commands.

**Map subnets across Availability Zones**

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To coordinate Availability Zones across accounts for VPC sharing, you must use an **AZ ID**, which is a unique and consistent identifier for an Availability Zone. For example, `use1-az1` is the AZ ID for one of the Availability Zones in the `us-east-1` Region. Use AZ IDs to determine the location of resources in one account relative to another account. You can view the AZ ID for each subnet in the Amazon VPC console.

The following diagram illustrates two accounts with different mappings of Availability Zone code to AZ ID.

**Unshare a shared subnet**

The owner can unshare a shared subnet with participants at any time. After the owner unshares a shared subnet, the following rules apply:

- Existing participant resources continue to run in the unshared subnet. AWS managed services (for example, Elastic Load Balancing) that have automated/managed workflows (such as auto scaling or node replacement) may require continuous access to the shared subnet for some resources.
- Participants can no longer create new resources in the unshared subnet.
- Participants can modify, describe, and delete their resources that are in the subnet.
• If participants still have resources in the unshared subnet, the owner cannot delete the shared subnet or the shared-subnet VPC. The owner can only delete the subnet or shared-subnet VPC after the participants delete all the resources in the unshared subnet.

To unshare a subnet using the console
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select your subnet and choose Actions, Share subnet.
4. Choose Actions, Stop sharing.

To unshare a subnet using the AWS CLI
Use the disassociate-resource-share command.

Identify the owner of a shared subnet
Participants can view the subnets that have been shared with them by using the Amazon VPC console, or the command line tool.

To identify a subnet owner using the console
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets. The Owner column displays the subnet owner.

To identify a subnet owner using the AWS CLI
Use the describe-subnets and describe-vpcs commands, which include the ID of the owner in their output.

Manage VPC resources
Owners and participants are responsible for the VPC resources that they own.

Owner resources
VPC owners are responsible for creating, managing, and deleting the resources associated with a shared VPC. These include subnets, route tables, network ACLs, peering connections, gateway endpoints, interface endpoints, Amazon Route 53 Resolver endpoints, internet gateways, NAT gateways, virtual private gateways, and transit gateway attachments.

VPC owners cannot modify or delete resources created by participants, such as EC2 instances and security groups. VPC owners can view the details for the network interfaces and security groups that are attached to participant resources, to facilitate troubleshooting and auditing. VPC owners can create flow log subscriptions for the VPC, its subnets, and its network interfaces.

Participant resources
Participants can create, manage, and delete resources in a shared VPC. Participants own the resources that they create in the VPC, such as EC2 instances, Amazon RDS databases, and Elastic Load Balancing load balancers.

Participants can view the details of resources that the VPC owners are responsible for, such as route tables and network ACLs, but they can't modify them. Participants can't view or modify resources that
belong to other participant accounts. Participants can create flow log subscriptions only for the network interfaces that they own.

Participants can reference security groups that belong to other participants or the owner as follows:

```
account-number/security-group-id
```

Participants cannot directly associate one of their private hosted zones with the shared VPC. A participant that needs to control the behavior of a private hosted zone associated with the VPC can use one of the following solutions:

- The participant can create and share a private hosted zone with the VPC owner. For information about sharing a private hosted zone, see Associating a VPC and a private hosted zone that you created with different AWS accounts in the Amazon Route 53 Developer Guide.
- The VPC owner can create a cross-account IAM role that provides control over a private hosted zone the owner has already associated with the VPC. The owner can then grant the participant account the necessary permissions to assume the role. For more information, see IAM Tutorial: Delegate access across AWS accounts using IAM roles in the IAM User Guide. The participate account can then assume the role, and exercise whatever control over the private hosted zone that the owner has delegated through the role’s permission.

**Billing and metering for the owner and participants**

In a shared VPC, each participant pays for their application resources including Amazon EC2 instances, Amazon Relational Database Service databases, Amazon Redshift clusters, and AWS Lambda functions. Participants also pay for data transfer charges associated with inter-Availability Zone data transfer, data transfer over VPC peering connections, and data transfer through an AWS Direct Connect gateway. VPC owners pay hourly charges (where applicable), data processing and data transfer charges across NAT gateways, virtual private gateways, transit gateways, AWS PrivateLink, and VPC endpoints. Data transfer within the same Availability Zone (uniquely identified using the AZ-ID) is free irrespective of account ownership of the communicating resources.

**Limitations**

The following limitations apply to working with VPC sharing:

- Owners can share subnets only with other accounts or organizational units that are in the same organization from AWS Organizations.
- Owners cannot share subnets that are in a default VPC.
- Participants cannot launch resources using security groups that are owned by other participants that share the VPC, or the VPC owner.
- Participants cannot launch resources using the default security group for the VPC because it belongs to the owner.
- Owners cannot launch resources using security groups that are owned by other participants.
- When participants launch resources in a shared subnet, they should make sure they attach their security group to the resource, and not rely on the default security group. Participants cannot use the default security group because it belongs to the VPC owner.
- Participants cannot create Route 53 Resolver endpoints in a VPC that they do not own. Only the VPC owner can create VPC-level resources such as inbound endpoints.
- VPC tags, and tags for the resources within the shared VPC are not shared with the participants.
- Only a subnet owner can attach a transit gateway to the shared subnet. Participants cannot.
- Participants can create Application Load Balancers and Network Load Balancers in a shared VPC, but they cannot register targets running in subnets that were not shared with them.
Example of sharing subnets

- Only a subnet owner can select a shared subnet when creating a Gateway Load Balancer. Participants cannot.
- Service quotas apply per individual account.

Example of sharing public subnets and private subnets

Consider this scenario where you want an account to be responsible for the infrastructure, including subnets, route tables, gateways, and CIDR ranges and other accounts that are in the same AWS Organization to use the subnets. A VPC owner (Account A) creates the routing infrastructure, including the VPCs, subnets, route tables, gateways, and network ACLs. Account D wants to create public facing applications. Account B and Account C want to create private applications that do not need to connect to the internet and should reside in private subnets. Account A can use AWS Resource Access Manager to create a Resource Share for the subnets and then share the subnets. Account A shares the public subnet with Account D and the private subnet with Account B, and Account C. Account B, Account C, and Account D can create resources in the subnets. Each account can only see the subnets that are shared with them, for example, Account D can only see the public subnet. Each of the accounts can control their resources, including instances, and security groups.

Account A manages the IP infrastructure, including the route tables for the public subnets, and the private subnets. There is no additional configuration required for shared subnets, so the route tables are the same as unshared subnet route tables.

Account A (Account ID 111111111111) shares the public subnet with Account D (444444444444). Account D sees the following subnet, and the **Owner** column provides two indicators that the subnet is shared.
Extend a VPC to another Zone

The Account ID is the VPC owner (111111111111) and is different from Account D's ID (444444444444). The word "shared" appears beside the owner account ID.

You can host VPC resources, such as subnets, in multiple locations world-wide. These locations are composed of Regions, Availability Zones, Local Zones, and Wavelength Zones. Each Region is a separate geographic area.

- Availability Zones are multiple, isolated locations within each Region.
- Local Zones allow you to place resources, such as compute and storage, in multiple locations closer to your end users.
- AWS Outposts brings native AWS services, infrastructure, and operating models to virtually any data center, co-location space, or on-premises facility.
- Wavelength Zones allow developers to build applications that deliver ultra-low latencies to 5G devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks.

AWS operates state-of-the-art, highly available data centers. Although rare, failures can occur that affect the availability of instances that are in the same location. If you host all of your instances in a single location that is affected by a failure, none of your instances would be available.

To help you determine which deployment is best for you, see AWS Wavelength FAQs.

Extend your VPC resources to Local Zones

AWS Local Zones allow you to place resources closer to your end users, and seamlessly connect to the full range of services in the AWS Region using familiar APIs and tool sets. You can extend your VPC Region by creating a new subnet that has a Local Zone assignment. When you create a subnet in a Local Zone, you extend the VPC to that Local Zone.

To use a Local Zone, you follow a three-step process:

- First, opt in to the Local Zone.
- Next, create a subnet in the Local Zone.
- Finally, launch select resources in the Local Zone subnet, so that your applications are closer to your end users.

When you create a VPC, you can choose to assign a set of Amazon-provided public IP addresses to the VPC. You can also set a network border group for the addresses that limits the addresses to the
group. When you set a network border group, the IP addresses can't move between network border
groups. Local Zone network traffic will go directly to the internet or to points-of-presence (PoPs) without
traversing the Local Zone's parent Region, enabling access to low-latency computing. The complete list
of Local Zones and their corresponding parent Regions can be found on the AWS Local Zones page.

The following rules apply to Local Zones:

- The Local Zone subnets follow the same routing rules as Availability Zone subnets, including route
tables, security groups, and network ACLs.
- You can assign subnets to Local Zones using the Amazon Virtual Private Cloud Console, AWS CLI, or
  API.
- You must provision public IP addresses for use in a Local Zone. When you allocate addresses, you
can specify the location from which the IP address is advertised. We refer to this as a network border
group, and you can set this parameter to limit the addresses to this location. After you provision the IP
addresses, you cannot move them between the Local Zone and the parent Region (for example, from
us-west-2-1ax-1a to us-west-2).
- You can request the IPv6 Amazon-provided IP addresses and associate them with the network border
group for a new or existing VPCs only for us-west-2-1ax-1a and use-west-2-1ax-1b. All other
Local Zones don't support IPv6.
- Outbound internet traffic leaves a Local Zone from the Local Zone.
- You cannot create VPC endpoints inside Local Zone subnets.

For information about working with Local Zones in Linux, see Local Zones in the Amazon EC2 User Guide
for Linux Instances. For information about working with Local Zones in Windows, see Local Zones in the
Amazon EC2 User Guide for Windows Instances. Both guides contain a list of available Local Zones and
the resources that you can launch in each Local Zone.

Considerations for internet gateways

Take the following information into account when you use internet gateways (in the parent Region) in
Local Zones:

- You can use internet gateways in Local Zones with Elastic IP addresses or Amazon auto-assigned public
  IP addresses. The Elastic IP addresses that you associate must include the network border group of the
  Local Zone. For more information, see the section called “Elastic IP addresses” (p. 134).

  You cannot associate an Elastic IP address that is set for the Region.
- Elastic IP addresses that are used in Local Zones have the same quotas as Elastic IP addresses in a
  Region. For more information, see the section called “Elastic IP addresses (IPv4)” (p. 353).
- You can use internet gateways in route tables that are associated with Local Zone resources. For more
  information, see the section called “Routing to an internet gateway” (p. 84).

Access Local Zones using a Direct Connect gateway

Consider the scenario where you want an on-premises data center to access resources that are in a Local
Zone. You use a virtual private gateway for the VPC that's associated with the Local Zone to connect to
a Direct Connect gateway. The Direct Connect gateway connects to an AWS Direct Connect location in a
Region. The on-premises data center has an AWS Direct Connect connection to the AWS Direct Connect
location.

Note
Traffic within the US that is destined for a subnet in a Local Zone using Direct Connect does not
travel through the parent Region of the Local Zone. Instead, traffic takes the shortest path to
the Local Zone. This decreases latency and helps make your applications more responsive.
You configure the following resources for this configuration:

- A virtual private gateway for the VPC that is associated with the Local Zone subnet. You can view the VPC for the subnet on the subnet details page in the Amazon Virtual Private Cloud Console, or use describe-subnets.

  For information about creating a virtual private gateway, see Create a target gateway in the AWS Site-to-Site VPN User Guide.

- A Direct Connect connection. For the best latency performance, AWS recommends that you use the Direct Connect location closest to the Local Zone to which you'll be extending your subnet.

  For information about ordering a connection, see Cross connects in the AWS Direct Connect User Guide.

- A virtual private gateway association to connect the VPC to the Direct Connect gateway. For information about creating a virtual private gateway association, see Associating and disassociating virtual private gateways in the AWS Direct Connect User Guide.

- A private virtual interface on the connection from the AWS Direct Connect location to the on-premises data center. For information about creating a Direct Connect gateway, see Creating a private virtual interface to the Direct Connect gateway in the AWS Direct Connect User Guide.

## Connect Local Zone subnets to a transit gateway

You can't create a transit gateway attachment for a subnet in a Local Zone. The following diagram shows how to configure your network so that subnets in the Local Zone connect to a transit gateway through the parent Availability Zone. Create subnets in the Local Zones and subnets in the parent Availability Zones. Connect the subnets in the parent Availability Zones to the transit gateway, and then create a route in the route table for each VPC that routes traffic destined for the other VPC CIDR to the network interface for the transit gateway attachment.

**Note**

Traffic destined for a subnet in a Local Zone that originates from a transit gateway will first traverse the parent Region.
Create the following resources for this scenario:

- A subnet in each parent Availability Zone. For more information, see the section called “Create a subnet in your VPC” (p. 59).
- A transit gateway. For more information, see Create a transit gateway in Amazon VPC Transit Gateways.
- A transit gateway attachment for each VPC using the parent Availability Zone. For more information, see Create a transit gateway attachment to a VPC in Amazon VPC Transit Gateways.
- A transit gateway route table associated with the transit gateway attachment. For more information, see Transit gateway route tables in Amazon VPC Transit Gateways.
- For each VPC, an entry in the VPC route table that has the other VPC CIDR as the destination, and the ID of the network interface for the transit gateway attachment as the target. To find the network interface for the transit gateway attachment, search the descriptions of your network interfaces for the ID of the transit gateway attachment. For more information, see the section called “Routing for a transit gateway” (p. 87).

The following is an example route table for VPC 1.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC 1 CIDR</td>
<td>local</td>
</tr>
<tr>
<td>VPC 2 CIDR</td>
<td>vpc1-attachment-network-interface-id</td>
</tr>
</tbody>
</table>

The following is an example route table for VPC 2.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC 2 CIDR</td>
<td>local</td>
</tr>
<tr>
<td>VPC 1 CIDR</td>
<td>vpc2-attachment-network-interface-id</td>
</tr>
</tbody>
</table>

The following is an example of the transit gateway route table. The CIDR blocks for each VPC propagate to the transit gateway route table.

<table>
<thead>
<tr>
<th>CIDR</th>
<th>Attachment</th>
<th>Route type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC 1 CIDR</td>
<td>Attachment for VPC 1</td>
<td>propagated</td>
</tr>
</tbody>
</table>
Extend your VPC resources to Wavelength Zones

AWS Wavelength allows developers to build applications that deliver ultra-low latencies to mobile devices and end-users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. Developers can extend an Amazon Virtual Private Cloud (VPC) to one or more Wavelength Zones, and then use AWS resources like Amazon Elastic Compute Cloud (EC2) instances to run applications that require ultra-low latency and connect to AWS services in the Region.

To use a Wavelength Zones, you must first opt in to the Zone. Next, create a subnet in the Wavelength Zone. You can create Amazon EC2 instances, Amazon EBS volumes, and Amazon VPC subnets and carrier gateways in Wavelength Zones. You can also use services that orchestrate or work with EC2, EBS, and VPC, such as Amazon EC2 Auto Scaling, Amazon EKS clusters, Amazon ECS clusters, Amazon EC2 Systems Manager, Amazon CloudWatch, AWS CloudTrail, and AWS CloudFormation. The services in Wavelength are part of a VPC that is connected over a reliable, high bandwidth connection to an AWS Region for easy access to services including Amazon DynamoDB and Amazon RDS.

The following rules apply to Wavelength Zones:

- A VPC extends to a Wavelength Zone when you create a subnet in the VPC and associate it with the Wavelength Zone.
- By default, every subnet that you create in a VPC that spans a Wavelength Zone inherits the main VPC route table, including the local route.
- When you launch an EC2 instance in a subnet in a Wavelength Zone, you assign a carrier IP address to it. The carrier gateway uses the address for traffic from the interface to the internet, or mobile devices. The carrier gateway uses NAT to translate the address, and then sends the traffic to the destination. Traffic from the telecommunication carrier network routes through the carrier gateway.
- You can set the target of a VPC route table, or subnet route table in a Wavelength Zone to a carrier gateway, which allows inbound traffic from a carrier network in a specific location, and outbound traffic to the carrier network and internet. For more information about routing options in a Wavelength Zone, see Routing in the AWS Wavelength Developer Guide.
- Subnets in Wavelength Zones have the same networking components as subnets in Availability Zones, including IPv4 addresses, DHCP option sets, and network ACLs.
- You can't create a transit gateway attachment to a subnet in a Wavelength Zone. Instead, create the attachment through a subnet in the parent Availability Zone, and then route traffic to the desired destinations through the transit gateway. For an example, see the next section.

Considerations for multiple Wavelength Zones

EC2 instances that are in different Wavelength Zones in the same VPC are not allowed to communicate with each other. If you need Wavelength Zone to Wavelength Zone communication, AWS recommends that you use multiple VPCs, one for each Wavelength Zone. You can use a transit gateway to connect the VPCs. This configuration enables communication between instances in the Wavelength Zones.

Wavelength Zone to Wavelength Zone traffic routes through the AWS Region. For more information, see AWS Transit Gateway.

The following diagram shows how to configure your network so that instances in two different Wavelength Zones can communicate. You have two Wavelength Zones (Wavelength Zone A and Wavelength Zone B). You need to create the following resources to enable communication:

<table>
<thead>
<tr>
<th>CIDR</th>
<th>Attachment</th>
<th>Route type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC 2 CIDR</td>
<td>Attachment for VPC 2</td>
<td>propagated</td>
</tr>
</tbody>
</table>
For each Wavelength Zone, a subnet in an Availability Zone that is the parent Availability Zone for the Wavelength Zone. In the example, you create subnet 1 and subnet 2. For information about creating subnets, see the section called “Create a subnet in your VPC” (p. 59). Use describe-availability-zones to find the parent zone.

A transit gateway. The transit gateway connects the VPCs. For information about creating a transit gateway, see Create a transit gateway in the Amazon VPC Transit Gateways Guide.

For each VPC, a VPC attachment to the transit gateway in the parent Availability Zone of the Wavelength Zone. For more information, see Transit gateway attachments to a VPC in the Amazon VPC Transit Gateways Guide.

Entries for each VPC in the transit gateway route table. For information about creating transit gateway routes, see Transit gateway route tables in the Amazon VPC Transit Gateways Guide.

For each VPC, an entry in the VPC route table that has the other VPC CIDR as the destination, and the transit gateway ID as the target. For more information, see the section called “Routing for a transit gateway” (p. 87).

In the example, the route table for VPC 1 has the following entry:

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.1.0.0/24</td>
<td>tgw-22222222222222222</td>
</tr>
</tbody>
</table>

The route table for VPC 2 has the following entry:

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/24</td>
<td>tgw-22222222222222222</td>
</tr>
</tbody>
</table>
Subnets in AWS Outposts

AWS Outposts offers you the same AWS hardware infrastructure, services, APIs, and tools to build and run your applications on premises and in the cloud. AWS Outposts is ideal for workloads that need low latency access to on-premises applications or systems, and for workloads that need to store and process data locally. For more information about AWS Outposts, see AWS Outposts.

Amazon VPC spans across all of the Availability Zones in an AWS Region. When you connect Outposts to the parent Region, all existing and newly created VPCs in your account span across all Availability Zones and any associated Outpost locations in the Region.

The following rules apply to AWS Outposts:

• The subnets must reside in one Outpost location.
• A local gateway handles the network connectivity between your VPC and on-premises networks. For information about local gateways, see Local Gateways in the AWS Outposts User Guide.
• If your account is associated with AWS Outposts, you assign the subnet to an Outpost by specifying the Outpost ARN when you create the subnet.
• By default, every subnet that you create in a VPC associated with an Outpost inherits the main VPC route table, including the local gateway route. You can also explicitly associate a custom route table with the subnets in your VPC and have a local gateway as a next-hop target for all traffic that needs to be routed to the on-premises network.
Subnets for your VPC

A subnet is a range of IP addresses in your VPC. You can launch AWS resources into a specified subnet. Use a public subnet for resources that must be connected to the internet, and a private subnet for resources that won't be connected to the internet.

To protect the AWS resources in each subnet, you can use multiple layers of security, including security groups and network access control lists (ACL).

Contents
- Subnet basics (p. 56)
- Subnet sizing (p. 58)
- Subnet routing (p. 59)
- Subnet security (p. 59)
- Work with subnets (p. 59)
- Use subnet CIDR reservations (p. 63)
- Group CIDR blocks using managed prefix lists (p. 65)
- Configure route tables (p. 74)
- Control traffic to subnets using Network ACLs (p. 108)

Subnet basics

A subnet is a range of IP addresses in your VPC. You can launch AWS resources, such as EC2 instances, into a specific subnet. When you create a subnet, you specify the IPv4 CIDR block for the subnet, which is a subset of the VPC CIDR block. Each subnet must reside entirely within one Availability Zone and cannot span zones. By launching instances in separate Availability Zones, you can protect your applications from the failure of a single zone.

You can optionally add subnets in a Local Zone, which is an AWS infrastructure deployment that places compute, storage, database, and other select services closer to your end users. A Local Zone enables your end users to run applications that require single-digit millisecond latencies. For more information, see Local Zones in the Amazon EC2 User Guide for Linux Instances.

Contents
- Subnet types (p. 56)
- Subnet settings (p. 57)
- Subnet diagram (p. 57)

Subnet types

Depending on how you configure your VPC, subnets are considered public, private, or VPN-only:

- **Public subnet**: The subnet traffic is routed to the public internet through an internet gateway or an egress-only internet gateway. For more information, see Connect to the internet using an internet gateway (p. 128).
- **Private subnet**: The subnet traffic can't reach the public internet through an internet gateway or egress-only internet gateway. Access to the public internet requires a NAT device.
- **VPN-only subnet**: The subnet traffic is routed to a Site-to-Site VPN connection through a virtual private gateway. The subnet traffic can't reach the public internet through an internet gateway. For more information, see the AWS Site-to-Site VPN User Guide.
When you create a subnet, you specify its IP addresses, depending on the configuration of the VPC:

- **IPv4 only**: The subnet has an IPv4 CIDR block but does not have an IPv6 CIDR block. Resources in an IPv4-only subnet must communicate over IPv4.
- **Dual stack**: The subnet has both an IPv4 CIDR block and an IPv6 CIDR block. The VPC must have both an IPv4 CIDR block and an IPv6 CIDR block. Resources in a dual-stack subnet can communicate over IPv4 and IPv6.
- **IPv6 only**: The subnet has an IPv6 CIDR block but does not have an IPv4 CIDR block. The VPC must have an IPv6 CIDR block. Resources in an IPv6-only subnet must communicate over IPv6.

Regardless of the type of subnet, the internal IPv4 address range of the subnet is always private—we do not announce the address block to the internet. For more information about private IP addressing in VPCs, see [IP addressing](#) (p. 4).

### Subnet settings

All subnets have a modifiable attribute that determines whether a network interface created in that subnet is assigned a public IPv4 address and, if applicable, an IPv6 address. This includes the primary network interface (eth0) that's created for an instance when you launch an instance in that subnet. Regardless of the subnet attribute, you can still override this setting for a specific instance during launch.

After you create a subnet, you can modify the following settings for the subnet.

- **Auto-assign IP settings**: Enables you to configure the auto-assign IP settings to automatically request a public IPv4 or IPv6 address for a new network interface in this subnet.
- **Resource-based Name (RBN) settings**: Enables you to specify the hostname type for EC2 instances in this subnet and configure how DNS A and AAAA record queries are handled. For more information about these settings, see [Amazon EC2 instance hostname types](#) in the *Amazon EC2 User Guide for Linux Instances*.

### Subnet diagram

The following diagram shows two VPCs in a Region. Each VPC has public and private subnets and an internet gateway. The VPC also spans a Local Zone.
Subnet sizing

The CIDR block of a subnet can be the same as the CIDR block for the VPC (for a single subnet in the VPC), or a subset of the CIDR block for the VPC (to create multiple subnets in the VPC). The allowed block size is between a /28 netmask and /16 netmask. If you create more than one subnet in a VPC, the CIDR blocks of the subnets cannot overlap.

For example, if you create a VPC with CIDR block 10.0.0.0/24, it supports 256 IP addresses. You can break this CIDR block into two subnets, each supporting 128 IP addresses. One subnet uses CIDR block 10.0.0.0/25 (for addresses 10.0.0.0 - 10.0.0.127) and the other uses CIDR block 10.0.0.128/25 (for addresses 10.0.0.128 - 10.0.0.255).

There are tools available on the internet to help you calculate and create IPv4 subnet CIDR blocks. You can find tools that suit your needs by searching for terms such as 'subnet calculator' or 'CIDR calculator'. Your network engineering group can also help you determine the CIDR blocks to specify for your subnets.

The first four IP addresses and the last IP address in each subnet CIDR block are not available for your use, and they cannot be assigned to a resource, such as an EC2 instance. For example, in a subnet with CIDR block 10.0.0.0/24, the following five IP addresses are reserved:

- 10.0.0.0: Network address.
- 10.0.0.1: Reserved by AWS for the VPC router.
- 10.0.0.2: Reserved by AWS. The IP address of the DNS server is the base of the VPC network range plus two. For VPCs with multiple CIDR blocks, the IP address of the DNS server is located in the primary CIDR. We also reserve the base of each subnet range plus two for all CIDR blocks in the VPC. For more information, see Amazon DNS server (p. 37).
- 10.0.0.3: Reserved by AWS for future use.
- 10.0.0.255: Network broadcast address. We do not support broadcast in a VPC, therefore we reserve this address.

If you create a subnet using a command line tool or the Amazon EC2 API, the CIDR block is automatically modified to its canonical form. For example, if you specify 100.68.0.18/18 for the CIDR block, we create a CIDR block of 100.68.0.0/18.

Subnet sizing for IPv6

If you've associated an IPv6 CIDR block with your VPC, you can associate an IPv6 CIDR block with an existing subnet in your VPC, or when you create a new subnet. A subnet's IPv6 CIDR block is a fixed prefix length of /64.

There are tools available on the internet to help you calculate and create IPv6 subnet CIDR blocks; for example, IPv6 Address Planner. You can find other tools that suit your needs by searching for terms such as 'IPv6 subnet calculator' or 'IPv6 CIDR calculator'. Your network engineering group can also help you determine the IPv6 CIDR blocks to specify for your subnets.

The first four IPv6 addresses and the last IPv6 address in each subnet CIDR block are not available for your use, and they cannot be assigned to an EC2 instance. For example, in a subnet with CIDR block 2001:db8:1234:1a00/64, the following five IP addresses are reserved:

- 2001:db8:1234:1a00::
- 2001:db8:1234:1a00::1
- 2001:db8:1234:1a00::2
- 2001:db8:1234:1a00::3
- 2001:db8:1234:1a00:ffff:ffff:ffff:ffff
Subnet routing

Each subnet must be associated with a route table, which specifies the allowed routes for outbound traffic leaving the subnet. Every subnet that you create is automatically associated with the main route table for the VPC. You can change the association, and you can change the contents of the main route table. For more information, see Configure route tables (p. 74).

Subnet security

AWS provides two features that you can use to increase security in your VPC: security groups and network ACLs. Security groups control inbound and outbound traffic for your instances, and network ACLs control inbound and outbound traffic for your subnets. In most cases, security groups can meet your needs; however, you can also use network ACLs if you want an additional layer of security for your VPC. For more information, see Internetwork traffic privacy in Amazon VPC (p. 224).

By design, each subnet must be associated with a network ACL. Every subnet that you create is automatically associated with the default network ACL for the VPC. You can change the association, and you can change the contents of the default network ACL. For more information, see Control traffic to subnets using Network ACLs (p. 108).

You can create a flow log on your VPC or subnet to capture the traffic that flows to and from the network interfaces in your VPC or subnet. You can also create a flow log on an individual network interface. For more information, see Logging IP traffic using VPC Flow Logs (p. 180).

Work with subnets

Use the following procedures to create and configure subnets for your virtual private cloud (VPC). Depending on the connectivity that you need, you might also need to add gateways and route tables.

Tasks
- Create a subnet in your VPC (p. 59)
- View your subnets (p. 60)
- Associate an IPv6 CIDR block with your subnet (p. 61)
- Disassociate an IPv6 CIDR block from your subnet (p. 61)
- Modify the public IPv4 addressing attribute for your subnet (p. 61)
- Modify the IPv6 addressing attribute for your subnet (p. 62)
- Delete a subnet (p. 62)
- API and command overview (p. 62)

Create a subnet in your VPC

To add a new subnet to your VPC, you must specify an IPv4 CIDR block for the subnet from the range of your VPC. You can specify the Availability Zone in which you want the subnet to reside. You can have multiple subnets in the same Availability Zone.

Considerations
- You can optionally specify an IPv6 CIDR block for a subnet if there is an IPv6 CIDR block associated with the VPC.
• If you create an IPv6-only subnet, be aware of the following. An EC2 instance launched in an IPv6-only subnet receives an IPv6 address but not an IPv4 address. Any instances that you launch into an IPv6-only subnet must be instances built on the Nitro System.

• To create the subnet in a Local Zone or a Wavelength Zone, you must enable the Zone. For more information, see Regions and Zones in the Amazon EC2 User Guide for Linux Instances.

To add a subnet to your VPC

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Choose Create subnet.
4. For VPC ID: Choose the VPC for the subnet.
5. (Optional) For Subnet name, enter a name for your subnet. Doing so creates a tag with a key of Name and the value that you specify.
6. For Availability Zone, you can choose a Zone for your subnet, or leave the default No Preference to let AWS choose one for you.
7. If the subnet should be an IPv6-only subnet, choose IPv6-only. This option is only available if the VPC has an associated IPv6 CIDR block. If you choose this option, you can't associate an IPv4 CIDR block with the subnet.
8. For IPv4 CIDR block, enter an IPv4 CIDR block for your subnet. For example, 10.0.1.0/24. For more information, see IPv4 VPC CIDR blocks (p. 14). If you chose IPv6-only, this option is unavailable.
9. For IPv6 CIDR block, choose Custom IPv6 CIDR and specify the hexadecimal pair value (for example, 00). This option is available only if the VPC has an associated IPv6 CIDR block.
10. Choose Create subnet.

Next steps

After you create a subnet, you can configure it as follows:

• Configure routing. You can then create a custom route table and route that send traffic to a gateway that's associated with the VPC, such as an internet gateway. For more information, see Configure route tables (p. 74).

• Modify the IP addressing behavior. You can specify whether instances launched in the subnet receive a public IPv4 address, an IPv6 address, or both. For more information, see Subnet settings (p. 57).

• Modify the resource-based name (RBN) settings. For more information, see Amazon EC2 instance hostname types.

• Create or modify your network ACLs. For more information, see Control traffic to subnets using Network ACLs (p. 108).

• Share the subnet with other accounts. For more information, see ??? (p. 44).

View your subnets

Use the following steps section to view the details about your subnet.

To view your subnets in the current Region

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select the checkbox for the subnet or choose the subnet ID to open the detail page.
To view your subnets across Regions

Open the Amazon EC2 Global View console at https://console.aws.amazon.com/ec2globalview/home. For more information, see List and filter resources using the Amazon EC2 Global View in the Amazon EC2 User Guide for Linux Instances.

Associate an IPv6 CIDR block with your subnet

You can associate an IPv6 CIDR block with an existing subnet in your VPC. The subnet must not have an existing IPv6 CIDR block associated with it.

To associate an IPv6 CIDR block with a subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select your subnet and choose Actions, Edit IPv6 CIDRs.
4. Choose Add IPv6 CIDR. Specify the hexadecimal pair for the subnet (for example, 00).
5. Choose Save.

Disassociate an IPv6 CIDR block from your subnet

If you no longer want IPv6 support in your subnet, but you want to continue to use your subnet to create and communicate with IPv4 resources, you can disassociate the IPv6 CIDR block.

To disassociate an IPv6 CIDR block, you must first unassign any IPv6 addresses that are assigned to any instances in your subnet.

To disassociate an IPv6 CIDR block from a subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select the subnet and choose Actions, Edit IPv6 CIDRs.
4. Find the IPv6 CIDR block and choose Remove.
5. Choose Save.

Modify the public IPv4 addressing attribute for your subnet

By default, nondefault subnets have the IPv4 public addressing attribute set to false, and default subnets have this attribute set to true. An exception is a nondefault subnet created by the Amazon EC2 launch instance wizard — the wizard sets the attribute to true. You can modify this attribute using the Amazon VPC console.

To modify your subnet's public IPv4 addressing behavior

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select your subnet and choose Actions, Edit subnet settings.
4. The Enable auto-assign public IPv4 address check box, if selected, requests a public IPv4 address for all instances launched into the selected subnet. Select or clear the check box as required, and then choose Save.
Modify the IPv6 addressing attribute for your subnet

By default, all subnets have the IPv6 addressing attribute set to false. You can modify this attribute using the Amazon VPC console. If you enable the IPv6 addressing attribute for your subnet, network interfaces created in the subnet receive an IPv6 address from the range of the subnet. Instances launched into the subnet receive an IPv6 address on the primary network interface.

Your subnet must have an associated IPv6 CIDR block.

**Note**
- If you enable the IPv6 addressing feature for your subnet, your network interface or instance only receives an IPv6 address if it's created using version 2016-11-15 or later of the Amazon EC2 API. The Amazon EC2 console uses the latest API version.

**To modify your subnet’s IPv6 addressing behavior**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select your subnet and choose Actions, Edit subnet settings.
4. The **Enable auto-assign IPv6 address** check box, if selected, requests an IPv6 address for all network interfaces created in the selected subnet. Select or clear the check box as required, and then choose Save.

Delete a subnet

If you no longer need a subnet, you can delete it. You cannot delete a subnet if it contains any network interfaces. For example, you must terminate any instances in a subnet before you can delete it.

**To delete a subnet**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Terminate all instances in the subnet. For more information, see Terminate Your Instance in the EC2 User Guide.
3. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
4. In the navigation pane, choose Subnets.
5. Select the subnet and choose Actions, Delete subnet.
6. When prompted for confirmation, type delete and then choose Delete.

API and command overview

You can perform the tasks described on this page using the command line or an API. For more information about the command line interfaces and a list of available API actions, see Working with Amazon VPC (p. 2).

**Add a subnet**

- create-subnet (AWS CLI)
- New-EC2Subnet (AWS Tools for Windows PowerShell)

**Describe your subnets**

- describe-subnets (AWS CLI)
- Get-EC2Subnet (AWS Tools for Windows PowerShell)
Use subnet CIDR reservations

A subnet CIDR reservation is a range of IPv4 or IPv6 addresses that you set aside so that AWS can’t assign them to your network interfaces. This enables you to specify IPv4 or IPv6 prefixes for use with your network interfaces.

When you create a subnet CIDR reservation, you specify how you will use the reserved IP addresses. The following options are available:

- **Prefix** — AWS assigns addresses from the reserved IP address range to network interfaces. For more information, see Assigning prefixes to Amazon EC2 network interfaces in the Amazon EC2 User Guide for Linux Instances.
- **Explicit** — You manually assign IP addresses to network interfaces.

The following rules apply to subnet CIDR reservations:

- When you create a subnet CIDR reservation, the IP address range can include addresses that are already in use. Creating a subnet reservation does not unassign any IP addresses that are already in use.
- You can reserve multiple CIDR ranges per subnet. When you reserve multiple CIDR ranges within the same VPC, the CIDR ranges cannot overlap.
- When you reserve more than one range in a subnet for Prefix Delegation, and Prefix Delegation is configured for automatic assignment, we choose the IP addresses to assign to network interfaces at random.
- When you delete a subnet reservation, the unused IP addresses are available for AWS to assign to your network interfaces. Deleting a subnet reservation does not unassign any IP addresses that are in use.

Work with subnet CIDR reservations using the console

You can create and manage subnet CIDR reservations as follows.

**To edit subnet CIDR reservations**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Subnets**.
3. Select the subnet.
4. Choose **Actions, Edit CIDR reservations** and do the following:
   - To add an IPv4 CIDR reservation, choose **IPv4, Add IPv4 CIDR reservation**. Choose the reservation type, enter the CIDR range, and choose **Add**.
   - To add an IPv6 CIDR reservation, choose **IPv6, Add IPv6 CIDR reservation**. Choose the reservation type, enter the CIDR range, and choose **Add**.
   - To remove a CIDR reservation, choose **Remove** at the end of the entry.

Work with subnet CIDR reservations using the AWS CLI

You can use the AWS CLI to create and manage subnet CIDR reservations.

**Tasks**
- Create a subnet CIDR reservation (p. 64)
- View subnet CIDR reservations (p. 64)
- Delete a subnet CIDR reservation (p. 64)

Create a subnet CIDR reservation

You can use `create-subnet-cidr-reservation` to create a subnet CIDR reservation.

```
aws ec2 create-subnet-cidr-reservation --subnet-id subnet-03c51e2eEXAMPLE --reservation-type prefix --cidr 2600:1f13:925:d240:3a1b::/80
```

The following is example output.

```
{
  "SubnetCidrReservation": {
    "SubnetCidrReservationId": "scr-044f977c4eEXAMPLE",
    "SubnetId": "subnet-03c51e2eEXAMPLE",
    "Cidr": "2600:1f13:925:d240:3a1b::/80",
    "ReservationType": "prefix",
    "OwnerId": "123456789012"
  }
}
```

View subnet CIDR reservations

You can use `get-subnet-cidr-reservations` to view the details of a subnet CIDR reservation.

```
aws ec2 get-subnet-cidr-reservations --subnet-id subnet-05eef9fb78EXAMPLE
```

Delete a subnet CIDR reservation

You can use `delete-subnet-cidr-reservation` to delete a subnet CIDR reservation.

```
aws ec2 delete-subnet-cidr-reservation --subnet-cidr-reservation-id scr-044f977c4eEXAMPLE
```
Group CIDR blocks using managed prefix lists

A managed prefix list is a set of one or more CIDR blocks. You can use prefix lists to make it easier to configure and maintain your security groups and route tables. You can create a prefix list from the IP addresses that you frequently use, and reference them as a set in security group rules and routes instead of referencing them individually. For example, you can consolidate security group rules with different CIDR blocks but the same port and protocol into a single rule that uses a prefix list. If you scale your network and need to allow traffic from another CIDR block, you can update the relevant prefix list and all security groups that use the prefix list are updated. You can also use managed prefix lists with other AWS accounts using Resource Access Manager (RAM).

There are two types of prefix lists:

- **Customer-managed prefix lists** — Sets of IP address ranges that you define and manage. You can share your prefix list with other AWS accounts, enabling those accounts to reference the prefix list in their own resources.
- **AWS-managed prefix lists** — Sets of IP address ranges for AWS services. You cannot create, modify, share, or delete an AWS-managed prefix list.

## Prefix lists concepts and rules

A prefix list consists of **entries**. Each entry consists of a CIDR block and, optionally, a description for the CIDR block.

### Customer-managed prefix lists

The following rules apply to customer-managed prefix lists:

- A prefix list supports a single type of IP addressing only (IPv4 or IPv6). You cannot combine IPv4 and IPv6 CIDR blocks in a single prefix list.
- A prefix list applies only to the Region where you created it.
- When you create a prefix list, you must specify the maximum number of entries that the prefix list can support.
- When you reference a prefix list in a resource, the maximum number of entries for the prefix lists counts against the quota for the number of entries for the resource. For example, if you create a prefix list with 20 maximum entries and you reference that prefix list in a security group rule, this counts as 20 security group rules.
- When you reference a prefix list in a route table, route priority rules apply. For more information, see **Route priority and prefix lists** (p. 83).
- You can modify a prefix list. When you add or remove entries, we create a new version of the prefix list. Resources that reference the prefix always use the current (latest) version. You can restore the entries from a previous version of the prefix list, which also creates a new version.
- There are quotas related to prefix lists. For more information, see **Customer-managed prefix lists** (p. 354).
AWS-managed prefix lists

The following rules apply to AWS-managed prefix lists:

- You cannot create, modify, share, or delete an AWS-managed prefix list.
- Different AWS-managed prefix lists have a different weight when you use them. For more information, see AWS-managed prefix list weight (p. 70).
- You cannot view the version number of an AWS-managed prefix list.

Identity and access management for prefix lists

By default, IAM users do not have permission to create, view, modify, or delete prefix lists. You can create an IAM policy that allows users to work with prefix lists.

To see a list of Amazon VPC actions and the resources and condition keys that you can use in an IAM policy, see Actions, Resources, and Condition Keys for Amazon EC2 in the IAM User Guide.

The following example policy allows users to view and work with prefix list pl-123456abcde123456 only. Users cannot create or delete prefix lists.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:GetManagedPrefixListAssociations", "ec2:GetManagedPrefixListEntries", "ec2:ModifyManagedPrefixList", "ec2:RestoreManagedPrefixListVersion"],
            "Resource": "arn:aws:ec2:region:account:prefix-list/pl-123456abcde123456"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:DescribeManagedPrefixLists",
            "Resource": "*
        }
    ]
}
```

For more information about working with IAM in Amazon VPC, see Identity and access management for Amazon VPC (p. 228).

Work with customer-managed prefix lists

You can create and manage customer-managed prefix lists. You can view AWS-managed prefix lists.

Tasks

- Create a prefix list (p. 67)
- View prefix lists (p. 67)
- View the entries for a prefix list (p. 67)
- View associations (references) for your prefix list (p. 68)
- Modify a prefix list (p. 68)
- Resize a prefix list (p. 69)
- Restore a previous version of a prefix list (p. 69)
- Delete a prefix list (p. 69)
Create a prefix list

When you create a prefix list, you must specify the maximum number of entries that the prefix list can support.

Limitation

You can’t add a prefix list to a security group rule if the number of rules plus the max entries for the prefix list exceeds the quota for rules per security group for your account.

To create a prefix list using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. Choose Create prefix list.
4. For Prefix list name, enter a name for the prefix list.
5. For Max entries, enter the maximum number of entries for the prefix list.
6. For Address family, choose whether the prefix list supports IPv4 or IPv6 entries.
7. For Prefix list entries, choose Add new entry, and enter the CIDR block and a description for the entry. Repeat this step for each entry.
8. (Optional) For Tags, add tags to the prefix list to help you identify it later.
9. Choose Create prefix list.

To create a prefix list using the AWS CLI

Use the create-managed-prefix-list command.

View prefix lists

You can view your prefix lists, prefix lists that are shared with you, and AWS-managed prefix lists.

To view prefix lists using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. The Owner ID column shows the AWS account ID of the prefix list owner. For AWS-managed prefix lists, the Owner ID is AWS.

To view prefix lists using the AWS CLI

Use the describe-managed-prefix-lists command.

View the entries for a prefix list

You can view the entries for your prefix lists, prefix lists that are shared with you, and AWS-managed prefix lists.

To view the entries for a prefix list using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. Select the checkbox for the prefix list.
4. In the lower pane, choose Entries to view the entries for the prefix list.
To view the entries for a prefix list using the AWS CLI

Use the `get-managed-prefix-list-entries` command.

View associations (references) for your prefix list

You can view the IDs and owners of the resources that are associated with your prefix list. Associated resources are resources that reference your prefix list in their entries or rules.

Limitation

You cannot view associated resources for an AWS-managed prefix list.

To view prefix list associations using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose `Managed Prefix Lists`.
3. Select the checkbox for the prefix list.
4. In the lower pane, choose `Associations` to view the resources that are referencing the prefix list.

To view prefix list associations using the AWS CLI

Use the `get-managed-prefix-list-associations` command.

Modify a prefix list

You can modify the name of your prefix list, and you can add or remove entries. To modify the maximum number of entries, see Resize a prefix list (p. 69).

Updating the entries of a prefix list creates a new version of the prefix list. Updating the name or maximum number of entries for a prefix list does not create a new version of the prefix list.

Considerations

- You cannot modify an AWS-managed prefix list.
- When you increase the maximum number of entries in a prefix list, the increased maximum size is applied to the quota of entries for the resources that reference the prefix list. If any of these resources can't support the increased maximum size, the modify operation fails and the previous maximum size is restored.

To modify a prefix list using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose `Managed Prefix Lists`.
3. Select the checkbox for prefix list, and choose `Actions`, `Modify prefix list`.
4. For `Prefix list name`, enter a new name for the prefix list.
5. For `Prefix list entries`, choose `Remove` to remove an existing entry. To add a new entry, choose `Add new entry` and enter the CIDR block and a description for the entry.
6. Choose `Save prefix list`.

To modify a prefix list using the AWS CLI

Use the `modify-managed-prefix-list` command.
Resize a prefix list

You can resize a prefix list and modify the maximum number of entries for the prefix list. The value must be greater than or equal to the number of prefix list entries. The new value must be different than the current value.

To resize a prefix list using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. Select the checkbox for the prefix list, and choose Actions, Resize prefix list.
4. For New max entries, enter a value.
5. Choose Resize.

To resize a prefix list using the AWS CLI

Use the modify-managed-prefix-list command.

Restore a previous version of a prefix list

You can restore the entries from a previous version of your prefix list. This creates a new version of the prefix list.

If you decreased the size of the prefix list, you must ensure that the prefix list is large enough to contain the entries from the previous version.

To restore a previous version of a prefix list using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. Select the checkbox for the prefix list, and choose Actions, Restore prefix list.
4. For Select prefix list version, choose a previous version. The entries for the selected version are displayed in Prefix list entries.
5. Choose Restore prefix list.

To restore a previous version of a prefix list using the AWS CLI

Use the restore-managed-prefix-list-version command.

Delete a prefix list

To delete a prefix list, you must first remove any references to it in your resources (such as in your route tables). If you’ve shared the prefix list using AWS RAM, any references in consumer-owned resources must first be removed.

Limitation

You cannot delete an AWS-managed prefix list.

To delete a prefix list using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. Select the prefix list, and choose Actions, Delete prefix list.
4. In the confirmation dialog box, enter delete, and choose Delete.
To delete a prefix list using the AWS CLI
Use the `delete-managed-prefix-list` command.

Work with AWS-managed prefix lists

AWS-managed prefix lists are sets of IP address ranges for AWS services.

Contents
- Use an AWS-managed prefix list (p. 70)
- AWS-managed prefix list weight (p. 70)
- Available AWS-managed prefix lists (p. 70)

Use an AWS-managed prefix list

AWS-managed prefix lists are created and maintained by AWS and can be used by anyone with an AWS account. You cannot create, modify, share, or delete an AWS-managed prefix list.

As with customer-managed prefix lists, you can use AWS-managed prefix lists with AWS resources such as security groups and route tables. For more information, see Reference prefix lists in your AWS resources (p. 73).

AWS-managed prefix list weight

The weight of an AWS-managed prefix list refers to the number of entries that it takes up in a resource.

For example, the weight of a Amazon CloudFront managed prefix list is 55. Here’s how the this affects your Amazon VPC quotas:

- **Security groups** – The default quota (p. 356) is 60 rules, leaving room for only 5 additional rules in a security group. You can request a quota increase for this quota.
- **Route tables** – The default quota (p. 355) is 50 routes, so you must request a quota increase before you can add the prefix list to a route table.

Available AWS-managed prefix lists

The following services provide AWS-managed prefix lists.

<table>
<thead>
<tr>
<th>AWS service</th>
<th>Prefix list name</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon CloudFront</td>
<td>com.amazonaws.global.cloudflare-facing</td>
<td>55</td>
</tr>
<tr>
<td>Amazon DynamoDB</td>
<td>com.amazonaws.region.dynamodb</td>
<td>1</td>
</tr>
<tr>
<td>AWS Ground Station</td>
<td>com.amazonaws.global.groundstation</td>
<td>5</td>
</tr>
<tr>
<td>Amazon S3</td>
<td>com.amazonaws.region.s3</td>
<td>1</td>
</tr>
</tbody>
</table>

To view the AWS-managed prefix lists using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. In the search field, add the **Owner ID: AWS** filter.
To view the AWS-managed prefix lists using the AWS CLI

Use the describe-managed-prefix-lists command as follows.

```
aws ec2 describe-managed-prefix-lists --filters Name=owner-id,Values=AWS
```

Work with shared prefix lists

With AWS Resource Access Manager (AWS RAM), the owner of a prefix list can share a prefix list with the following:

- Specific AWS accounts inside or outside of its organization in AWS Organizations
- An organizational unit inside its organization in AWS Organizations
- An entire organization in AWS Organizations

Consumers with whom a prefix list has been shared can view the prefix list and its entries, and they can reference the prefix list in their AWS resources.

For more information about AWS RAM, see the AWS RAM User Guide.

Contents

- Prerequisites for sharing prefix lists (p. 71)
- Share a prefix list (p. 71)
- Identify a shared prefix list (p. 72)
- Identify references to a shared prefix list (p. 72)
- Unshare a shared prefix list (p. 72)
- Shared prefix list permissions (p. 73)
- Billing and metering (p. 73)
- Quotas for AWS RAM (p. 73)

Prerequisites for sharing prefix lists

- To share a prefix list, you must own it. You cannot share a prefix list that has been shared with you. You cannot share an AWS-managed prefix list.
- To share a prefix list with your organization or an organizational unit in AWS Organizations, you must enable sharing with AWS Organizations. For more information, see Enable sharing with AWS Organizations in the AWS RAM User Guide.

Share a prefix list

To share a prefix list, you must add it to a resource share. If you do not have a resource share, you must first create one using the AWS RAM console.

If you are part of an organization in AWS Organizations, and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared prefix list. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared prefix list after accepting the invitation.

You can create a resource share and share a prefix list that you own using the AWS RAM console, or the AWS CLI.

To create a resource share and share a prefix list using the AWS RAM console
Follow the steps in Create a resource share in the AWS RAM User Guide. For Select resource type, choose Prefix Lists, and then select the check box for your prefix list.

To add a prefix list to an existing resource share using the AWS RAM console

To add a managed prefix that you own to an existing resource share, follow the steps in Updating a resource share in the AWS RAM User Guide. For Select resource type, choose Prefix Lists, and then select the check box for your prefix list.

To share a prefix list that you own using the AWS CLI

Use the following commands to create and update a resource share:

• create-resource-share
• associate-resource-share
• update-resource-share

Identify a shared prefix list

Owners and consumers can identify shared prefix lists using the Amazon VPC console and AWS CLI.

To identify a shared prefix list using the Amazon VPC console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. The page displays the prefix lists that you own and the prefix lists that are shared with you. The Owner ID column shows the AWS account ID of the prefix list owner.
4. To view the resource share information for a prefix list, select the prefix list and choose Sharing in the lower pane.

To identify a shared prefix list using the AWS CLI

Use the describe-managed-prefix-lists command. The command returns the prefix lists that you own and the prefix lists that are shared with you. OwnerId shows the AWS account ID of the prefix list owner.

Identify references to a shared prefix list

Owners can identify the consumer-owned resources that are referencing a shared prefix list.

To identify references to a shared prefix list using the Amazon VPC console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Managed Prefix Lists.
3. Select the prefix list and choose Associations in the lower pane.
4. The IDs of the resources that are referencing the prefix list are listed in the Resource ID column. The owners of the resources are listed in the Resource Owner column.

To identify references to a shared prefix list using the AWS CLI

Use the get-managed-prefix-list-associations command.

Unshare a shared prefix list

When you unshare a prefix list, consumers can no longer view the prefix list or its entries in their account, and they cannot reference the prefix list in their resources. If the prefix list is already referenced in the
consumer's resources, those references continue to function as normal, and you can continue to view those references (p. 72). If you update the prefix list to a new version, the references use the latest version.

To unshare a shared prefix list that you own, you must remove it from the resource share using AWS RAM.

**To unshare a shared prefix list that you own using the AWS RAM console**

See Updating a resource share in the AWS RAM User Guide.

**To unshare a shared prefix list that you own using the AWS CLI**

Use the disassociate-resource-share command.

### Shared prefix list permissions

#### Permissions for owners

Owners are responsible for managing a shared prefix list and its entries. Owners can view the IDs of the AWS resources that reference the prefix list. However, they cannot add or remove references to a prefix list in AWS resources that are owned by consumers.

Owners cannot delete a prefix list if the prefix list is referenced in a resource that's owned by a consumer.

#### Permissions for consumers

Consumers can view the entries in a shared prefix list, and they can reference a shared prefix list in their AWS resources. However, consumers can't modify, restore, or delete a shared prefix list.

### Billing and metering

There are no additional charges for sharing prefix lists.

### Quotas for AWS RAM

For more information, see Service quotas.

### Reference prefix lists in your AWS resources

You can reference a prefix list in the following AWS resources.

**Resources**

- VPC security groups (p. 73)
- Subnet route tables (p. 74)
- Transit gateway route tables (p. 74)
- AWS Network Firewall rule groups (p. 74)

### VPC security groups

You can specify a prefix list as the source for an inbound rule, or as the destination for an outbound rule. For more information about security groups, see Control traffic to resources using security groups (p. 245).

**To reference a prefix list in a security group rule using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Security Groups**.
3. Select the security group to update.
4. Choose **Actions, Edit inbound rules** or **Actions, Edit outbound rules**.
5. Choose **Add rule**. For **Type**, select the traffic type. For **Source** (inbound rules) or **Destination** (outbound rules), choose the ID of the prefix list.
6. Choose **Save rules**.

**To reference a prefix list in a security group rule using the AWS CLI**

Use the **authorize-security-group-ingress** and **authorize-security-group-egress** commands. For the **--ip-permissions** parameter, specify the ID of the prefix list using **PrefixListIds**.

**Subnet route tables**

You can specify a prefix list as the destination for route table entry. You cannot reference a prefix list in a gateway route table. For more information about route tables, see **Configure route tables** (p. 74).

**To reference a prefix list in a route table using the console**

1. Open the Amazon VPC console at **https://console.aws.amazon.com/vpc/**.
2. In the navigation pane, choose **Route Tables**, and select the route table.
3. Choose **Actions, Edit routes**.
4. To add a route, choose **Add route**.
5. For **Destination** enter the ID of a prefix list.
6. For **Target**, choose a target.
7. Choose **Save changes**.

**To reference a prefix list in a route table using the AWS CLI**

Use the **create-route** (AWS CLI) command. Use the **--destination-prefix-list-id** parameter to specify the ID of a prefix list.

**Transit gateway route tables**

You can specify a prefix list as the destination for a route. For more information, see **Prefix list references** in **Amazon VPC Transit Gateways**.

**AWS Network Firewall rule groups**

An AWS Network Firewall rule group is a reusable set of criteria for inspecting and handling network traffic. If you create Suricata-compatible stateful rule groups in AWS Network Firewall, you can reference a prefix list from the rule group. For more information, see **Referencing Amazon VPC prefix lists** and **Creating a stateful rule group** in the **AWS Network Firewall Developer Guide**.

**Configure route tables**

**A route table** contains a set of rules, called **routes**, that determine where network traffic from your subnet or gateway is directed.

**Contents**

- Route table concepts (p. 75)
- Subnet route tables (p. 75)
Route table concepts

The following are the key concepts for route tables.

- **Main route table**—The route table that automatically comes with your VPC. It controls the routing for all subnets that are not explicitly associated with any other route table.
- **Custom route table**—A route table that you create for your VPC.
- **Destination**—The range of IP addresses where you want traffic to go (destination CIDR). For example, an external corporate network with the CIDR 172.16.0.0/12.
- **Target**—The gateway, network interface, or connection through which to send the destination traffic; for example, an internet gateway.
- **Route table association**—The association between a route table and a subnet, internet gateway, or virtual private gateway.
- **Subnet route table**—A route table that’s associated with a subnet.
- **Local route**—A default route for communication within the VPC.
- **Propagation**—Route propagation allows a virtual private gateway to automatically propagate routes to the route tables. This means that you don’t need to manually enter VPN routes to your route tables. For more information about VPN routing options, see Site-to-Site VPN routing options in the Site-to-Site VPN User Guide.
- **Gateway route table**—A route table that’s associated with an internet gateway or virtual private gateway.
- **Edge association**—A route table that you use to route inbound VPC traffic to an appliance. You associate a route table with the internet gateway or virtual private gateway, and specify the network interface of your appliance as the target for VPC traffic.
- **Transit gateway route table**—A route table that’s associated with a transit gateway. For more information, see Transit gateway route tables in Amazon VPC Transit Gateways.
- **Local gateway route table**—A route table that’s associated with an Outposts local gateway. For more information, see Local gateways in the AWS Outposts User Guide.

Subnet route tables

Your VPC has an implicit router, and you use route tables to control where network traffic is directed. Each subnet in your VPC must be associated with a route table, which controls the routing for the subnet (subnet route table). You can explicitly associate a subnet with a particular route table. Otherwise, the subnet is implicitly associated with the main route table. A subnet can only be associated with one route table at a time, but you can associate multiple subnets with the same subnet route table.
Routes

Each route in a table specifies a destination and a target. For example, to enable your subnet to access the internet through an internet gateway, add the following route to your subnet route table. The destination for the route is 0.0.0.0/0, which represents all IPv4 addresses. The target is the internet gateway that’s attached to your VPC.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td><em>igw-id</em></td>
</tr>
</tbody>
</table>

CIDR blocks for IPv4 and IPv6 are treated separately. For example, a route with a destination CIDR of 0.0.0.0/0 does not automatically include all IPv6 addresses. You must create a route with a destination CIDR of ::/0 for all IPv6 addresses.

If you frequently reference the same set of CIDR blocks across your AWS resources, you can create a customer-managed prefix list (p. 65) to group them together. You can then specify the prefix list as the destination in your route table entry.

Every route table contains a local route for communication within the VPC. This route is added by default to all route tables. If your VPC has more than one IPv4 CIDR block, your route tables contain a local route for each IPv4 CIDR block. If you’ve associated an IPv6 CIDR block with your VPC, your route tables contain a local route for the IPv6 CIDR block. You cannot modify or delete these routes in a subnet route table or in the main route table.

Rules and considerations

- You can add a route to your route tables that is more specific than the local route. The destination must match the entire IPv4 or IPv6 CIDR block of a subnet in your VPC. The target must be a NAT gateway, network interface, or Gateway Load Balancer endpoint.
- If your route table has multiple routes, we use the most specific route that matches the traffic (longest prefix match) to determine how to route the traffic.
- You can’t add routes to IPv4 addresses that are an exact match or a subset of the following range: 169.254.169.0/22. This range is within the link-local address space and is reserved for use by AWS services. For example, Amazon EC2 uses addresses in this range for services that are accessible only from EC2 instances, such as the Instance Metadata Service (IMDS) and the Amazon DNS server. You can use a CIDR block that is larger than but overlaps 169.254.169.0/22, but packets destined for addresses in 169.254.169.0/22 will not be forwarded.
- You can’t add routes to IPv6 addresses that are an exact match or a subset of the following range: fd00:ec2::/32. This range is within the unique local address (ULA) space and is reserved for use by AWS services. For example, Amazon EC2 uses addresses in this range for services that are accessible only from EC2 instances, such as the Instance Metadata Service (IMDS) and the Amazon DNS server. You can use a CIDR block that is larger than but overlaps fd00:ec2::/32, but packets destined for addresses in fd00:ec2::/32 will not be forwarded.
- You can add middlebox appliances to the routing paths for your VPC. For more information, see the section called “Routing for a middlebox appliance” (p. 88).

Example

In the following example, suppose that the VPC has both an IPv4 CIDR block and an IPv6 CIDR block. In the route table:

- IPv6 traffic destined to remain within the VPC (2001:db8:1234:1a00::/56) is covered by the Local route, and is routed within the VPC.
Subnet route tables

- IPv4 and IPv6 traffic are treated separately; therefore, all IPv6 traffic (except for traffic within the VPC) is routed to the egress-only internet gateway.
- There is a route for 172.31.0.0/16 IPv4 traffic that points to a peering connection.
- There is a route for all IPv4 traffic (0.0.0.0/0) that points to an internet gateway.
- There is a route for all IPv6 traffic (::/0) that points to an egress-only internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>Local</td>
</tr>
<tr>
<td>172.31.0.0/16</td>
<td>pcx-112233455677889</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-12345678901234567</td>
</tr>
<tr>
<td>::/0</td>
<td>eigw-aabbccddeee1122334</td>
</tr>
</tbody>
</table>

Main route table

When you create a VPC, it automatically has a main route table. When a subnet does not have an explicit routing table associated with it, the main routing table is used by default. On the Route tables page in the Amazon VPC console, you can view the main route table for a VPC by looking for Yes in the Main column.

By default, when you create a nondefault VPC, the main route table contains only a local route. If you Create a VPC and choose a NAT gateway, Amazon VPC automatically adds routes to the main route table for the gateways.

The following rules apply to the main route table:

- You cannot delete the main route table.
- You cannot set a gateway route table as the main route table.
- You can replace the main route table with a custom subnet route table.
- You can add, remove, and modify routes in the main route table.
- You can explicitly associate a subnet with the main route table, even if it’s already implicitly associated.

You might want to do that if you change which table is the main route table. When you change which table is the main route table, it also changes the default for additional new subnets, or for any subnets that are not explicitly associated with any other route table. For more information, see Replace the main route table (p. 96).

Custom route tables

By default, a custom route table is empty and you add routes as needed. If you Create a VPC and choose a public subnet, Amazon VPC creates a custom route table and adds a route that points to the internet gateway. One way to protect your VPC is to leave the main route table in its original default state. Then, explicitly associate each new subnet that you create with one of the custom route tables you’ve created. This ensures that you explicitly control how each subnet routes traffic.

You can add, remove, and modify routes in a custom route table. You can delete a custom route table only if it has no associations.
Subnet route table association

Each subnet in your VPC must be associated with a route table. A subnet can be explicitly associated with custom route table, or implicitly or explicitly associated with the main route table. For more information about viewing your subnet and route table associations, see [Determine which subnets and or gateways are explicitly associated](p. 93).

Subnets that are in VPCs associated with Outposts can have an additional target type of a local gateway. This is the only routing difference from non-Outposts subnets.

**Example 1: Implicit and explicit subnet association**

The following diagram shows the routing for a VPC with an internet gateway, a virtual private gateway, a public subnet, and a VPN-only subnet.

![Diagram of VPC routing](image)

Route table A is a custom route table that is explicitly associated with the public subnet. It has a route that sends all traffic to the internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-id</td>
</tr>
</tbody>
</table>

Route table B is the main route table. It has a route that sends all traffic to the virtual private gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Local</td>
</tr>
</tbody>
</table>
If you create a new subnet in this VPC, it’s automatically implicitly associated with the main route table, which routes traffic to the virtual private gateway. If you set up the reverse configuration (where the main route table has the route to the internet gateway, and the custom route table has the route to the virtual private gateway), then traffic to the new subnet is routed to the internet gateway.

**Example 2: Replacing the main route table**

You might want to make changes to the main route table. To avoid any disruption to your traffic, we recommend that you first test the route changes using a custom route table. After you're satisfied with the testing, you can replace the main route table with the new custom table.

The following diagram shows a VPC with two subnets that are implicitly associated with the main route table (Route Table A), and a custom route table (Route Table B) that isn't associated with any subnets.

![Diagram of VPC with two subnets and two route tables](image)

You can create an explicit association between Subnet 2 and Route Table B.

![Diagram of explicit association between Subnet 2 and Route Table B](image)

After you've tested Route Table B, you can make it the main route table. Note that Subnet 2 still has an explicit association with Route Table B, and Subnet 1 has an implicit association with Route Table B because it is the new main route table. Route Table A is no longer in use.
If you disassociate Subnet 2 from Route Table B, there's still an implicit association between Subnet 2 and Route Table B. If you no longer need Route Table A, you can delete it.

Gateway route tables

You can associate a route table with an internet gateway or a virtual private gateway. When a route table is associated with a gateway, it's referred to as a gateway route table. You can create a gateway route table for fine-grain control over the routing path of traffic entering your VPC. For example, you can intercept the traffic that enters your VPC through an internet gateway by redirecting that traffic to a middlebox appliance (such as a security appliance) in your VPC.

Contents

- Gateway route table routes (p. 80)
- Rules and considerations (p. 81)

Gateway route table routes

A gateway route table associated with an internet gateway supports routes with the following targets:

- The default local route
- A Gateway Load Balancer endpoint
A network interface for a middlebox appliance

A gateway route table associated with a virtual private gateway supports routes with the following targets:

- The default local route
- A network interface for a middlebox appliance

When the target is a Gateway Load Balancer endpoint or a network interface, the following destinations are allowed:

- The entire IPv4 or IPv6 CIDR block of your VPC. In this case, you replace the target of the default local route.
- The entire IPv4 or IPv6 CIDR block of a subnet in your VPC. This is a more specific route than the default local route.

If you change the target of the local route in a gateway route table to a network interface in your VPC, you can later restore it to the default local target. For more information, see Replace or restore the target for a local route (p. 98).

Example

In the following gateway route table, traffic destined for a subnet with the 172.31.0.0/20 CIDR block is routed to a specific network interface. Traffic destined for all other subnets in the VPC uses the local route.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.31.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>172.31.0.0/20</td>
<td>eni-id</td>
</tr>
</tbody>
</table>

Example

In the following gateway route table, the target for the local route is replaced with a network interface ID. Traffic destined for all subnets within the VPC is routed to the network interface.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.31.0.0/16</td>
<td>eni-id</td>
</tr>
</tbody>
</table>

Rules and considerations

You cannot associate a route table with a gateway if any of the following applies:

- The route table contains existing routes with targets other than a network interface, Gateway Load Balancer endpoint, or the default local route.
- The route table contains existing routes to CIDR blocks outside of the ranges in your VPC.
- Route propagation is enabled for the route table.

In addition, the following rules and considerations apply:
Route priority

In general, we direct traffic using the most specific route that matches the traffic. This is known as the longest prefix match. If your route table has overlapping or matching routes, additional rules apply.

Contents

• Longest prefix match (p. 82)
• Route priority and propagated routes (p. 83)
• Route priority and prefix lists (p. 83)

Longest prefix match

Routes to IPv4 and IPv6 addresses or CIDR blocks are independent of each other. We use the most specific route that matches either IPv4 traffic or IPv6 traffic to determine how to route the traffic.

The following example subnet route table has a route for IPv4 internet traffic (0.0.0.0/0) that points to an internet gateway, and a route for 172.31.0.0/16 IPv4 traffic that points to a peering connection (pcx-11223344556677889). Any traffic from the subnet that's destined for the 172.31.0.0/16 IP address range uses the peering connection, because this route is more specific than the route for internet gateway. Any traffic destined for a target within the VPC (10.0.0.0/16) is covered by the local route, and therefore is routed within the VPC. All other traffic from the subnet uses the internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>172.31.0.0/16</td>
<td>pcx-11223344556677889</td>
</tr>
</tbody>
</table>
Route priority and propagated routes

If you've attached a virtual private gateway to your VPC and enabled route propagation on your subnet route table, routes representing your Site-to-Site VPN connection automatically appear as propagated routes in your route table.

If the destination of a propagated route overlaps a static route, the static route takes priority.

If the destination of a propagated route is identical to the destination of a static route, the static route takes priority if the target is one of the following:

- internet gateway
- NAT gateway
- Network interface
- Instance ID
- Gateway VPC endpoint
- Transit gateway
- VPC peering connection
- Gateway Load Balancer endpoint

For more information, see Route tables and VPN route priority in the AWS Site-to-Site VPN User Guide.

The following example route table has a static route to an internet gateway and a propagated route to a virtual private gateway. Both routes have a destination of 172.31.0.0/24. Because a static route to an internet gateway takes priority, all traffic destined for 172.31.0.0/24 is routed to the internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Propagated</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>igw-12345678901234567</td>
<td>No</td>
</tr>
</tbody>
</table>

Route priority and prefix lists

If your route table references a prefix list, the following rules apply:

- If your route table contains a static route with a destination CIDR block that overlaps a static route with a prefix list, the static route with the CIDR block takes priority.
- If your route table contains a propagated route that matches a route that references a prefix list, the route that references the prefix list takes priority. Please note that for routes that overlap, more specific routes always take priority irrespective of whether they are propagated routes, static routes, or routes that reference prefix lists.
- If your route table references multiple prefix lists that have overlapping CIDR blocks to different targets, we randomly choose which route takes priority. Thereafter, the same route always takes priority.
If the CIDR block in a prefix list entry is not valid for the route table, that CIDR block is ignored.

route table quotas

There is a quota on the number of route tables that you can create per VPC. There is also a quota on the number of routes that you can add per route table. For more information, see Amazon VPC quotas (p. 353).

Example routing options

The following topics describe routing for specific gateways or connections in your VPC.

Contents

- Routing to an internet gateway (p. 84)
- Routing to a NAT device (p. 84)
- Routing to a virtual private gateway (p. 85)
- Routing to an AWS Outposts local gateway (p. 85)
- Routing to a VPC peering connection (p. 85)
- Routing to a gateway VPC endpoint (p. 87)
- Routing to an egress-only internet gateway (p. 87)
- Routing for a transit gateway (p. 87)
- Routing for a middlebox appliance (p. 88)
- Routing using a prefix list (p. 91)
- Routing to a Gateway Load Balancer endpoint (p. 92)

Routing to an internet gateway

You can make a subnet a public subnet by adding a route in your subnet route table to an internet gateway. To do this, create and attach an internet gateway to your VPC, and then add a route with a destination of 0.0.0.0/0 for IPv4 traffic or ::/0 for IPv6 traffic, and a target of the internet gateway ID (igw-xxxxxxxxxxxxxxxxxx).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>igw-id</td>
</tr>
<tr>
<td>::/0</td>
<td>igw-id</td>
</tr>
</tbody>
</table>

For more information, see Connect to the internet using an internet gateway (p. 128).

Routing to a NAT device

To enable instances in a private subnet to connect to the internet, you can create a NAT gateway or launch a NAT instance in a public subnet. Then add a route for the private subnet's route table that routes IPv4 internet traffic (0.0.0.0/0) to the NAT device.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>nat-gateway-id</td>
</tr>
</tbody>
</table>
You can also create more specific routes to other targets to avoid unnecessary data processing charges for using a NAT gateway, or to route certain traffic privately. In the following example, Amazon S3 traffic (pl-xxxxxxxx; a specific IP address range for Amazon S3) is routed to a gateway VPC endpoint, and 10.25.0.0/16 traffic is routed to a VPC peering connection. The pl-xxxxxxxx and 10.25.0.0/16 IP address ranges are more specific than 0.0.0.0/0. When instances send traffic to Amazon S3 or the peer VPC, the traffic is sent to the gateway VPC endpoint or the VPC peering connection. All other traffic is sent to the NAT gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>nat-gateway-id</td>
</tr>
<tr>
<td>pl-xxxxxxxx</td>
<td>vpce-id</td>
</tr>
<tr>
<td>10.25.0.0/16</td>
<td>pcx-id</td>
</tr>
</tbody>
</table>

For more information, see NAT gateways (p. 143) and NAT instances (p. 168). NAT devices cannot be used for IPv6 traffic.

**Routing to a virtual private gateway**

You can use an AWS Site-to-Site VPN connection to enable instances in your VPC to communicate with your own network. To do this, create and attach a virtual private gateway to your VPC. Then add a route in your subnet route table with the destination of your network and a target of the virtual private gateway (vgw-xxxxxxxxxxxxxxxx).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>vgw-id</td>
</tr>
</tbody>
</table>

You can then create and configure your Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN? and Route tables and VPN route priority in the AWS Site-to-Site VPN User Guide.

A Site-to-Site VPN connection on a virtual private gateway does not support IPv6 traffic. However, we support IPv6 traffic routed through a virtual private gateway to an AWS Direct Connect connection. For more information, see the AWS Direct Connect User Guide.

**Routing to an AWS Outposts local gateway**

Subnets that are in VPCs associated with AWS Outposts can have an additional target type of a local gateway. Consider the case where you want to have the local gateway route traffic with a destination address of 192.168.10.0/24 to the customer network. To do this, add the following route with the destination network and a target of the local gateway (lgw-x).  

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.10.0/24</td>
<td>lgw-id</td>
</tr>
</tbody>
</table>

**Routing to a VPC peering connection**

A VPC peering connection is a networking connection between two VPCs that allows you to route traffic between them using private IPv4 addresses. Instances in either VPC can communicate with each other as if they are part of the same network.
To enable the routing of traffic between VPCs in a VPC peering connection, you must add a route to one or more of your subnet route tables that points to the VPC peering connection. This allows you to access all or part of the CIDR block of the other VPC in the peering connection. Similarly, the owner of the other VPC must add a route to their subnet route table to route traffic back to your VPC.

For example, you have a VPC peering connection (pcx-11223344556677889) between two VPCs, with the following information:

- VPC A: CIDR block is 10.0.0.0/16
- VPC B: CIDR block is 172.31.0.0/16

To enable traffic between the VPCs and allow access to the entire IPv4 CIDR block of either VPC, the VPC A route table is configured as follows.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>172.31.0.0/16</td>
<td>pcx-11223344556677889</td>
</tr>
</tbody>
</table>

The VPC B route table is configured as follows.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.31.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>10.0.0.0/16</td>
<td>pcx-11223344556677889</td>
</tr>
</tbody>
</table>

Your VPC peering connection can also support IPv6 communication between instances in the VPCs, if the VPCs and instances are enabled for IPv6 communication. To enable the routing of IPv6 traffic between VPCs, you must add a route to your route table that points to the VPC peering connection to access all or part of the IPv6 CIDR block of the peer VPC.

For example, using the same VPC peering connection (pcx-11223344556677889) above, assume the VPCs have the following information:

- VPC A: IPv6 CIDR block is 2001:db8:1234:1a00::/56
- VPC B: IPv6 CIDR block is 2001:db8:5678:2b00::/56

To enable IPv6 communication over the VPC peering connection, add the following route to the subnet route table for VPC A.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>172.31.0.0/16</td>
<td>pcx-11223344556677889</td>
</tr>
<tr>
<td>2001:db8:5678:2b00::/56</td>
<td>pcx-11223344556677889</td>
</tr>
</tbody>
</table>

Add the following route to the route table for VPC B.
Example routing options

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.31.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>10.0.0.0/16</td>
<td>pcx-112233455677889</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>pcx-112233455677889</td>
</tr>
</tbody>
</table>

For more information about VPC peering connections, see the Amazon VPC Peering Guide.

Routing to a gateway VPC endpoint

A gateway VPC endpoint enables you to create a private connection between your VPC and another AWS service. When you create a gateway endpoint, you specify the subnet route tables in your VPC that are used by the gateway endpoint. A route is automatically added to each of the route tables with a destination that specifies the prefix list ID of the service (pl-xxxxxxxx), and a target with the endpoint ID (vpce-xxxxxxxxxxxxxxxxxx). You cannot explicitly delete or modify the endpoint route, but you can change the route tables that are used by the endpoint.

For more information about routing for endpoints, and the implications for routes to AWS services, see Routing for gateway endpoints.

Routing to an egress-only internet gateway

You can create an egress-only internet gateway for your VPC to enable instances in a private subnet to initiate outbound communication to the internet, but prevent the internet from initiating connections with the instances. An egress-only internet gateway is used for IPv6 traffic only. To configure routing for an egress-only internet gateway, add a route in the private subnet's route table that routes IPv6 internet traffic (::/0) to the egress-only internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>::/0</td>
<td>eigw-id</td>
</tr>
</tbody>
</table>

For more information, see Enable outbound IPv6 traffic using an egress-only internet gateway (p. 139).

Routing for a transit gateway

When you attach a VPC to a transit gateway, you need to add a route to your subnet route table for traffic to route through the transit gateway.

Consider the following scenario where you have three VPCs that are attached to a transit gateway. In this scenario, all attachments are associated with the transit gateway route table and propagate to the transit gateway route table. Therefore, all attachments can route packets to each other, with the transit gateway serving as a simple layer 3 IP hub.

For example, you have two VPCs, with the following information:

- VPC A: 10.1.0.0/16, attachment ID tgw-attach-1111111111111111
- VPC B: 10.2.0.0/16, attachment ID tgw-attach-2222222222222222

To enable traffic between the VPCs and allow access to the transit gateway, the VPC A route table is configured as follows.
Example routing options

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.1.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>10.0.0.0/8</td>
<td>tgw-id</td>
</tr>
</tbody>
</table>

The following is an example of the transit gateway route table entries for the VPC attachments.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.1.0.0/16</td>
<td>tgw-attach-11111111111111111</td>
</tr>
<tr>
<td>10.2.0.0/16</td>
<td>tgw-attach-22222222222222222</td>
</tr>
</tbody>
</table>

For more information about transit gateway route tables, see Routing in Amazon VPC Transit Gateways.

Routing for a middlebox appliance

You can add middlebox appliances into the routing paths for your VPC. The following are possible use cases:

- Intercept traffic that enters your VPC through an internet gateway or a virtual private gateway by directing it to a middlebox appliance in your VPC. You can use the middlebox routing wizard to have AWS automatically configure the appropriate route tables for your gateway, middlebox, and destination subnet. For more information, see the section called “Middlebox routing wizard” (p. 99).

- Direct traffic between two subnets to a middlebox appliance. You can do so by creating a route for one subnet route table that matches the subnet CIDR of the other subnet and specifies a Gateway Load Balancer endpoint, NAT gateway, Network Firewall endpoint, or the network interface for an appliance as a target. Alternatively, to redirect all traffic from the subnet to any other subnet, replace the target of the local route with a Gateway Load Balancer endpoint, NAT gateway, or network interface.

You can configure the appliance to suit your needs. For example, you can configure a security appliance that screens all traffic, or a WAN acceleration appliance. The appliance is deployed as an Amazon EC2 instance in a subnet in your VPC, and is represented by an elastic network interface (network interface) in your subnet.

If you enable route propagation for the destination subnet route table, be aware of route priority. We prioritize the most specific route, and if the routes match, we prioritize static routes over propagated routes. Review your routes to ensure that traffic is routed correctly and that there are no unintended consequences if you enable or disable route propagation (for example, route propagation is required for an AWS Direct Connect connection that supports jumbo frames).

To route inbound VPC traffic to an appliance, you associate a route table with the internet gateway or virtual private gateway, and specify the network interface of your appliance as the target for VPC traffic. For more information, see Gateway route tables (p. 80). You can also route outbound traffic from your subnet to a middlebox appliance in another subnet.

For middlebox routing examples, see Middlebox scenarios (p. 102).

Contents
- Appliance considerations (p. 89)
- Routing traffic between a gateway and an appliance (p. 89)
• Routing inter-subnet traffic to an appliance (p. 90)

Appliance considerations

You can choose a third-party appliance from AWS Marketplace, or you can configure your own appliance. When you create or configure an appliance, take note of the following:

• The appliance must be configured in a separate subnet to the source or destination traffic.

• You must disable source/destination checking on the appliance. For more information, see Changing the Source or Destination Checking in the Amazon EC2 User Guide for Linux Instances.

• You cannot route traffic between hosts in the same subnet through an appliance.

• The appliance does not have to perform network address translation (NAT).

• You can add a route to your route tables that is more specific than the local route. You can use more specific routes to redirect traffic between subnets within a VPC (East-West traffic) to a middlebox appliance. The destination of the route must match the entire IPv4 or IPv6 CIDR block of a subnet in your VPC.

• To intercept IPv6 traffic, ensure that you configure your VPC, subnet, and appliance for IPv6. For more information, see Work with VPCs (p. 18). Virtual private gateways do not support IPv6 traffic.

Routing traffic between a gateway and an appliance

To route inbound VPC traffic to an appliance, you associate a route table with the internet gateway or virtual private gateway, and specify the network interface of your appliance as the target for VPC traffic. In the following example, the VPC has an internet gateway, an appliance, and a subnet with instances. Traffic from the internet is routed through an appliance.

Associate this route table with your internet gateway or virtual private gateway. The first entry is the local route. The second entry sends IPv4 traffic destined for the subnet to the network interface for the appliance. This route is more specific than the local route.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Local</td>
</tr>
<tr>
<td>Subnet CIDR</td>
<td>Appliance network interface ID</td>
</tr>
</tbody>
</table>

Alternatively, you can replace the target for the local route with the network interface of the appliance. You can do this to ensure that all traffic is automatically routed to the appliance, including traffic destined for subnets that you add to the VPC in the future.
Example routing options

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Appliance network interface ID</td>
</tr>
</tbody>
</table>

To route traffic from your subnet to an appliance in another subnet, add a route to your subnet route table that routes traffic to the appliance's network interface. The destination must be less specific than the destination for the local route. For example, for traffic destined for the internet, specify 0.0.0.0/0 (all IPv4 addresses) for the destination.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>Appliance network interface ID</td>
</tr>
</tbody>
</table>

Then, in the route table associated with the appliance's subnet, add a route that sends the traffic back to the internet gateway or virtual private gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-id</td>
</tr>
</tbody>
</table>

Routing inter-subnet traffic to an appliance

You can route traffic destined for a specific subnet to the network interface of an appliance. In the following example, the VPC contains two subnets and an appliance. Traffic between the subnets is routed through an appliance.

Security groups

When you route traffic between instances in different subnets through a middlebox appliance, the security groups for both instances must allow traffic to flow between the instances. The security group for each instance must reference the private IP address of the other instance, or the CIDR range of the subnet that contains the other instance, as the source. If you reference the security group of the other instance as the source, this does not allow traffic to flow between the instances.

Routing
The following is an example route table for subnet A. The first entry enables instances in the VPC to communicate with each other. The second entry routes all traffic from subnet A to subnet B to the network interface of the appliance.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Local</td>
</tr>
<tr>
<td>Subnet B CIDR</td>
<td>Appliance network interface ID</td>
</tr>
</tbody>
</table>

The following is an example route table for subnet B. The first entry enables instances in the VPC to communicate with each other. The second entry routes all traffic from subnet B to subnet A to the network interface of the appliance.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Local</td>
</tr>
<tr>
<td>Subnet A CIDR</td>
<td>Appliance network interface ID</td>
</tr>
</tbody>
</table>

Alternatively, you can replace the target for the local route with the network interface of the appliance. You can do this to ensure that all traffic is automatically routed to the appliance, including traffic destined for subnets that you add to the VPC in the future.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Appliance network interface ID</td>
</tr>
</tbody>
</table>

Routing using a prefix list

If you frequently reference the same set of CIDR blocks across your AWS resources, you can create a customer-managed prefix list (p. 65) to group them together. You can then specify the prefix list as the destination in your route table entry. You can later add or remove entries for the prefix list without needing to update your route tables.

For example, you have a transit gateway with multiple VPC attachments. The VPCs must be able to communicate with two specific VPC attachments that have the following CIDR blocks:

- 10.0.0.0/16
- 10.2.0.0/16

You create a prefix list with both entries. In your subnet route tables, you create a route and specify the prefix list as the destination, and the transit gateway as the target.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.31.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>pl-123abc123abc123ab</td>
<td>tgw-id</td>
</tr>
</tbody>
</table>

The maximum number of entries for the prefix lists equals the same number of entries in the route table.
Routing to a Gateway Load Balancer endpoint

A Gateway Load Balancer enables you to distribute traffic to a fleet of virtual appliances, such as firewalls. You can configure the load balancer as a service by creating a VPC endpoint service configuration. You then create a Gateway Load Balancer endpoint in your VPC to connect your VPC to the service.

To route your traffic to the Gateway Load Balancer (for example, for security inspection), specify the Gateway Load Balancer endpoint as a target in your route tables.

For an example of a security appliances behind a Gateway Load Balancer, see the section called “Inspect traffic using security appliances” (p. 104).

To specify the Gateway Load Balancer endpoint in the route table, use the ID of the VPC endpoint. For example to route traffic for 10.0.1.0/24 to a Gateway Load Balancer endpoint, add the following route.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.1.0/24</td>
<td>vpc-endpoint-id</td>
</tr>
</tbody>
</table>

For more information, see Gateway Load Balancers.

Work with route tables

This section explains how to work with route tables.

Contents
- Determine the route table for a subnet (p. 92)
- Determine which subnets and or gateways are explicitly associated (p. 93)
- Create a custom route table (p. 93)
- Add and remove routes from a route table (p. 94)
- Enable or disable route propagation (p. 94)
- Associate a subnet with a route table (p. 95)
- Change the route table for a subnet (p. 95)
- Disassociate a subnet from a route table (p. 96)
- Replace the main route table (p. 96)
- Associate a gateway with a route table (p. 97)
- Disassociate a gateway from a route table (p. 97)
- Replace or restore the target for a local route (p. 98)
- Delete a route table (p. 98)

Determine the route table for a subnet

You can determine which route table a subnet is associated with by looking at the subnet details in the Amazon VPC console.

To determine the route table for a subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select the subnet.
4. Choose the Route table tab to view information about the route table and its routes. To determine whether the association is to the main route table, and if that association is explicit, see Determine which subnets and or gateways are explicitly associated (p. 93).

Determine which subnets and or gateways are explicitly associated

You can determine how many and which subnets or gateways are explicitly associated with a route table.

The main route table can have explicit and implicit subnet associations. Custom route tables have only explicit associations.

Subnets that aren’t explicitly associated with any route table have an implicit association with the main route table. You can explicitly associate a subnet with the main route table. For an example of why you might do that, see Replace the main route table (p. 96).

To determine which subnets are explicitly associated using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables.
3. Check the Explicit subnet association column to determine the explicitly associated subnets and the Main column to determine whether this is the main route table.
4. Select the route table and choose the Subnet associations tab.
5. The subnets under Explicit subnet associations are explicitly associated with the route table. The subnets under Subnets without explicit associations belong to the same VPC as the route table, but are not associated with any route table, so they are implicitly associated with the main route table for the VPC.

To determine which gateways are explicitly associated using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables.
3. Select the route table and choose the Edge associations tab.

To describe one or more route tables and view its associations using the command line

- describe-route-tables (AWS CLI)
- Get-EC2RouteTable (AWS Tools for Windows PowerShell)

Create a custom route table

You can create a custom route table for your VPC using the Amazon VPC console.

To create a custom route table using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables.
3. Choose Create route table.
4. (Optional) For Name, enter a name for your route table.
5. For VPC, choose your VPC.
6. (Optional) To add a tag, choose Add new tag and enter the tag key and tag value.
7. Choose Create route table.

To create a custom route table using the command line

- create-route-table (AWS CLI)
- New-EC2RouteTable (AWS Tools for Windows PowerShell)

Add and remove routes from a route table

You can add, delete, and modify routes in your route tables. You can only modify routes that you've added.

For more information about working with static routes for a Site-to-Site VPN connection, see Editing Static Routes for a Site-to-Site VPN Connection in the AWS Site-to-Site VPN User Guide.

To update the routes for a route table using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and select the route table.
3. Choose Actions, Edit routes.
4. To add a route, choose Add route. For Destination enter the destination CIDR block, a single IP address, or the ID of a prefix list.
5. To modify a route, for Destination, replace the destination CIDR block or single IP address. For Target, choose a target.
6. To delete a route, choose Remove.
7. Choose Save changes.

To update the routes for a route table using the command line

- create-route (AWS CLI)
- replace-route (AWS CLI)
- delete-route (AWS CLI)
- New-EC2Route (AWS Tools for Windows PowerShell)
- Set-EC2Route (AWS Tools for Windows PowerShell)
- Remove-EC2Route (AWS Tools for Windows PowerShell)

**Note**
If you add a route using a command line tool or the API, the destination CIDR block is automatically modified to its canonical form. For example, if you specify 100.68.0.18/18 for the CIDR block, we create a route with a destination CIDR block of 100.68.0.0/18.

Enable or disable route propagation

Route propagation allows a virtual private gateway to automatically propagate routes to the route tables. This means that you don't need to manually enter VPN routes to your route tables. You can enable or disable route propagation.

To complete this process, you must have a virtual private gateway.
For more information about VPN routing options, see Site-to-Site VPN routing options in the Site-to-Site VPN User Guide.

**To enable route propagation using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and then select the route table.
3. Choose Actions, Edit route propagation.
4. Select the Enable check box next to the virtual private gateway, and then choose Save.

**To enable route propagation using the command line**

- `enable-vgw-route-propagation` (AWS CLI)
- `Enable-EC2VgwRoutePropagation` (AWS Tools for Windows PowerShell)

**To disable route propagation using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and then select the route table.
3. Choose Actions, Edit route propagation.
4. Clear the Enable check box next to the virtual private gateway, and then choose Save.

**To disable route propagation using the command line**

- `disable-vgw-route-propagation` (AWS CLI)
- `Disable-EC2VgwRoutePropagation` (AWS Tools for Windows PowerShell)

**Associate a subnet with a route table**

To apply route table routes to a particular subnet, you must associate the route table with the subnet. A route table can be associated with multiple subnets. However, a subnet can only be associated with one route table at a time. Any subnet not explicitly associated with a table is implicitly associated with the main route table by default.

**To associate a route table with a subnet using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and then select the route table.
3. On the Subnet associations tab, choose Edit subnet associations.
4. Select the check box for the subnet to associate with the route table.
5. Choose Save associations.

**To associate a subnet with a route table using the command line**

- `associate-route-table` (AWS CLI)
- `Register-EC2RouteTable` (AWS Tools for Windows PowerShell)

**Change the route table for a subnet**

You can change the route table association for a subnet.
When you change the route table, your existing connections in the subnet are dropped unless the new route table contains a route for the same traffic to the same target.

**To change a subnet route table association using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets, and then select the subnet.
3. From the Route table tab, choose Edit route table association.
4. For Route table ID, select the new route table.
5. Choose Save.

**To change the route table associated with a subnet using the command line**

- replace-route-table-association (AWS CLI)
- Set-EC2RouteTableAssociation (AWS Tools for Windows PowerShell)

**Disassociate a subnet from a route table**

You can disassociate a subnet from a route table. Until you associate the subnet with another route table, it's implicitly associated with the main route table.

**To disassociate a subnet from a route table using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and then select the route table.
3. From the Subnet associations tab, choose Edit subnet associations.
4. Clear the check box for the subnet.
5. Choose Save associations.

**To disassociate a subnet from a route table using the command line**

- disassociate-route-table (AWS CLI)
- Unregister-EC2RouteTable (AWS Tools for Windows PowerShell)

**Replace the main route table**

You can change which route table is the main route table in your VPC.

**To replace the main route table using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and then select the new main route table.
3. Choose Actions, Set main route table.
4. When prompted for confirmation, enter set, and then choose OK.

**To replace the main route table using the command line**

- replace-route-table-association (AWS CLI)
• **Set-EC2RouteTableAssociation** (AWS Tools for Windows PowerShell)

The following procedure describes how to remove an explicit association between a subnet and the main route table. The result is an implicit association between the subnet and the main route table. The process is the same as disassociating any subnet from any route table.

**To remove an explicit association with the main route table**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Route tables**, and then select the route table.
3. From the **Subnet associations** tab, choose **Edit subnet associations**.
4. Clear the checkbox for the subnet.
5. Choose **Save associations**.

**Associate a gateway with a route table**

You can associate an internet gateway or a virtual private gateway with a route table. For more information, see **Gateway route tables** (p. 80).

**To associate a gateway with a route table using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Route tables**, and then select the route table.
3. From the **Edge associations** tab, choose **Edit edge associations**.
4. Select the checkbox for the gateway.
5. Choose **Save changes**.

**To associate a gateway with a route table using the AWS CLI**

Use the `associate-route-table` command. The following example associates internet gateway `igw-11aa22bb33cc44dd1` with route table `rtb-01234567890123456`.

```
aws ec2 associate-route-table --route-table-id rtb-01234567890123456 --gateway-id igw-11aa22bb33cc44dd1
```

**Disassociate a gateway from a route table**

You can disassociate an internet gateway or a virtual private gateway from a route table.

**To associate a gateway with a route table using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Route tables**, and then select the route table.
3. From the **Edge associations** tab, choose **Edit edge associations**.
4. Clear the checkbox for the gateway.
5. Choose **Save changes**.

**To disassociate a gateway from a route table using the command line**

• **disassociate-route-table** (AWS CLI)
• Unregister-EC2RouteTable (AWS Tools for Windows PowerShell)

Replace or restore the target for a local route

You can change the target of the default local route. If you replace the target of a local route, you can later restore it to the default local target. If your VPC has multiple CIDR blocks (p. 15), your route tables have multiple local routes—one per CIDR block. You can replace or restore the target of each of the local routes as needed.

To update the local route using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and then select the route table.
3. From the Routes tab, choose Edit routes.
4. For the local route, clear Target and then choose a new target.
5. Choose Save changes.

To restore the target for a local route using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and then select the route table.
3. Choose Actions, Edit routes.
4. For the route, clear Target, and then choose local.
5. Choose Save changes.

To replace the target for a local route using the AWS CLI

Use the replace-route command. The following example replaces the target of the local route with eni-11223344556677889.

```
aws ec2 replace-route --route-table-id rtb-01234567890123456 --destination-cidr-block 10.0.0.0/16 --network-interface-id eni-11223344556677889
```

To restore the target for a local route using the AWS CLI

The following example restores the local target for route table rtb-01234567890123456.

```
aws ec2 replace-route --route-table-id rtb-01234567890123456 --destination-cidr-block 10.0.0.0/16 --local-target
```

Delete a route table

You can delete a route table only if there are no subnets associated with it. You can't delete the main route table.

To delete a route table using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route tables, and then select the route table.
3. Choose **Actions, Delete route table**.
4. When prompted for confirmation, enter **delete**, and then choose **Delete**.

**To delete a route table using the command line**

- `delete-route-table` (AWS CLI)
- `Remove-EC2RouteTable` (AWS Tools for Windows PowerShell)

## Middlebox routing wizard

If you want to configure fine-grain control over the routing path of traffic entering or leaving your VPC, for example, by redirecting traffic to a security appliance, you can use the middlebox routing wizard in the VPC console. The middlebox routing wizard helps you by automatically creating the necessary route tables and routes (hops) to redirect traffic as needed.

The middlebox routing wizard can help you configure routing for the following scenarios:

- Routing traffic to a middlebox appliance, for example, an Amazon EC2 instance that's configured as a security appliance.
- Routing traffic to a Gateway Load Balancer. For more information, see the [User Guide for Gateway Load Balancers](#).

For more information, see the section called "Middlebox scenarios" (p. 102).

### Contents

- Middlebox routing wizard prerequisites (p. 99)
- Manage middlebox routes (p. 99)
- Middlebox routing wizard considerations (p. 101)
- Middlebox scenarios (p. 102)

## Middlebox routing wizard prerequisites

Review the the section called “Middlebox routing wizard considerations” (p. 101). Then, make sure that you have the following information before you use the middlebox routing wizard.

- The VPC.
- The resource where traffic originates from or enters the VPC, for example, an internet gateway, virtual private gateway, or network interface.
- The middlebox network interface or Gateway Load Balancer endpoint.
- The destination subnet for the traffic.

## Manage middlebox routes

The middlebox routing wizard is available in the Amazon Virtual Private Cloud Console.

### Contents

- Create routes using the middlebox routing wizard (p. 100)
- Modify middlebox routes (p. 100)
Create routes using the middlebox routing wizard

To create routes using the middlebox routing wizard

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Select your VPC, and then choose Actions, Manage middlebox routes.
4. Choose Create routes.
5. On the Specify routes page, do the following:
   - For Source, choose the source for your traffic. If you choose a virtual private gateway, for Destination IPv4 CIDR, enter the CIDR for the on-premises traffic entering the VPC from the virtual private gateway.
   - For Middlebox, choose the network interface ID that is associated with your middlebox appliance, or when you use a Gateway Load Balancer endpoint, choose the VPC endpoint ID.
   - For Destination subnet, choose the destination subnet.
6. (Optional) To add another destination subnet, choose Add additional subnet, and then do the following:
   - For Middlebox, choose the network interface ID that is associated with your middlebox appliance, or when you use a Gateway Load Balancer endpoint, choose the VPC endpoint ID.
   - You must use the same middlebox appliance for multiple subnets.
   - For Destination subnet, choose the destination subnet.
7. (Optional) To add another source, choose Add source, and then repeat the previous steps.
8. Choose Next.
9. On the Review and create page, verify the routes and then choose Create routes.

Modify middlebox routes

You can edit your route configuration by changing the gateway, the middlebox, or the destination subnet.

When you make any modifications, the middlebox routing wizard automatically perform the following operations:

- Creates new route tables for the gateway, middlebox, and destination subnet.
- Adds the necessary routes to the new route tables.
- Disassociates the current route tables that the middlebox routing wizard associated with the resources.
- Associates the new route tables that the middlebox routing wizard creates with the resources.

To modify middlebox routes using the middlebox routing wizard

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Select your VPC, and then choose Actions, Manage middlebox routes.
4. Choose **Edit routes**.

5. To change the gateway, for **Source**, choose the gateway through which traffic enters your VPC. If you choose a virtual private gateway, for **Destination IPv4 CIDR**, enter the destination subnet CIDR.

6. To add another destination subnet, choose **Add additional subnet**, and then do the following:
   - For **Middlebox**, choose the network interface ID that is associated with your middlebox appliance, or when you use a Gateway Load Balancer endpoint, choose the VPC endpoint ID.
   - You must use the same middlebox appliance for multiple subnets.
   - For **Destination subnet**, choose the destination subnet.

7. Choose **Next**.

8. On the **Review and update** page, a list of route tables and their routes that will be created by the middlebox routing wizard is displayed. Verify the routes, and then in the confirmation dialog box, choose **Update routes**.

**View the middlebox routing wizard route tables**

**To view the middlebox routing wizard route tables**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Your VPCs**.
3. Select your VPC, and then choose **Actions, Manage middlebox routes**.
4. Under **Middlebox route tables**, the number indicates how many routes the middlebox routing wizard created. Choose the number to view the routes.

We display the middlebox routing wizard routes on a separate route table page.

**Delete the middlebox routing wizard configuration**

If you decide that you no longer want the middlebox routing wizard configuration, you must manually delete the route tables.

**To delete the middlebox routing wizard configuration**

1. View the middlebox routing wizard route tables. For more information, see the section called “View the middlebox routing wizard route tables” (p. 101).

   After you perform the operation, the route tables that the middlebox routing wizard created are displayed on a separate route table page.

2. Delete each route table that is displayed. For more information, see the section called “Delete a route table” (p. 98).

**Middlebox routing wizard considerations**

Take the following into consideration when you use the middlebox routing wizard:

- If you want to inspect traffic, you can use an internet gateway or a virtual private gateway for the source.
- If you use the same middlebox in a multiple middlebox configuration within the same VPC, make sure that the middlebox is in the same hop position for both subnets.
- The appliance must be configured in a separate subnet from the source or destination subnet.
• You must disable source/destination checking on the appliance. For more information, see Changing the Source or Destination Checking in the Amazon EC2 User Guide for Linux Instances.

• The route tables and routes that the middlebox routing wizard creates count toward your quotas. For more information, see the section called “Route tables” (p. 355).

• If you delete a resource, for example a network interface, the route table associations with the resource are removed. If the resource is a target, the route destination is set to blackhole. The route tables are not deleted.

• The middlebox subnet and the destination subnet must be associated with a non-default route table.

  Note
  We recommend that you use the middlebox routing wizard to modify or delete any route tables that you created using the middlebox routing wizard.

Middlebox scenarios

The following examples describe scenarios for the middlebox routing wizard.

Contents

• Inspect traffic destined for a subnet (p. 102)
• Inspect traffic using appliances in a security VPC (p. 104)
• Inspect traffic between subnets (p. 106)

Inspect traffic destined for a subnet

Consider the scenario where you have traffic coming into the VPC through an internet gateway and you want to inspect all traffic that is destined for a subnet, say subnet B, using a firewall appliance installed on an EC2 instance. The firewall appliance should be installed and configured on an EC2 instance in a separate subnet from subnet B in your VPC, say subnet C. You can then use the middlebox routing wizard to configure routes for traffic between subnet B and the internet gateway.

The middlebox routing wizard, automatically performs the following operations:

• Creates the following route tables:
  • A route table for the internet gateway
  • A route table for the destination subnet
  • A route table for the middlebox subnet
• Adds the necessary routes to the new route tables as described in the following sections.
• Disassociates the current route tables associated with the internet gateway, subnet B, and subnet C.
• Associates route table A with the internet gateway (the Source in the middlebox routing wizard), route table C with subnet C (the Middlebox in the middlebox routing wizard), and route table B with subnet B (the Destination in the middlebox routing wizard).
• Creates a tag that indicates it was created by the middlebox routing wizard, and a tag that indicates the creation date.

The middlebox routing wizard does not modify your existing route tables. It creates new route tables, and then associates them with your gateway and subnet resources. If your resources are already explicitly associated with existing route tables, the existing route tables are first disassociated, and then the new route tables are associated with your resources. Your existing route tables are not deleted.

If you do not use the middlebox routing wizard, you must manually configure, and then assign the route tables to the subnets and internet gateway.
Internet gateway route table

Add the following routes to the route table for the internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
<td>Local route for IPv4</td>
</tr>
<tr>
<td>10.0.1.0/24</td>
<td>appliance-eni</td>
<td>Route IPv4 traffic destined for subnet B to the middlebox</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>Local</td>
<td>Local route for IPv6</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/64</td>
<td>appliance-eni</td>
<td>Route IPv6 traffic destined for subnet B to the middlebox</td>
</tr>
</tbody>
</table>

There is an edge association between the internet gateway and the VPC.

When you use the middlebox routing wizard, it associates the following tags with the route table:

- The key is "Origin" and the value is "Middlebox wizard"
- The key is "date_created" and the value is the creation time (for example, "2021-02-18T22:25:49.137Z")

Destination subnet route table

Add the following routes to the route table for the destination subnet (subnet B in the example diagram).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
<td>Local route for IPv4</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>appliance-eni</td>
<td>Route IPv4 traffic destined for the internet to the middlebox</td>
</tr>
</tbody>
</table>
Middlebox subnet route table

Add the following routes to the route table for the middlebox subnet (subnet C in the example diagram).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
<td>Local route for IPv4</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-id</td>
<td>Route IPv4 traffic to the internet gateway</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>Local</td>
<td>Local route for IPv6</td>
</tr>
<tr>
<td>::/0</td>
<td>eigw-id</td>
<td>Route IPv6 traffic to the egress-only internet gateway</td>
</tr>
</tbody>
</table>

There is a subnet association with the destination subnet.

When you use the middlebox routing wizard, it associates the following tags with the route table:

- The key is "Origin" and the value is "Middlebox wizard"
- The key is "date_created" and the value is the creation time (for example, "2021-02-18T22:25:49.137Z")

Inspect traffic using appliances in a security VPC

Consider the scenario where you need to inspect the traffic entering a VPC from the internet gateway and destined for a subnet using a fleet of security appliances configured behind a Gateway Load Balancer. The owner of the service consumer VPC creates a Gateway Load Balancer endpoint in a subnet in their VPC (represented by an endpoint network interface). All traffic entering the VPC through the internet gateway is first routed to the Gateway Load Balancer endpoint for inspection before it's routed to the application subnet. Similarly, all traffic leaving the application subnet is first routed to Gateway Load Balancer endpoint for inspection before it is routed to the internet.

The middlebox routing wizard, automatically performs the following operations:

- Creates the route tables.
- Adds the necessary routes to the new route tables.
- Disassociates the current route tables associated with the subnets.
• Associates the route tables that the middlebox routing wizard creates with the subnets.
• Creates a tag that indicates it was created by the middlebox routing wizard, and a tag that indicates the creation date.

The middlebox routing wizard does not modify your existing route tables. It creates new route tables, and then associates them with your gateway and subnet resources. If your resources are already explicitly associated with existing route tables, the existing route tables are first disassociated, and then the new route tables are associated with your resources. Your existing route tables are not deleted.

If you do not use the middlebox routing wizard, you must manually configure, and then assign the route tables to the subnets and internet gateway.

**Internet gateway route table**

The route table for the internet gateway has the following routes.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Consumer VPC CIDR</td>
<td>Local</td>
<td>Local route</td>
</tr>
<tr>
<td>Application subnet CIDR</td>
<td>endpoint-id</td>
<td>Routes traffic destined for the application subnet to the Gateway Load Balancer endpoint.</td>
</tr>
</tbody>
</table>

There is an edge association with the gateway.

When you use the middlebox routing wizard, it associates the following tags with the route table:

• The key is "Origin" and the value is "Middlebox wizard"
• The key is "date_created" and the value is the creation time (for example, "2021-02-18T22:25:49.137Z")

**Application subnet route table**

The route table for the application subnet has the following routes.
### Middlebox routing wizard

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Consumer VPC CIDR</strong></td>
<td>Local</td>
<td>Local route</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td><strong>endpoint-id</strong></td>
<td>Route traffic from the application servers to the Gateway Load Balancer endpoint before it is routed to the internet.</td>
</tr>
</tbody>
</table>

When you use the middlebox routing wizard, it associates the following tags with the route table:

- The key is "Origin" and the value is "Middlebox wizard"
- The key is "date_created" and the value is the creation time (for example, "2021-02-18T22:25:49.137Z")

### Provider subnet route table

The route table for the provider subnet has the following routes.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Provider VPC CIDR</strong></td>
<td>Local</td>
<td>Local route. Ensures that traffic originating from the internet is routed to the application servers.</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td><strong>igw-id</strong></td>
<td>Routes all traffic to the internet gateway</td>
</tr>
</tbody>
</table>

When you use the middlebox routing wizard, it associates the following tags with the route table:

- The key is "Origin" and the value is "Middlebox wizard"
- The key is "date_created" and the value is the creation time (for example, "2021-02-18T22:25:49.137Z")

### Inspect traffic between subnets

Consider the scenario where you have multiple subnets in a VPC and you want to inspect the traffic between them using a firewall appliance. Configure and install the firewall appliance on an EC2 instance in a separate subnet in your VPC.

The following diagram shows a firewall appliance installed on an EC2 instance in subnet C. The appliance inspects all traffic that travels from subnet A to subnet B (see 1) and from subnet B to subnet A (see 2).
You use the main route table for the VPC and the middlebox subnet. Subnets A and B each have a custom route table.

The middlebox routing wizard, automatically performs the following operations:

• Creates the route tables.
• Adds the necessary routes to the new route tables.
• Disassociates the current route tables associated with the subnets.
• Associates the route tables that the middlebox routing wizard creates with the subnets.
• Creates a tag that indicates it was created by the middlebox routing wizard, and a tag that indicates the creation date.

The middlebox routing wizard does not modify your existing route tables. It creates new route tables, and then associates them with your gateway and subnet resources. If your resources are already explicitly associated with existing route tables, the existing route tables are first disassociated, and then the new route tables are associated with your resources. Your existing route tables are not deleted.

If you do not use the middlebox routing wizard, you must manually configure, and then assign the route tables to the subnets and internet gateway.

**Custom route table for subnet A**

The route table for subnet A has the following routes.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>Local</td>
<td>Local route</td>

Control traffic to subnets using Network ACLs

A network access control list (ACL) allows or denies specific inbound or outbound traffic at the subnet level. You can use the default network ACL for your VPC, or you can create a custom network ACL for your VPC with rules that are similar to the rules for your security groups in order to add an additional layer of security to your VPC.

The following diagram shows a VPC with two subnets. Each subnet has a network ACL. When traffic enters the VPC (for example, from a peered VPCs, VPN connection, or the internet), the router sends
the traffic to its destination. Network ACL A determines which traffic destined for subnet 1 is allowed to enter subnet 1, and which traffic destined for a location outside subnet 1 is allowed to leave subnet 1. Similarly, network ACL B determines which traffic is allowed to enter and leave subnet 2.

For more information about the differences between security groups and network ACLs, see Compare security groups and network ACLs (p. 225).

- Recommended rules for VPC scenarios (p. 126)

Network ACL basics

The following are the basic things that you need to know about network ACLs:

- Your VPC automatically comes with a modifiable default network ACL. By default, it allows all inbound and outbound IPv4 traffic and, if applicable, IPv6 traffic.
- You can create a custom network ACL and associate it with a subnet. By default, each custom network ACL denies all inbound and outbound traffic until you add rules.
Each subnet in your VPC must be associated with a network ACL. If you don't explicitly associate a
subnet with a network ACL, the subnet is automatically associated with the default network ACL.

You can associate a network ACL with multiple subnets. However, a subnet can be associated with only
one network ACL at a time. When you associate a network ACL with a subnet, the previous association
is removed.

A network ACL has inbound rules and outbound rules. Each rule can either allow or deny traffic. Each
rule has a number 1 from to 32766. We evaluate the rules in order, starting with the lowest numbered
rule, when deciding whether allow or deny traffic. If the traffic matches a rule, the rule is applied and
we do not evaluate any additional rules. We recommend that you start by creating rules in increments
(for example, increments of 10 or 100) so that you can insert new rules later on, if needed.

We evaluate the network ACL rules when traffic enters and leaves the subnet, not as it is routed within
a subnet.

Network ACLs are stateless, which means that responses to allowed inbound traffic are subject to the
rules for outbound traffic (and vice versa).

There are quotas (also known as limits) for the number of network ACLs per VPC and the number of rules
per network ACL. For more information, see Amazon VPC quotas (p. 353).

Network ACL rules

You can add or remove rules from the default network ACL, or create additional network ACLs for your
VPC. When you add or remove rules from a network ACL, the changes are automatically applied to the
subnets that it's associated with.

The following are the parts of a network ACL rule:

- **Rule number.** Rules are evaluated starting with the lowest numbered rule. As soon as a rule matches
  traffic, it's applied regardless of any higher-numbered rule that might contradict it.
- **Type.** The type of traffic; for example, SSH. You can also specify all traffic or a custom range.
- **Protocol.** You can specify any protocol that has a standard protocol number. For more information, see
  Protocol Numbers. If you specify ICMP as the protocol, you can specify any or all of the ICMP types and
codes.
- **Port range.** The listening port or port range for the traffic. For example, 80 for HTTP traffic.
- **Source.** [Inbound rules only] The source of the traffic (CIDR range).
- **Destination.** [Outbound rules only] The destination for the traffic (CIDR range).
- **Allow/Deny.** Whether to allow or deny the specified traffic.

If you add a rule using a command line tool or the Amazon EC2 API, the CIDR range is automatically
modified to its canonical form. For example, if you specify 100.68.0.18/18 for the CIDR range, we
create a rule with a 100.68.0.0/18 CIDR range.

Default network ACL

The default network ACL is configured to allow all traffic to flow in and out of the subnets with which it
is associated. Each network ACL also includes a rule whose rule number is an asterisk. This rule ensures
that if a packet doesn't match any of the other numbered rules, it's denied. You can't modify or remove
this rule.

The following is an example default network ACL for a VPC that supports IPv4 only.

<table>
<thead>
<tr>
<th>Inbound</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule #</td>
<td>Type</td>
<td>Protocol</td>
<td>Port range</td>

<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule #</td>
<td>Type</td>
<td>Protocol</td>
<td>Port range</td>
<td>Source</td>
</tr>
</tbody>
</table>

110
If you create a VPC with an IPv6 CIDR block or if you associate an IPv6 CIDR block with your existing VPC, we automatically add rules that allow all IPv6 traffic to flow in and out of your subnet. We also add rules whose rule numbers are an asterisk that ensures that a packet is denied if it doesn’t match any of the other numbered rules. You can’t modify or remove these rules. The following is an example default network ACL for a VPC that supports IPv4 and IPv6.

**Note**
If you’ve modified your default network ACL’s inbound rules, we do not automatically add an allow rule for inbound IPv6 traffic when you associate an IPv6 block with your VPC. Similarly, if you’ve modified the outbound rules, we do not automatically add an allow rule for outbound IPv6 traffic.

</tbody>
</table>

**Custom network ACL**

The following table shows an example of a custom network ACL for a VPC that supports IPv4 only. It includes rules that allow HTTP and HTTPS traffic in (inbound rules 100 and 110). There’s a corresponding outbound rule that enables responses to that inbound traffic (outbound rule 140, which covers ephemeral ports 32768-65535). For more information about how to select the appropriate ephemeral port range, see Ephemeral ports (p. 120).

The network ACL also includes inbound rules that allow SSH and RDP traffic into the subnet. The outbound rule 120 enables responses to leave the subnet.
The network ACL has outbound rules (100 and 110) that allow outbound HTTP and HTTPS traffic out of the subnet. There's a corresponding inbound rule that enables responses to that outbound traffic (inbound rule 140, which covers ephemeral ports 32768-65535).

**Note**
Each network ACL includes a default rule whose rule number is an asterisk. This rule ensures that if a packet doesn't match any of the other rules, it's denied. You can't modify or remove this rule.

<td></td>
<td></td>
</tr>
<tr>
<td>*</td>
<td>All traffic</td>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

Allows outbound IPv4 responses to clients on the internet (for example, serving webpages to people visiting the web servers in the subnet).

This range is an example only. For more information about how to select the appropriate ephemeral port range, see Ephemeral ports (p. 120).

Denies all outbound IPv4 traffic not already handled by a preceding rule (not modifiable).

As a packet comes to the subnet, we evaluate it against the inbound rules of the ACL that the subnet is associated with (starting at the top of the list of rules, and moving to the bottom). Here's how the evaluation goes if the packet is destined for the HTTPS port (443). The packet doesn't match the first rule evaluated (rule 100). It does match the second rule (110), which allows the packet into the subnet.

If the packet had been destined for port 139 (NetBIOS), it doesn't match any of the rules, and the * rule ultimately denies the packet.

You might want to add a deny rule in a situation where you legitimately need to open a wide range of ports, but there are certain ports within the range that you want to deny. Just make sure to place the deny rule earlier in the table than the rule that allows the wide range of port traffic.

You add allow rules depending on your use case. For example, you can add a rule that allows outbound TCP and UDP access on port 53 for DNS resolution. For every rule that you add, ensure that there is a corresponding inbound or outbound rule that allows response traffic.

The following table shows the same example of a custom network ACL for a VPC that has an associated IPv6 CIDR block. This network ACL includes rules for all IPv6 HTTP and HTTPS traffic. In this case, new rules were inserted between the existing rules for IPv4 traffic. You can also add the rules as higher
number rules after the IPv4 rules. IPv4 and IPv6 traffic are separate, and therefore none of the rules for the IPv4 traffic apply to the IPv6 traffic.

<table>
<thead>

| 140 | Custom TCP | TCP | 32768-65535 | 0.0.0.0/0 | ALLOW | Allows outbound IPv4 responses to clients on the internet (for example, serving webpages to people visiting the web servers in the subnet). This range is an example only. For more information about how to select the appropriate ephemeral port range, see Ephemeral ports (p. 120). |
Custom network ACLs and other AWS services

If you create a custom network ACL, be aware of how it might affect resources that you create using other AWS services.

For more examples, see Recommended rules for VPC scenarios (p. 126).
With Elastic Load Balancing, if the subnet for your backend instances has a network ACL in which you've added a *deny* rule for all traffic with a source of either 0.0.0.0/0 or the subnet's CIDR, your load balancer can't carry out health checks on the instances. For more information about the recommended network ACL rules for your load balancers and backend instances, see Network ACLs for Load Balancers in a VPC in the User Guide for Classic Load Balancers.

**Ephemeral ports**

The example network ACL in the preceding section uses an ephemeral port range of 32768-65535. However, you might want to use a different range for your network ACLs depending on the type of client that you're using or with which you're communicating.

The client that initiates the request chooses the ephemeral port range. The range varies depending on the client's operating system.

- Many Linux kernels (including the Amazon Linux kernel) use ports 32768-61000.
- Requests originating from Elastic Load Balancing use ports 1024-65535.
- Windows operating systems through Windows Server 2003 use ports 1025-5000.
- A NAT gateway uses ports 1024-65535.
- AWS Lambda functions use ports 1024-65535.

For example, if a request comes into a web server in your VPC from a Windows 10 client on the internet, your network ACL must have an outbound rule to enable traffic destined for ports 49152-65535.

If an instance in your VPC is the client initiating a request, your network ACL must have an inbound rule to enable traffic destined for the ephemeral ports specific to the type of instance (Amazon Linux, Windows Server 2008, and so on).

In practice, to cover the different types of clients that might initiate traffic to public-facing instances in your VPC, you can open ephemeral ports 1024-65535. However, you can also add rules to the ACL to deny traffic on any malicious ports within that range. Ensure that you place the *deny* rules earlier in the table than the *allow* rules that open the wide range of ephemeral ports.

**Path MTU Discovery**

Path MTU Discovery is used to determine the path MTU between two devices. The path MTU is the maximum packet size that's supported on the path between the originating host and the receiving host.

For IPv4, when a host sends a packet that's larger than the MTU of the receiving host or that's larger than the MTU of a device along the path, the receiving host or device drops the packet, and then returns the following ICMP message: *Destination Unreachable: Fragmentation Needed and Don't Fragment was Set* (Type 3, Code 4). This instructs the transmitting host to split the payload into multiple smaller packets, and then retransmit them.

The IPv6 protocol does not support fragmentation in the network. When a host sends a packet that's larger than the MTU of the receiving host or that's larger than the MTU of a device along the path, the receiving host or device drops the packet, and then returns the following ICMP message: *ICMPv6 Packet Too Big (PTB)* (Type 2). This instructs the transmitting host to split the payload into multiple smaller packets, and then retransmit them.

If the maximum transmission unit (MTU) between hosts in your subnets is different, or your instances communicate with peers over the internet, you must add the following network ACL rule, both inbound and outbound. This ensures that Path MTU Discovery can function correctly and prevent packet loss. Select *Custom ICMP Rule* for the type and *Destination Unreachable, fragmentation required, and DF flag set* for the port range (type 3, code 4). If you use traceroute, also add the following rule: select
Custom ICMP Rule for the type and Time Exceeded, TTL expired transit for the port range (type 11, code 0). For more information, see Network maximum transmission unit (MTU) for your EC2 instance in the Amazon EC2 User Guide for Linux Instances.

Work with network ACLs

The following tasks show you how to work with network ACLs using the Amazon VPC console.

Tasks

- Determine network ACL associations (p. 121)
- Create a network ACL (p. 121)
- Add and delete rules (p. 122)
- Associate a subnet with a network ACL (p. 123)
- Disassociate a network ACL from a subnet (p. 123)
- Change a subnet's network ACL (p. 123)
- Delete a network ACL (p. 123)
- API and command overview (p. 124)

Determine network ACL associations

You can use the Amazon VPC console to determine the network ACL that's associated with a subnet. Network ACLs can be associated with more than one subnet, so you can also determine which subnets are associated with a network ACL.

To determine which network ACL is associated with a subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets, and then select the subnet.

   The network ACL associated with the subnet is included in the Network ACL tab, along with the network ACL's rules.

To determine which subnets are associated with a network ACL

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Network ACLs. The Associated With column indicates the number of associated subnets for each network ACL.
3. Select a network ACL.
4. In the details pane, choose Subnet Associations to display the subnets that are associated with the network ACL.

Create a network ACL

You can create a custom network ACL for your VPC. By default, a network ACL that you create blocks all inbound and outbound traffic until you add rules, and is not associated with a subnet until you explicitly associate it with one.

To create a network ACL

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Network ACLs.
3. Choose Create Network ACL.
4. In the Create Network ACL dialog box, optionally name your network ACL, and select the ID of your VPC from the VPC list. Then choose Yes, Create.

Add and delete rules

When you add or delete a rule from an ACL, any subnets that are associated with the ACL are subject to the change. You don't have to terminate and relaunch the instances in the subnet. The changes take effect after a short period.

**Important**

Be very careful if you are adding and deleting rules at the same time. Network ACL rules define which types of network traffic can enter or exit your VPCs. If you delete inbound or outbound rules and then add more new entries than are allowed in Amazon VPC quotas (p. 353), the entries selected for deletion will be removed and new entries will not be added. This could cause unexpected connectivity issues and unintentionally prevent access to and from your VPCs.

If you’re using the Amazon EC2 API or a command line tool, you can’t modify rules. You can only add and delete rules. If you’re using the Amazon VPC console, you can modify the entries for existing rules. The console removes the existing rule and adds a new rule for you. If you need to change the order of a rule in the ACL, you must add a new rule with the new rule number, and then delete the original rule.

**To add rules to a network ACL**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Network ACLs.
3. In the details pane, choose either the Inbound Rules or Outbound Rules tab, depending on the type of rule that you need to add, and then choose Edit.
4. In Rule #, enter a rule number (for example, 100). The rule number must not already be in use in the network ACL. We process the rules in order, starting with the lowest number.

   We recommend that you leave gaps between the rule numbers (such as 100, 200, 300), rather than using sequential numbers (101, 102, 103). This makes it easier add a new rule without having to renumber the existing rules.
5. Select a rule from the Type list. For example, to add a rule for HTTP, choose HTTP. To add a rule to allow all TCP traffic, choose All TCP. For some of these options (for example, HTTP), we fill in the port for you. To use a protocol that's not listed, choose Custom Protocol Rule.
6. (Optional) If you're creating a custom protocol rule, select the protocol's number and name from the Protocol list. For more information, see IANA List of Protocol Numbers.
7. (Optional) If the protocol you selected requires a port number, enter the port number or port range separated by a hyphen (for example, 49152-65535).
8. In the Source or Destination field (depending on whether this is an inbound or outbound rule), enter the CIDR range that the rule applies to.
9. From the Allow/Deny list, select ALLOW to allow the specified traffic or DENY to deny the specified traffic.
10. (Optional) To add another rule, choose Add another rule, and repeat steps 4 to 9 as required.
11. When you are done, choose Save.

**To delete a rule from a network ACL**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Network ACLs, and then select the network ACL.
3. In the details pane, choose either the Inbound Rules or Outbound Rules tab, and then choose Edit.

   Choose Remove for the rule you want to delete, and then choose Save.
**Associate a subnet with a network ACL**

To apply the rules of a network ACL to a particular subnet, you must associate the subnet with the network ACL. You can associate a network ACL with multiple subnets. However, a subnet can be associated with only one network ACL. Any subnet that is not associated with a particular ACL is associated with the default network ACL by default.

**To associate a subnet with a network ACL**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Network ACLs, and then select the network ACL.
3. In the details pane, on the Subnet Associations tab, choose Edit. Select the Associate check box for the subnet to associate with the network ACL, and then choose Save.

**Disassociate a network ACL from a subnet**

You can disassociate a custom network ACL from a subnet. When the subnet has been disassociated from the custom network ACL, it is then automatically associated with the default network ACL.

**To disassociate a subnet from a network ACL**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Network ACLs, and then select the network ACL.
3. In the details pane, choose the Subnet Associations tab.
4. Choose Edit, and then deselect the Associate check box for the subnet. Choose Save.

**Change a subnet's network ACL**

You can change the network ACL that's associated with a subnet. For example, when you create a subnet, it is initially associated with the default network ACL. You might want to instead associate it with a custom network ACL that you've created.

After changing a subnet's network ACL, you don't have to terminate and relaunch the instances in the subnet. The changes take effect after a short period.

**To change a subnet's network ACL association**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets, and then select the subnet.
3. Choose the Network ACL tab, and then choose Edit.
4. From the Change to list, select the network ACL to associate the subnet with, and then choose Save.

**Delete a network ACL**

You can delete a network ACL only if there are no subnets associated with it. You can't delete the default network ACL.

**To delete a network ACL**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Network ACLs.
3. Select the network ACL, and then choose Delete.
4. In the confirmation dialog box, choose Yes, Delete.
API and command overview

You can perform the tasks described on this page using the command line or an API. For more information about the command line interfaces and a list of available APIs, see Working with Amazon VPC (p. 2).

Create a network ACL for your VPC

- `create-network-acl` (AWS CLI)
- `New-EC2NetworkAcl` (AWS Tools for Windows PowerShell)

Describe one or more of your network ACLs

- `describe-network-acls` (AWS CLI)
- `Get-EC2NetworkAcl` (AWS Tools for Windows PowerShell)

Add a rule to a network ACL

- `create-network-acl-entry` (AWS CLI)
- `New-EC2NetworkAclEntry` (AWS Tools for Windows PowerShell)

Delete a rule from a network ACL

- `delete-network-acl-entry` (AWS CLI)
- `Remove-EC2NetworkAclEntry` (AWS Tools for Windows PowerShell)

Replace an existing rule in a network ACL

- `replace-network-acl-entry` (AWS CLI)
- `Set-EC2NetworkAclEntry` (AWS Tools for Windows PowerShell)

Replace a network ACL association

- `replace-network-acl-association` (AWS CLI)
- `Set-EC2NetworkAclAssociation` (AWS Tools for Windows PowerShell)

Delete a network ACL

- `delete-network-acl` (AWS CLI)
- `Remove-EC2NetworkAcl` (AWS Tools for Windows PowerShell)

Example: Control access to instances in a subnet

In this example, instances in your subnet can communicate with each other, and are accessible from a trusted remote computer. The remote computer might be a computer in your local network or an instance in a different subnet or VPC. You use it to connect to your instances to perform administrative tasks. Your security group rules and network ACL rules allow access from the IP address of your remote computer (172.31.1.2/32). All other traffic from the internet or other networks is denied. This scenario gives you the flexibility to change the security groups or security group rules for your instances, and have the network ACL as the backup layer of defense.
The following is an example security group to associate with the instances. Security groups are stateful. Therefore you don’t need a rule that allows responses to inbound traffic.

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Protocol Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>All traffic</td>
<td>All</td>
<td>All</td>
<td>sg-1234567890abcdef0</td>
<td>All instances associated with this security group can communicate with each other.</td>
<td></td>
</tr>
<tr>
<td>SSH</td>
<td>TCP</td>
<td>22</td>
<td>172.31.1.2/32</td>
<td>Allows inbound SSH access from the remote computer.</td>
<td></td>
</tr>
</tbody>
</table>

The following is an example network ACL to associate with the subnets for the instances. The network ACL rules apply to all instances in the subnet. Network ACLs are stateless. Therefore, you need a rule that allows responses to inbound traffic.

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Rule #</th>
<th>Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>SSH</td>
<td>TCP</td>
<td>22</td>
<td>172.31.1.2/32 ALLOW</td>
<td>Allows inbound</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Outbound

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Destination</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>Custom TCP</td>
<td>TCP</td>
<td>1024-65535</td>
<td>172.31.1.2/32</td>
<td>ALLOW</td>
<td>Allows outbound responses to the remote computer.</td>
</tr>
<tr>
<td>*</td>
<td>All traffic</td>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
<td>DENY</td>
<td>Denies all other outbound traffic.</td>
</tr>
</tbody>
</table>

If you accidentally make your security group rules too permissive, the network ACL in this example continues to permit access only from the specified IP address. For example, the following security group contains a rule that allow inbound SSH access from any IP address. However, if you associate this security group with an instance in a subnet that uses the network ACL, only other instances within the subnet and your remote computer can access the instance, because the network ACL rules deny other inbound traffic to the subnet.

### Inbound

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>All traffic</td>
<td>All</td>
<td>All</td>
<td>sg-1234567890abcdef0</td>
<td>All instances associated with this security group can communicate with each other.</td>
</tr>
<tr>
<td>SSH</td>
<td>TCP</td>
<td>22</td>
<td>0.0.0.0/0</td>
<td>Allows SSH access from any IP address.</td>
</tr>
</tbody>
</table>

### Outbound

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Destination</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>All traffic</td>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
<td>Allows all outbound traffic.</td>
</tr>
</tbody>
</table>

---

**Recommended rules for VPC scenarios**

You can follow the processes in *Scenarios (p. 260)* to implement common scenarios for Amazon VPC. Each scenario in that section includes recommended network ACL rules. If you implement these scenarios as described in the documentation, you use the default network access control list (ACL) which allows all...
inbound and outbound traffic. If you need an additional layer of security, you can create a network ACL and add rules.
Connect your VPC to other networks

You can connect your virtual private cloud (VPC) to other networks. For example, other VPCs, the internet, or your on-premises network.

The following diagram demonstrates some of these connectivity options. VPC A is connected to the internet through an internet gateway. The EC2 instance in the private subnet of VPC A can connect to the internet using the NAT gateway in the public subnet of VPC A. VPC B is connected to the internet through an internet gateway. The EC2 instance in the public subnet of VPC B can connect to the internet using the internet gateway. VPC A and VPC B are connected to each other through a VPC peering connection and a transit gateway. The transit gateway has a VPN attachment to a data center. VPC B has an AWS Direct Connect connection to a data center.

For more information, see Amazon Virtual Private Cloud Connectivity Options.

Contents
- Connect to the internet using an internet gateway (p. 128)
- Enable outbound IPv6 traffic using an egress-only internet gateway (p. 139)
- Connect to the internet or other networks using NAT devices (p. 142)
- Connect your VPC to other VPCs and networks using a transit gateway (p. 177)
- Connect your VPC to remote networks using AWS Virtual Private Network (p. 177)
- Connect VPCs using VPC peering (p. 178)

Connect to the internet using an internet gateway

An internet gateway is a horizontally scaled, redundant, and highly available VPC component that allows communication between your VPC and the internet. It supports IPv4 and IPv6 traffic. It does not cause availability risks or bandwidth constraints on your network traffic.
An internet gateway enables resources in your public subnets (such as EC2 instances) to connect to the internet if the resource has a public IPv4 address or an IPv6 address. Similarly, resources on the internet can initiate a connection to resources in your subnet using the public IPv4 address or IPv6 address. For example, an internet gateway enables you to connect to an EC2 instance in AWS using your local computer.

An internet gateway provides a target in your VPC route tables for internet-routable traffic. For communication using IPv4, the internet gateway also performs network address translation (NAT). For communication using IPv6, NAT is not needed because IPv6 addresses are public. For more information, see IP addresses and NAT (p. 129).

There's no additional charge for creating an internet gateway.

Enable internet access

To enable access to or from the internet for instances in a subnet in a VPC using an internet gateway, you must do the following.

- Create an internet gateway and attach it to your VPC.
- Add a route to your subnet's route table that directs internet-bound traffic to the internet gateway.
- Ensure that instances in your subnet have a public IPv4 address or an IPv6 address.
- Ensure that your network access control lists and security group rules allow the desired internet traffic to flow to and from your instance.

Public and private subnets

If a subnet is associated with a route table that has a route to an internet gateway, it's known as a public subnet. If a subnet is associated with a route table that does not have a route to an internet gateway, it's known as a private subnet.

In your public subnet's route table, you can specify a route for the internet gateway to all destinations not explicitly known to the route table (0.0.0.0/0 for IPv4 or ::/0 for IPv6). Alternatively, you can scope the route to a narrower range of IP addresses; for example, the public IPv4 addresses of your company's public endpoints outside of AWS, or the Elastic IP addresses of other Amazon EC2 instances outside your VPC.

IP addresses and NAT

To enable communication over the internet for IPv4, your instance must have a public IPv4 address. You can either configure your VPC to automatically assign public IPv4 addresses to your instances, or you can assign Elastic IP addresses to your instances. Your instance is only aware of the private (internal) IP address space defined within the VPC and subnet. The internet gateway logically provides the one-to-one NAT on behalf of your instance, so that when traffic leaves your VPC subnet and goes to the internet, the reply address field is set to the public IPv4 address or Elastic IP address of your instance, and not its private IP address. Conversely, traffic that's destined for the public IPv4 address or Elastic IP address of your instance has its destination address translated into the instance's private IPv4 address before the traffic is delivered to the VPC.

To enable communication over the internet for IPv6, your VPC and subnet must have an associated IPv6 CIDR block, and your instance must be assigned an IPv6 address from the range of the subnet. IPv6 addresses are globally unique, and therefore public by default.

In the following diagram, the subnet in Availability Zone A is a public subnet. The route table for this subnet has a route that sends all internet-bound IPv4 traffic to the internet gateway. The instances in the public subnet must have public IP addresses or Elastic IP addresses to enable communication with the internet over the internet gateway. For comparison, the subnet in Availability Zone B is a private subnet because its route table does not have a route to the internet gateway. Instances in the private subnet can't communicate with the internet over the internet gateway, even if they have public IP addresses.
To provide your instances with internet access without assigning them public IP addresses, you can use a NAT device instead. A NAT device enables instances in a private subnet to connect to the internet, but prevents hosts on the internet from initiating connections with the instances. For more information, see Connect to the internet or other networks using NAT devices (p. 142).

Internet access for default and nondefault VPCs

The following table provides an overview of whether your VPC automatically comes with the components required for internet access over IPv4 or IPv6.

<table>
<thead>
<tr>
<th>Component</th>
<th>Default VPC</th>
<th>Nondefault VPC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet gateway</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Route table with route to internet gateway for IPv4 traffic (0.0.0.0/0)</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Route table with route to internet gateway for IPv6 traffic (::/0)</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Public IPv4 address automatically assigned to instance launched into subnet</td>
<td>Yes (default subnet)</td>
<td>No (nondefault subnet)</td>
</tr>
<tr>
<td>IPv6 address automatically assigned to instance launched into subnet</td>
<td>No (default subnet)</td>
<td>No (nondefault subnet)</td>
</tr>
</tbody>
</table>

For more information about default VPCs, see Default VPCs (p. 25). For more information about creating a VPC, see Create a VPC (p. 18).

For more information about IP addressing in your VPC, and controlling how instances are assigned public IPv4 or IPv6 addresses, see IP addressing (p. 4).
When you add a new subnet to your VPC, you must set up the routing and security that you want for the subnet.

Access the internet from a subnet in your VPC

The following describes how to support internet access from a subnet in your VPC using an internet gateway. To remove internet access, you can detach the internet gateway from your VPC and then delete it.

Tasks
- Create a subnet (p. 131)
- Create and attach an internet gateway (p. 131)
- Create a custom route table (p. 132)
- Create a security group for internet access (p. 132)
- Assign an Elastic IP address to an instance (p. 133)
- Detach an internet gateway from your VPC (p. 133)
- Delete an internet gateway (p. 134)

Create a subnet

To add a subnet to your VPC

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets, Create subnet.
3. Specify the subnet details as needed:
   - **Name tag**: Optionally provide a name for your subnet. Doing so creates a tag with a key of Name and the value that you specify.
   - **VPC**: Choose the VPC for which you're creating the subnet.
   - **Availability Zone**: Optionally choose an Availability Zone or Local Zone in which your subnet will reside, or leave the default **No Preference** to let AWS choose an Availability Zone for you.
     For information about the Regions that support Local Zones, see Available Regions in the Amazon EC2 User Guide for Linux Instances.
   - **IPv4 CIDR block**: Specify an IPv4 CIDR block for your subnet, for example, 10.0.1.0/24. For more information, see IPv4 VPC CIDR blocks (p. 14).
   - **IPv6 CIDR block**: (Optional) If you've associated an IPv6 CIDR block with your VPC, choose Specify a custom IPv6 CIDR. Specify the hexadecimal pair value for the subnet, or leave the default value.
4. Choose Create.

For more information, see Subnets (p. 56).

Create and attach an internet gateway

After you create an internet gateway, attach it to your VPC.

To create an internet gateway and attach it to your VPC

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Internet gateways, and then choose Create internet gateway.
3. Optionally name your internet gateway.
4. Optionally add or remove a tag.
   [Add a tag] Choose Add tag and do the following:
   • For Key, enter the key name.
   • For Value, enter the key value.
   [Remove a tag] Choose Remove to the right of the tag’s Key and Value.
5. Choose Create internet gateway.
6. Select the internet gateway that you just created, and then choose Actions, Attach to VPC.
7. Select your VPC from the list, and then choose Attach internet gateway.

Create a custom route table

When you create a subnet, we automatically associate it with the main route table for the VPC. By default, the main route table doesn't contain a route to an internet gateway. The following procedure creates a custom route table with a route that sends traffic destined outside the VPC to the internet gateway, and then associates it with your subnet.

To create a custom route table

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route Tables, and then choose Create route table.
3. In the Create route table dialog box, optionally name your route table, then select your VPC, and then choose Create route table.
4. Select the custom route table that you just created. The details pane displays tabs for working with its routes, associations, and route propagation.
5. On the Routes tab, choose Edit routes, Add route, and add the following routes as necessary. Choose Save changes when you're done.
   • For IPv4 traffic, specify 0.0.0.0/0 in the Destination box, and select the internet gateway ID in the Target list.
   • For IPv6 traffic, specify ::/0 in the Destination box, and select the internet gateway ID in the Target list.
6. On the Subnet associations tab, choose Edit subnet associations, select the check box for the subnet, and then choose Save associations.

For more information, see Configure route tables (p. 74).

Create a security group for internet access

By default, a VPC security group allows all outbound traffic. You can create a new security group and add rules that allow inbound traffic from the internet. You can then associate the security group with instances in the public subnet.

To create a security group and associate it with an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups, and then choose Create security group.
3. Enter a name and description for the security group.
4. For VPC, select your VPC.
Access the internet from a subnet in your VPC

For Inbound Rules, choose Add Rule, and complete the required information. For example, select HTTP or HTTPS from Type, and enter the Source as 0.0.0.0/0 for IPv4 traffic, or ::/0 for IPv6 traffic.

Choose Create security group.

In the navigation pane, choose Instances.

Select the instance, and then choose Actions, Security, Change security groups.

For Associated security groups, select an existing security group and then choose Add security group. To remove a security group that's already associated, choose Remove. When you're finished making changes, choose Save.

Assign an Elastic IP address to an instance

After you've launched an instance into the subnet, you must assign it an Elastic IP address if you want it to be reachable from the internet over IPv4.

**Note**

If you assigned a public IPv4 address to your instance during launch, then your instance is reachable from the internet, and you do not need to assign it an Elastic IP address. For more information about IP addressing for your instance, see IP addressing (p. 4).

To allocate an Elastic IP address and assign it to an instance using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs.
3. Choose Allocate new address.
4. Choose Allocate.

**Note**

If your account supports EC2-Classic, first choose VPC.

5. Select the Elastic IP address from the list, choose Actions, and then choose Associate address.
6. Choose Instance or Network interface, and then select either the instance or network interface ID. Select the private IP address with which to associate the Elastic IP address, and then choose Associate.

For more information, see Associate Elastic IP addresses with resources in your VPC (p. 134).

Detach an internet gateway from your VPC

If you no longer need internet access for instances that you launch into a nondefault VPC, you can detach an internet gateway from a VPC. You can't detach an internet gateway if the VPC has resources with associated public IP addresses or Elastic IP addresses.

To detach an internet gateway

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs and select the Elastic IP address.
3. Choose Actions, Disassociate address. Choose Disassociate address.
4. In the navigation pane, choose Internet gateways.
5. Select the internet gateway and choose Actions, Detach from VPC.
6. In the Detach from VPC dialog box, choose Detach internet gateway.
Delete an internet gateway

If you no longer need an internet gateway, you can delete it. You can't delete an internet gateway if it's still attached to a VPC.

To delete an internet gateway
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Internet gateways.
3. Select the internet gateway and choose Actions, Delete internet gateway.
4. In the Delete internet gateway dialog box, enter delete, and choose Delete internet gateway.

API and command overview

You can perform the tasks described on this page using the command line or an API. For more information about the command line interfaces and a list of available API actions, see Working with Amazon VPC (p. 2).

Create an internet gateway
- create-internet-gateway (AWS CLI)
- New-EC2InternetGateway (AWS Tools for Windows PowerShell)

Attach an internet gateway to a VPC
- attach-internet-gateway (AWS CLI)
- Add-EC2InternetGateway (AWS Tools for Windows PowerShell)

Describe an internet gateway
- describe-internet-gateways (AWS CLI)
- Get-EC2InternetGateway (AWS Tools for Windows PowerShell)

Detach an internet gateway from a VPC
- detach-internet-gateway (AWS CLI)
- Dismount-EC2InternetGateway (AWS Tools for Windows PowerShell)

Delete an internet gateway
- delete-internet-gateway (AWS CLI)
- Remove-EC2InternetGateway (AWS Tools for Windows PowerShell)

Associate Elastic IP addresses with resources in your VPC

An Elastic IP address is a static, public IPv4 address designed for dynamic cloud computing. You can associate an Elastic IP address with any instance or network interface in any VPC in your account. With an
Elastic IP address, you can mask the failure of an instance by rapidly remapping the address to another instance in your VPC.

**Elastic IP address concepts and rules**

To use an Elastic IP address, you first allocate it for use in your account. Then, you can associate it with an instance or network interface in your VPC. Your Elastic IP address remains allocated to your AWS account until you explicitly release it.

An Elastic IP address is a property of a network interface. You can associate an Elastic IP address with an instance by updating the network interface attached to the instance. The advantage of associating the Elastic IP address with the network interface instead of directly with the instance is that you can move all the attributes of the network interface from one instance to another in a single step. For more information, see Elastic network interfaces in the *Amazon EC2 User Guide for Linux Instances*.

The following rules apply:

- An Elastic IP address can be associated with a single instance or network interface at a time.
- You can move an Elastic IP address from one instance or network interface to another.
- If you associate an Elastic IP address with the eth0 network interface of your instance, its current public IPv4 address (if it had one) is released to the EC2-VPC public IP address pool. If you disassociate the Elastic IP address, the eth0 network interface is automatically assigned a new public IPv4 address within a few minutes. This doesn't apply if you've attached a second network interface to your instance.
- To ensure efficient use of Elastic IP addresses, we impose a small hourly charge when they aren't associated with a running instance, or when they are associated with a stopped instance or an unattached network interface. While your instance is running, you aren't charged for one Elastic IP address associated with the instance, but you are charged for any additional Elastic IP addresses associated with the instance. For more information, see Amazon EC2 Pricing.
- You're limited to five Elastic IP addresses. To help conserve them, you can use a NAT device. For more information, see Connect to the internet or other networks using NAT devices (p. 142).
- Elastic IP addresses for IPv6 are not supported.
- You can tag an Elastic IP address that's allocated for use in a VPC, however, cost allocation tags are not supported. If you recover an Elastic IP address, tags are not recovered.
- You can access an Elastic IP address from the internet when the security group and network ACL allow traffic from the source IP address. The reply traffic from within the VPC back to the internet requires an internet gateway. For more information, see the section called “Security groups” (p. 245) and the section called “Network ACLs” (p. 108).
- You can use any of the following options for the Elastic IP addresses:
  - Have Amazon provide the Elastic IP addresses. When you select this option, you can associate the Elastic IP addresses with a network border group. This is the location from which we advertise the CIDR block. Setting the network border group limits the CIDR block to this group.
  - Use your own IP addresses. For information about bringing your own IP addresses, see Bring your own IP addresses (BYOIP) in the *Amazon EC2 User Guide for Linux Instances*.

There are differences between an Elastic IP address that you use in a VPC and one that you use in EC2-Classic. For more information, see Differences between EC2-Classic and VPC in the *Amazon EC2 User Guide for Linux Instances*. You can move an Elastic IP address that you’ve allocated for use in the EC2-Classic platform to the VPC platform. For more information, see Elastic IP addresses in the *Amazon EC2 User Guide for Linux Instances*.

Elastic IP addresses are regional. For more information about using Global Accelerator to provision global IP addresses, see Using global static IP addresses instead of regional static IP addresses in the *AWS Global Accelerator Developer Guide*. 

135
Work with Elastic IP addresses

The following sections describe how you can work with Elastic IP addresses.

Tasks

- Allocate an Elastic IP address (p. 136)
- Associate an Elastic IP address (p. 136)
- View your Elastic IP addresses (p. 137)
- Tag an Elastic IP address (p. 137)
- Disassociate an Elastic IP address (p. 137)
- Release an Elastic IP address (p. 137)
- Recover an Elastic IP address (p. 138)

Allocate an Elastic IP address

Before you use an Elastic IP, you must allocate one for use in your VPC.

To allocate an Elastic IP address

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs.
3. Choose Allocate Elastic IP address.
4. For Public IPv4 address pool choose one of the following:
   - Amazon's pool of IP addresses—If you want an IPv4 address to be allocated from Amazon's pool of IP addresses.
   - My pool of public IPv4 addresses—If you want to allocate an IPv4 address from an IP address pool that you have brought to your AWS account. This option is disabled if you do not have any IP address pools.
   - Customer owned pool of IPv4 addresses—If you want to allocate an IPv4 address from a pool created from your on-premises network for use with an Outpost. This option is only available if you have an Outpost.
5. (Optional) Add or remove a tag.
   - [Add a tag] Choose Add new tag and do the following:
     - For Key, enter the key name.
     - For Value, enter the key value.
   - [Remove a tag] Choose Remove to the right of the tag's Key and Value.
6. Choose Allocate.

   Note
   If your account supports EC2-Classic, first choose VPC.

Associate an Elastic IP address

You can associate an Elastic IP with a running instance or network interface in your VPC.

After you associate the Elastic IP address with your instance, the instance receives a public DNS hostname if DNS hostnames are enabled. For more information, see DNS attributes for your VPC (p. 37).
To associate an Elastic IP address with an instance or network interface

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs.
3. Select an Elastic IP address that's allocated for use with a VPC (the Scope column has a value of vpc), and then choose Actions, Associate Elastic IP address.
4. Choose Instance or Network interface, and then select either the instance or network interface ID. Select the private IP address with which to associate the Elastic IP address. Choose Associate.

View your Elastic IP addresses

You can view the Elastic IP addresses that are allocated to your account.

To view your Elastic IP addresses

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs.
3. To filter the displayed list, start typing part of the Elastic IP address or one of its attributes in the search box.

Tag an Elastic IP address

You can apply tags to your Elastic IP address to help you identify it or categorize it according to your organization’s needs.

To tag an Elastic IP address

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs.
3. Select the Elastic IP address and choose Tags.
4. Choose Manage tags, enter the tag keys and values as required, and choose Save.

Disassociate an Elastic IP address

To change the resource that the Elastic IP address is associated with, you must first disassociate it from the currently associated resource.

To disassociate an Elastic IP address

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs.
3. Select the Elastic IP address, and then choose Actions, Disassociate Elastic IP address.
4. When prompted, choose Disassociate.

Release an Elastic IP address

If you no longer need an Elastic IP address, we recommend that you release it. You incur charges for any Elastic IP address that's allocated for use with a VPC but not associated with an instance. The Elastic IP address must not be associated with an instance or network interface.
To release an Elastic IP address

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs.
3. Select the Elastic IP address, and then choose Actions, Release Elastic IP addresses.

Recover an Elastic IP address

If you release your Elastic IP address, you might be able to recover it. You cannot recover the Elastic IP address if it has been allocated to another AWS account, or if it results in you exceeding your Elastic IP address quota.

You can recover an Elastic IP address using the Amazon EC2 API or a command line tool.

To recover an Elastic IP address using the AWS CLI

Use the `allocate-address` command and specify the IP address using the `--address` parameter.

```
aws ec2 allocate-address --domain vpc --address 203.0.113.3
```

API and command overview

You can perform the tasks described on this page using the command line or an API. For more information about the command line interfaces and a list of available API actions, see Working with Amazon VPC (p. 2).

Allocate an Elastic IP address

- `allocate-address` (AWS CLI)
- `New-EC2Address` (AWS Tools for Windows PowerShell)

Associate an Elastic IP address with an instance or network interface

- `associate-address` (AWS CLI)
- `Register-EC2Address` (AWS Tools for Windows PowerShell)

View your Elastic IP addresses

- `describe-addresses` (AWS CLI)
- `Get-EC2Address` (AWS Tools for Windows PowerShell)

Tag an Elastic IP address

- `create-tags` (AWS CLI)
- `New-EC2Tag` (AWS Tools for Windows PowerShell)

Disassociate an Elastic IP address

- `disassociate-address` (AWS CLI)
Unregister-EC2Address (AWS Tools for Windows PowerShell)

Release an Elastic IP address

- release-address (AWS CLI)
- Remove-EC2Address (AWS Tools for Windows PowerShell)

Enable outbound IPv6 traffic using an egress-only internet gateway

An egress-only internet gateway is a horizontally scaled, redundant, and highly available VPC component that allows outbound communication over IPv6 from instances in your VPC to the internet, and prevents the internet from initiating an IPv6 connection with your instances.

Note
An egress-only internet gateway is for use with IPv6 traffic only. To enable outbound-only internet communication over IPv4, use a NAT gateway instead. For more information, see NAT gateways (p. 143).

Contents
- Egress-only internet gateway basics (p. 139)
- Work with egress-only internet gateways (p. 140)
- API and CLI overview (p. 142)

Egress-only internet gateway basics

IPv6 addresses are globally unique, and are therefore public by default. If you want your instance to be able to access the internet, but you want to prevent resources on the internet from initiating communication with your instance, you can use an egress-only internet gateway. To do this, create an egress-only internet gateway in your VPC, and then add a route to your route table that points all IPv6 traffic (:/0) or a specific range of IPv6 address to the egress-only internet gateway. IPv6 traffic in the subnet that's associated with the route table is routed to the egress-only internet gateway.

An egress-only internet gateway is stateful: it forwards traffic from the instances in the subnet to the internet or other AWS services, and then sends the response back to the instances.

An egress-only internet gateway has the following characteristics:

- You cannot associate a security group with an egress-only internet gateway. You can use security groups for your instances in the private subnet to control the traffic to and from those instances.
- You can use a network ACL to control the traffic to and from the subnet for which the egress-only internet gateway routes traffic.

In the following diagram, the VPC has both IPv4 and IPv6 CIDR blocks, and the subnet both IPv4 and IPv6 CIDR blocks. The VPC has an egress-only internet gateway.
Work with egress-only internet gateways

The following tasks describe how to create an egress-only (outbound) internet gateway for your private subnet, and to configure routing for the subnet.

Tasks
- Create an egress-only internet gateway (p. 140)
- View your egress-only internet gateway (p. 141)
- Create a custom route table (p. 141)
- Delete an egress-only internet gateway (p. 141)

Create an egress-only internet gateway

You can create an egress-only internet gateway for your VPC using the Amazon VPC console.

To create an egress-only internet gateway
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Egress Only Internet Gateways.
3. Choose Create Egress Only Internet Gateway.
4. (Optional) Add or remove a tag.
   - [Add a tag] Choose Add new tag and do the following:
     - For Key, enter the key name.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/64</td>
<td>Local</td>
</tr>
<tr>
<td>::/0</td>
<td>eigw-id</td>
</tr>
</tbody>
</table>
• For Value, enter the key value.

[Remove a tag] Choose Remove to the right of the tag’s Key and Value.

5. Select the VPC in which to create the egress-only internet gateway.
6. Choose Create.

**View your egress-only internet gateway**

You can view information about your egress-only internet gateway in the Amazon VPC console.

**To view information about an egress-only internet gateway**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Egress Only Internet Gateways.
3. Select the egress-only internet gateway to view its information in the details pane.

**Create a custom route table**

To send traffic destined outside the VPC to the egress-only internet gateway, you must create a custom route table, add a route that sends traffic to the gateway, and then associate it with your subnet.

**To create a custom route table and add a route to the egress-only internet gateway**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route Tables, Create route table.
3. In the Create route table dialog box, optionally name your route table, then select your VPC and choose Create route table.
4. Select the custom route table that you just created. The details pane displays tabs for working with its routes, associations, and route propagation.
5. On the Routes tab, choose Edit routes, specify :/0 in the Destination box, select the egress-only internet gateway ID in the Target list, and then choose Save changes.
6. On the Subnet associations tab, choose Edit subnet associations, and select the check box for the subnet. Choose Save.

Alternatively, you can add a route to an existing route table that's associated with your subnet. Select your existing route table, and follow steps 5 and 6 above to add a route for the egress-only internet gateway.

For more information about route tables, see Configure route tables (p. 74).

**Delete an egress-only internet gateway**

If you no longer need an egress-only internet gateway, you can delete it. Any route in a route table that points to the deleted egress-only internet gateway remains in a blackhole status until you manually delete or update the route.

**To delete an egress-only internet gateway**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Egress Only Internet Gateways**, and select the egress-only internet gateway.
3. Choose **Delete**.
4. Choose **Delete Egress Only Internet Gateway** in the confirmation dialog box.

## API and CLI overview

You can perform the tasks described on this page using the command line or an API. For more information about the command line interfaces and a list of available API actions, see *Working with Amazon VPC* (p. 2).

### Create an egress-only internet gateway

- `create-egress-only-internet-gateway` (AWS CLI)
- `New-EC2EgressOnlyInternetGateway` (AWS Tools for Windows PowerShell)

### Describe an egress-only internet gateway

- `describe-egress-only-internet-gateways` (AWS CLI)
- `Get-EC2EgressOnlyInternetGatewayList` (AWS Tools for Windows PowerShell)

### Delete an egress-only internet gateway

- `delete-egress-only-internet-gateway` (AWS CLI)
- `Remove-EC2EgressOnlyInternetGateway` (AWS Tools for Windows PowerShell)

## Connect to the internet or other networks using NAT devices

You can use a NAT device to allow resources in private subnets to connect to the internet, other VPCs, or on-premises networks. These instances can communicate with services outside the VPC, but they cannot receive unsolicited connection requests.

The NAT device replaces the source IPv4 address of the instances with the address of the NAT device. When sending response traffic to the instances, the NAT device translates the addresses back to the original source IPv4 addresses.

You can use a managed NAT device offered by AWS, called a **NAT gateway**, or you can create your own NAT device on an EC2 instance, called a **NAT instance**. We recommend that you use NAT gateways because they provide better availability and bandwidth and require less effort on your part to administer.

### Considerations

- NAT devices are not supported for IPv6 traffic—use an egress-only internet gateway instead. For more information, see *Enable outbound IPv6 traffic using an egress-only internet gateway* (p. 139).
- We use the term **NAT** in this documentation to follow common IT practice, though the actual role of a NAT device is both address translation and port address translation (PAT).

142
NAT gateways

A NAT gateway is a Network Address Translation (NAT) service. You can use a NAT gateway so that instances in a private subnet can connect to services outside your VPC but external services cannot initiate a connection with those instances.

When you create a NAT gateway, you specify one of the following connectivity types:

- **Public** – (Default) Instances in private subnets can connect to the internet through a public NAT gateway, but cannot receive unsolicited inbound connections from the internet. You create a public NAT gateway in a public subnet and must associate an elastic IP address with the NAT gateway at creation. You route traffic from the NAT gateway to the internet gateway for the VPC. Alternatively, you can use a public NAT gateway to connect to other VPCs or your on-premises network. In this case, you route traffic from the NAT gateway through a transit gateway or a virtual private gateway.

- **Private** – Instances in private subnets can connect to other VPCs or your on-premises network through a private NAT gateway. You can route traffic from the NAT gateway through a transit gateway or a virtual private gateway. You cannot associate an elastic IP address with a private NAT gateway. You can attach an internet gateway to a VPC with a private NAT gateway, but if you route traffic from the private NAT gateway to the internet gateway, the internet gateway drops the traffic.

The NAT gateway replaces the source IP address of the instances with the IP address of the NAT gateway. For a public NAT gateway, this is the elastic IP address of the NAT gateway. For a private NAT gateway, this is the private IP address of the NAT gateway. When sending response traffic to the instances, the NAT device translates the addresses back to the original source IP address.

Pricing

When you provision a NAT gateway, you are charged for each hour that your NAT gateway is available and each Gigabyte of data that it processes. For more information, see Amazon VPC Pricing.

The following strategies can help you reduce the data transfer charges for your NAT gateway:

- If your AWS resources send or receive a significant volume of traffic across Availability Zones, ensure that the resources are in the same Availability Zone as the NAT gateway, or create a NAT gateway in the same Availability Zone as the resources.

- If most traffic through your NAT gateway is to AWS services that support interface endpoints or gateway endpoints, consider creating an interface endpoint or gateway endpoint for these services. For more information about the potential cost savings, see AWS PrivateLink pricing.

Contents

- NAT gateways (p. 143)
- NAT instances (p. 168)
- Compare NAT gateways and NAT instances (p. 175)
NAT gateway basics

Each NAT gateway is created in a specific Availability Zone and implemented with redundancy in that zone. There is a quota on the number of NAT gateways that you can create in each Availability Zone. For more information, see Amazon VPC quotas (p. 353).

If you have resources in multiple Availability Zones and they share one NAT gateway, and if the NAT gateway’s Availability Zone is down, resources in the other Availability Zones lose internet access. To create an Availability Zone-independent architecture, create a NAT gateway in each Availability Zone and configure your routing to ensure that resources use the NAT gateway in the same Availability Zone.

The following characteristics and rules apply to NAT gateways:

- A NAT gateway supports the following protocols: TCP, UDP, and ICMP.
- NAT gateways are supported for IPv4 or IPv6 traffic. For IPv6 traffic, NAT gateway performs NAT64. By using this in conjunction with DNS64 (available on Route 53 resolver), your IPv6 workloads in a subnet in Amazon VPC can communicate with IPv4 resources. These IPv4 services may be present in the same VPC (in a separate subnet) or a different VPC, on your on-premises environment or on the internet.
- A NAT gateway supports 5 Gbps of bandwidth and automatically scales up to 100 Gbps. If you require more bandwidth, you can split your resources into multiple subnets and create a NAT gateway in each subnet.
- A NAT gateway can process one million packets per second and automatically scales up to ten million packets per second. Beyond this limit, a NAT gateway will drop packets. To prevent packet loss, split your resources into multiple subnets and create a separate NAT gateway for each subnet.
- A NAT gateway can support up to 55,000 simultaneous connections to each unique destination. This limit also applies if you create approximately 900 connections per second to a single destination (about 55,000 connections per minute). If the destination IP address, the destination port, or the protocol (TCP/UDP/ICMP) changes, you can create an additional 55,000 connections. For more than 55,000 connections, there is an increased chance of connection errors due to port allocation errors. These errors can be monitored by viewing the ErrorPortAllocation CloudWatch metric for your NAT gateway. For more information, see Monitor NAT gateways with Amazon CloudWatch (p. 157).
- You can associate exactly one Elastic IP address with a public NAT gateway. You cannot disassociate an Elastic IP address from a NAT gateway after it's created. To use a different Elastic IP address for your NAT gateway, you must create a new NAT gateway with the required address, update your route tables, and then delete the existing NAT gateway if it's no longer required.
- A private NAT gateway receives an available private IP address from the subnet in which it is configured. The assigned private IP address persists until you delete the private NAT gateway. You cannot detach the private IP address and you cannot attach additional private IP addresses.
- You cannot associate a security group with a NAT gateway. You can associate security groups with your instances to control inbound and outbound traffic.
- You can use a network ACL to control the traffic to and from the subnet for your NAT gateway. NAT gateways use ports 1024–65535. For more information, see Control traffic to subnets using Network ACLs (p. 108).
- A NAT gateway receives a network interface that's automatically assigned a private IP address from the IP address range of the subnet. You can view the network interface for the NAT gateway using the Amazon EC2 console. For more information, see Viewing details about a network interface. You cannot modify the attributes of this network interface.
- A NAT gateway cannot be accessed through a ClassicLink connection that is associated with your VPC.
- You cannot route traffic to a NAT gateway through a VPC peering connection, a Site-to-Site VPN connection, or AWS Direct Connect. A NAT gateway cannot be used by resources on the other side of these connections.
Control the use of NAT gateways

By default, IAM users do not have permission to work with NAT gateways. You can create an IAM user policy that grants users permissions to create, describe, and delete NAT gateways. For more information, see Identity and access management for Amazon VPC (p. 228).

Work with NAT gateways

You can use the Amazon VPC console to create and manage your NAT gateways.

Tasks

- Create a NAT gateway (p. 145)
- Tag a NAT gateway (p. 145)
- Delete a NAT gateway (p. 146)

Create a NAT gateway

To create a NAT gateway, enter an optional name, a subnet, and an optional connectivity type. With a public NAT gateway, you must specify an available elastic IP address. A private NAT gateway receives a primary private IP address selected at random from its subnet. You cannot detach the primary private IP address or add secondary private IP addresses.

To create a NAT gateway

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose NAT Gateways.
3. Choose Create NAT Gateway and do the following:
   a. (Optional) Specify a name for the NAT gateway. This creates a tag where the key is Name and the value is the name that you specify.
   b. Select the subnet in which to create the NAT gateway.
   c. For Connectivity type, select Private to create a private NAT gateway or Public (the default) to create a public NAT gateway.
   d. (Public NAT gateway only) For Elastic IP allocation ID, select an Elastic IP address to associate with the NAT gateway.
   e. (Optional) For each tag, choose Add new tag and enter the key name and value.
   f. Choose Create a NAT Gateway.
4. The initial status of the NAT gateway is Pending. After the status changes to Available, the NAT gateway is ready for you to use. Be sure to update your route tables as needed. For examples, see the section called “Use cases” (p. 147).

   If the status of the NAT gateway changes to Failed, there was an error during creation. For more information, see NAT gateway creation fails (p. 162).

Tag a NAT gateway

You can tag your NAT gateway to help you identify it or categorize it according to your organization's needs. For information about working with tags, see Tagging your Amazon EC2 resources in the Amazon EC2 User Guide for Linux Instances.

Cost allocation tags are supported for NAT gateways. Therefore, you can also use tags to organize your AWS bill and reflect your own cost structure. For more information, see Using cost allocation tags in the
Delete a NAT gateway

If you no longer need a NAT gateway, you can delete it. After you delete a NAT gateway, its entry remains visible in the Amazon VPC console for about an hour, after which it's automatically removed. You cannot remove this entry yourself.

Deleting a NAT gateway disassociates its Elastic IP address, but does not release the address from your account. If you delete a NAT gateway, the NAT gateway routes remain in a blackhole status until you delete or update the routes.

To delete a NAT gateway

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose NAT Gateways.
3. Select the radio button for the NAT gateway, and then choose Actions, Delete NAT gateway.
4. When prompted for confirmation, enter delete and then choose Delete.
5. If you no longer need the Elastic IP address that was associated with a public NAT gateway, we recommend that you release it. For more information, see Release an Elastic IP address (p. 137).

API and CLI overview

You can perform the tasks described on this page using the command line or API. For more information about the command line interfaces and a list of available API operations, see Working with Amazon VPC (p. 2).

Create a NAT gateway

- create-nat-gateway (AWS CLI)
- New-EC2NatGateway (AWS Tools for Windows PowerShell)
- CreateNatGateway (Amazon EC2 Query API)

Describe a NAT gateway

- describe-nat-gateways (AWS CLI)
- Get-EC2NatGateway (AWS Tools for Windows PowerShell)
- DescribeNatGateways (Amazon EC2 Query API)

Tag a NAT gateway

- create-tags (AWS CLI)
- New-EC2Tag (AWS Tools for Windows PowerShell)
- CreateTags (Amazon EC2 Query API)

Delete a NAT gateway

- delete-nat-gateway (AWS CLI)
- Remove-EC2NatGateway (AWS Tools for Windows PowerShell)
- DeleteNatGateway (Amazon EC2 Query API)
NAT gateway use cases

The following are example use cases for public and private NAT gateways.

**Scenarios**
- Access the internet from a private subnet (p. 147)
- Access your network using allow-listed IP addresses (p. 150)
- Enable communication between overlapping networks (p. 152)

**Access the internet from a private subnet**

You can use a public NAT gateway to enable instances in a private subnet to send outbound traffic to the internet, while preventing the internet from establishing connections to the instances.

**Contents**
- Overview (p. 147)
- Routing (p. 147)
- Test the public NAT gateway (p. 148)

**Overview**

The following diagram illustrates this use case. There are two Availability Zones, with two subnets in each Availability Zone. The route table for each subnet determines how traffic is routed. In Availability Zone A, the instances in the public subnet can reach the internet through a route to the internet gateway, while the instances in the private subnet have no route to the internet. In Availability Zone B, the public subnet contains a NAT gateway, and the instances in the private subnet can reach the internet through a route to the NAT gateway in the public subnet. The NAT gateway sends the traffic to the internet gateway, using its Elastic IP address as the source IP address.

**Routing**

The following is the route table associated with the public subnet in Availability Zone A. The first entry is the local route; it enables the instances in the subnet to communicate with other instances in the VPC...
using private IP addresses. The second entry sends all other subnet traffic to the internet gateway, which enables the instances in the subnet to access the internet.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>internet-gateway-id</td>
</tr>
</tbody>
</table>

The following is the route table associated with the private subnet in Availability Zone A. The entry is the local route, which enables the instances in the subnet to communicate with other instances in the VPC using private IP addresses. The instances in this subnet have no access to the internet.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>local</td>
</tr>
</tbody>
</table>

The following is the route table associated with the public subnet in Availability Zone B. The first entry is the local route, which enables the instances in the subnet to communicate with other instances in the VPC using private IP addresses. The second entry sends all other subnet traffic to the internet gateway, which enables the NAT gateway in the subnet to access the internet.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>internet-gateway-id</td>
</tr>
</tbody>
</table>

The following is the route table associated with the private subnet in Availability Zone B. The first entry is the local route; it enables the instances in the subnet to communicate with other instances in the VPC using private IP addresses. The second entry sends all other subnet traffic to the NAT gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC CIDR</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>nat-gateway-id</td>
</tr>
</tbody>
</table>

For more information, see the section called “Work with route tables” (p. 92).

Test the public NAT gateway

After you've created your NAT gateway and updated your route tables, you can ping remote addresses on the internet from an instance in your private subnet to test whether it can connect to the internet. For an example of how to do this, see Test the internet connection (p. 149).

If you can connect to the internet, you can also test whether internet traffic is routed through the NAT gateway:

- Trace the route of traffic from an instance in your private subnet. To do this, run the `traceroute` command from a Linux instance in your private subnet. In the output, you should see the private IP address of the NAT gateway in one of the hops (usually the first hop).
• Use a third-party website or tool that displays the source IP address when you connect to it from an instance in your private subnet. The source IP address should be the elastic IP address of the NAT gateway.

If these tests fail, see Troubleshoot NAT gateways (p. 162).

Test the internet connection

The following example demonstrates how to test whether an instance in a private subnet can connect to the internet.

1. Launch an instance in your public subnet (use this as a bastion host). In the launch wizard, ensure that you select an Amazon Linux AMI, and assign a public IP address to your instance. Ensure that your security group rules allow inbound SSH traffic from the range of IP addresses for your local network, and outbound SSH traffic to the IP address range of your private subnet (you can also use 0.0.0.0/0 for both inbound and outbound SSH traffic for this test).

2. Launch an instance in your private subnet. In the launch wizard, ensure that you select an Amazon Linux AMI. Do not assign a public IP address to your instance. Ensure that your security group rules allow inbound SSH traffic from the private IP address of your instance that you launched in the public subnet, and all outbound ICMP traffic. You must choose the same key pair that you used to launch your instance in the public subnet.

3. Configure SSH agent forwarding on your local computer, and connect to your bastion host in the public subnet. For more information, see To configure SSH agent forwarding for Linux or macOS (p. 149) or To configure SSH agent forwarding for Windows (PuTTY) (p. 149).

4. From your bastion host, connect to your instance in the private subnet, and then test the internet connection from your instance in the private subnet. For more information, see To test the internet connection (p. 150).

To configure SSH agent forwarding for Linux or macOS

1. From your local machine, add your private key to the authentication agent.

   For Linux, use the following command.

   ```bash
   ssh-add -c mykeypair.pem
   ```

   For macOS, use the following command.

   ```bash
   ssh-add -K mykeypair.pem
   ```

2. Connect to your instance in the public subnet using the -A option to enable SSH agent forwarding, and use the instance's public address, as shown in the following example.

   ```bash
   ssh -A ec2-user@54.0.0.123
   ```

To configure SSH agent forwarding for Windows (PuTTY)

1. Download and install Pageant from the PuTTY download page, if not already installed.

2. Convert your private key to .ppk format. For more information, see Converting your private key using PuTTYgen in the Amazon EC2 User Guide for Linux Instances.

3. Start Pageant, right-click the Pageant icon on the taskbar (it may be hidden), and choose Add Key. Select the .ppk file that you created, enter the passphrase if necessary, and choose Open.
4. Start a PuTTY session and connect to your instance in the public subnet using its public IP address. For more information, see Connecting to your Linux instance. In the Auth category, ensure that you select the Allow agent forwarding option, and leave the Private key file for authentication box blank.

To test the internet connection

1. From your instance in the public subnet, connect to your instance in your private subnet by using its private IP address as shown in the following example.

```
ssh ec2-user@10.0.1.123
```

2. From your private instance, test that you can connect to the internet by running the ping command for a website that has ICMP enabled.

```
ping ietf.org
```

PING ietf.org (4.31.198.44) 56(84) bytes of data.
64 bytes from mail.ietf.org (4.31.198.44): icmp_seq=1 ttl=47 time=86.0 ms
64 bytes from mail.ietf.org (4.31.198.44): icmp_seq=2 ttl=47 time=75.6 ms
...

Press Ctrl+C on your keyboard to cancel the ping command. If the ping command fails, see Instances cannot access the internet (p. 165).

3. (Optional) If you no longer require your instances, terminate them. For more information, see Terminate your instance in the Amazon EC2 User Guide for Linux Instances.

Access your network using allow-listed IP addresses

You can use a private NAT gateway to enable communication from your VPCs to your on-premises network using a pool of allow-listed addresses. Instead of assigning each instance a separate IP address from the allow-listed IP address range, you can route traffic from the subnet that is destined for the on-premises network through a private NAT gateway with an IP address from the allow-listed IP address range.

Contents

- Overview (p. 150)
- Resources (p. 151)
- Routing (p. 151)

Overview

The following diagram shows how instances can access on-premises resources through AWS VPN. Traffic from the instances is routed to a virtual private gateway, over the VPN connection, to the customer gateway, and then to the destination in the on-premises network. However, suppose that the destination allows traffic only from a specific IP address range, such as 100.64.1.0/28. This would prevent traffic from these instances from reaching the on-premises network.
The following diagram shows the key components of the configuration for this scenario. The VPC has its original IP address range plus the allowed IP address range. The VPC has a subnet from the allowed IP address range with a private NAT gateway. Traffic from the instances that is destined for the on-premises network is sent to the NAT gateway before being routed to the VPN connection. The on-premises network receives the traffic from the instances with the source IP address of the NAT gateway, which is from the allowed IP address range.

**Resources**

Create or update resources as follows:

- Associate the allowed IP address range with the VPC.
- Create a subnet in the VPC from the allowed IP address range.
- Create a private NAT gateway in the new subnet.
- Update the route table for the subnet with the instances to send traffic destined for the on-premises network to the NAT gateway. Add a route to the route table for the subnet with the private NAT gateway that sends traffic destined for the on-premises network to the virtual private gateway.

**Routing**

The following is the route table associated with the first subnet. There is a local route for each VPC CIDR. Local routes enable resources in the subnet to communicate with other resources in the VPC using private IP addresses. The third entry sends traffic destined for the on-premises network to the private NAT gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>100.64.1.0/24</td>
<td>local</td>
</tr>
<tr>
<td>192.168.0.0/16</td>
<td>nat-gateway-id</td>
</tr>
</tbody>
</table>

The following is the route table associated with the second subnet. There is a local route for each VPC CIDR. Local routes enable resources in the subnet to communicate with other resources in the VPC using...
private IP addresses. The third entry sends traffic destined for the on-premises network to the virtual private gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>100.64.1.0/24</td>
<td>local</td>
</tr>
<tr>
<td>192.168.0.0/16</td>
<td>vgw-id</td>
</tr>
</tbody>
</table>

### Enable communication between overlapping networks

You can use a private NAT gateway to enable communication between networks even if they have overlapping CIDR ranges. For example, suppose that the instances in VPC A need to access the services provided by the instances in VPC B.

### Contents

- Overview (p. 152)
- Resources (p. 153)
- Routing (p. 153)

### Overview

The following diagram shows the key components of the configuration for this scenario. First, your IP management team determines which address ranges can overlap (non-routable address ranges) and which cannot (routable address ranges). The IP management team allocates address ranges from the pool of routable address ranges to projects on request.

Each VPC has its original IP address range, which is non-routable, plus the routable IP address range assigned to it by the IP management team. VPC A has a subnet from its routable range with a private NAT gateway. The private NAT gateway gets its IP address from its subnet. VPC B has a subnet from its routable range with an Application Load Balancer. The Application Load Balancer gets its IP addresses from its subnets.

Traffic from an instance in the non-routable subnet of VPC A that is destined for the instances in the non-routable subnet of VPC B is sent through the private NAT gateway and then routed to the transit gateway. The transit gateway sends the traffic to the Application Load Balancer, which routes the traffic to one of the target instances in the non-routable subnet of VPC B. The traffic from the transit gateway to the Application Load Balancer has the source IP address of the private NAT gateway. Therefore, response traffic from the load balancer uses the address of the private NAT gateway as its destination.
The response traffic is sent to the transit gateway and then routed to the private NAT gateway, which translates the destination to the instance in the non-routable subnet of VPC A.

**Resources**

Create or update resources as follows:

- Associate the assigned routable IP address ranges with their respective VPCs.
- Create a subnet in VPC A from its routable IP address range, and create a private NAT gateway in this new subnet.
- Create a subnet in VPC B from its routable IP address range, and create an Application Load Balancer in this new subnet. Register the instances in the non-routable subnet with the target group for the load balancer.
- Create a transit gateway to connect the VPCs. Be sure to disable route propagation. When you attach each VPC to the transit gateway, use the routable address range of the VPC.
- Update the route table of the non-routable subnet in VPC A to send all traffic destined for the routable address range of VPC B to the private NAT gateway. Update the route table of the routable subnet in VPC A to send all traffic destined for the routable address range of VPC B to the transit gateway.
- Update the route table of the routable subnet in VPC B to send all traffic destined for the routable address range of VPC A to the transit gateway.

**Routing**

The following is the route table for the non-routable subnet in VPC A.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>100.64.1.0/24</td>
<td>local</td>
</tr>
<tr>
<td>100.64.2.0/24</td>
<td>nat-gateway-id</td>
</tr>
</tbody>
</table>

The following is the route table for the routable subnet in VPC A.
The following is the route table for the non-routable subnet in VPC B.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>100.64.1.0/24</td>
<td>local</td>

### DNS64 and NAT64

A NAT gateway supports network address translation from IPv6 to IPv4, popularly known as NAT64. NAT64 helps your IPv6 AWS resources communicate with IPv4 resources in the same VPC or a different VPC, in your on-premises network or over the internet. You can use NAT64 with DNS64 on Amazon Route 53 Resolver or use your own DNS64 server.

**Contents**

- What is DNS64? (p. 154)
- What is NAT64? (p. 155)
- Configure DNS64 and NAT64 (p. 155)

**What is DNS64?**

Your IPv6-only workloads running in VPCs can only send and receive IPv6 network packets. Without DNS64, a DNS query for an IPv4-only service will yield an IPv4 destination address in response and your
IPv6-only service cannot communicate with it. To bridge this communication gap, you can enable DNS64 for a subnet and it applies to all the AWS resources within that subnet. With DNS64, the Amazon Route 53 Resolver looks up the DNS record for the service you queried for and does one of the following:

- If the record contains an IPv6 address, it returns the original record and the connection is established without any translation over IPv6.
- If there is no IPv6 address associated with the destination in the DNS record, the Route 53 Resolver synthesizes one by prepending the well-known /96 prefix, defined in RFC6052 (64:ff9b::/96), to the IPv4 address in the record. Your IPv6-only service sends network packets to the synthesized IPv6 address. You will then need to route this traffic through the NAT gateway, which performs the necessary translation on the traffic to allow IPv6 services in your subnet to access IPv4 services outside that subnet.

You can enable or disable DNS64 on a subnet using the modify-subnet-attribute using the AWS CLI or with the VPC console by selecting a subnet and choosing Actions > Edit subnet settings.

What is NAT64?

NAT64 enables your IPv6-only services in Amazon VPCs to communicate with IPv4-only services within the same VPC (in different subnets) or connected VPCs, in your on-premises networks, or over the internet.

NAT64 is automatically available on your existing NAT gateways or on any new NAT gateways you create. It's not a feature you enable or disable.

Once you have enabled DNS64 and your IPv6-only service sends network packets to the synthesized IPv6 address through the NAT gateway, the following happens:

- From the 64:ff9b::/96 prefix, the NAT gateway recognizes that the original destination is IPv4 and translates the IPv6 packets to IPv4 by replacing:
  - Source IPv6 with its own private IP which is translated to Elastic IP address by the internet gateway.
  - Destination IPv6 to IPv4 by truncating the 64:ff9b::/96 prefix.
- The NAT gateway sends the translated IPv4 packets to the destination through the internet gateway, virtual private gateway, or transit gateway and initiates a connection.
- The IPv4-only host sends back IPv4 response packets. Once a connection is established, NAT gateway accepts the response IPv4 packets from the external hosts.
- The response IPv4 packets are destined for NAT gateway, which receives the packets and de-NATs them by replacing its IP (destination IP) with the host's IPv6 address and prepending back 64:ff9b::/96 to the source IPv4 address. The packet then flows to the host following the local route.

In this way, the NAT gateway enables your IPv6-only workloads in an Amazon VPC subnet to communicate with IPv4-only services anywhere outside the subnet.

Configure DNS64 and NAT64

Follow the steps in this section to configure DNS64 and NAT64 to enable communication with IPv4-only services.

Contents

- Enable communication with IPv4-only services on the internet with the AWS CLI (p. 156)
- Enable communication with IPv4-only services in your on-premises environment (p. 156)
Enable communication with IPv4-only services on the internet with the AWS CLI

If you have a subnet with IPv6-only workloads that needs to communicate with IPv4-only services outside the subnet, this example shows you how to enable these IPv6-only services to communicate with IPv4-only services on the internet.

You should first configure a NAT gateway in a public subnet (separate from the subnet containing the IPv6-only workloads). For example, the subnet containing the NAT gateway should have a 0.0.0/0 route pointing to the internet gateway.

Complete these steps to enable these IPv6-only services to connect with IPv4-only services on the internet:

1. Add the following three routes to the route table of the subnet containing the IPv6-only workloads:
   - IPv4 route (if any) pointing to the NAT gateway.
   - 64:ff9b::/96 route pointing to the NAT gateway. This will allow traffic from your IPv6-only workloads destined for IPv4-only services to be routed through the NAT gateway.
   - IPv6 ::/0 route pointing to the egress-only internet gateway (or the internet gateway).

   Note that pointing ::/0 to the internet gateway will allow external IPv6 hosts (outside the VPC) to initiate connection over IPv6.

   ```bash
   aws ec2 create-route --route-table-id rtb-34056078 --destination-cidr-block 0.0.0.0/0 --nat-gateway-id nat-05dba92075d71c408
   ```

   ```bash
   aws ec2 create-route --route-table-id rtb-34056078 --destination-ipv6-cidr-block 64:ff9b::/96 --nat-gateway-id nat-05dba92075d71c408
   ```

   ```bash
   aws ec2 create-route --route-table-id rtb-34056078 --destination-ipv6-cidr-block ::/0 --egress-only-internet-gateway-id eigw-c0a643a9
   ```

2. Enable DNS64 capability in the subnet containing the IPv6-only workloads.

   ```bash
   aws ec2 modify-subnet-attribute --subnet-id subnet-1a2b3c4d --enable-dns64
   ```

Now, resources in your private subnet can establish stateful connections with both IPv4 and IPv6 services on the internet. Configure your security group and NACLs appropriately to allow egress and ingress traffic to 64:ff9b::/96 traffic.

Enable communication with IPv4-only services in your on-premises environment

Amazon Route 53 Resolver enables you to forward DNS queries from your VPC to an on-premises network and vice versa. You can do this by doing the following:

- You create a Route 53 Resolver outbound endpoint in a VPC and assign it the IPv4 addresses that you want Route 53 Resolver to forward queries from. For your on-premises DNS resolver, these are the IP addresses that the DNS queries originate from and, therefore, should be IPv4 addresses.
- You create one or more rules which specify the domain names of the DNS queries that you want Route 53 Resolver to forward to your on-premises resolvers. You also specify the IPv4 addresses of the on-premises resolvers.
Now that you have set up a Route 53 Resolver outbound endpoint, you need to enable DNS64 on the subnet containing your IPv6-only workloads and route any data destined for your on-premises network through a NAT gateway.

**How DNS64 works for IPv4-only destinations in on-premises networks:**

1. You assign an IPv4 address to the Route 53 Resolver outbound endpoint in your VPC.
2. The DNS query from your IPv6 service goes to Route 53 Resolver over IPv6. Route 53 Resolver matches the query against the forwarding rule and gets an IPv4 address for your on-premises resolver.
3. Route 53 Resolver converts the query packet from IPv6 into IPv4 and forwards it to the outbound endpoint. Each IP address of the endpoint represents one ENI that forwards the request to the on-premises IPv4 address of your DNS resolver.
4. The on-premises resolver sends the response packet over IPv4 back through the outbound endpoint to Route 53 Resolver.
5. Assuming the query was made from a DNS64-enabled subnet, Route 53 Resolver does two things:
   a. Checks the content of the response packet. If there’s an IPv6 address in the record, it keeps the content as is, but if it contains only an IPv4 record. It synthesizes an IPv6 record as well by prepending 64:ff9b::/96 to the IPv4 address.
   b. Repackages the content and sends it to the service in your VPC over IPv6.

### Monitor NAT gateways with Amazon CloudWatch

You can monitor your NAT gateway using CloudWatch, which collects information from your NAT gateway and creates readable, near real-time metrics. You can use this information to monitor and troubleshoot your NAT gateway. NAT gateway metric data is provided at 1-minute intervals, and statistics are recorded for a period of 15 months.

For more information about Amazon CloudWatch, see the [Amazon CloudWatch User Guide](#). For more information about pricing, see [Amazon CloudWatch Pricing](#).

#### NAT gateway metrics and dimensions

The following metrics are available for your NAT gateways.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveConnectionCount</td>
<td>The total number of concurrent active TCP connections through the NAT gateway. A value of zero indicates that there are no active connections through the NAT gateway. Units: Count Statistics: The most useful statistic is Max.</td>
</tr>
<tr>
<td>BytesInFromDestination</td>
<td>The number of bytes received by the NAT gateway from the destination. If the value for BytesOutToSource is less than the value for BytesInFromDestination, there might be data loss during NAT gateway processing, or traffic being actively blocked by the NAT gateway.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>BytesInFromSource</strong></td>
<td>The number of bytes received by the NAT gateway from clients in your VPC.</td>
</tr>
<tr>
<td></td>
<td>If the value for BytesOutToDestination is less than the value for BytesInFromSource, there might be data loss during NAT gateway processing.</td>
</tr>
<tr>
<td></td>
<td>Units: Bytes</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is Sum.</td>
</tr>
<tr>
<td><strong>BytesOutToDestination</strong></td>
<td>The number of bytes sent out through the NAT gateway to the destination.</td>
</tr>
<tr>
<td></td>
<td>A value greater than zero indicates that there is traffic going to the internet from clients that are behind the NAT gateway. If the value for BytesOutToDestination is less than the value for BytesInFromSource, there might be data loss during NAT gateway processing.</td>
</tr>
<tr>
<td></td>
<td>Unit: Bytes</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is Sum.</td>
</tr>
<tr>
<td><strong>BytesOutToSource</strong></td>
<td>The number of bytes sent through the NAT gateway to the clients in your VPC.</td>
</tr>
<tr>
<td></td>
<td>A value greater than zero indicates that there is traffic coming from the internet to clients that are behind the NAT gateway. If the value for BytesOutToSource is less than the value for BytesInFromDestination, there might be data loss during NAT gateway processing, or traffic being actively blocked by the NAT gateway.</td>
</tr>
<tr>
<td></td>
<td>Units: Bytes</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is Sum.</td>
</tr>
<tr>
<td><strong>ConnectionAttemptCount</strong></td>
<td>The number of connection attempts made through the NAT gateway.</td>
</tr>
<tr>
<td></td>
<td>If the value for ConnectionEstablishedCount is less than the value for ConnectionAttemptCount, this indicates that clients behind the NAT gateway attempted to establish new connections for which there was no response.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is Sum.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>ConnectionEstablishedCount</strong></td>
<td>The number of connections established through the NAT gateway.</td>
</tr>
<tr>
<td></td>
<td>If the value for <code>ConnectionEstablishedCount</code> is less than the value for <code>ConnectionAttemptCount</code>, this indicates that clients behind the NAT gateway attempted to establish new connections for which there was no response.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is <strong>Sum</strong>.</td>
</tr>
<tr>
<td><strong>ErrorPortAllocation</strong></td>
<td>The number of times the NAT gateway could not allocate a source port.</td>
</tr>
<tr>
<td></td>
<td>A value greater than zero indicates that too many concurrent connections are open through the NAT gateway.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is <strong>Sum</strong>.</td>
</tr>
<tr>
<td><strong>IdleTimeoutCount</strong></td>
<td>The number of connections that transitioned from the active state to the idle state. An active connection transitions to idle if it was not closed gracefully and there was no activity for the last 350 seconds.</td>
</tr>
<tr>
<td></td>
<td>A value greater than zero indicates that there are connections that have been moved to an idle state. If the value for <code>IdleTimeoutCount</code> increases, it might indicate that clients behind the NAT gateway are re-using stale connections.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is <strong>Sum</strong>.</td>
</tr>
<tr>
<td><strong>PacketsDropCount</strong></td>
<td>The number of packets dropped by the NAT gateway.</td>
</tr>
<tr>
<td></td>
<td>A value greater than zero might indicate an ongoing transient issue with the NAT gateway. If this value exceeds 0.01 percent of the total traffic on the NAT gateway, check the <a href="https://console.aws.amazon.com/support/home#serviceHealth">AWS service health dashboard</a>.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is <strong>Sum</strong>.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PacketsInFromDestination</td>
<td>The number of packets received by the NAT gateway from the destination.</td>
</tr>
<tr>
<td></td>
<td>If the value for PacketsOutToSource is less than the value for PacketsInFromDestination, there might be data loss during NAT gateway processing, or traffic being actively blocked by the NAT gateway.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is Sum.</td>
</tr>
<tr>
<td>PacketsInFromSource</td>
<td>The number of packets received by the NAT gateway from clients in your VPC.</td>
</tr>
<tr>
<td></td>
<td>If the value for PacketsOutToDestination is less than the value for PacketsInFromSource, there might be data loss during NAT gateway processing.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is Sum.</td>
</tr>
<tr>
<td>PacketsOutToDestination</td>
<td>The number of packets sent out through the NAT gateway to the destination.</td>
</tr>
<tr>
<td></td>
<td>A value greater than zero indicates that there is traffic going to the internet from clients that are behind the NAT gateway. If the value for PacketsOutToDestination is less than the value for PacketsInFromSource, there might be data loss during NAT gateway processing.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is Sum.</td>
</tr>
<tr>
<td>PacketsOutToSource</td>
<td>The number of packets sent through the NAT gateway to the clients in your VPC.</td>
</tr>
<tr>
<td></td>
<td>A value greater than zero indicates that there is traffic coming from the internet to clients that are behind the NAT gateway. If the value for PacketsOutToSource is less than the value for PacketsInFromDestination, there might be data loss during NAT gateway processing, or traffic being actively blocked by the NAT gateway.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td></td>
<td>Statistics: The most useful statistic is Sum.</td>
</tr>
</tbody>
</table>

To filter the metric data, use the following dimension.
<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NatGatewayId</td>
<td>Filter the metric data by the NAT gateway ID.</td>
</tr>
</tbody>
</table>

**View NAT gateway CloudWatch metrics**

NAT gateway metrics are sent to CloudWatch at 1-minute intervals. Metrics are grouped first by the service namespace, and then by the possible combinations of dimensions within each namespace. You can view the metrics for your NAT gateways as follows.

**To view metrics using the CloudWatch console**

2. In the navigation pane, choose **Metrics, All metrics**.
3. Choose the **NATGateway** metric namespace.
4. Choose a metric dimension.

**To view metrics using the AWS CLI**

At a command prompt, use the following command to list the metrics that are available for the NAT gateway service.

```
aws cloudwatch list-metrics --namespace "AWS/NATGateway"
```

**Create CloudWatch alarms to monitor a NAT gateway**

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. It sends a notification to an Amazon SNS topic based on the value of the metric relative to a given threshold over a number of time periods.

For example, you can create an alarm that monitors the amount of traffic coming in or leaving the NAT gateway. The following alarm monitors the amount of outbound traffic from clients in your VPC through the NAT gateway to the internet. It sends a notification when the number of bytes reaches a threshold of 5,000,000 during a 15-minute period.

**To create an alarm for outbound traffic through the NAT gateway**

2. In the navigation pane, choose **Alarms, All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**.
5. Choose the **NATGateway** metric namespace and then choose a metric dimension. When you get to the metrics, select the check box next to the **BytesOutToDestination** metric for the NAT gateway, and then choose **Select metric**.
6. Configure the alarm as follows, and then choose **Next**:

   - For **Statistic**, choose **Sum**.
   - For **Period**, choose **15 minutes**.
   - For **Whenever**, choose **Greater/Equal** and enter 5000000 for the threshold.
7. For **Notification**, select an existing SNS topic or choose **Create new topic** to create a new one. Choose **Next**.
8. Enter a name and description for the alarm and choose **Next**.
When you done configuring the alarm, choose Create alarm.

As another example, you can create an alarm that monitors port allocation errors and sends a notification when the value is greater than zero (0) for three consecutive 5-minute periods.

To create an alarm to monitor port allocation errors

2. In the navigation pane, choose Alarms, All alarms.
3. Choose Create alarm.
4. Choose Select metric.
5. Choose the NATGateway metric namespace and then choose a metric dimension. When you get to the metrics, select the check box next to the ErrorPortAllocation metric for the NAT gateway, and then choose Select metric.
6. Configure the alarm as follows, and then choose Next:
   - For Statistic, choose Maximum.
   - For Period, choose 5 minutes.
   - For Whenever, choose Greater and enter 0 for the threshold.
   - For Additional configuration, Datapoints to alarm, enter 3.
7. For Notification, select an existing SNS topic or choose Create new topic to create a new one. Choose Next.
8. Enter a name and description for the alarm and choose Next.
9. When you are done configuring the alarm, choose Create alarm.

For more information, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

Troubleshoot NAT gateways

The following topics help you to troubleshoot common issues that you might encounter when creating or using a NAT gateway.

Issues
- NAT gateway creation fails (p. 162)
- NAT gateway quota (p. 163)
- Elastic IP address quota (p. 164)
- Availability Zone is unsupported (p. 164)
- NAT gateway is no longer visible (p. 164)
- NAT gateway doesn't respond to a ping command (p. 165)
- Instances cannot access the internet (p. 165)
- TCP connection to a destination fails (p. 166)
- Traceroute output does not display NAT gateway private IP address (p. 167)
- Internet connection drops after 350 seconds (p. 167)
- IPsec connection cannot be established (p. 167)
- Cannot initiate more connections (p. 168)

NAT gateway creation fails

Problem
You create a NAT gateway and it goes to a state of Failed.

**Note**
A failed NAT gateway is automatically deleted, usually in about an hour.

**Cause**
There was an error when the NAT gateway was created. The returned state message provides the reason for the error.

**Solution**
To view the error message, open the Amazon VPC console, and then choose **NAT Gateways**. Select the radio button for your NAT gateway, and then find **State message** on the **Details** tab.

The following table lists the possible causes of the failure as indicated in the Amazon VPC console. After you've applied any of the remedial steps indicated, you can try to create a NAT gateway again.

<table>
<thead>
<tr>
<th>Displayed error</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subnet has insufficient free addresses to create this NAT gateway</td>
<td>The subnet that you specified does not have any free private IP addresses. The NAT gateway requires a network interface with a private IP address allocated from the subnet's range.</td>
<td>Check how many IP addresses are available in your subnet by going to the <strong>Subnets</strong> page in the Amazon VPC console. You can view the <strong>Available IPs</strong> in the details pane for your subnet. To create free IP addresses in your subnet, you can delete unused network interfaces, or terminate instances that you do not require.</td>
</tr>
<tr>
<td>Network vpc-xxxxxxxx has no internet gateway attached</td>
<td>A NAT gateway must be created in a VPC with an internet gateway.</td>
<td>Create and attach an internet gateway to your VPC. For more information, see [Create and attach an internet gateway](p. 131).</td>
</tr>
<tr>
<td>Elastic IP address eipalloc-xxxxxxxx is already associated</td>
<td>The Elastic IP address that you specified is already associated with another resource, and cannot be associated with the NAT gateway.</td>
<td>Check which resource is associated with the Elastic IP address. Go to the <strong>Elastic IPs</strong> page in the Amazon VPC console, and view the values specified for the instance ID or network interface ID. If you do not require the Elastic IP address for that resource, you can disassociate it. Alternatively, allocate a new Elastic IP address to your account. For more information, see [Work with Elastic IP addresses](p. 136).</td>
</tr>
</tbody>
</table>

**NAT gateway quota**
When you try to create a NAT gateway, you get the following error.

Performing this operation would exceed the limit of 5 NAT gateways
Cause
You've reached the quota for the number of NAT gateways for that Availability Zone.

Solution
If you've reached this NAT gateway quota for your account, you can do one of the following:

• Request an increase in the NAT gateways per Availability Zone quota using the Service Quotas console.
• Check the status of your NAT gateway. A status of Pending, Available, or Deleting counts against your quota. If you've recently deleted a NAT gateway, wait a few minutes for the status to go from Deleting to Deleted. Then try creating a new NAT gateway.
• If you do not need your NAT gateway in a specific Availability Zone, try creating a NAT gateway in an Availability Zone where you haven't reached your quota.

For more information, see Amazon VPC quotas (p. 353).

Elastic IP address quota

Problem
When you try to allocate an Elastic IP address for your public NAT gateway, you get the following error.

The maximum number of addresses has been reached.

Cause
You've reached the quota for the number of Elastic IP addresses for your account for that Region.

Solution
If you've reached your Elastic IP address quota, you can disassociate an Elastic IP address from another resource. Alternatively, you can request an increase in the Elastic IPs quota using the Service Quotas console.

Availability Zone is unsupported

Problem
When you try to create a NAT gateway, you get the following error: NotAvailableInZone.

Cause
You might be trying to create the NAT gateway in a constrained Availability Zone — a zone in which our ability to expand is constrained.

Solution
We cannot support NAT gateways in these Availability Zones. You can create a NAT gateway in a different Availability Zone and use it for private subnets in the constrained zone. You can also move your resources to an unconstrained Availability Zone so that your resources and your NAT gateway are in the same zone.

NAT gateway is no longer visible

Problem
You created a NAT gateway but it's no longer visible in the Amazon VPC console.

Cause
There might have been an error during the creation of your NAT gateway, and creation failed. A NAT gateway with a status of Failed is visible in the Amazon VPC console for about an hour. After an hour, it’s automatically deleted.

**Solution**

Review the information in [NAT gateway creation fails](p. 162), and try creating a new NAT gateway.

**NAT gateway doesn't respond to a ping command**

**Problem**

When you try to ping a NAT gateway's Elastic IP address or private IP address from the internet (for example, from your home computer) or from an instance in your VPC, you do not get a response.

**Cause**

A NAT gateway only passes traffic from an instance in a private subnet to the internet.

**Solution**

To test that your NAT gateway is working, see [Test the public NAT gateway](p. 148).

**Instances cannot access the internet**

**Problem**

You created a public NAT gateway and followed the steps to test it, but the ping command fails, or your instances in the private subnet cannot access the internet.

**Causes**

The cause of this problem might be one of the following:

- The NAT gateway is not ready to serve traffic.
- Your route tables are not configured correctly.
- Your security groups or network ACLs are blocking inbound or outbound traffic.
- You're using an unsupported protocol.

**Solution**

Check the following information:

- Check that the NAT gateway is in the Available state. In the Amazon VPC console, go to the [NAT Gateways](p. 162) page and view the status information in the details pane. If the NAT gateway is in a failed state, there may have been an error when it was created. For more information, see [NAT gateway creation fails](p. 162).
- Check that you've configured your route tables correctly:
  - The NAT gateway must be in a public subnet with a route table that routes internet traffic to an internet gateway.
  - Your instance must be in a private subnet with a route table that routes internet traffic to the NAT gateway.
  - Check that there are no other route table entries that route all or part of the internet traffic to another device instead of the NAT gateway.
- Ensure that your security group rules for your private instance allow outbound internet traffic. For the ping command to work, the rules must also allow outbound ICMP traffic.
The NAT gateway itself allows all outbound traffic and traffic received in response to an outbound request (it is therefore stateful).

- Ensure that the network ACLs that are associated with the private subnet and public subnets do not have rules that block inbound or outbound internet traffic. For the ping command to work, the rules must also allow inbound and outbound ICMP traffic.

You can enable flow logs to help you diagnose dropped connections because of network ACL or security group rules. For more information, see Logging IP traffic using VPC Flow Logs (p. 180).

- If you are using the ping command, ensure that you are pinging a host that has ICMP enabled. If ICMP is not enabled, you will not receive reply packets. To test this, perform the same ping command from the command line terminal on your own computer.

- Check that your instance is able to ping other resources, for example, other instances in the private subnet (assuming that security group rules allow this).

- Ensure that your connection is using a TCP, UDP, or ICMP protocol only.

**TCP connection to a destination fails**

**Problem**

Some of your TCP connections from instances in a private subnet to a specific destination through a NAT gateway are successful, but some are failing or timing out.

**Causes**

The cause of this problem might be one of the following:

- The destination endpoint is responding with fragmented TCP packets. NAT gateways do not support IP fragmentation for TCP or ICMP. For more information, see Compare NAT gateways and NAT instances (p. 175).
- The tcp_tw_recycle option is enabled on the remote server, which is known to cause issues when there are multiple connections from behind a NAT device.

**Solutions**

Verify whether the endpoint to which you're trying to connect is responding with fragmented TCP packets by doing the following:

1. Use an instance in a public subnet with a public IP address to trigger a response large enough to cause fragmentation from the specific endpoint.
2. Use the tcpdump utility to verify that the endpoint is sending fragmented packets.

**Important**

You must use an instance in a public subnet to perform these checks. You cannot use the instance from which the original connection was failing, or an instance in a private subnet behind a NAT gateway or a NAT instance.

Diagnostic tools that send or receive large ICMP packets will report packet loss. For example, the command ping -s 10000 example.com does not work behind a NAT gateway.

3. If the endpoint is sending fragmented TCP packets, you can use a NAT instance instead of a NAT gateway.

If you have access to the remote server, you can verify whether the tcp_tw_recycle option is enabled by doing the following:

1. From the server, run the following command.
cat /proc/sys/net/ipv4/tcp_tw_recycle

If the output is 1, then the tcp_tw_recycle option is enabled.

2. If tcp_tw_recycle is enabled, we recommend disabling it. If you need to reuse connections, tcp_tw_reuse is a safer option.

If you don't have access to the remote server, you can test by temporarily disabling the tcp_timestamps option on an instance in the private subnet. Then connect to the remote server again. If the connection is successful, the cause of the previous failure is likely because tcp_tw_recycle is enabled on the remote server. If possible, contact the owner of the remote server to verify if this option is enabled and request for it to be disabled.

**Traceroute output does not display NAT gateway private IP address**

**Problem**

Your instance can access the internet, but when you perform the traceroute command, the output does not display the private IP address of the NAT gateway.

**Cause**

Your instance is accessing the internet using a different gateway, such as an internet gateway.

**Solution**

In the route table of the subnet in which your instance is located, check the following information:

- Ensure that there is a route that sends internet traffic to the NAT gateway.
- Ensure that there isn't a more specific route that's sending internet traffic to other devices, such as a virtual private gateway or an internet gateway.

**Internet connection drops after 350 seconds**

**Problem**

Your instances can access the internet, but the connection drops after 350 seconds.

**Cause**

If a connection that's using a NAT gateway is idle for 350 seconds or more, the connection times out.

When a connection times out, a NAT gateway returns an RST packet to any resources behind the NAT gateway that attempt to continue the connection (it does not send a FIN packet).

**Solution**

To prevent the connection from being dropped, you can initiate more traffic over the connection. Alternatively, you can enable TCP keepalive on the instance with a value less than 350 seconds.

**IPsec connection cannot be established**

**Problem**

You cannot establish an IPsec connection to a destination.
Cause

NAT gateways currently do not support the IPsec protocol.

Solution

You can use NAT-Traversal (NAT-T) to encapsulate IPsec traffic in UDP, which is a supported protocol for
NAT gateways. Ensure that you test your NAT-T and IPsec configuration to verify that your IPsec traffic is
not dropped.

Cannot initiate more connections

Problem

You have existing connections to a destination through a NAT gateway, but cannot establish more
connections.

Cause

You might have reached the limit for simultaneous connections for a single NAT gateway. For more
information, see NAT gateway basics (p. 144). If your instances in the private subnet create a large
number of connections, you might reach this limit.

Solution

Do one of the following:

• Create a NAT gateway per Availability Zone and spread your clients across those zones.
• Create additional NAT gateways in the public subnet and split your clients into multiple private
  subnets, each with a route to a different NAT gateway.
• Limit the number of connections your clients can create to the destination.
• Use the IdleTimeoutCount (p. 157) metric in CloudWatch to monitor for increases in idle
  connections. Close idle connections to release capacity.

NAT instances

Important

NAT AMI is built on the last version of Amazon Linux, 2018.03, which reached the end of
standard support on December 31, 2020. For more information, see the following blog post:
Amazon Linux AMI end of life. This AMI will receive only critical security updates (there will be
no regular updates).

If you use an existing NAT AMI, AWS recommends that you migrate to a NAT gateway (p. 176).
NAT gateways provide better availability, higher bandwidth, and requires less administrative
effort. If NAT instances are a better match for your use case, you can create your own NAT AMI.
For more information, see Compare NAT gateways and NAT instances (p. 175).

You can create your own AMI that provides network address translation and use your AMI to launch an
EC2 instance as a NAT instance. You launch a NAT instance in a public subnet to enable instances in the
private subnet to initiate outbound IPv4 traffic to the internet or other AWS services, but prevent the
instances from receiving inbound traffic initiated on the internet.

Your NAT instance quota depends on your instance quota for the Region. For more information, see
Amazon EC2 service quotas in the Amazon EC2 User Guide for Linux Instances.

Contents

• NAT instance basics (p. 169)
• Set up the NAT instance (p. 169)
NAT instance basics

The following figure illustrates the NAT instance basics. The main route table is associated with the private subnet and sends the traffic from the instances in the private subnet to the NAT instance in the public subnet. The NAT instance then sends the traffic to the internet gateway for the VPC. The traffic is attributed to the Elastic IP address of the NAT instance. The NAT instance specifies a high port number for the response; if a response comes back, the NAT instance sends it to an instance in the private subnet based on the port number for the response.

Internet traffic from the instances in the private subnet is routed to the NAT instance, which then communicates with the internet. Therefore, the NAT instance must have internet access. It must be in a public subnet (a subnet that has a route table with a route to the internet gateway), and it must have a public IP address or an Elastic IP address.

Set up the NAT instance

Use the following procedure to set up a VPC and a NAT instance.
Requirement

Before you begin, create an AMI that's configured to run NAT on your instance. The specific commands to configure NAT depend on the operating system that you use. For example, for Amazon Linux 2, use the following commands:

```bash
sudo sysctl -w net.ipv4.ip_forward=1
sudo /sbin/iptables -t nat -A POSTROUTING -o eth0 -j MASQUERADE
sudo yum install iptables-services
sudo service iptables save
```

To set up a NAT instance

1. Create a VPC with two subnets.
   a. Create a VPC (see Create a VPC (p. 18)).
   b. Create two subnets (see Create a subnet (p. 131)).
   c. Attach an internet gateway to the VPC (see Create and attach an internet gateway (p. 131)).
   d. Create a custom route table that sends traffic destined outside the VPC to the internet gateway, and then associate it with one subnet, making it a public subnet (see Create a custom route table (p. 132)).

2. Create the NATSG security group (see Create the NATSG security group (p. 171)). You'll specify this security group when you launch the NAT instance.

3. Launch an instance into your public subnet from an AMI that's been configured to run as a NAT instance.
   a. Open the Amazon EC2 console.
   b. On the dashboard, choose the Launch Instance button, and complete the wizard as follows:
      i. On the Choose an Amazon Machine Image (AMI) page, set the filter to Owned by me, and then select your AMI.
      ii. On the Choose an Instance Type page, select the instance type, then choose Next: Configure Instance Details.
      iii. On the Configure Instance Details page, select the VPC you created from the Network list, and select your public subnet from the Subnet list.
      iv. (Optional) Select the Public IP check box to request that your NAT instance receives a public IP address. If you choose not to assign a public IP address now, you can allocate an Elastic IP address and assign it to your instance after it's launched. Choose Next: Add Storage.
      v. You can choose to add storage to your instance, and on the next page, you can add tags. Choose Next: Configure Security Group when you are done.
      vi. On the Configure Security Group page, select the Select an existing security group option, and select the NATSG security group that you created. Choose Review and Launch.
      vii. Review the settings that you've chosen. Make any changes that you need, and then choose Launch to choose a key pair and launch your instance.

4. Disable the SrcDestCheck attribute for the NAT instance (see Disable source/destination checks (p. 172))

5. If you did not assign a public IP address to your NAT instance during launch (step 3), you need to associate an Elastic IP address with it.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. In the navigation pane, choose Elastic IPs, and then choose Allocate new address.
   c. Choose Allocate.
   d. Select the Elastic IP address from the list, and then choose Actions, Associate address.
e. Select the network interface resource, then select the network interface for the NAT instance. Select the address to associate the Elastic IP with from the Private IP list, and then choose Associate.

6. Update the main route table to send traffic to the NAT instance. For more information, see Update the main route table (p. 173).

Launch a NAT instance using the command line

To launch a NAT instance into your subnet, use one of the following commands. For more information, see Working with Amazon VPC (p. 2). You can use the AMI ID of the AMI that you configured to run as a NAT instance. For information about how to create an AMI on Amazon Linux 2, see Creating Amazon EBS-backed AMIs in the Amazon EC2 User Guide for Linux Instances.

- run-instances (AWS CLI)
- New-EC2Instance (AWS Tools for Windows PowerShell)

Create the NATSG security group

Define the NATSG security group as described in the following table to enable your NAT instance to receive internet-bound traffic from instances in a private subnet, as well as SSH traffic from your network. The NAT instance can also send traffic to the internet, which enables the instances in the private subnet to get software updates.

The following are the recommended rules.

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Private subnet CIDR</td>
<td>TCP</td>
<td>80</td>
<td>Allow inbound HTTP traffic from servers in the private subnet</td>
</tr>
<tr>
<td></td>
<td>Private subnet CIDR</td>
<td>TCP</td>
<td>443</td>
<td>Allow inbound HTTPS traffic from servers in the private subnet</td>
</tr>
<tr>
<td></td>
<td>Public IP address range of your network</td>
<td>TCP</td>
<td>22</td>
<td>Allow inbound SSH access to the NAT instance from your network (over the internet gateway)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Outbound</th>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>Allow outbound HTTP access to the internet</td>
<td></td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>Allow outbound HTTPS access to the internet</td>
<td></td>
</tr>
</tbody>
</table>

To create the NATSG security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups, and then choose Create Security Group.
3. In the Create Security Group dialog box, specify NATSG as the name of the security group, and provide a description. Select the ID of your VPC from the VPC list, and then choose Yes, Create.
4. Select the NATSG security group that you just created. The details pane displays the details for the security group, plus tabs for working with its inbound and outbound rules.
5. Add rules for inbound traffic using the Inbound Rules tab as follows:
   a. Choose Edit.
   b. Choose Add another rule, and select HTTP from the Type list. In the Source field, specify the IP address range of your private subnet.
   c. Choose Add another rule, and select HTTPS from the Type list. In the Source field, specify the IP address range of your private subnet.
   d. Choose Add another rule, and select SSH from the Type list. In the Source field, specify the public IP address range of your network.
   e. Choose Save.
6. Add rules for outbound traffic using the Outbound Rules tab as follows:
   a. Choose Edit.
   b. Choose Add another rule, and select HTTP from the Type list. In the Destination field, specify 0.0.0.0/0
   c. Choose Add another rule, and select HTTPS from the Type list. In the Destination field, specify 0.0.0.0/0
   d. Choose Save.

For more information, see Control traffic to resources using security groups (p. 245).

Disable source/destination checks

Each EC2 instance performs source/destination checks by default. This means that the instance must be the source or destination of any traffic it sends or receives. However, a NAT instance must be able to send and receive traffic when the source or destination is not itself. Therefore, you must disable source/destination checks on the NAT instance.

You can disable the SrcDestCheck attribute for a NAT instance that’s either running or stopped using the console or the command line.

To disable source/destination checking using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the NAT instance, choose Actions, Networking, Change source/destination check.
4. Verify that source/destination checking is stopped. Otherwise, choose Stop.
5. Choose Save.
6. If the NAT instance has a secondary network interface, choose it from Network interfaces on the Networking tab. Choose the interface ID to go to the network interfaces page. Choose Actions, Change source/dest. check, clear Enable, and choose Save.

To disable source/destination checking using the command line

You can use one of the following commands. For more information, see Working with Amazon VPC (p. 2).

- modify-instance-attribute (AWS CLI)
- Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)
Update the main route table

The private subnet in your VPC is not associated with a custom route table, therefore it uses the main route table. By default, the main route table enables the instances in your VPC to communicate with each other. You must add a route that sends all other subnet traffic to the NAT instance.

To update the main route table

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route Tables.
3. Select the main route table for your VPC (the Main column displays Yes). The details pane displays tabs for working with its routes, associations, and route propagation.
4. On the Routes tab, do the following:
   a. Choose Edit routes and then choose Add route.
   b. Specify 0.0.0.0/0 for Destination and the instance ID of the NAT instance for Target.
   c. Choose Save changes.
5. On the Subnet associations tab, choose Edit subnet associations. Select the check box for the private subnet, and then choose Save associations.

For more information, see Configure route tables (p. 74).

Test your NAT instance configuration

After you have launched a NAT instance and completed the configuration steps above, you can perform a test to check if an instance in your private subnet can access the internet through the NAT instance by using the NAT instance as a bastion server. To do this, update the NATSG security group rules to allow inbound and outbound ICMP traffic and allow outbound SSH traffic, launch an instance into your private subnet, configure SSH agent forwarding to access instances in your private subnet, connect to your instance, and then test the internet connectivity.

To update your NAT instance's security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the checkbox for the NATSG security group associated with your NAT instance.
5. Choose Add rule. Choose All ICMP - IPv4 for Type. Choose Custom for Source and enter the IP address range of your private subnet (for example, 10.0.0.0/24). Choose Save rules.
7. Choose Add rule. Choose SSH for Type. Choose Custom for Destination and enter the IP address range of your private subnet (for example, 10.0.0.0/24).

To launch an instance into your private subnet

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Launch an instance into your private subnet. Ensure that you configure the following options in the launch wizard, and then choose Launch:
On the Choose an Amazon Machine Image (AMI) page, select an Amazon Linux AMI from the Quick Start category.

On the Configure Instance Details page, select your private subnet from the Subnet list, and do not assign a public IP address to your instance.

On the Configure Security Group page, ensure that your security group includes an inbound rule that allows SSH access from your NAT instance's private IP address, or from the IP address range of your public subnet, and ensure that you have an outbound rule that allows outbound ICMP traffic.

In the Select an existing key pair or create a new key pair dialog box, select the same key pair you used to launch the NAT instance.

To configure SSH agent forwarding for Linux or OS X

1. From your local machine, add your private key to the authentication agent.
   
   For Linux, use the following command:

   ```bash
   ssh-add -c mykeypair.pem
   ```

   For OS X, use the following command:

   ```bash
   ssh-add -K mykeypair.pem
   ```

2. Connect to your NAT instance using the -A option to enable SSH agent forwarding, for example:

   ```bash
   ssh -A ec2-user@54.0.0.123
   ```

To configure SSH agent forwarding for Windows (PuTTY)

1. Download and install Pageant from the PuTTY download page, if not already installed.

2. Convert your private key to .ppk format. For more information, see Converting your private key using PuTTYgen.

3. Start Pageant, right-click the Pageant icon on the taskbar (it may be hidden), and choose Add Key. Select the .ppk file you created, enter the passphrase if required, and choose Open.

4. Start a PuTTY session to connect to your NAT instance. In the Auth category, ensure that you select the Allow agent forwarding option, and leave the Private key file for authentication field blank.

To test the internet connection

1. Test that your NAT instance can communicate with the internet by running the ping command for a website that has ICMP enabled; for example:

   ```bash
   ping ietf.org
   ```

   PING ietf.org (4.31.198.44) 56(84) bytes of data.
   64 bytes from mail.ietf.org (4.31.198.44): icmp_seq=1 ttl=48 time=74.9 ms
   64 bytes from mail.ietf.org (4.31.198.44): icmp_seq=2 ttl=48 time=75.1 ms
   ...

   Press Ctrl+C on your keyboard to cancel the ping command.
2. From your NAT instance, connect to your instance in your private subnet by using its private IP address, for example:

```
ssh ec2-user@10.0.1.123
```

3. From your private instance, test that you can connect to the internet by running the `ping` command:

```
ping ietf.org
```

```
PING ietf.org (4.31.198.44) 56(84) bytes of data.
64 bytes from mail.ietaf.org (4.31.198.44): icmp_seq=1 ttl=47 time=86.0 ms
64 bytes from mail.ietaf.org (4.31.198.44): icmp_seq=2 ttl=47 time=75.6 ms
...```

Press **Ctrl+C** on your keyboard to cancel the `ping` command.

If the `ping` command fails, check the following information:

- Check that your NAT instance's security group rules allow inbound ICMP traffic from your private subnet. If not, your NAT instance cannot receive the `ping` command from your private instance.
- Check that you've configured your route tables correctly. For more information, see Update the main route table (p. 173).
- Ensure that you've disabled source/destination checking for your NAT instance. For more information, see Disable source/destination checks (p. 172).
- Ensure that you are pinging a website that has ICMP enabled. If not, you will not receive reply packets. To test this, perform the same `ping` command from the command line terminal on your own computer.

4. (Optional) Terminate your private instance if you no longer require it. For more information, see Terminate your instance in the Amazon EC2 User Guide for Linux Instances.

### Compare NAT gateways and NAT instances

The following is a high-level summary of the differences between NAT gateways and NAT instances. We recommend that you use NAT gateways because they provide better availability and bandwidth and require less effort on your part to administer.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>NAT gateway</th>
<th>NAT instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>Highly available. NAT gateways in each Availability Zone are implemented with redundancy. Create a NAT gateway in each Availability Zone to ensure zone-independent architecture.</td>
<td>Use a script to manage failover between instances.</td>
</tr>
<tr>
<td>Bandwidth</td>
<td>Scale up to 100 Gbps.</td>
<td>Depends on the bandwidth of the instance type.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Managed by AWS. You do not need to perform any maintenance.</td>
<td>Managed by you, for example, by installing software updates or operating system patches on the instance.</td>
</tr>
<tr>
<td>Performance</td>
<td>Software is optimized for handling NAT traffic.</td>
<td>A generic AMI that's configured to perform NAT.</td>
</tr>
</tbody>
</table>
### Compare NAT devices

<table>
<thead>
<tr>
<th>Attribute</th>
<th>NAT gateway</th>
<th>NAT instance</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Cost</strong></td>
<td>Charged depending on the number of NAT gateways you use, duration of usage, and amount of data that you send through the NAT gateways.</td>
<td>Charged depending on the number of NAT instances that you use, duration of usage, and instance type and size.</td>
</tr>
<tr>
<td><strong>Type and size</strong></td>
<td>Uniform offering; you don’t need to decide on the type or size.</td>
<td>Choose a suitable instance type and size, according to your predicted workload.</td>
</tr>
<tr>
<td><strong>Public IP addresses</strong></td>
<td>Choose the Elastic IP address to associate with a public NAT gateway at creation.</td>
<td>Use an Elastic IP address or a public IP address with a NAT instance. You can change the public IP address at any time by associating a new Elastic IP address with the instance.</td>
</tr>
<tr>
<td><strong>Private IP addresses</strong></td>
<td>Automatically selected from the subnet’s IP address range when you create the gateway.</td>
<td>Assign a specific private IP address from the subnet’s IP address range when you launch the instance.</td>
</tr>
<tr>
<td><strong>Security groups</strong></td>
<td>You cannot associate security groups with NAT gateways. You can associate them with the resources behind the NAT gateway to control inbound and outbound traffic.</td>
<td>Associate with your NAT instance and the resources behind your NAT instance to control inbound and outbound traffic.</td>
</tr>
<tr>
<td><strong>Network ACLs</strong></td>
<td>Use a network ACL to control the traffic to and from the subnet in which your NAT gateway resides.</td>
<td>Use a network ACL to control the traffic to and from the subnet in which your NAT instance resides.</td>
</tr>
<tr>
<td><strong>Flow logs</strong></td>
<td>Use flow logs to capture the traffic.</td>
<td>Use flow logs to capture the traffic.</td>
</tr>
<tr>
<td><strong>Port forwarding</strong></td>
<td>Not supported.</td>
<td>Manually customize the configuration to support port forwarding.</td>
</tr>
<tr>
<td><strong>Bastion servers</strong></td>
<td>Not supported.</td>
<td>Use as a bastion server.</td>
</tr>
<tr>
<td><strong>Traffic metrics</strong></td>
<td>View CloudWatch metrics for the NAT gateway (p. 157).</td>
<td>View CloudWatch metrics for the instance.</td>
</tr>
<tr>
<td><strong>Timeout behavior</strong></td>
<td>When a connection times out, a NAT gateway returns an RST packet to any resources behind the NAT gateway that attempt to continue the connection (it does not send a FIN packet).</td>
<td>When a connection times out, a NAT instance sends a FIN packet to resources behind the NAT instance to close the connection.</td>
</tr>
<tr>
<td><strong>IP fragmentation</strong></td>
<td>Supports forwarding of IP fragmented packets for the UDP protocol.</td>
<td>Supports reassembly of IP fragmented packets for the UDP, TCP, and ICMP protocols.</td>
</tr>
<tr>
<td></td>
<td>Does not support fragmentation for the TCP and ICMP protocols. Fragmented packets for these protocols will get dropped.</td>
<td></td>
</tr>
</tbody>
</table>

### Migrate from a NAT instance to a NAT gateway

If you’re already using a NAT instance, we recommend that you replace it with a NAT gateway. You can create a NAT gateway in the same subnet as your NAT instance, and then replace the existing route in your route table that points to the NAT instance with a route that points to the NAT gateway. To use the
same Elastic IP address for the NAT gateway that you currently use for your NAT instance, you must first
disassociate the Elastic IP address from your NAT instance and then associate it with your NAT gateway
when you create the gateway.

If you change your routing from a NAT instance to a NAT gateway, or if you disassociate the Elastic IP
address from your NAT instance, any current connections are dropped and have to be re-established.
Ensure that you do not have any critical tasks (or any other tasks that operate through the NAT instance)
running.

Connect your VPC to other VPCs and networks using a transit gateway

You can connect your virtual private clouds (VPC) and on-premises networks using a transit gateway,
which acts as a central hub, routing traffic between VPCs, VPN connections, and AWS Direct Connect
connections. For more information, see AWS Transit Gateway.

The following table describes some common use case for transit gateways and provides links to more
information in the Amazon VPC Transit Gateways.

<table>
<thead>
<tr>
<th>Example</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Centralized router</td>
<td>Configure your transit gateway as a centralized router that connects all of your VPCs, AWS Direct Connect, and AWS Site-to-Site VPN connections. For more information, see Example: Centralized router.</td>
</tr>
<tr>
<td>Isolated VPCs</td>
<td>Configure your transit gateway as multiple isolated routers. This is similar to using multiple transit gateways, but provides more flexibility in cases where the routes and attachments might change. For more information, see Example: Isolated VPCs.</td>
</tr>
<tr>
<td>Isolated VPCs with shared services</td>
<td>Configure your transit gateway as multiple isolated routers that use a shared service. This is similar to using multiple transit gateways, but provides more flexibility in cases where the routes and attachments might change. For more information, see Example: Isolated VPCs with shared services.</td>
</tr>
</tbody>
</table>

Connect your VPC to remote networks using AWS Virtual Private Network

You can connect your Amazon VPC to remote networks and users using the following VPN connectivity options.

<table>
<thead>
<tr>
<th>VPN connectivity option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Site-to-Site VPN</td>
<td>You can create an IPsec VPN connection between your VPC and your remote network. On the AWS side of the Site-to-Site VPN connection, a virtual private gateway or transit gateway provides two VPN endpoints (tunnels) for automatic failover. You configure your customer gateway device on the remote side of the Site-to-Site VPN connection. For more information, see the AWS Site-to-Site VPN User Guide.</td>
</tr>
<tr>
<td>VPN connectivity option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>AWS Client VPN</td>
<td>AWS Client VPN is a managed client-based VPN service that enables you to securely access your AWS resources or your on-premises network. With AWS Client VPN, you configure an endpoint to which your users can connect to establish a secure TLS VPN session. This enables clients to access resources in AWS or on-premises from any location using an OpenVPN-based VPN client. For more information, see the <a href="#">AWS Client VPN Administrator Guide</a>.</td>
</tr>
<tr>
<td>AWS VPN CloudHub</td>
<td>If you have more than one remote network (for example, multiple branch offices), you can create multiple AWS Site-to-Site VPN connections via your virtual private gateway to enable communication between these networks. For more information, see <a href="#">Providing secure communication between sites using VPN CloudHub</a> in the <a href="#">AWS Site-to-Site VPN User Guide</a>.</td>
</tr>
<tr>
<td>Third party software VPN appliance</td>
<td>You can create a VPN connection to your remote network by using an Amazon EC2 instance in your VPC that's running a third party software VPN appliance. AWS does not provide or maintain third party software VPN appliances; however, you can choose from a range of products provided by partners and open source communities. Find third party software VPN appliances on the <a href="#">AWS Marketplace</a>.</td>
</tr>
</tbody>
</table>

You can also use AWS Direct Connect to create a dedicated private connection from a remote network to your VPC. You can combine this connection with an AWS Site-to-Site VPN to create an IPsec-encrypted connection. For more information, see [What is AWS Direct Connect?](#) in the [AWS Direct Connect User Guide](#).

## Connect VPCs using VPC peering

A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them privately. Instances in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region.

AWS uses the existing infrastructure of a VPC to create a VPC peering connection; it is neither a gateway nor an AWS Site-to-Site VPN connection, and does not rely on a separate piece of physical hardware. There is no single point of failure for communication or a bandwidth bottleneck.

For more information about working with VPC peering connections, and examples of scenarios in which you can use a VPC peering connection, see the [Amazon VPC Peering Guide](#).

### Examples: Services using VPC peering and AWS PrivateLink

While VPC peering enables you to privately connect VPCs, AWS PrivateLink enables you to configure applications or services in VPCs as endpoints that your VPC peering connections can connect to.

An AWS PrivateLink service provider configures instances running services in their VPC with a Network Load Balancer as the front end. Use intra-region VPC peering (VPCs are in the same Region) and inter-region VPC peering (VPCs are in different Regions) with AWS PrivateLink to allow private access to consumers across VPC peering connections.

Consumers in remote VPCs cannot use Private DNS names across peering connections. They can however create their own private hosted zone on Route 53, and attach it to their VPCs to use the same Private...
DNS name. For information about using transit gateway with Amazon Route 53 Resolver, to share
PrivateLink interface endpoints between multiple connected VPCs and an on-premises environment, see
Integrating AWS Transit Gateway with AWS PrivateLink and Amazon Route 53 Resolver.

For information about the following use-cases, see Securely Access Services Over AWS PrivateLink:

• Private Access to SaaS Applications
• Shared Services
• Hybrid Services
• Inter-Region Endpoint Services
• Inter-Region Access to Endpoint Services

Additional resources

The following topics can help you configure the components needed for the use-cases:

• VPC endpoint services
• Getting Started with Network Load Balancers
• Working with VPC peering connections
• Create an interface endpoint

For more VPC peering examples, see the following topics in the Amazon VPC Peering Guide:

• VPC peering configurations
• Unsupported VPC peering configurations
Monitoring your VPC

You can use the following tools to monitor traffic or network access in your virtual private cloud (VPC).

**VPC Flow Logs**

You can use VPC Flow Logs to capture detailed information about the traffic going to and from network interfaces in your VPCs.

**Amazon VPC IP Address Manager (IPAM)**

You can use IPAM to plan, track, and monitor IP addresses for your workloads. For more information, see IP Address Manager.

**Traffic Mirroring**

You can use this feature to copy network traffic from a network interface of an Amazon EC2 instance and send it to out-of-band security and monitoring appliances for deep packet inspection. You can detect network and security anomalies, gain operational insights, implement compliance and security controls, and troubleshoot issues. For more information, see Traffic Mirroring.

**VPC Reachability Analyzer**

You can use this tool to analyze and debug network reachability between two resources in your VPC. After you specify the source and destination resources, Reachability Analyzer produces hop-by-hop details of the virtual path between them when they are reachable, and identifies the blocking component when they are unreachable. For more information, see VPC Reachability Analyzer.

**Network Access Analyzer**

You can use Network Access Analyzer to understand network access to your resources. This helps you identify improvements to your network security posture and demonstrate that your network meets specific compliance requirements. For more information, see Network Access Analyzer.

**CloudTrail logs**

You can use AWS CloudTrail to capture detailed information about the calls made to the Amazon VPC API. You can use the generated CloudTrail logs to determine which calls were made, the source IP address where the call came from, who made the call, when the call was made, and so on. For more information, see Logging Amazon EC2 Amazon EBS, and Amazon VPC API calls using AWS CloudTrail in the Amazon EC2 API Reference.

Logging IP traffic using VPC Flow Logs

VPC Flow Logs is a feature that enables you to capture information about the IP traffic going to and from network interfaces in your VPC. Flow log data can be published to the following locations: Amazon CloudWatch Logs, Amazon S3, or Amazon Kinesis Data Firehose. After you create a flow log, you can retrieve and view the flow log records in the log group, bucket, or delivery stream that you configured.

Flow logs can help you with a number of tasks, such as:

- Diagnosing overly restrictive security group rules
Flow logs basics

You can create a flow log for a VPC, a subnet, or a network interface. If you create a flow log for a subnet or VPC, each network interface in that subnet or VPC is monitored.

Flow log data for a monitored network interface is recorded as flow log records, which are log events consisting of fields that describe the traffic flow. For more information, see Flow log records (p. 184).

To create a flow log, you specify:

- The resource for which to create the flow log
- The type of traffic to capture (accepted traffic, rejected traffic, or all traffic)
- The destinations to which you want to publish the flow log data

In the following example, you create a flow log that captures accepted traffic for the network interface for one of the EC2 instances in a private subnet and publishes the flow log records to an Amazon S3 bucket.
In the following example, a flow log captures all traffic for a subnet and publishes the flow log records to Amazon CloudWatch Logs. The flow log captures traffic for all network interfaces in the subnet.
After you create a flow log, it can take several minutes to begin collecting and publishing data to the chosen destinations. Flow logs do not capture real-time log streams for your network interfaces. For more information, see Create a flow log (p. 212).

If you launch an instance into your subnet after you create a flow log for your subnet or VPC, we create a log stream (for CloudWatch Logs) or log file object (for Amazon S3) for the new network interface as soon as there is network traffic for the network interface.

You can create flow logs for network interfaces that are created by other AWS services, such as:

- Elastic Load Balancing
- Amazon RDS
- Amazon ElastiCache
- Amazon Redshift
Flow log records

A flow log record represents a network flow in your VPC. By default, each record captures a network internet protocol (IP) traffic flow (characterized by a 5-tuple on a per network interface basis) that occurs within an aggregation interval, also referred to as a capture window.

Each record is a string with fields separated by spaces. A record includes values for the different components of the IP flow, for example, the source, destination, and protocol.

When you create a flow log, you can use the default format for the flow log record, or you can specify a custom format.

Contents

- Aggregation interval (p. 184)
- Default format (p. 184)
- Custom format (p. 185)
- Available fields (p. 185)

Aggregation interval

The aggregation interval is the period of time during which a particular flow is captured and aggregated into a flow log record. By default, the maximum aggregation interval is 10 minutes. When you create a flow log, you can optionally specify a maximum aggregation interval of 1 minute. Flow logs with a maximum aggregation interval of 1 minute produce a higher volume of flow log records than flow logs with a maximum aggregation interval of 10 minutes.

When a network interface is attached to a Nitro-based instance, the aggregation interval is always 1 minute or less, regardless of the specified maximum aggregation interval.

After data is captured within an aggregation interval, it takes additional time to process and publish the data to CloudWatch Logs or Amazon S3. The flow log service typically delivers logs to CloudWatch Logs in about 5 minutes and to Amazon S3 in about 10 minutes. However, log delivery is on a best effort basis, and your logs might be delayed beyond the typical delivery time.

Default format

With the default format, the flow log records include the version 2 fields, in the order shown in the available fields (p. 185) table. You cannot customize or change the default format. To capture additional fields or a different subset of fields, specify a custom format instead.
Custom format

With a custom format, you specify which fields are included in the flow log records and in which order. This enables you to create flow logs that are specific to your needs and to omit fields that are not relevant. Using a custom format can reduce the need for separate processes to extract specific information from the published flow logs. You can specify any number of the available flow log fields, but you must specify at least one.

Available fields

The following table describes all of the available fields for a flow log record. The Version column indicates the VPC Flow Logs version in which the field was introduced. The default format includes all version 2 fields, in the same order that they appear in the table.

When publishing flow log data to Amazon S3, the data type for the fields depends on the flow log format. If the format is plain text, all fields are of type STRING. If the format is Parquet, see the table for the field data types.

If a field is not applicable or could not be computed for a specific record, the record displays a '-' symbol for that entry. Metadata fields that do not come directly from the packet header are best effort approximations, and their values might be missing or inaccurate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Version</th>

</table>
Flow log record examples

The following are examples of flow log records that capture specific traffic flows.

For information about flow log record format, see Flow log records (p. 184). For information about how to create flow logs, see Work with flow logs (p. 211).

Contents

- Accepted and rejected traffic (p. 189)
- No data and skipped records (p. 190)
- Security group and network ACL rules (p. 190)
- IPv6 traffic (p. 190)
- TCP flag sequence (p. 191)
- Traffic through a NAT gateway (p. 192)
- Traffic through a transit gateway (p. 193)
- Service name, traffic path, and flow direction (p. 194)

Accepted and rejected traffic

The following are examples of default flow log records.

In this example, SSH traffic (destination port 22, TCP protocol) to network interface eni-1235b8ca123456789 in account 123456789010 was allowed.

```
2 123456789010 eni-1235b8ca123456789 172.31.16.139 172.31.16.21 20641 22 6 20 4249
1418530010 1418530070 ACCEPT OK
```

In this example, RDP traffic (destination port 3389, TCP protocol) to network interface eni-1235b8ca123456789 in account 123456789010 was rejected.

```
2 123456789010 eni-1235b8ca123456789 172.31.9.69 172.31.9.12 49761 3389 6 20 4249
1418530010 1418530070 REJECT OK
```
No data and skipped records

The following are examples of default flow log records.

In this example, no data was recorded during the aggregation interval.

| Time   | Source IPv4 Address | Source IPv6 Address | Destination IPv4 Address | Destination IPv6 Address | Protocol | Port | Bytes | Duration | Flow Log Record
|--------|---------------------|---------------------|--------------------------|--------------------------|----------|------|-------|----------|-------------------|
| 1431280876 | 123456789010        | eni-1235b8ca123456789 | -                        | -                        | -        | -    | -     | -        | NODATA

In this example, records were skipped during the aggregation interval. VPC Flow Logs skips records when it can't capture flow log data during an aggregation interval because it exceeds internal capacity. A single skipped record can represent multiple flows that were not captured for the network interface during the aggregation interval.

| Time   | Source IPv4 Address | Source IPv6 Address | Destination IPv4 Address | Destination IPv6 Address | Protocol | Port | Bytes | Duration | Flow Log Record
|--------|---------------------|---------------------|--------------------------|--------------------------|----------|------|-------|----------|-------------------|
| 1431280876 | 123456789010        | eni-1111111111111111 | -                        | -                        | -        | -    | -     | -        | SKIPDATA

Security group and network ACL rules

If you're using flow logs to diagnose overly restrictive or permissive security group rules or network ACL rules, be aware of the statefulness of these resources. Security groups are stateful — this means that responses to allowed traffic are also allowed, even if the rules in your security group do not permit it. Conversely, network ACLs are stateless, therefore responses to allowed traffic are subject to network ACL rules.

For example, you use the ping command from your home computer (IP address is 203.0.113.12) to your instance (the network interface's private IP address is 172.31.16.139). Your security group's inbound rules allow ICMP traffic but the outbound rules do not allow ICMP traffic. Because security groups are stateful, the response ping from your instance is allowed. Your network ACL permits inbound ICMP traffic but does not permit outbound ICMP traffic. Because network ACLs are stateless, the response ping is dropped and does not reach your home computer. In a default flow log, this is displayed as two flow log records:

- An ACCEPT record for the originating ping that was allowed by both the network ACL and the security group, and therefore was allowed to reach your instance.
- A REJECT record for the response ping that the network ACL denied.

| Time   | Source IPv4 Address | Source IPv6 Address | Destination IPv4 Address | Destination IPv6 Address | Protocol | Port | Bytes | Duration | Flow Log Record
|--------|---------------------|---------------------|--------------------------|--------------------------|----------|------|-------|----------|-------------------|
| 1432917027 | 123456789010        | eni-1235b8ca123456789 | 203.0.113.12             | 172.31.16.139            | 0        | 4    | 336   | 1477913820 | ACCEPT OK
| 1432917142 | eni-1235b8ca123456789 | 203.0.113.12             | 172.31.16.139            | 0        | 4    | 336   | 1477913820 | REJECT OK

If your network ACL permits outbound ICMP traffic, the flow log displays two ACCEPT records (one for the originating ping and one for the response ping). If your security group denies inbound ICMP traffic, the flow log displays a single REJECT record, because the traffic was not permitted to reach your instance.

IPv6 traffic

The following is an example of a default flow log record. In the example, SSH traffic (port 22) from IPv6 address 2001:db8:1234:a100:8d6e:3477:df66:f105 to network interface eni-1235b8ca123456789 in account 123456789010 was allowed.

| Time   | Source IPv4 Address | Source IPv6 Address | Destination IPv4 Address | Destination IPv6 Address | Protocol | Port | Bytes | Duration | Flow Log Record
|--------|---------------------|---------------------|--------------------------|--------------------------|----------|------|-------|----------|-------------------|
TCP flag sequence

This section contains examples of custom flow logs that capture the following fields in the following order.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>vpc-id</td>
</tr>
<tr>
<td>vpc-id</td>
<td></td>
</tr>
<tr>
<td>subnet-id</td>
<td></td>
</tr>
<tr>
<td>instance-id</td>
<td></td>
</tr>
<tr>
<td>interface-id</td>
<td></td>
</tr>
<tr>
<td>account-id</td>
<td></td>
</tr>
<tr>
<td>type</td>
<td></td>
</tr>
<tr>
<td>srcaddr</td>
<td></td>
</tr>
<tr>
<td>dstaddr</td>
<td></td>
</tr>
<tr>
<td>srcport</td>
<td></td>
</tr>
<tr>
<td>dstport</td>
<td></td>
</tr>
<tr>
<td>pkt-srcaddr</td>
<td></td>
</tr>
<tr>
<td>pkt-dstaddr</td>
<td></td>
</tr>
<tr>
<td>protocol</td>
<td></td>
</tr>
<tr>
<td>bytes</td>
<td></td>
</tr>
<tr>
<td>packets</td>
<td></td>
</tr>
<tr>
<td>start</td>
<td></td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td>action</td>
<td></td>
</tr>
<tr>
<td>tcp-flags</td>
<td></td>
</tr>
<tr>
<td>log-status</td>
<td></td>
</tr>
</tbody>
</table>

The tcp-flags field in the examples in this section are represented by the second-to-last value in the flow log. TCP flags can help you identify the direction of the traffic, for example, which server initiated the connection.

**Note**
For more information about the tcp-flags option and an explanation of each of the TCP flags, see *Available fields* (p. 185).

In the following records (starting at 7:47:55 PM and ending at 7:48:53 PM), two connections were started by a client to a server running on port 5001. Two SYN flags (2) were received by server from the client from different source ports on the client (43416 and 43418). For each SYN, a SYN-ACK was sent from the server to the client (18) on the corresponding port.

```
3 vpc-abcdefab012345678 subnet-aaaaaaaa012345678 vpc-id i-01234567890123456 eni-01234567890123456123456789010 IPv4 52.213.180.42 10.0.0.62 43416 5001 52.213.180.42 10.0.0.62 6 568 8
1566848875 1566848933 ACCEPT 2 OK
3 vpc-abcdefab012345678 subnet-aaaaaaaa012345678 vpc-id i-01234567890123456 eni-01234567890123456123456789010 IPv4 52.213.180.42 10.0.0.62 43416 5001 52.213.180.42 10.0.0.62 6 376 7
1566848875 1566848933 ACCEPT 18 OK
```

In the second aggregation interval, one of the connections that was established during the previous flow is now closed. The client sent a FIN flag (1) to the server for the connection on port 43418. The server sent a FIN to the client on port 43418.

```
3 vpc-abcdefab012345678 subnet-aaaaaaaa012345678 vpc-id i-01234567890123456 eni-01234567890123456123456789010 IPv4 52.213.180.42 10.0.0.62 43418 5001 52.213.180.42 10.0.0.62 6 632 12
1566848875 1566848933 ACCEPT 18 OK
```

For short connections (for example, a few seconds) that are opened and closed within a single aggregation interval, the flags might be set on the same line in the flow log record for traffic flow in the same direction. In the following example, the connection is established and finished within the same aggregation interval. In the first line, the TCP flag value is 3, which indicates that there was a SYN and a FIN message sent from the client to the server. In the second line, the TCP flag value is 19, which indicates that there was SYN-ACK and a FIN message sent from the server to the client.

```
3 vpc-abcdefab012345678 subnet-aaaaaaaa012345678 vpc-id i-01234567890123456 eni-01234567890123456123456789010 IPv4 52.213.180.42 10.0.0.62 43418 5001 52.213.180.42 10.0.0.62 6 1260 17
1566933133 1566933193 ACCEPT 3 OK
3 vpc-abcdefab012345678 subnet-aaaaaaaa012345678 vpc-id i-01234567890123456 eni-01234567890123456123456789010 IPv4 52.213.180.42 10.0.0.62 43418 5001 52.213.180.42 10.0.0.62 6 23294588 15774 1566849113 ACCEPT 19 OK
```
Traffic through a NAT gateway

In this example, an instance in a private subnet accesses the internet through a NAT gateway that's in a public subnet.

The following custom flow log for the NAT gateway network interface captures the following fields in the following order.

<table>
<thead>
<tr>
<th>instance-id</th>
<th>interface-id</th>
<th>srcaddr</th>
<th>dstaddr</th>
<th>pkt-srcaddr</th>
<th>pkt-dstaddr</th>
</tr>
</thead>
<tbody>
<tr>
<td>eni-1235b8ca123456789</td>
<td>10.0.1.5</td>
<td>10.0.0.220</td>
<td>10.0.1.5</td>
<td>203.0.113.5</td>
<td></td>
</tr>
</tbody>
</table>

The flow log shows the flow of traffic from the instance IP address (10.0.1.5) through the NAT gateway network interface to a host on the internet (203.0.113.5). The NAT gateway network interface is a requester-managed network interface, therefore the flow log record displays a '-' symbol for the instance-id field. The following line shows traffic from the source instance to the NAT gateway network interface. The values for the dstaddr and pkt-dstaddr fields are different. The dstaddr field displays the private IP address of the NAT gateway network interface, and the pkt-dstaddr field displays the final destination IP address of the host on the internet.

- eni-1235b8ca123456789 10.0.1.5 10.0.0.220 10.0.1.5 203.0.113.5

The next two lines show the traffic from the NAT gateway network interface to the target host on the internet, and the response traffic from the host to the NAT gateway network interface.
Flow log record examples

The following line shows the response traffic from the NAT gateway network interface to the source instance. The values for the srcaddr and pkt-srcaddr fields are different. The srcaddr field displays the private IP address of the NAT gateway network interface, and the pkt-srcaddr field displays the IP address of the host on the internet.

- eni-1235b8ca123456789 10.0.0.220 203.0.113.5 10.0.0.220 203.0.113.5
- eni-1235b8ca123456789 203.0.113.5 10.0.0.220 203.0.113.5 10.0.0.220

You create another custom flow log using the same set of fields as above. You create the flow log for the network interface for the instance in the private subnet. In this case, the instance-id field returns the ID of the instance that's associated with the network interface, and there is no difference between the dstaddr and pkt-dstaddr fields and the srcaddr and pkt-srcaddr fields. Unlike the network interface for the NAT gateway, this network interface is not an intermediate network interface for traffic.

- eni-1235b8ca123456789 10.0.0.220 10.0.1.5 203.0.113.5 10.0.1.5
- eni-1235b8ca123456789 10.0.0.220 10.0.1.5 203.0.113.5 10.0.1.5

Traffic through a transit gateway

In this example, a client in VPC A connects to a web server in VPC B through a transit gateway. The client and server are in different Availability Zones. Traffic arrives at the server in VPC B using one elastic network interface ID (in this example, let's say the ID is eni-1111aaa2222bbbbb3) and leaves VPC B using another (for example eni-2222222222222222).

You create a custom flow log for VPC B with the following format.
Flow log record examples

The following lines from the flow log records demonstrate the flow of traffic on the network interface for the web server. The first line is the request traffic from the client, and the last line is the response traffic from the web server.

```
3 eni-33333333333333333 123456789010 vpc-abcdefab012345678 subnet-22222222bbbbbbbbb i-01234567890123456 10.20.33.164 10.40.2.236 39812 80 6 3 IPv4 10.20.33.164 10.40.2.236 ACCEPT OK
```

```
3 eni-33333333333333333 123456789010 vpc-abcdefab012345678 subnet-22222222bbbbbbbbb i-01234567890123456 10.40.2.236 10.20.33.164 80 39812 6 19 IPv4 10.40.2.236 10.20.33.164 ACCEPT OK
```

The following line is the request traffic on eni-11111111111111111, a requester-managed network interface for the transit gateway in subnet subnet-11111111aaaaaa. The flow log record therefore displays a '-' symbol for the instance-id field. The srcaddr field displays the private IP address of the transit gateway network interface, and the pkt-srcaddr field displays the source IP address of the client in VPC A.

```
3 eni-11111111111111111 123456789010 vpc-abcdefab012345678 subnet-11111111aaaaaa - 10.40.1.175 10.40.2.236 39812 80 6 3 IPv4 10.20.33.164 10.40.2.236 ACCEPT OK
```

The following line is the response traffic on eni-22222222222222222, a requester-managed network interface for the transit gateway in subnet subnet-22222222bbbbbbbbb. The dstaddr field displays the private IP address of the transit gateway network interface, and the pkt-dstaddr field displays the IP address of the client in VPC A.

```
3 eni-22222222222222222 123456789010 vpc-abcdefab012345678 subnet-22222222bbbbbbbbb - 10.40.2.236 10.40.2.31 80 39812 6 19 IPv4 10.40.2.236 10.20.33.164 ACCEPT OK
```

Service name, traffic path, and flow direction

The following is an example of the fields for a custom flow log record.

```
version srcaddr dstaddr srcport dstport protocol start end type packets bytes account-id vpc-id subnet-id instance-id interface-id region az-id sublocation-type sublocation-id action tcp-flags pkt-srcaddr pkt-dstaddr pkt-src-aws-service pkt-dst-aws-service traffic-path flow-direction log-status
```

In the following example, the version is 5 because the records include version 5 fields. An EC2 instance calls the Amazon S3 service. Flow logs are captured on the network interface for the instance. The first record has a flow direction of ingress and the second record has a flow direction of egress. For the egress record, traffic-path is 8, indicating that the traffic goes through an internet gateway. The traffic-path field is not supported for ingress traffic. When pkt-srcaddr or pkt-dstaddr is a public IP address, the service name is shown.

```
5 52.95.128.179 10.0.0.71 80 34210 6 1616729292 1616729349 IPv4 14 15044 123456789012 vpc-abcd6fab0123645678 subnet-aabaaa012345678 1-0c505961beb2d47b eni-1235b8ca123456789 ap-southeast-2 apse2-aaz - - ACCEPT 19 52.95.128.179 10.0.0.71 S3 - - ingress OK
5 10.0.0.71 52.95.128.179 34210 80 6 1616729292 1616729349 IPv4 7 471 123456789012 vpc-abcd6fab0123645678 subnet-aabaaa012345678 1-0c505961beb2d47b eni-1235b8ca123456789 ap-southeast-2 apse2-aaz - - ACCEPT 3 10.0.0.71 52.95.128.179 - S3 8 egress OK
```
Flow log limitations

To use flow logs, you need to be aware of the following limitations:

- You cannot enable flow logs for network interfaces that are in the EC2-Classic platform. This includes EC2-Classic instances that have been linked to a VPC through ClassicLink.
- You can't enable flow logs for VPCs that are peered with your VPC unless the peer VPC is in your account.
- After you create a flow log, you cannot change its configuration or the flow log record format. For example, you can't associate a different IAM role with the flow log, or add or remove fields in the flow log record. Instead, you can delete the flow log and create a new one with the required configuration.
- If your network interface has multiple IPv4 addresses and traffic is sent to a secondary private IPv4 address, the flow log displays the primary private IPv4 address in the dstaddr field. To capture the original destination IP address, create a flow log with the pkt-dstaddr field.
- If traffic is sent to a network interface and the destination is not any of the network interface's IP addresses, the flow log displays the primary private IPv4 address in the dstaddr field. To capture the original destination IP address, create a flow log with the pkt-dstaddr field.
- If traffic is sent from a network interface and the source is not any of the network interface's IP addresses, the flow log displays the primary private IPv4 address in the srcaddr field. To capture the original source IP address, create a flow log with the pkt-srcaddr field.
- If traffic is sent to or sent from a network interface, the srcaddr and dstaddr fields in the flow log always display the primary private IPv4 address, regardless of the packet source or destination. To capture the packet source or destination, create a flow log with the pkt-srcaddr and pkt-dstaddr fields.
- When your network interface is attached to a Nitro-based instance, the aggregation interval is always 1 minute or less, regardless of the specified maximum aggregation interval.

Flow logs do not capture all IP traffic. The following types of traffic are not logged:

- Traffic generated by instances when they contact the Amazon DNS server. If you use your own DNS server, then all traffic to that DNS server is logged.
- Traffic generated by a Windows instance for Amazon Windows license activation.
- Traffic to and from 169.254.169.254 for instance metadata.
- Traffic to and from 169.254.169.123 for the Amazon Time Sync Service.
- DHCP traffic.
- Mirrored traffic.
- Traffic to the reserved IP address for the default VPC router.
- Traffic between an endpoint network interface and a Network Load Balancer network interface.

Flow logs pricing

Data ingestion and archival charges for vended logs apply when you publish flow logs. For more information about pricing when publishing vended logs, open Amazon CloudWatch Pricing, select Logs and find Vended Logs.

To track charges from publishing flow logs, you can apply cost allocation tags to your destination resource. Thereafter, your AWS cost allocation report includes usage and costs aggregated by these tags. You can apply tags that represent business categories (such as cost centers, application names, or owners) to organize your costs. For more information, see the following:

- Using Cost Allocation Tags in the AWS Billing User Guide
Publish flow logs to CloudWatch Logs

Flow logs can publish flow log data directly to Amazon CloudWatch.

When publishing to CloudWatch Logs, flow log data is published to a log group, and each network interface has a unique log stream in the log group. Log streams contain flow log records. You can create multiple flow logs that publish data to the same log group. If the same network interface is present in one or more flow logs in the same log group, it has one combined log stream. If you've specified that one flow log should capture rejected traffic, and the other flow log should capture accepted traffic, then the combined log stream captures all traffic.

In CloudWatch Logs, the timestamp field corresponds to the start time that's captured in the flow log record. The ingestionTime field indicates the date and time when the flow log record was received by CloudWatch Logs. This timestamp is later than the end time that's captured in the flow log record.

For more information about CloudWatch Logs, see Logs sent to CloudWatch Logs in the Amazon CloudWatch Logs User Guide.

Pricing

Data ingestion and archival charges for vended logs apply when you publish flow logs to CloudWatch Logs. For more information, open Amazon CloudWatch Pricing, select Logs and find Vended Logs.

Contents

- IAM role for publishing flow logs to CloudWatch Logs (p. 196)
- Permissions for IAM principals that publish flow logs to CloudWatch Logs (p. 198)
- Create a flow log that publishes to CloudWatch Logs (p. 198)
- View flow log records (p. 199)
- Search flow log records (p. 199)
- Process flow log records in CloudWatch Logs (p. 200)

IAM role for publishing flow logs to CloudWatch Logs

The IAM role that's associated with your flow log must have sufficient permissions to publish flow logs to the specified log group in CloudWatch Logs. The IAM role must belong to your AWS account.

The IAM policy that's attached to your IAM role must include at least the following permissions.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:DescribeLogGroups",
        "logs:DescribeLogStreams"
      ],
      "Resource": "*"
    }
  ]
}
```
Ensure that your role has the following trust policy, which allows the flow logs service to assume the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "vpc-flow-logs.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

We recommend that you use the `aws:SourceAccount` and `aws:SourceArn` condition keys to protect yourself against the confused deputy problem. For example, you could add the following condition block to the previous trust policy. The source account is the owner of the flow log and the source ARN is the flow log ARN. If you don't know the flow log ID, you can replace that portion of the ARN with a wildcard (*) and then update the policy after you create the flow log.

```
"Condition": {
  "StringEquals": {
    "aws:SourceAccount": "account_id"
  },
  "ArnLike": {
  }
}
```

Create an IAM role for flow logs

You can update an existing role as described above. Alternatively, you can use the following procedure to create a new role for use with flow logs. You'll specify this role when you create the flow log.

**To create an IAM role for flow logs**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Create policy page, do the following:
   a. Choose JSON.
   b. Replace the contents of this window with the permissions policy at the start of this section.
   c. Choose Next: Tags and Next: Review.
   d. Enter a name for your policy and an optional description, and then choose Create policy.
5. In the navigation pane, choose Roles.
6. Choose Create role.
7. For Trusted entity type, choose Custom trust policy. For Custom trust policy, replace "Principal": {}, with the following, then and choose Next.

```
"Principal": {
```
8. On the **Add permissions** page, select the checkbox for the policy that you created earlier in this procedure, and then choose **Next**.
9. Enter a name for your role and optionally provide a description.
10. Choose **Create role**.

### Permissions for IAM principals that publish flow logs to CloudWatch Logs

Users must have permissions to use the `iam:PassRole` action for the IAM role that's associated with the flow log.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iam:PassRole"],
      "Resource": "arn:aws:iam::<account-id>:role/flow-log-role-name"
    }
  ]
}
```

### Create a flow log that publishes to CloudWatch Logs

You can create flow logs for your VPCs, subnets, or network interfaces. If you perform these steps as an IAM user, ensure that you have permissions to use the `iam:PassRole` action. For more information, see Permissions for IAM principals that publish flow logs to CloudWatch Logs (p. 198).

#### Prerequisites

- Create the destination log group. Open the **Log groups page** in the CloudWatch console and choose **Create log group**. Enter a name for the log group and choose **Create**.
- Create an IAM role, as described in the section called “IAM role for publishing flow logs to CloudWatch Logs” (p. 196).

#### To create a flow log using the console

1. Do one of the following:
   - Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/). In the navigation pane, choose **Network Interfaces**. Select the checkbox for the network interface.
   - Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/). In the navigation pane, choose **Your VPCs**. Select the checkbox for the VPC.
   - Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/). In the navigation pane, choose **Subnets**. Select the checkbox for the subnet.
2. Choose **Actions**, **Create flow log**.
3. For **Filter**, specify the type of traffic to log. Choose **All** to log accepted and rejected traffic, **Reject** to log only rejected traffic, or **Accept** to log only accepted traffic.
4. For **Maximum aggregation interval**, choose the maximum period of time during which a flow is captured and aggregated into one flow log record.
5. For **Destination**, choose **Send to CloudWatch Logs**.
6. For **Destination log group**, choose the name of the destination log group that you created.
7. For **IAM role**, specify the name of the role that has permissions to publish logs to CloudWatch Logs.
8. For **Log record format**, select the format for the flow log record.
   - To use the default format, choose **AWS default format**.
   - To use a custom format, choose **Custom format** and then select fields from **Log format**.
9. (Optional) Choose **Add new tag** to apply tags to the flow log.
10. Choose **Create flow log**.

**To create a flow log using the command line**

Use one of the following commands.

- **create-flow-logs** (AWS CLI)
- **New-EC2FlowLogs** (AWS Tools for Windows PowerShell)

The following AWS CLI example creates a flow log that captures all accepted traffic for the specified subnet. The flow logs are delivered to the specified log group. The `--deliver-logs-permission-arn` parameter specifies the IAM role required to publish to CloudWatch Logs.

```bash
aws ec2 create-flow-logs --resource-type Subnet --resource-ids subnet-1a2b3c4d --traffic-type ACCEPT --log-group-name my-flow-logs --deliver-logs-permission-arn arn:aws:iam::123456789101:role/publishFlowLogs
```

**View flow log records**

You can view your flow log records using the CloudWatch Logs console. After you create your flow log, it might take a few minutes for it to be visible in the console.

**To view flow log records published to CloudWatch Logs using the console**

2. In the navigation pane, choose **Logs**, **Log groups**.
3. Select the name of the log group that contains your flow logs to open its details page.
4. Select the name of the log stream that contains the flow log records. For more information, see **Flow log records** (p. 184).

**To view flow log records published to CloudWatch Logs using the command line**

- **get-log-events** (AWS CLI)
- **Get-CWLLogEvent** (AWS Tools for Windows PowerShell)

**Search flow log records**

You can search your flow log records that are published to CloudWatch Logs using the CloudWatch Logs console. You can use **metric filters** to filter flow log records. Flow log records are space delimited.

**To search flow log records using the CloudWatch Logs console**

2. In the navigation pane, choose **Logs, Log groups**.

3. Select the log group that contains your flow log, and then select the log stream, if you know the network interface that you are searching for. Alternatively, choose **Search log group**. This might take some time if there are many network interfaces in your log group, or depending on the time range that you select.

4. For **Filter events**, enter the following string. This assumes that the flow log record uses the **default format** (p. 184).

   ```
   [version, accountid, interfaceid, srcaddr, dstaddr, srcport, dstport, protocol, packets, bytes, start, end, action, logstatus]
   ```

5. Modify the filter as needed by specifying values for the fields. The following examples filter by specific source IP addresses.

   ```
   [version, accountid, interfaceid, srcaddr = 10.0.0.1, dstaddr, srcport, dstport, protocol, packets, bytes, start, end, action, logstatus]
   
   [version, accountid, interfaceid, srcaddr = 10.0.2.*, dstaddr, srcport, dstport, protocol, packets, bytes, start, end, action, logstatus]
   ```

The following examples filter by destination port, the number of bytes, and whether the traffic was rejected.

```
[version, accountid, interfaceid, srcaddr, dstaddr, srcport, dstport = 80 || dstport = 8080, protocol, packets, bytes, start, end, action, logstatus]

[version, accountid, interfaceid, srcaddr, dstaddr, srcport, dstport = 80 || dstport = 8080, protocol, packets, bytes >= 400, start, end, action = REJECT, logstatus]
```

**Process flow log records in CloudWatch Logs**

You can work with flow log records as you would with any other log events collected by CloudWatch Logs. For more information about monitoring log data and metric filters, see Searching and Filtering Log Data in the Amazon CloudWatch User Guide.

**Example: Create a CloudWatch metric filter and alarm for a flow log**

In this example, you have a flow log for eni-1a2b3c4d. You want to create an alarm that alerts you if there have been 10 or more rejected attempts to connect to your instance over TCP port 22 (SSH) within a 1-hour time period. First, you must create a metric filter that matches the pattern of the traffic for which to create the alarm. Then, you can create an alarm for the metric filter.

**To create a metric filter for rejected SSH traffic and create an alarm for the filter**

2. In the navigation pane, choose **Logs, Log groups**.
3. Select the check box for the log group, and then choose **Actions, Create metric filter**.
4. For **Filter pattern**, enter the following string.

   ```
   [version, account, eni, source, destination, srcport, destport="22", protocol="6", packets, bytes, windowstart, windowend, action="REJECT", flowlogstatus]
   ```

5. For **Select log data to test**, select the log stream for your network interface. (Optional) To view the lines of log data that match the filter pattern, choose **Test pattern**.
6. When you're ready, choose **Next**.
7. Enter a filter name, metric namespace, and metric name. Set the metric value to 1. When you're done, choose Next and then choose Create metric filter.

8. In the navigation pane, choose Alarms, All alarms.

9. Choose Create alarm.

10. Choose the namespace for the metric filter that you created.

   It can take a few minutes for a new metric to display in the console.

11. Select the metric name that you created, and then choose Select metric.

12. Configure the alarm as follows, and then choose Next:

   • For Statistic, choose Sum. This ensure that you capture the total number of data points for the specified time period.
   • For Period, choose 1 hour.
   • For Whenever, choose Greater/Equal and enter 10 for the threshold.
   • For Additional configuration, Datapoints to alarm, leave the default of 1.

13. For Notification, select an existing SNS topic or choose Create new topic to create a new one. Choose Next.

14. Enter a name and description for the alarm and choose Next.

15. When you are done configuring the alarm, choose Create alarm.

Publish flow logs to Amazon S3

Flow logs can publish flow log data to Amazon S3.

When publishing to Amazon S3, flow log data is published to an existing Amazon S3 bucket that you specify. Flow log records for all of the monitored network interfaces are published to a series of log file objects that are stored in the bucket. If the flow log captures data for a VPC, the flow log publishes flow log records for all of the network interfaces in the selected VPC.

To create an Amazon S3 bucket for use with flow logs, see Create a bucket in the Amazon Simple Storage Service User Guide.

For more information about multiple account logging, see Central Logging in the AWS Solutions Library.

For more information about CloudWatch Logs, see Logs sent to Amazon S3 in the Amazon CloudWatch Logs User Guide.

Pricing

Data ingestion and archival charges for vended logs apply when you publish flow logs to Amazon S3. For more information, open Amazon CloudWatch Pricing, select Logs and find Vended Logs.

Contents

• Flow log files (p. 202)
• Permissions for IAM principals that publish flow logs to Amazon S3 (p. 203)
• Amazon S3 bucket permissions for flow logs (p. 203)
• Required key policy for use with SSE-KMS (p. 204)
• Amazon S3 log file permissions (p. 205)
• Create a flow log that publishes to Amazon S3 (p. 205)
• View flow log records (p. 206)
• Process flow log records in Amazon S3 (p. 206)
Flow log files

VPC Flow Logs collects flow log records, consolidates them into log files, and then publishes the log files to the Amazon S3 bucket at 5-minute intervals. Each log file contains flow log records for the IP traffic recorded in the previous five minutes.

The maximum file size for a log file is 75 MB. If the log file reaches the file size limit within the 5-minute period, the flow log stops adding flow log records to it. Then it publishes the flow log to the Amazon S3 bucket, and creates a new log file.

In Amazon S3, the Last modified field for the flow log file indicates the date and time at which the file was uploaded to the Amazon S3 bucket. This is later than the timestamp in the file name, and differs by the amount of time taken to upload the file to the Amazon S3 bucket.

Log file format

You can specify one of the following formats for the log files. Each file is compressed into a single Gzip file.

- **Text** – Plain text. This is the default format.
- **Parquet** – Apache Parquet is a columnar data format. Queries on data in Parquet format are 10 to 100 times faster compared to queries on data in plain text. Data in Parquet format with Gzip compression takes 20 percent less storage space than plain text with Gzip compression.

**Note**

If data in Parquet format with Gzip compression is less than 100 KB per aggregation period, storing data in Parquet format may take up more space than plain text with Gzip compression due to Parquet file memory requirements.

Log file options

You can optionally specify the following options.

- **Hive-compatible S3 prefixes** – Enable Hive-compatible prefixes instead of importing partitions into your Hive-compatible tools. Before you run queries, use the MSCK REPAIR TABLE command.
- **Hourly partitions** – If you have a large volume of logs and typically target queries to a specific hour, you can get faster results and save on query costs by partitioning logs on an hourly basis.

Log file S3 bucket structure

Log files are saved to the specified Amazon S3 bucket using a folder structure that is based on the flow log's ID, Region, creation date, and destination options.

By default, the files are delivered to the following location.

```
bucket-and-optional-prefix/AWSLogs/account_id/vpcflowlogs/region/year/month/day/
```

If you enable Hive-compatible S3 prefixes, the files are delivered to the following location.

```
bucket-and-optional-prefix/AWSLogs/aws-account-id=account_id/service=vpcflowlogs/aws-region=region/year=year/month=month/day=day/
```

If you enable hourly partitions, the files are delivered to the following location.

```
bucket-and-optional-prefix/AWSLogs/account_id/vpcflowlogs/region/year/month/day/hour/
```
If you enable Hive-compatible partitions and partition the flow log per hour, the files are delivered to the following location.

`bucket-and-optional-prefix/AWSLogs/aws-account-id=account_id/service=vpcflowlogs/aws-region=region/year=year/month=month/day=day/hour=hour`

**Log file names**

The file name of a log file is based on the flow log ID, Region, and creation date and time. File names use the following format.

`aws_account_id_vpcflowlogs_region_flow_log_id_YYYYMMDDTHHmZ_hash.log.gz`

The following is an example of a log file for a flow log created by AWS account 123456789012, for a resource in the us-east-1 Region, on June 20, 2018 at 16:20 UTC. The file contains the flow log records with an end time between 16:20:00 and 16:24:59.

`123456789012_vpcflowlogs_us-east-1_fl-1234abcd_20180620T1620Z_fe123456.log.gz`

**Permissions for IAM principals that publish flow logs to Amazon S3**

The IAM principal that creates the flow log, such as an IAM user, must have the following permissions, which are required to publish flow logs to the destination Amazon S3 bucket.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogDelivery",
        "logs:DeleteLogDelivery"
      ],
      "Resource": "*"
    }
  ]
}
```

**Amazon S3 bucket permissions for flow logs**

By default, Amazon S3 buckets and the objects they contain are private. Only the bucket owner can access the bucket and the objects stored in it. However, the bucket owner can grant access to other resources and users by writing an access policy.

If the user creating the flow log owns the bucket and has PutBucketPolicy and GetBucketPolicy permissions for the bucket, we automatically attach the following policy to the bucket. This policy overwrites any existing policy attached to the bucket.

Otherwise, the bucket owner must add this policy to the bucket, specifying the AWS account ID of the flow log creator, or flow log creation fails. For more information, see Using bucket policies in the Amazon Simple Storage Service User Guide.

```json
{
  "Version": "2012-10-17",
  "Statement": [
```
Publish to Amazon S3

```
{
    "Sid": "AWSLogDeliveryWrite",
    "Effect": "Allow",
    "Principal": {
        "Service": "delivery.logs.amazonaws.com"
    },
    "Action": "s3:PutObject",
    "Resource": "my-s3-arn",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": account_id,
            "s3:x-amz-acl": "bucket-owner-full-control"
        },
        "ArnLike": {
            "aws:SourceArn": "arn:aws:logs:region:account_id:*"
        }
    }
},
{
    "Sid": "AWSLogDeliveryAclCheck",
    "Effect": "Allow",
    "Principal": {
        "Service": "delivery.logs.amazonaws.com"
    },
    "Action": "s3:GetBucketAcl",
    "Resource": "arn:aws:s3:::bucket_name",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": account_id
        },
        "ArnLike": {
            "aws:SourceArn": "arn:aws:logs:region:account_id:*"
        }
    }
}
```

The ARN that you specify for `my-s3-arn` depends on whether you use Hive-compatible S3 prefixes.

- Default prefixes

  `arn:aws:s3:::bucket_name/optional_folder/AWSLogs/account_id/*`

- Hive-compatible S3 prefixes

  `arn:aws:s3:::bucket_name/optional_folder/AWSLogs/aws-account-id=account_id/*`

It is a best practice to grant these permissions to the log delivery service principal instead of individual AWS account ARNs. It is also a best practice to use the `aws:SourceAccount` and `aws:SourceArn` condition keys to protect against the confused deputy problem. The source account is the owner of the flow log and the source ARN is the wildcard (*) ARN of the logs service.

### Required key policy for use with SSE-KMS

You can protect the data in your Amazon S3 bucket by enabling either Server-Side Encryption with Amazon S3-Managed Keys (SSE-S3) or Server-Side Encryption with KMS Keys (SSE-KMS). For more information, see Protecting data using server-side encryption in the Amazon S3 User Guide.

If you choose SSE-S3, no additional configuration is required. Amazon S3 handles the encryption key.
If you choose SSE-KMS, you must use a customer managed key. You must update the key policy for your customer managed key so that the log delivery account can write to your S3 bucket. For more information about the required key policy for use with SSE-KMS, see Amazon S3 bucket server-side encryption in the Amazon CloudWatch Logs User Guide.

Amazon S3 log file permissions

In addition to the required bucket policies, Amazon S3 uses access control lists (ACLs) to manage access to the log files created by a flow log. By default, the bucket owner has FULL_CONTROL permissions on each log file. The log delivery owner, if different from the bucket owner, has no permissions. The log delivery account has READ and WRITE permissions. For more information, see Access Control List (ACL) Overview in the Amazon Simple Storage Service User Guide.

Create a flow log that publishes to Amazon S3

After you have created and configured your Amazon S3 bucket, you can create flow logs for your network interfaces, subnets, and VPCs.

To create a flow log using the console

1. Do one of the following:
   - Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. In the navigation pane, choose Network Interfaces. Select the checkbox for the network interface.
   - Open the Amazon VPC console at https://console.aws.amazon.com/vpc/. In the navigation pane, choose Your VPCs. Select the checkbox for the VPC.
   - Open the Amazon VPC console at https://console.aws.amazon.com/vpc/. In the navigation pane, choose Subnets. Select the checkbox for the subnet.
2. Choose Actions, Create flow log.
3. For Filter, specify the type of IP traffic data to log.
   - Accepted – Log only accepted traffic.
   - Rejected – Log only rejected traffic.
   - All – Log accepted and rejected traffic.
4. For Maximum aggregation interval, choose the maximum period of time during which a flow is captured and aggregated into one flow log record.
5. For Destination, choose Send to an S3 bucket.
6. For S3 bucket ARN, specify the Amazon Resource Name (ARN) of an existing Amazon S3 bucket. You can optionally include a subfolder. For example, to specify a subfolder named my-logs in a bucket named my-bucket, use the following ARN:

```
arn:aws:s3:::my-bucket/my-logs/
```

The bucket cannot use AWSLogs as a subfolder name, as this is a reserved term.

If you own the bucket, we automatically create a resource policy and attach it to the bucket. For more information, see Amazon S3 bucket permissions for flow logs (p. 203).
7. For Log record format, specify the format for the flow log record.
   - To use the default flow log record format, choose AWS default format.
   - To create a custom format, choose Custom format. For Log format, choose the fields to include in the flow log record.
8. For Log file format, specify the format for the log file.
   - Text – Plain text. This is the default format.
• **Parquet** – Apache Parquet is a columnar data format. Queries on data in Parquet format are 10 to 100 times faster compared to queries on data in plain text. Data in Parquet format with Gzip compression takes 20 percent less storage space than plain text with Gzip compression.

9. (Optional) To use Hive-compatible S3 prefixes, choose **Hive-compatible S3 prefix, Enable**.

10. (Optional) To partition your flow logs per hour, choose **Every 1 hour (60 mins)**.

11. (Optional) To add a tag to the flow log, choose **Add new tag** and specify the tag key and value.

12. Choose **Create flow log**.

### To create a flow log that publishes to Amazon S3 using a command line tool

Use one of the following commands:

- `create-flow-logs` (AWS CLI)

The following AWS CLI example creates a flow log that captures all traffic for the specified VPC and delivers the flow logs to the specified Amazon S3 bucket. The `--log-format` parameter specifies a custom format for the flow log records.

```bash
aws ec2 create-flow-logs --resource-type VPC --resource-ids vpc-0011223344556677 --traffic-type ALL --log-destination-type s3 --log-destination arn:aws:s3:::flow-log-bucket/custom-flow-logs/ --log-format '${version} ${vpc-id} ${subnet-id} ${instance-id} ${srcaddr} ${dstaddr} ${srcport} ${dstport} ${protocol} ${tcp-flags} ${type} ${pkt-srcaddr} ${pkt-dstaddr}'
```

### View flow log records

You can view your flow log records using the Amazon S3 console. After you create your flow log, it might take a few minutes for it to be visible in the console.

#### To view flow log records published to Amazon S3

1. Open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).
2. Select the name of the bucket to open its details page.
3. Navigate to the folder with the log files. For example, `prefix/AWSLogs/account_id/vpcflowlogs/region/year/month/day/`.
4. Select the checkbox next to the file name, and then choose **Download**.

### Process flow log records in Amazon S3

The log files are compressed. If you open the log files using the Amazon S3 console, they are decompressed and the flow log records are displayed. If you download the files, you must decompress them to view the flow log records.

You can also query the flow log records in the log files using Amazon Athena. Amazon Athena is an interactive query service that makes it easier to analyze data in Amazon S3 using standard SQL. For more information, see [Querying Amazon VPC Flow Logs](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/monitoring-flow-logs.html) in the **Amazon Athena User Guide**.

### Publish flow logs to Kinesis Data Firehose

Flow logs can publish flow log data directly to Kinesis Data Firehose.
When publishing to Kinesis Data Firehose, flow log data is published to a Kinesis Data Firehose delivery stream, in plain text format.

**Pricing**

Standard ingestion and delivery charges apply. For more information, open Amazon CloudWatch Pricing, select Logs and find Vended Logs.

**Contents**

- IAM roles for cross account delivery (p. 207)
- Create a flow log that publishes to Kinesis Data Firehose (p. 210)
- Process flow log records in Kinesis Data Firehose (p. 211)

**IAM roles for cross account delivery**

When you publish to Kinesis Data Firehose, you can choose a delivery stream that's in the same account as the resource to monitor (the source account), or in a different account (the destination account). To enable cross account delivery of flow logs to Kinesis Data Firehose, you must create an IAM role in the source account and an IAM role in the destination account.

**Roles**

- Source account role (p. 207)
- Destination account role (p. 209)

**Source account role**

In the source account, create a role that grants the following permissions. In this example, the name of the role is mySourceRole, but you can choose a different name for this role. The last statement allows the role in the destination account to assume this role. The condition statements ensure that this role is passed only to the log delivery service, and only when monitoring the specified resource. When you create your policy, specify the VPCs, network interfaces, or subnets that you're monitoring with the condition key iam:AssociatedResourceARN.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iam:PassRole"],
      "Resource": "arn:aws:iam::source-account:role/mySourceRole",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "delivery.logs.amazonaws.com"
        },
        "StringLike": {
          "iam:AssociatedResourceARN": [
          ]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": ["logs:CreateLogDelivery", "logs:DeleteLogDelivery",
```
"logs:ListLog Deliveries",
"logs:GetLogDelivery"
],
"Resource": "*
",
{
"Effect": "Allow",
"Action": "sts:AssumeRole",
"Resource": "arn:aws:iam::destination-account:role/AWSLogDeliveryFirehoseCrossAccountRole"
}
]}
}

Ensure that this role has the following trust policy, which allows the log delivery service to assume the role.

[
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "delivery.logs.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
]}

From the source account, use the following procedure to create the role.

**To create the source account role**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Create policy page, do the following:
   a. Choose JSON.
   b. Replace the contents of this window with the permissions policy at the start of this section.
   c. Choose Next: Tags and Next: Review.
   d. Enter a name for your policy and an optional description, and then choose Create policy.
5. In the navigation pane, choose Roles.
6. Choose Create role.
7. For Trusted entity type, choose Custom trust policy. For Custom trust policy, replace "Principal": {}, with the following, which specifies the log delivery service. Choose Next.

   "Principal": {
      "Service": "delivery.logs.amazonaws.com"
    },

8. On the Add permissions page, select the checkbox for the policy that you created earlier in this procedure, and then choose Next.
9. Enter a name for your role and optionally provide a description.
10. Choose Create role.
Destination account role

In the destination account, create a role with a name that starts with `AWSLogDeliveryFirehoseCrossAccountRole`. This role must grant the following permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:CreateServiceLinkedRole",
                "firehose:TagDeliveryStream"
            ],
            "Resource": "*"
        }
    ]
}
```

Ensure that this role has the following trust policy, which allows the role that you created in the source account to assume this role.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::source-account:role/mySourceRole"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

From the destination account, use the following procedure to create the role.

**To create the destination account role**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create policy** page, do the following:
   a. Choose **JSON**.
   b. Replace the contents of this window with the permissions policy at the start of this section.
   c. Choose **Next: Tags** and **Next: Review**.
   d. Enter a name for your policy that starts with `AWSLogDeliveryFirehoseCrossAccountRole`, and then choose **Create policy**.
5. In the navigation pane, choose **Roles**.
6. Choose **Create role**.
7. For **Trusted entity type**, choose **Custom trust policy**. For **Custom trust policy**, replace "Principal": {}, with the following, which specifies the source account role. Choose **Next**.

```json
"Principal": {
    "AWS": "arn:aws:iam::source-account:role/mySourceRole"
}
```
8. On the **Add permissions** page, select the checkbox for the policy that you created earlier in this procedure, and then choose **Next**.

9. Enter a name for your role and optionally provide a description.

10. Choose **Create role**.

### Create a flow log that publishes to Kinesis Data Firehose

You can create flow logs for your VPCs, subnets, or network interfaces.

**Prerequisites**

- Create the destination Kinesis Data Firehose delivery stream. Use **Direct Put** as the source. For more information, see [Creating a Kinesis Data Firehose delivery stream](https://docs.aws.amazon.com/).
- If you're publishing flow logs to a different account, create the required IAM roles, as described in the section called “IAM roles for cross account delivery” (p. 207).

**To create a flow log that publishes to Kinesis Data Firehose**

1. Do one of the following:
   - Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/). In the navigation pane, choose **Network Interfaces**. Select the checkbox for the network interface.
   - Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/). In the navigation pane, choose **Your VPCs**. Select the checkbox for the VPC.
   - Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/). In the navigation pane, choose **Subnets**. Select the checkbox for the subnet.
2. Choose **Actions**, **Create flow log**.
3. For **Filter**, specify the type of traffic to log.
   - **Accept** – Log only accepted traffic
   - **Reject** – Log only rejected traffic
   - **All** – Log accepted and rejected traffic
4. For **Maximum aggregation interval**, choose the maximum period of time during which a flow is captured and aggregated into one flow log record.
5. For **Destination**, choose either of the following options:
   - **Send to Kinesis Data Firehose in the same account** – The delivery stream and the resource to monitor are in the same account.
   - **Send to Kinesis Data Firehose in a different account** – The delivery stream and the resource to monitor are in different accounts.
6. For **Kinesis Data Firehose delivery stream**, choose the delivery stream that you created.
7. [Cross account delivery only] For **IAM roles**, specify the required roles (see the section called “IAM roles for cross account delivery” (p. 207)).
8. (Optional) Choose **Add new tag** to apply tags to the flow log.
9. Choose **Create flow log**.

**To create a flow log that publishes to Kinesis Data Firehose using a command line tool**

Use one of the following commands:
Work with flow logs

The following AWS CLI example creates a flow log that captures all traffic for the specified VPC and delivers the flow logs to the specified Kinesis Data Firehose delivery stream in the same account.

```bash
aws ec2 create-flow-logs --traffic-type ALL
  --resource-type VPC
  --resource-ids vpc-001122334456677
  --log-destination-type kinesis-data-firehose
```

The following AWS CLI example creates a flow log that captures all traffic for the specified VPC and delivers the flow logs to the specified Kinesis Data Firehose delivery stream in a different account.

```bash
aws ec2 create-flow-logs --traffic-type ALL
  --resource-type VPC
  --resource-ids vpc-001122334456677
  --log-destination-type kinesis-data-firehose
  --deliver-logs-permission-arn arn:aws:iam::source-account:role/mySourceRole
  --deliver-cross-account-role arn:aws:iam::destination-account:role/AWSLogDeliveryFirehoseCrossAccountRole
```

Process flow log records in Kinesis Data Firehose

You can get the flow log data from the destination that you configured for the delivery stream.

Work with flow logs

You can work with flow logs using consoles for Amazon EC2 and Amazon VPC.

Tasks
- Control the use of flow logs (p. 211)
- Create a flow log (p. 212)
- View a flow log (p. 212)
- Tag a flow log (p. 212)
- Delete a flow log (p. 213)
- API and CLI overview (p. 213)

Control the use of flow logs

By default, IAM users do not have permission to work with flow logs. You can create an IAM user policy that grants users the permissions to create, describe, and delete flow logs.

The following is an example policy that grants users full permissions to create, describe, and delete flow logs.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    
  
```
"Effect": "Allow",
"Action": [
"ec2:DeleteFlowLogs",
"ec2:CreateFlowLogs",
"ec2:DescribeFlowLogs"
],
"Resource": "*"
}
}

For more information, see the section called "How Amazon VPC works with IAM" (p. 232).

Create a flow log

You can create flow logs for your VPCs, subnets, or network interfaces. When you create a flow log, you must specify a destination for the flow log. For more information, see the following:

- the section called “Create a flow log that publishes to CloudWatch Logs” (p. 198)
- the section called “Create a flow log that publishes to Amazon S3” (p. 205)
- the section called “Create a flow log that publishes to Kinesis Data Firehose” (p. 210)

View a flow log

You can view information about the flow logs for a resource, such as a network interface. The information displayed includes the ID of the flow log, the flow log configuration, and information about the status of the flow log.

To view information about flow logs

1. Do one of the following:
   - Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. In the navigation pane, choose Network Interfaces. Select the checkbox for the network interface.
   - Open the Amazon VPC console at https://console.aws.amazon.com/vpc/. In the navigation pane, choose Your VPCs. Select the checkbox for the VPC.
   - Open the Amazon VPC console at https://console.aws.amazon.com/vpc/. In the navigation pane, choose Subnets. Select the checkbox for the subnet.
2. Choose Flow Logs.
3. (Optional) To view the flow log data, open the log destination.

Tag a flow log

You can add or remove tags for a flow log at any time.

To manage tags for a flow log

1. Do one of the following:
   - Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. In the navigation pane, choose Network Interfaces. Select the checkbox for the network interface.
   - Open the Amazon VPC console at https://console.aws.amazon.com/vpc/. In the navigation pane, choose Your VPCs. Select the checkbox for the VPC.
   - Open the Amazon VPC console at https://console.aws.amazon.com/vpc/. In the navigation pane, choose Subnets. Select the checkbox for the subnet.
2. Choose Flow Logs.
3. Choose Actions, Manage tags.
4. To add a new tag, choose Add new tag and enter the key and value. To remove a tag, choose Remove.
5. When you are finished adding or removing tags, choose Save.

Delete a flow log

You can delete a flow log at any time. After you delete a flow log, it can take several minutes to stop collecting data.

Deleting a flow log does not delete the log data from the destination or modify the destination resource. You must delete the existing flow log data directly from the destination, and clean up the destination resource, using the console for the destination service.

To delete a flow log

1. Do one of the following:
   • Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. In the navigation pane, choose Network Interfaces. Select the checkbox for the network interface.
   • Open the Amazon VPC console at https://console.aws.amazon.com/vpc/. In the navigation pane, choose Your VPCs. Select the checkbox for the VPC.
   • Open the Amazon VPC console at https://console.aws.amazon.com/vpc/. In the navigation pane, choose Subnets. Select the checkbox for the subnet.
2. Choose Flow Logs.
3. Choose Actions, Delete flow logs.
4. When prompted for confirmation, type delete and then choose Delete.

API and CLI overview

You can perform the tasks described on this page using the command line or API. For more information about the command line interfaces and a list of available API actions, see Working with Amazon VPC (p. 2).

Create a flow log

• create-flow-logs (AWS CLI)
• New-EC2FlowLog (AWS Tools for Windows PowerShell)
• CreateFlowLogs (Amazon EC2 Query API)

Describe a flow log

• describe-flow-logs (AWS CLI)
• Get-EC2FlowLog (AWS Tools for Windows PowerShell)
• DescribeFlowLogs (Amazon EC2 Query API)

Tag a flow log

• create-tags and delete-tags (AWS CLI)
• New-EC2Tag and Remove-EC2Tag (AWS Tools for Windows PowerShell)
Query flow logs using Amazon Athena

Amazon Athena is an interactive query service that enables you to analyze data in Amazon S3, such as your flow logs, using standard SQL. You can use Athena with VPC Flow Logs to quickly get actionable insights about the traffic flowing through your VPC. For example, you can identify which resources in your virtual private clouds (VPCs) are the top talkers or identify the IP addresses with the most rejected TCP connections.

Options

- You can streamline and automate the integration of your VPC flow logs with Athena by generating a CloudFormation template that creates the required AWS resources and predefined queries that you can run to obtain insights about the traffic flowing through your VPC.
- You can create your own queries using Athena. For more information, see Query flow logs using Amazon Athena in the Amazon Athena User Guide.

Pricing

You incur standard Amazon Athena charges for running queries. You incur standard AWS Lambda charges for the Lambda function that loads new partitions on a recurring schedule (when you specify a partition load frequency but do not specify a start and end date.)

To use the predefined queries

- Generate the CloudFormation template using the console (p. 214)
- Generate the CloudFormation template using the AWS CLI (p. 215)
- Run a predefined query (p. 216)

Generate the CloudFormation template using the console

After the first flow logs are delivered to your S3 bucket, you can integrate with Athena by generating a CloudFormation template and using the template to create a stack.

Requirements

- The selected Region must support AWS Lambda and Amazon Athena.
- The Amazon S3 buckets must be in the selected Region.
- The log record format for the flow log must include the fields used by the specific predefined queries that you’d like to run.

To generate the template using the console

1. Do one of the following:
• Open the Amazon VPC console. In the navigation pane, choose **Your VPCs** and then select your VPC.

• Open the Amazon VPC console. In the navigation pane, choose **Subnets** and then select your subnet.

• Open the Amazon EC2 console. In the navigation pane, choose **Network Interfaces** and then select your network interface.

2. On the **Flow logs** tab, select a flow log that publishes to Amazon S3 and then choose **Actions**, **Generate Athena integration**.

3. Specify the partition load frequency. If you choose **None**, you must specify the partition start and end date, using dates that are in the past. If you choose **Daily**, **Weekly**, or **Monthly**, the partition start and end dates are optional. If you do not specify start and end dates, the CloudFormation template creates a Lambda function that loads new partitions on a recurring schedule.

4. Select or create an S3 bucket for the generated template, and an S3 bucket for the query results.

5. Choose **Generate Athena integration**.

6. (Optional) In the success message, choose the link to navigate to the bucket that you specified for the CloudFormation template, and customize the template.

7. In the success message, choose **Create CloudFormation stack** to open the **Create Stack** wizard in the AWS CloudFormation console. The URL for the generated CloudFormation template is specified in the **Template** section. Complete the wizard to create the resources that are specified in the template.

**Resources created by the CloudFormation template**

- An Athena database. The database name is vpcflowlogsathenadatabase<flow-logs-subscription-id>.

- An Athena workgroup. The workgroup name is <flow-log-subscription-id><partition-load-frequency><start-date><end-date>workgroup

- A partitioned Athena table that corresponds to your flow log records. The table name is <flow-log-subscription-id><partition-load-frequency><start-date><end-date>.

- A set of Athena named queries. For more information, see Predefined queries (p. 216).

- A Lambda function that loads new partitions to the table on the specified schedule (daily, weekly, or monthly).

- An IAM role that grants permission to run the Lambda functions.

**Generate the CloudFormation template using the AWS CLI**

After the first flow logs are delivered to your S3 bucket, you can generate and use a CloudFormation template to integrate with Athena.

Use the following **get-flow-logs-integration-template** command to generate the CloudFormation template.

```bash
aws ec2 get-flow-logs-integration-template --cli-input-json file://config.json
```

The following is an example of the config.json file.

```json
{
    "FlowLogId": "fl-12345678901234567",
    "ConfigDeliveryS3DestinationArn": "arn:aws:s3:::my-flow-logs-athena-integration/templates/",
    "IntegrateServices": {
```
Use the following `create-stack` command to create a stack using the generated CloudFormation template.

```bash
aws cloudformation create-stack --stack-name my-vpc-flow-logs --template-body file://my-cloudformation-template.json
```

### Run a predefined query

The generated CloudFormation template provides a set of predefined queries that you can run to quickly get meaningful insights about the traffic in your AWS network. After you create the stack and verify that all resources were created correctly, you can run one of the predefined queries.

**To run a predefined query using the console**

1. Open the Athena console. In the **Workgroups** panel, select the workgroup created by the CloudFormation template.
2. Select one of the predefined queries (p. 216), modify the parameters as needed, and then run the query.
3. Open the Amazon S3 console. Navigate to the bucket that you specified for the query results, and view the results of the query.

### Predefined queries

The following is the complete list of Athena named queries. The predefined queries that are provided when you generate the template depend on the fields that are part of the log record format for the flow log. Therefore, the template might not contain all of these predefined queries.

- **VpcFlowLogsAcceptedTraffic** – The TCP connections that were allowed based on your security groups and network ACLs.
- **VpcFlowLogsAdminPortTraffic** – The top 10 IP addresses with the most traffic, as recorded by applications serving requests on administrative ports.
- **VpcFlowLogsIPv4Traffic** – The total bytes of IPv4 traffic recorded.
- **VpcFlowLogsIPv6Traffic** – The total bytes of IPv6 traffic recorded.
- **VpcFlowLogsRejectedTCP Traffic** – The TCP connections that were rejected based on your security groups or network ACLs.
- **VpcFlowLogsRejectedTraffic** – The traffic that was rejected based on your security groups or network ACLs.
- **VpcFlowLogsSshRdpTraffic** – The SSH and RDP traffic.
- **VpcFlowLogsTopTalkers** – The 50 IP addresses with the most traffic recorded.
- **VpcFlowLogsTopTalkersPacketLevel** – The 50 packet-level IP addresses with the most traffic recorded.
• **VpcFlowLogsTopTalkingInstances** – The IDs of the 50 instances with the most traffic recorded.
• **VpcFlowLogsTopTalkingSubnets** – The IDs of the 50 subnets with the most traffic recorded.
• **VpcFlowLogsTopTCPTraffic** – All TCP traffic recorded for a source IP address.
• **VpcFlowLogsTotalBytesTransferred** – The 50 pairs of source and destination IP addresses with the most bytes recorded.
• **VpcFlowLogsTotalBytesTransferredPacketLevel** – The 50 pairs of packet-level source and destination IP addresses with the most bytes recorded.
• **VpcFlowLogsTrafficFrmSrcAddr** – The traffic recorded for a specific source IP address.
• **VpcFlowLogsTrafficToDstAddr** – The traffic recorded for a specific destination IP address.

### Troubleshoot VPC Flow Logs

The following are possible issues you might have when working with flow logs.

**Issues**

- **Incomplete flow log records** (p. 217)
- **Flow log is active, but no flow log records or log group** (p. 218)
- **'LogDestinationNotFoundException' or 'Access Denied for LogDestination' error** (p. 218)
- **Exceeding the Amazon S3 bucket policy limit** (p. 218)

#### Incomplete flow log records

**Problem**

Your flow log records are incomplete, or are no longer being published.

**Cause**

There might be a problem delivering the flow logs to the CloudWatch Logs log group.

**Solution**

In either the Amazon EC2 console or the Amazon VPC console, choose the **Flow Logs** tab for the relevant resource. For more information, see [View a flow log](p. 212). The flow logs table displays any errors in the **Status** column. Alternatively, use the `describe-flow-logs` command, and check the value that's returned in the `DeliverLogsErrorMessage` field. One of the following errors might be displayed:

- **Rate limited**: This error can occur if CloudWatch Logs throttling has been applied — when the number of flow log records for a network interface is higher than the maximum number of records that can be published within a specific timeframe. This error can also occur if you've reached the quota for the number of CloudWatch Logs log groups that you can create. For more information, see [CloudWatch Service Quotas](in the [Amazon CloudWatch User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/)).

- **Access error**: This error can occur for one of the following reasons:
  - The IAM role for your flow log does not have sufficient permissions to publish flow log records to the CloudWatch log group
  - The IAM role does not have a trust relationship with the flow logs service
  - The trust relationship does not specify the flow logs service as the principal

For more information, see [IAM role for publishing flow logs to CloudWatch Logs](p. 196).

- **Unknown error**: An internal error has occurred in the flow logs service.
Flow log is active, but no flow log records or log group

Problem
You created a flow log, and the Amazon VPC or Amazon EC2 console displays the flow log as Active. However, you cannot see any log streams in CloudWatch Logs or log files in your Amazon S3 bucket.

Possible causes
- The flow log is still being created. In some cases, it can take ten minutes or more after you create the flow log for the log group to be created, and for data to be displayed.
- There has been no traffic recorded for your network interfaces yet. The log group in CloudWatch Logs is only created when traffic is recorded.

Solution
Wait a few minutes for the log group to be created, or for traffic to be recorded.

'LogDestinationNotFoundException' or 'Access Denied for LogDestination' error

Problem
You get a Access Denied for LogDestination or a LogDestinationNotFoundException error when you create a flow log.

Possible causes
- When creating a flow log that publishes data to an Amazon S3 bucket, this error indicates that the specified S3 bucket could not be found or that the bucket policy does not allow logs to be delivered to the bucket.
- When creating a flow log that publishes data to Amazon CloudWatch Logs, this error indicates that the IAM role does not allow logs to be delivered to the log group.

Solution
- When publishing to Amazon S3, ensure that you have specified the ARN for an existing S3 bucket, and that the ARN is in the correct format. If you do not own the S3 bucket, verify that the bucket policy (p. 203) has the required permissions and uses the correct account ID and bucket name in the ARN.
- When publishing to CloudWatch Logs, verify that the IAM role (p. 196) has the required permissions.

Exceeding the Amazon S3 bucket policy limit

Problem
You get the following error when you try to create a flow log: LogDestinationPermissionIssueException.

Possible causes
Amazon S3 bucket policies are limited to 20 KB in size.
Each time that you create a flow log that publishes to an Amazon S3 bucket, we automatically add the specified bucket ARN, which includes the folder path, to the Resource element in the bucket's policy.

Creating multiple flow logs that publish to the same bucket could cause you to exceed the bucket policy limit.

**Solution**

- Clean up the bucket policy by removing the flow log entries that are no longer needed.
- Grant permissions to the entire bucket by replacing the individual flow log entries with the following.

```
arn:aws:s3:::bucket_name/*
```

If you grant permissions to the entire bucket, new flow log subscriptions do not add new permissions to the bucket policy.

---

**CloudWatch metrics for your VPCs**

Amazon VPC publishes data about your VPCs to Amazon CloudWatch. You can retrieve statistics about your VPCs as an ordered set of time-series data, known as metrics. Think of a metric as a variable to monitor and the data as the value of that variable over time. For more information, see the *Amazon CloudWatch User Guide*.

**Contents**

- NAU metrics and dimensions (p. 219)
- Enable or disable NAU monitoring (p. 221)
- NAU CloudWatch alarm example (p. 221)

**NAU metrics and dimensions**

*Network Address Usage* (p. 42) (NAU) is a metric applied to resources in your virtual network to help you plan for and monitor the size of your VPC. There is no cost to monitor NAU. Monitoring NAU is helpful because if you exhaust the NAU or peered NAU quotas for your VPC, you can’t launch new EC2 instances or provision new resources, such as Network Load Balancers VPC endpoints, Lambda functions, transit gateway attachments, or NAT gateways.

If you’ve enabled Network Address Usage monitoring for a VPC, Amazon VPC sends metrics related to NAU to Amazon CloudWatch. The size of a VPC is measured by the number of Network Address Usage (NAU) units that the VPC contains.

You can use these metrics to understand the rate of your VPC growth, forecast when your VPC will reach its size limit, or create alarms when size thresholds are crossed.

The *AWS/EC2* namespace includes the following metrics for monitoring NAU.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NetworkAddressUsage</td>
<td>The percentage of the NAU quota that is currently in use in a single VPC.</td>
</tr>
<tr>
<td></td>
<td><strong>Reporting criteria</strong></td>
</tr>
<tr>
<td></td>
<td>• Every 24 hours.</td>
</tr>
</tbody>
</table>

---
NAU metrics and dimensions

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dimensions</strong></td>
<td></td>
</tr>
<tr>
<td>• Name: Per-VPC Metrics, Value: The VPC ID.</td>
<td></td>
</tr>
<tr>
<td>NetworkAddressUsagePeered</td>
<td>The percentage of the peered NAU quota that is currently in use between a VPC and all VPCs that it's peered with.</td>
</tr>
<tr>
<td><strong>Reporting criteria</strong></td>
<td></td>
</tr>
<tr>
<td>• Every 24 hours.</td>
<td></td>
</tr>
<tr>
<td><strong>Dimensions</strong></td>
<td></td>
</tr>
<tr>
<td>• Name: Per-VPC Metrics, Value: The VPC ID.</td>
<td></td>
</tr>
</tbody>
</table>

The AWS/Usage namespace includes the following metrics for monitoring NAU.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ResourceCount</strong></td>
<td>The NAU count per VPC.</td>
</tr>
<tr>
<td><strong>Reporting criteria</strong></td>
<td></td>
</tr>
<tr>
<td>• Every 24 hours.</td>
<td></td>
</tr>
<tr>
<td><strong>Dimensions</strong></td>
<td></td>
</tr>
<tr>
<td>• Name: Service, Value: EC2</td>
<td></td>
</tr>
<tr>
<td>• Name: Type, Value: Resource</td>
<td></td>
</tr>
<tr>
<td>• Name: Resource, Value: The VPC ID.</td>
<td></td>
</tr>
<tr>
<td>• Name: Class, Value: NetworkAddressUsage</td>
<td></td>
</tr>
<tr>
<td>ResourceCount</td>
<td>The NAU count for the VPC and all VPCs that it's peered with.</td>
</tr>
<tr>
<td><strong>Reporting criteria</strong></td>
<td></td>
</tr>
<tr>
<td>• Every 24 hours.</td>
<td></td>
</tr>
<tr>
<td><strong>Dimensions</strong></td>
<td></td>
</tr>
<tr>
<td>• Name: Service, Value: EC2</td>
<td></td>
</tr>
<tr>
<td>• Name: Type, Value: Resource</td>
<td></td>
</tr>
<tr>
<td>• Name: Resource, Value: The VPC ID.</td>
<td></td>
</tr>
<tr>
<td>• Name: Class, Value: NetworkAddressUsagePeered</td>
<td></td>
</tr>
<tr>
<td>ResourceCount</td>
<td>A combined view of NAU usage across VPCs.</td>
</tr>
<tr>
<td><strong>Reporting criteria</strong></td>
<td></td>
</tr>
<tr>
<td>• Every 24 hours.</td>
<td></td>
</tr>
</tbody>
</table>
Enable or disable NAU monitoring

To view NAU metrics in CloudWatch, you must first enable monitoring on each VPC to monitor.

To enable or disable monitoring NAU

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs.
3. Select the check box for the VPC.
5. Do one of the following:
   • To enable monitoring, select Network mapping units metrics settings, Enable network address usage metrics.
   • To disable monitoring, clear Network mapping units metrics settings, Enable network address usage metrics.

To enable or disable monitoring using the command line

- modify-vpc-attribute (AWS CLI)
- Edit-EC2VpcAttribute (AWS Tools for Windows PowerShell)

NAU CloudWatch alarm example

You can use the following AWS CLI command and example .json to create an Amazon CloudWatch alarm and SNS notification that tracks NAU utilization of the VPC with 50,000 NAUs as the threshold.
This sample requires you to first create an Amazon SNS topic. For more information, see Getting started with Amazon SNS in the Amazon Simple Notification Service Developer Guide.

```
aws cloudwatch put-metric-alarm --cli-input-json file://nau-alarm.json
```

The following is an example of `nau-alarm.json`.

```
{
   "Namespace": "AWS/EC2",
   "MetricName": "NetworkAddressUsage",
   "Dimensions": [
      {
         "Name": "Per-VPC Metrics",
         "Value": "vpc-0123456798"
      }
   ],
   "ComparisonOperator": "GreaterThanThreshold",
   "Period": 86400,
   "EvaluationPeriods": 1,
   "Threshold": 50000,
   "AlarmDescription": "Tracks NAU utilization of the VPC with 50k NAUs as the threshold",
   "AlarmName": "VPC NAU Utilization",
   "Statistic": "Maximum"
}
```
Security in Amazon Virtual Private Cloud

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to Amazon Virtual Private Cloud, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon VPC. The following topics show you how to configure Amazon VPC to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon VPC resources.

Contents

- Data protection in Amazon Virtual Private Cloud (p. 223)
- Infrastructure security in Amazon VPC (p. 226)
- Identity and access management for Amazon VPC (p. 228)
- Control traffic to resources using security groups (p. 245)
- Resilience in Amazon Virtual Private Cloud (p. 255)
- Compliance validation for Amazon Virtual Private Cloud (p. 255)
- Configuration and vulnerability analysis in Amazon Virtual Private Cloud (p. 256)
- Security best practices for your VPC (p. 256)

Data protection in Amazon Virtual Private Cloud

The AWS shared responsibility model applies to data protection in Amazon Virtual Private Cloud. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given
only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers’ email addresses, into tags or free-form fields such as a Name field. This includes when you work with Amazon VPC or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Internetwork traffic privacy in Amazon VPC

Amazon Virtual Private Cloud provides features that you can use to increase and monitor the security for your virtual private cloud (VPC):

- **Security groups**: Security groups allow or deny specific inbound and outbound traffic at the resource level (such as an EC2 instance). When you launch an instance, you can associate it with one or more security groups. Each instance in your VPC could belong to a different set of security groups. If you don’t specify a security group when you launch an instance, the instance is automatically associated with the default security group for its VPC. For more information, see the section called “Security groups” (p. 245).
- **Network access control lists (ACL)**: Network ACLs allow or deny specific inbound and outbound traffic at the subnet level. For more information, see Control traffic to subnets using Network ACLs (p. 108).
- **Flow logs**: Flow logs capture information about the IP traffic going to and from network interfaces in your VPC. You can create a flow log for a VPC, subnet, or individual network interface. Flow log data is published to CloudWatch Logs or Amazon S3, and it can help you diagnose overly restrictive or overly permissive security group and network ACL rules. For more information, see Logging IP traffic using VPC Flow Logs (p. 180).
- **Traffic mirroring**: You can copy network traffic from an elastic network interface of an Amazon EC2 instance. You can then send the traffic to out-of-band security and monitoring appliances. For more information, see the Traffic Mirroring Guide.

You can use AWS Identity and Access Management (IAM) to control who in your organization has permission to create and manage security groups, network ACLs, and flow logs. For example, you can give your network administrators that permission, but not give permission to personnel who only need to launch instances. For more information, see Identity and access management for Amazon VPC (p. 228).

Amazon security groups and network ACLs do not filter traffic destined to and from the following:

- Amazon Domain Name Services (DNS)
- Amazon Dynamic Host Configuration Protocol (DHCP)
- Amazon EC2 instance metadata
- Amazon ECS task metadata endpoints
- License activation for Windows instances
- Amazon Time Sync Service
- Reserved IP addresses used by the default VPC router

## Compare security groups and network ACLs

The following table summarizes the basic differences between security groups and network ACLs.

<table>
<thead>
<tr>
<th>Security group</th>
<th>Network ACL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operates at the instance level</td>
<td>Operates at the subnet level</td>
</tr>
<tr>
<td>Applies to an instance only if it is associated with the instance</td>
<td>Applies to all instances deployed in the associated subnet (providing an additional layer of defense if security group rules are too permissive)</td>
</tr>
<tr>
<td>Supports allow rules only</td>
<td>Supports allow rules and deny rules</td>
</tr>
<tr>
<td>We evaluate all rules before deciding whether to allow traffic</td>
<td>We evaluate rules in order, starting with the lowest numbered rule, when deciding whether to allow traffic</td>
</tr>
<tr>
<td>Stateful: Return traffic is allowed, regardless of the rules</td>
<td>Stateless: Return traffic must be explicitly allowed by rules</td>
</tr>
</tbody>
</table>

The following diagram illustrates the layers of security provided by security groups and network ACLs. For example, traffic from an internet gateway is routed to the appropriate subnet using the routes in the routing table. The rules of the network ACL that is associated with the subnet control which traffic is allowed to the subnet. The rules of the security group that is associated with an instance control which traffic is allowed to the instance.
You can secure your instances using only security groups. However, you can add network ACLs as an additional layer of defense. For an example, see Example: Control access to instances in a subnet (p. 124).

Encryption in transit

AWS provides secure and private connectivity between EC2 instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. For more information, see Encryption in transit in the Amazon EC2 User Guide for Linux Instances.

Infrastructure security in Amazon VPC

As a managed service, Amazon VPC is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use AWS published API calls to access Amazon VPC through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.
Additionally, requests must be signed using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

**Network isolation**

A virtual private cloud (VPC) is a virtual network in your own logically isolated area in the AWS Cloud. Use separate VPCs to isolate infrastructure by workload or organizational entity.

A subnet is a range of IP addresses in a VPC. When you launch an instance, you launch it into a subnet in your VPC. Use subnets to isolate the tiers of your application (for example, web, application, and database) within a single VPC. Use private subnets for your instances if they should not be accessed directly from the internet.

To call the Amazon EC2 API from your VPC without sending traffic over the public internet, use AWS PrivateLink.

**Control network traffic**

Consider the following options for controlling network traffic to your EC2 instances:

- Restrict access to your subnets using the section called “Security groups” (p. 245). For example, you can allow traffic only from the address ranges for your corporate network.
- Leverage security groups as the primary mechanism for controlling network access to VPCs. When necessary, use network ACLs sparingly to provide stateless, coarse-grain network control. Security groups are more versatile than network ACLs due to their ability to perform stateful packet filtering and create rules that reference other security groups. However, network ACLs can be effective as a secondary control for denying a specific subset of traffic or providing high-level subnet guard rails. Also, because network ACLs apply to an entire subnet, they can be used as defense-in-depth in case an instance is ever launched unintentionally without a correct security group.
- Use private subnets for your instances if they should not be accessed directly from the internet. Use a bastion host or NAT gateway for internet access from an instance in a private subnet.
- Configure Amazon VPC subnet route tables with the minimal required network routes. For example, place only Amazon EC2 instances that require direct internet access into subnets with routes to an internet gateway, and place only Amazon EC2 instances that need direct access to internal networks into subnets with routes to a virtual private gateway.
- Consider using additional security groups or network interfaces to control and audit Amazon EC2 instance management traffic separately from regular application traffic. This approach allows customers to implement special IAM policies for change control, making it easier to audit changes to security group rules or automated rule-verification scripts. Multiple network interfaces also provide additional options for controlling network traffic including the ability to create host-based routing policies or leverage different VPC subnet routing rules based on an network interfaces assigned to a subnet.
- Use AWS Virtual Private Network or AWS Direct Connect to establish private connections from your remote networks to your VPCs. For more information, see Network-to-Amazon VPC connectivity options.
- Use VPC Flow Logs to monitor the traffic that reaches your instances.
- Use AWS Security Hub to check for unintended network accessibility from your instances.

In addition to restricting network access to each Amazon EC2 instance, Amazon VPC supports implementing additional network security controls. For more information, see Protecting Networks.
Identity and access management for Amazon VPC

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon VPC resources. IAM is an AWS service that you can use with no additional charge.

Contents

- Audience (p. 228)
- Authenticate with identities (p. 228)
- Manage access using policies (p. 230)
- How Amazon VPC works with IAM (p. 232)
- Amazon VPC policy examples (p. 235)
- Troubleshoot Amazon VPC identity and access (p. 242)
- AWS managed policies for Amazon Virtual Private Cloud (p. 244)

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon VPC.

Service user – If you use the Amazon VPC service to do your job, your administrator provides you with the credentials and permissions that you need. As you use more Amazon VPC features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon VPC, see Troubleshoot Amazon VPC identity and access (p. 242).

Service administrator – If you're in charge of Amazon VPC resources at your company, you probably have full access to Amazon VPC. It's your job to determine which Amazon VPC features and resources your employees should access. You submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon VPC, see How Amazon VPC works with IAM (p. 232).

IAM administrator – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon VPC. To view example policies, see Amazon VPC policy examples (p. 235).

Authenticate with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (successor to AWS Single Sign-On) (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the AWS Sign-In User Guide.
If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests using your credentials. If you don’t use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide and Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the AWS General Reference.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about
permissions sets, see Permissions sets in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.

- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon Elastic Compute Cloud in the Service Authorization Reference.

- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

To learn whether to use IAM roles or IAM users, see When to create an IAM role (instead of a user) in the IAM User Guide.

**Manage access using policies**

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

Every IAM entity (user or role) starts with no permissions. By default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.
IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

**Identity-based policies**

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see *Choosing between managed policies and inline policies* in the *IAM User Guide*.

**Resource-based policies**

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

**Access control lists (ACLs)**

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see *Access control list (ACL) overview* in the *Amazon Simple Storage Service Developer Guide*.

**Other policy types**

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see *Permissions boundaries for IAM entities* in the *IAM User Guide*.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see *How SCPs work* in the *AWS Organizations User Guide*. 231
• **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.

**Multiple policy types**

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

**How Amazon VPC works with IAM**

Before you use IAM to manage access to Amazon VPC, you should understand what IAM features are available to use with Amazon VPC. To get a high-level view of how Amazon VPC and other AWS services work with IAM, see AWS Services That Work with IAM in the IAM User Guide.

**Contents**

- Actions (p. 232)
- Resources (p. 233)
- Condition keys (p. 234)
- Amazon VPC resource-based policies (p. 234)
- Authorization based on tags (p. 234)
- IAM roles (p. 235)

With IAM identity-based policies, you can specify allowed or denied actions. For some actions, you can specify the resources and conditions under which actions are allowed or denied. Amazon VPC supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON Policy Elements Reference in the IAM User Guide.

**Actions**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Amazon VPC shares its API namespace with Amazon EC2. Policy actions in Amazon VPC use the following prefix before the action: ec2:. For example, to grant someone permission to create a VPC with the Amazon EC2 CreateVpc API operation, you include the ec2:CreateVpc action in their policy. Policy statements must include either an Action or NotAction element.

To specify multiple actions in a single statement, separate them with commas as shown in the following example.

```
"Action": [
...
```

232
You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "ec2:Describe*"
```

To see a list of Amazon VPC actions, see Actions, Resources, and Condition Keys for Amazon EC2 in the IAM User Guide.

**Resources**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

**Important**  
Currently, not all Amazon EC2 API actions support resource-level permissions. If an Amazon EC2 API action does not support resource-level permissions, you can grant users permission to use the action, but you have to specify a * for the resource element of your policy statement. To view the actions for which you can specify an ARN for the resource element, see Actions Defined by Amazon EC2.

The VPC resource has the ARN shown in the following example.

```
arn:${Partition}:ec2:${Region}:${Account}:vpc/${VpcId}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs).

For example, to specify the `vpc-1234567890abcdef0` VPC in your statement, use the ARN shown in the following example.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:vpc/vpc-1234567890abcdef0"
```

To specify all VPCs in a specific Region that belong to a specific account, use the wildcard (*).

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:vpc/*"
```

Some Amazon VPC actions, such as those for creating resources, cannot be performed on a specific resource. In those cases, you must use the wildcard (*).

```
"Resource": "*"
```
Many Amazon EC2 API actions involve multiple resources. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
    "resource1",
    "resource2"
]
```

To see a list of Amazon VPC resource types and their ARNs, see Resources Defined by Amazon EC2 in the IAM User Guide.

**Condition keys**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

Amazon VPC defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS Global Condition Context Keys in the IAM User Guide.

All Amazon EC2 actions support the aws:RequestedRegion and ec2:Region condition keys. For more information, see Example: Restricting Access to a Specific Region.

To see a list of Amazon VPC condition keys, see Condition Keys for Amazon EC2 in the IAM User Guide. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon EC2.

**Amazon VPC resource-based policies**

Resource-based policies are JSON policy documents that specify what actions a specified principal can perform on the Amazon VPC resource and under what conditions.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, you must also grant the principal entity permission to access the resource. Grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see How IAM Roles Differ from Resource-based Policies in the IAM User Guide.

**Authorization based on tags**

You can attach tags to Amazon VPC resources or pass tags in a request. To control access based on tags, you provide tag information in the condition element of a policy using the ec2:ResourceTag/key-
name, aws:RequestTag/key-name, or aws:TagKeys condition keys. For more information, see Resource-Level Permissions for Tagging in the Amazon EC2 User Guide.

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Launch instances into a specific VPC (p. 241).

IAM roles

An IAM role is an entity within your AWS account that has specific permissions.

Use temporary credentials

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

Amazon VPC supports using temporary credentials.

Service-linked roles

Service-linked roles allow AWS services to access resources in other services to complete an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view but not edit the permissions for service-linked roles.

Transit gateways support service-linked roles.

Service roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

Amazon VPC supports service roles for flow logs. When you create a flow log, you must choose a role that allows the flow logs service to access CloudWatch Logs. For more information, see the section called “IAM role for publishing flow logs to CloudWatch Logs” (p. 196).

Amazon VPC policy examples

By default, IAM users and roles don't have permission to create or modify VPC resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating Policies on the JSON Tab in the IAM User Guide.

Contents

- Policy best practices (p. 236)
- Use the Amazon VPC console (p. 236)
- Create a VPC with a public subnet (p. 237)
- Modify and delete VPC resources (p. 238)
- Manage security groups (p. 239)
Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon VPC resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see *AWS managed policies* or *AWS managed policies for job functions* in the *IAM User Guide*.

- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see *Policies and permissions in IAM* in the *IAM User Guide*.

- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see *IAM JSON policy elements: Condition* in the *IAM User Guide*.

- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see *IAM Access Analyzer policy validation* in the *IAM User Guide*.

- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or root users in your account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see *Configuring MFA-protected API access* in the *IAM User Guide*.

For more information about best practices in IAM, see *Security best practices in IAM* in the *IAM User Guide*.

Use the Amazon VPC console

To access the Amazon VPC console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon VPC resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (IAM users or roles) with that policy.

The following policy grants users permission to list resources in the VPC console, but not to create, update, or delete them.

```json
{
    "Version": "2012-10-17",
```
"Statement": [ {
    "Effect": "Allow",
    "Action": [ "ec2:DescribeAccountAttributes",
                  "ec2:DescribeAddresses",
                  "ec2:DescribeAvailabilityZones",
                  "ec2:DescribeClassicLinkInstances",
                  "ec2:DescribeClientVpnEndpoints",
                  "ec2:DescribeCustomerGateways",
                  "ec2:DescribeDhcpOptions",
                  "ec2:DescribeEgressOnlyInternetGateways",
                  "ec2:DescribeFlowLogs",
                  "ec2:DescribeInternetGateways",
                  "ec2:DescribeManagedPrefixLists",
                  "ec2:DescribeMovingAddresses",
                  "ec2:DescribeNatGateways",
                  "ec2:DescribeNetworkAcls",
                  "ec2:DescribeNetworkInterfaceAttribute",
                  "ec2:DescribeNetworkInterfacePermissions",
                  "ec2:DescribeNetworkInterfaces",
                  "ec2:DescribePrefixLists",
                  "ec2:DescribeRouteTables",
                  "ec2:DescribeSecurityGroupReferences",
                  "ec2:DescribeSecurityGroups",
                  "ec2:DescribeSecurityGroupRules",
                  "ec2:DescribeStaleSecurityGroups",
                  "ec2:DescribeSubnets",
                  "ec2:DescribeTags",
                  "ec2:DescribeTrafficMirrorFilters",
                  "ec2:DescribeTrafficMirrorSessions",
                  "ec2:DescribeTrafficMirrorTargets",
                  "ec2:DescribeTransitGateways",
                  "ec2:DescribeTransitGatewayVpcAttachments",
                  "ec2:DescribeTransitGatewayRouteTables",
                  "ec2:DescribeVpcAttribute",
                  "ec2:DescribeVpcClassicLink",
                  "ec2:DescribeVpcClassicLinkDnsSupport",
                  "ec2:DescribeVpcEndpoints",
                  "ec2:DescribeVpcEndpointConnections",
                  "ec2:DescribeVpcEndpointConnectionNotifications",
                  "ec2:DescribeVpcEndpointConnections",
                  "ec2:DescribeVpcEndpointServiceConfigurations",
                  "ec2:DescribeVpcEndpointServicePermissions",
                  "ec2:DescribeVpcEndpointServices",
                  "ec2:DescribeVpcPeeringConnections",
                  "ec2:DescribeVpcs",
                  "ec2:DescribeVpnConnections",
                  "ec2:DescribeVpnGateways",
                  "ec2:GetManagedPrefixListAssociations",
                  "ec2:GetManagedPrefixListEntries"
              ],
    "Resource": "*"
} ]
}

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, for those users, allow access only to actions that match the API operation that they need to perform.

### Create a VPC with a public subnet

The following example enables users to create VPCs, subnets, route tables, and internet gateways. Users can also attach an internet gateway to a VPC and create routes in route tables. The
ec2:ModifyVpcAttribute action enables users to enable DNS hostnames for the VPC, so that each instance launched into a VPC receives a DNS hostname.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:CreateVpc",
      "ec2:CreateSubnet",
      "ec2:DescribeAvailabilityZones",
      "ec2:CreateRouteTable",
      "ec2:CreateRoute",
      "ec2:CreateInternetGateway",
      "ec2:AttachInternetGateway",
      "ec2:AssociateRouteTable",
      "ec2:ModifyVpcAttribute"
    ],
    "Resource": "*"
  }
}
```

The preceding policy also enables users to create a VPC in the Amazon VPC console.

### Modify and delete VPC resources

You might want to control which VPC resources users can modify or delete. For example, the following policy allows users to work with and delete route tables that have the tag `Purpose=Test`. The policy also specifies that users can only delete internet gateways that have the tag `Purpose=Test`. Users cannot work with route tables or internet gateways that do not have this tag.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:DeleteInternetGateway",
      "Resource": "arn:aws:ec2::*:internet-gateway/**",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/Purpose": "Test"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DeleteRouteTable",
        "ec2:CreateRoute",
        "ec2:ReplaceRoute",
        "ec2:DeleteRoute"
      ],
      "Resource": "arn:aws:ec2::*:route-table/**",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/Purpose": "Test"
        }
      }
    }
  ]
}
```
Manage security groups

The following policy allows users to manage security groups. The first statement allows users to delete any security group with the tag Stack=test and to manage the inbound and outbound rules for any security group with the tag Stack=test. The second statement requires users to tag any security groups that they create with the tag Stack=Test. The third statement allows users to create a security group. The fourth statement allows users to view any security group and security group rule. The fifth statement allows users to create a security group in a VPC.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:RevokeSecurityGroupIngress",
                "ec2:AuthorizeSecurityGroupEgress",
                "ec2:AuthorizeSecurityGroupIngress",
                "ec2:UpdateSecurityGroupRuleDescriptionsEgress",
                "ec2:RevokeSecurityGroupEgress",
                "ec2:DeleteSecurityGroup",
                "ec2:ModifySecurityGroupRules",
                "ec2:UpdateSecurityGroupRuleDescriptionsIngress"
            ],
            "Resource": "arn:aws:ec2::*:security-group/*",
            "Condition": {
                "StringEquals": {
                    "ec2:ResourceTag/Stack": "test"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:CreateSecurityGroup",
            "Resource": "arn:aws:ec2::*:security-group/*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/Stack": "test"
                },
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": "Stack"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "arn:aws:ec2::*:security-group/*",
            "Condition": {
                "StringEquals": {
                    "ec2:CreateAction": "CreateSecurityGroup"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeSecurityGroupRules",
                "ec2:DescribeVpcs",
                "ec2:DescribeSecurityGroups"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:CreateSecurityGroup",
            "Resource": "arn:aws:ec2::*:security-group/*",
            "Condition": {
                "StringEquals": {
                    "ec2:ResourceTag/Stack": "test"
                }
            }
        }
    ]
}
```
Policy examples

To allow users to change the security group that's associated with an instance, add the 
`ec2:ModifyInstanceAttribute` action to your policy.

To allow users to change security groups for a network interface, add the 
`ec2:ModifyNetworkInterfaceAttribute` action to your policy.

Manage security group rules

The following policy grants users permission to view all security groups and security group rules, 
add and remove inbound and outbound rules for the security groups for a specific VPC, and modify 
rule descriptions for the specified VPC. The first statement uses the `ec2:Vpc` condition key to scope 
permissions to a specific VPC.

The second statement grants users permission to describe all security groups, security group rules, and 
tags. This enables users to view security group rules in order to modify them.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:AuthorizeSecurityGroupIngress",
            "ec2:RevokeSecurityGroupIngress",
            "ec2:AuthorizeSecurityGroupRuleDescriptionsIngress",
            "ec2:DescribeSecurityGroups",
            "ec2:DescribeSecurityGroupIngress",
            "ec2:DescribeSecurityGroupEgress",
            "ec2:DescribeSecurityGroupRuleDescriptionsEgress",
            "ec2:DescribeSecurityGroupRules"
         ],
         "Resource": "arn:aws:ec2:*:account-id:security-group/*",
         "Condition": {
            "ArnEquals": {
               "ec2:Vpc": "arn:aws:ec2:*:account-id:vpc/vpc-id"
            }
         }
      },
      {

            "ec2:DescribeSecurityGroups",
            "ec2:DescribeSecurityGroupRules",
            "ec2:DescribeSecurityGroupTags"
         ],
         "Resource": "*"
      }
   ]
}
```

Launch instances into a specific subnet

The following policy grants users permission to launch instances into a specific subnet, and to use a 
specific security group in the request. The policy does this by specifying the ARN for the subnet and 
the ARN for the security group. If users attempt to launch an instance into a different subnet or using a
different security group, the request will fail (unless another policy or statement grants users permission to do so).

The policy also grants permission to use the network interface resource. When launching into a subnet, the `RunInstances` request creates a primary network interface by default, so the user needs permission to create this resource when launching the instance.

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": [
            "arn:aws:ec2::image/ami-*",
            "arn:aws:ec2:region:account:instance/",
            "arn:aws:ec2:region:account:volume/",
            "arn:aws:ec2:region:account:key-pair/",
            "arn:aws:ec2:region:account:security-group/sg-id"
        ]
    }]
}
```

### Launch instances into a specific VPC

The following policy grants users permission to launch instances into any subnet within a specific VPC. The policy does this by applying a condition key (`ec2:Vpc`) to the subnet resource.

The policy also grants users permission to launch instances using only AMIs that have the tag 
"department=dev".

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Condition": {
            "ArnEquals": {
                "ec2:Vpc": "arn:aws:ec2:region:account-id:vpc/vpc-id"
            }
        }
    }, {
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": "arn:aws:ec2::image/ami-*",
        "Condition": {
            "StringEquals": {
                "ec2:ResourceTag/departmen": "dev"
            }
        }
    }, {
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": [
            "arn:aws:ec2:region:account:instance/**",
            "arn:aws:ec2:region:account:volume/**",
            "arn:aws:ec2:region:account:key-pair/**"
        ]
    }]
}
```
Additional Amazon VPC policy examples

You can find additional example IAM policies related to Amazon VPC in the following documentation:

• ClassicLink
• Managed prefix lists (p. 66)
• Traffic mirroring
• Transit gateways
• VPC endpoints and VPC endpoint services
• VPC endpoint policies
• VPC peering
• AWS Wavelength

Troubleshoot Amazon VPC identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon VPC and IAM.

Issues

• I am not authorized to perform an action in Amazon VPC (p. 242)
• I am not authorized to perform iam:PassRole (p. 242)
• I want to view my access keys (p. 243)
• I'm an administrator and want to allow others to access Amazon VPC (p. 243)
• I want to allow people outside of my AWS account to access my Amazon VPC resources (p. 243)

I am not authorized to perform an action in Amazon VPC

If the AWS Management Console tells you that you’re not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a subnet but does not have ec2:DescribeSubnets permissions.

User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: ec2:DescribeSubnets on resource: subnet-id

In this case, Mateo asks his administrator to update his policies to allow him to access the subnet.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, your policies must be updated to allow you to pass a role to Amazon VPC.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.
The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Amazon VPC. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

**I want to view my access keys**

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtznFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

**Important**

Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the *IAM User Guide*.

**I'm an administrator and want to allow others to access Amazon VPC**

To allow others to access Amazon VPC, you must create an IAM entity (user or role) for the person or application that needs access. They will use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Amazon VPC.

To get started right away, see Creating your first IAM delegated user and group in the *IAM User Guide*.

**I want to allow people outside of my AWS account to access my Amazon VPC resources**

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon VPC supports these features, see How Amazon VPC works with IAM (p. 232).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*. 
• To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.

• To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

AWS managed policies for Amazon Virtual Private Cloud

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

AWS managed policy: AmazonVPCFullAccess

You can attach the AmazonVPCFullAccess policy to your IAM identities. This policy grants permissions that allow full access to Amazon VPC.

To view the permissions for this policy, see AmazonVPCFullAccess in the AWS Management Console.

AWS managed policy: AmazonVPCReadOnlyAccess

You can attach the AmazonVPCReadOnlyAccess policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon VPC.

To view the permissions for this policy, see AmazonVPCReadOnlyAccess in the AWS Management Console.

AWS managed policy: AmazonVPCCrossAccountNetworkInterfaceOperations

You can attach the AmazonVPCCrossAccountNetworkInterfaceOperations policy to your IAM identities. This policy grants permissions that allow the identity to create network interfaces and attach them to cross-account resources.

To view the permissions for this policy, see AmazonVPCCrossAccountNetworkInterfaceOperations in the AWS Management Console.

Amazon VPC updates to AWS managed policies

View details about updates to AWS managed policies for Amazon VPC since this service began tracking these changes in March 2021.
Control traffic to resources using security groups

A security group controls the traffic that is allowed to reach and leave the resources that it is associated with. For example, after you associate a security group with an EC2 instance, it controls the inbound and outbound traffic for the instance.

When you create a VPC, it comes with a default security group. You can create additional security groups for each VPC. You can associate a security group only with resources in the VPC for which it is created.

For each security group, you add rules that control the traffic based on protocols and port numbers. There are separate sets of rules for inbound traffic and outbound traffic.

Contents

- Security group basics (p. 245)
- Default security groups for your VPCs (p. 246)
- Security group rules (p. 247)
- Work with security groups (p. 249)
- Work with security group rules (p. 251)
- Centrally manage VPC security groups using AWS Firewall Manager (p. 254)

Security group basics

Characteristics of security groups

- When you create a security group, you must provide it with a name and a description. The following rules apply:
  - A security group name must be unique within the VPC.
• Names and descriptions can be up to 255 characters in length.
• Names and descriptions are limited to the following characters: a-z, A-Z, 0-9, spaces, and _.-/ (!#,@[]+=&;{}!$*).
• When the name contains trailing spaces, we trim the space at the end of the name. For example, if you enter "Test Security Group " for the name, we store it as "Test Security Group".
• A security group name cannot start with sg-.
• Security groups are stateful. For example, if you send a request from an instance, the response traffic for that request is allowed to reach the instance regardless of the inbound security group rules. Responses to allowed inbound traffic are allowed to leave the instance, regardless of the outbound rules.
• There are quotas on the number of security groups that you can create per VPC, the number of rules that you can add to each security group, and the number of security groups that you can associate with a network interface. For more information, see Amazon VPC quotas (p. 353).

Characteristics of security group rules

• You can specify allow rules, but not deny rules.
• When you first create a security group, it has no inbound rules. Therefore, no inbound traffic is allowed until you add inbound rules to the security group.
• When you first create a security group, it has an outbound rule that allows all outbound traffic from the resource. You can remove the rule and add outbound rules that allow specific outbound traffic only. If your security group has no outbound rules, no outbound traffic is allowed.
• When you associate multiple security groups with a resource, the rules from each security group are aggregated to form a single set of rules that are used to determine whether to allow access.
• When you add, update, or remove rules, your changes are automatically applied to all resources associated with the security group. The effect of some rule changes can depend on how the traffic is tracked. For more information, see Connection tracking in the Amazon EC2 User Guide for Linux Instances.
• When you create a security group rule, AWS assigns a unique ID to the rule. You can use the ID of a rule when you use the API or CLI to modify or delete the rule.

Best practices

• Authorize only specific IAM principals to create and modify security groups.
• Create the minimum number of security groups that you need, to decrease the risk of error. Use each security group to manage access to resources that have similar functions and security requirements.
• When you add inbound rules for ports 22 (SSH) or 3389 (RDP) so that you can access your EC2 instances, authorize only specific IP address ranges. If you specify 0.0.0.0/0 (IPv4) and ::/ (IPv6), this enables anyone to access your instances from any IP address using the specified protocol.
• Do not open large port ranges. Ensure that access through each port is restricted to the sources or destinations that require it.
• Consider creating network ACLs with rules similar to your security groups, to add an additional layer of security to your VPC. For more information about the differences between security groups and network ACLs, see Compare security groups and network ACLs (p. 225).

Default security groups for your VPCs

Your default VPCs and any VPCs that you create come with a default security group. With some resources, if you don’t associate a security group when you create the resource, we associate the default security group. For example, if you do not specify a security group when you launch an EC2 instance, we associate the default security group.
You can change the rules for a default security group. You can't delete a default security group. If you try to delete the default security group, you get the following error: Client.CannotDelete.

The following table describes the default rules for a default security group.

<table>
<thead>
<tr>
<th>Inbound</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Protocol</td>
<td>Port range</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>The security group ID (its own resource ID)</td>
<td>All</td>
<td>All</td>
<td>Allows inbound traffic from resources that are assigned to the same security group.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Outbound</th>
<th></th>
<th></th>
<th></th>

<td></td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>All</td>
<td>All</td>
<td>Allows all outbound IPv4 traffic.</td>
<td></td>
</tr>
<tr>
<td>::/0</td>
<td>All</td>
<td>All</td>
<td>Allows all outbound IPv6 traffic. This rule is added only if your VPC has an associated IPv6 CIDR block.</td>
<td></td>
</tr>
</tbody>
</table>

### Security group rules

The rules of a security group control the inbound traffic that's allowed to reach the resources that are associated with the security group. The rules also control the outbound traffic that's allowed to leave them.

You can add or remove rules for a security group (also referred to as authorizing or revoking inbound or outbound access). A rule applies either to inbound traffic (ingress) or outbound traffic (egress). You can grant access to a specific CIDR range, or to another security group in your VPC or in a peer VPC (requires a VPC peering connection).

**Warning**

When you add rules for ports 22 (SSH) or 3389 (RDP) so that you can access your EC2 instances, we recommend that you authorize only specific IP address ranges. If you specify 0.0.0.0/0 (IPv4) and ::/ (IPv6), this enables anyone to access your instances from any IP address using the specified protocol.

For each rule, you specify the following:

- **Protocol**: The protocol to allow. The most common protocols are 6 (TCP), 17 (UDP), and 1 (ICMP).
- **Port range**: For TCP, UDP, or a custom protocol, the range of ports to allow. You can specify a single port number (for example, 22), or range of port numbers (for example, 7000–8000).
- **ICMP type and code**: For ICMP, the ICMP type and code. For example, use type 8 for ICMP Echo Request or type 128 for ICMPv6 Echo Request.
- **Source or destination**: The source (inbound rules) or destination (outbound rules) for the traffic to allow. Specify one of the following:
  - A single IPv4 address. You must use the /32 prefix length. For example, 203.0.113.1/32.
  - A single IPv6 address. You must use the /128 prefix length. For example, 2001:db8:1234:1a00::123/128.
• A range of IPv4 addresses, in CIDR block notation. For example, 203.0.113.0/24.
• A range of IPv6 addresses, in CIDR block notation. For example, 2001:db8:1234:1a00::/64.
• The ID of a prefix list. For example, pl-1234abc1234abc123. For more information, see Group CIDR blocks using managed prefix lists (p. 65).
• The ID of a security group (referred to here as the specified security group). For example, the current security group, a security group from the same VPC, or a security group for a peered VPC. This allows traffic based on the private IP addresses of the resources associated with the specified security group. This does not add rules from the specified security group to the current security group. †
• *(Optional) Description:* You can add a description for the rule, which can help you identify it later. A description can be up to 255 characters in length. Allowed characters are a-z, A-Z, 0-9, spaces, and _:-/()#,@[]+=;{}!$*.

† If you configure routes to forward the traffic between two instances in different subnets through a middlebox appliance, you must ensure that the security groups for both instances allow traffic to flow between the instances. The security group for each instance must reference the private IP address of the other instance, or the CIDR range of the subnet that contains the other instance, as the source. If you reference the security group of the other instance as the source, this does not allow traffic to flow between the instances.

### Example rules

The rules that you add to a security group often depend on the purpose of the security group. The following table describes example rules for a security group that's associated with web servers. Your web servers can receive HTTP and HTTPS traffic from all IPv4 and IPv6 addresses and send SQL or MySQL traffic to your database servers.

<table>
<thead>
<tr>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>Allows inbound HTTP access from all IPv4 addresses</td>
</tr>
<tr>
<td>::/0</td>
<td>TCP</td>
<td>80</td>
<td>Allows inbound HTTP access from all IPv6 addresses</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>Allows inbound HTTPS access from all IPv4 addresses</td>
</tr>
<tr>
<td>::/0</td>
<td>TCP</td>
<td>443</td>
<td>Allows inbound HTTPS access from all IPv6 addresses</td>
</tr>
<tr>
<td>Your network's public IPv4 address range</td>
<td>TCP</td>
<td>22</td>
<td>Allows inbound SSH access from IPv4 IP addresses in your network</td>
</tr>
<tr>
<td>Your network's public IPv4 address range</td>
<td>TCP</td>
<td>3389</td>
<td>Allows inbound RDP access from IPv4 IP addresses in your network</td>
</tr>
</tbody>
</table>
Work with security groups

The following tasks show you how to work with security groups using the Amazon VPC console.

**Required permissions**

- Manage security groups (p. 239)

**Tasks**

- Create a security group (p. 249)
- View your security groups (p. 250)
- Tag your security groups (p. 250)
- Delete a security group (p. 251)

**Create a security group**

By default, new security groups start with only an outbound rule that allows all traffic to leave the resource. You must add rules to enable any inbound traffic or to restrict the outbound traffic.

A security group can be used only in the VPC for which it is created.
For information about the permissions required to create security groups and manage security group rules, see Manage security groups (p. 239) and Manage security group rules (p. 240).

To create a security group using the console
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. Choose Create security group.
4. Enter a name and description for the security group. You cannot change the name and description of a security group after it is created.
5. From VPC, choose the VPC.
6. You can add security group rules now, or you can add them later. For more information, see Add rules to a security group (p. 252).
7. You can add tags now, or you can add them later. To add a tag, choose Add new tag and enter the tag key and value.
8. Choose Create security group.

To create a security group using the command line
- create-security-group (AWS CLI)

View your security groups
You can view information about your security groups as follows.

To view your security groups using the console
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. Your security groups are listed. To view the details for a specific security group, including its inbound and outbound rules, select the security group.

To view your security groups using the command line
- describe-security-groups and describe-security-group-rules (AWS CLI)

To view all of your security groups across Regions
Open the Amazon EC2 Global View console at https://console.aws.amazon.com/ec2globalview/home.

For more information about using Amazon EC2 Global View, see List and filter resources using the Amazon EC2 Global View in the Amazon EC2 User Guide for Linux Instances.

Tag your security groups
Add tags to your resources to help organize and identify them, such as by purpose, owner, or environment. You can add tags to your security groups. Tag keys must be unique for each security group. If you add a tag with a key that is already associated with the rule, it updates the value of that tag.
To tag a security group using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. Select the check box for the security group.
4. Choose Actions, Manage tags.
5. The Manage tags page displays any tags that are assigned to the security group. To add a tag, choose Add tag and enter the tag key and value. To delete a tag, choose Remove next to the tag that you want to delete.
6. Choose Save changes.

To tag a security group using the command line

- create-tags (AWS CLI)
- New-EC2Tag (AWS Tools for Windows PowerShell)

Delete a security group

You can delete a security group only if it is not associated with any resources. You can't delete a default security group.

If you're using the console, you can delete more than one security group at a time. If you're using the command line or the API, you can delete only one security group at a time.

To delete a security group using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. Select one or more security groups and choose Actions, Delete security groups.
4. When prompted for confirmation, enter delete and then choose Delete.

To delete a security group using the command line

- delete-security-group (AWS CLI)
- Remove-EC2SecurityGroup (AWS Tools for Windows PowerShell)

Work with security group rules

The following tasks show you how to work with security group rules using the Amazon VPC console.

Required permissions

- Manage security group rules (p. 240)

Tasks

- Add rules to a security group (p. 252)
- Update security group rules (p. 253)
- Tag security group rules (p. 253)
• Delete security group rules (p. 254)

Add rules to a security group

When you add a rule to a security group, the new rule is automatically applied to any resources that are associated with the security group.

If you have a VPC peering connection, you can reference security groups from the peer VPC as the source or destination in your security group rules. For more information, see Updating your security groups to reference peer VPC security groups in the Amazon VPC Peering Guide.

For information about the permissions required to manage security group rules, see Manage security group rules (p. 240).

To add a rule using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. Select the security group.
4. Choose Actions, Edit inbound rules or Actions, Edit outbound rules.
5. For each rule, choose Add rule and do the following.
   a. For Type, choose the type of protocol to allow.
      • For TCP or UDP, you must enter the port range to allow.
      • For custom ICMP, you must choose the ICMP type name from Protocol, and, if applicable, the code name from Port range.
      • For any other type, the protocol and port range are configured automatically.
   b. For Source type (inbound rules) or Destination type (outbound rules), do one of the following to allow traffic:
      • Choose Custom and then enter an IP address in CIDR notation, a CIDR block, another security group, or a prefix list.
      • Choose Anywhere-IPv4 to allow traffic from any IPv4 address (inbound rules) or to allow traffic to reach all IPv4 addresses (outbound rules). This automatically adds a rule for the 0.0.0.0/0 IPv4 CIDR block.

         **Warning**
         If you choose Anywhere-IPv4, you enable all IPv4 addresses to access your instance using the specified protocol. If you are adding rules for ports 22 (SSH) or 3389 (RDP), you should authorize only a specific IP address or range of addresses to access your instance.
      • Choose Anywhere-IPv6 to allow traffic from any IPv6 address (inbound rules) or to allow traffic to reach all IPv6 addresses (outbound rules). This automatically adds a rule for the ::/0 IPv6 CIDR block.

         **Warning**
         If you choose Anywhere-IPv6, you enable all IPv6 addresses to access your instance using the specified protocol. If you are adding rules for ports 22 (SSH) or 3389 (RDP), you should authorize only a specific IP address or range of addresses to access your instance.
      • Choose My IP to allow traffic only from (inbound rules) or to (outbound rules) your local computer’s public IPv4 address.
   c. (Optional) For Description, specify a brief description for the rule.
6. Choose Save rules.
To add a rule to a security group using the command line

- `authorize-security-group-ingress` and `authorize-security-group-egress` (AWS CLI)
- `Grant-EC2SecurityGroupIngress` and `Grant-EC2SecurityGroupEgress` (AWS Tools for Windows PowerShell)

Update security group rules

When you update a rule, the updated rule is automatically applied to any resources that are associated with the security group.

For information about the permissions required to manage security group rules, see Manage security group rules (p. 240).

To update a rule using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. Select the security group.
4. Choose Actions, Edit inbound rules or Actions, Edit outbound rules.
5. Update the rule as required.
6. Choose Save rules.

To update the description for a security group rule using the command line

- `modify-security-group-rules`, `update-security-group-rule-descriptions-ingress`, and `update-security-group-rule-descriptions-egress` (AWS CLI)

Tag security group rules

Add tags to your resources to help organize and identify them, such as by purpose, owner, or environment. You can add tags to security group rules. Tag keys must be unique for each security group rule. If you add a tag with a key that is already associated with the security group rule, it updates the value of that tag.

To tag a rule using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. Select the security group.
4. On the Inbound rules or Outbound rules tab, select the check box for the rule and then choose Manage tags.
5. The Manage tags page displays any tags that are assigned to the rule. To add a tag, choose Add tag and enter the tag key and value. To delete a tag, choose Remove next to the tag that you want to delete.
6. Choose Save changes.

To tag a rule using the command line

- `create-tags` (AWS CLI)
Delete security group rules

When you delete a rule from a security group, the change is automatically applied to any instances that are associated with the security group.

To delete a security group rule using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. Select the security group.
4. Choose Actions, and then choose Edit inbound rules to remove an inbound rule or Edit outbound rules to remove an outbound rule.
5. Choose the Delete button next to the rule that you want to delete.
6. Choose Save rules.

To delete a security group rule using the command line

- `revoke-security-group-ingress` and `revoke-security-group-egress` (AWS CLI)

Centrally manage VPC security groups using AWS Firewall Manager

AWS Firewall Manager simplifies your VPC security groups administration and maintenance tasks across multiple accounts and resources. With Firewall Manager, you can configure and audit your security groups for your organization from a single central administrator account. Firewall Manager automatically applies the rules and protections across your accounts and resources, even as you add new resources. Firewall Manager is particularly useful when you want to protect your entire organization, or if you frequently add new resources that you want to protect from a central administrator account.

You can use Firewall Manager to centrally manage security groups in the following ways:

- **Configure common baseline security groups across your organization:** You can use a common security group policy to provide a centrally controlled association of security groups to accounts and resources across your organization. You specify where and how to apply the policy in your organization.

- **Audit existing security groups in your organization:** You can use an audit security group policy to check the existing rules that are in use in your organization’s security groups. You can scope the policy to audit all accounts, specific accounts, or resources tagged within your organization. Firewall Manager automatically detects new accounts and resources and audits them. You can create audit rules to set guardrails on which security group rules to allow or disallow within your organization, and to check for unused or redundant security groups.

- **Get reports on non-compliant resources and remediate them:** You can get reports and alerts for non-compliant resources for your baseline and audit policies. You can also set auto-remediation workflows to remediate any non-compliant resources that Firewall Manager detects.

To learn more about using Firewall Manager to manage your security groups, see the following topics in the AWS WAF Developer Guide:
Resilience in Amazon Virtual Private Cloud

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon VPC offers several features to help support your data resiliency and backup needs.

• Amazon VPC-to-Amazon VPC Connectivity Options
• Network-to-Amazon VPC Connectivity Options

Compliance validation for Amazon Virtual Private Cloud

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, and HIPAA.

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

• Security and Compliance Quick Start Guides – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
• Architecting for HIPAA Security and Compliance on Amazon Web Services – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

Note
Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.

• AWS Compliance Resources – This collection of workbooks and guides might apply to your industry and location.
• Evaluating Resources with Rules in the AWS Config Developer Guide – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
• **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

• **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

### Configuration and vulnerability analysis in Amazon Virtual Private Cloud

Configuration and IT controls are a shared responsibility between AWS and you, our customer. For more information, see the AWS shared responsibility model. In addition, VPC users should be aware of the following:

- It is the customer responsibility to patch their client applications with the relevant client side dependencies.
- Customers should consider penetration testing for NAT gateways and EC2 instances (see Penetration Testing/).

### Security best practices for your VPC

The following best practices are general guidelines and don’t represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

- When you add subnets to your VPC to host your application, create them in multiple Availability Zones. An Availability Zone is one or more discrete data centers with redundant power, networking, and connectivity in an AWS Region. Using multiple Availability Zones makes your production applications highly available, fault tolerant, and scalable. For more information, see Building a Modular and Scalable Virtual Network Architecture with Amazon VPC.

- Use network ACLs to control access to your subnets and use security groups to control traffic to EC2 instances in your subnets. For more information, see Control traffic to subnets using Network ACLs (p. 108) and Control traffic to resources using security groups (p. 245).

- Manage access to AWS VPC resources and APIs using AWS Identity and Access Management (IAM) identity federation, users, and roles. For more information, see Identity and access management for Amazon VPC (p. 228).

- Use Amazon CloudWatch with VPC flow logs to monitor the IP traffic going to and from network interfaces in your VPC. For more information, see Publish flow logs to CloudWatch Logs (p. 196).

For answers to frequently asked questions related to VPC security, see Security and Filtering in the Amazon VPC FAQs.
Use Amazon VPC with other AWS services

You can use Amazon VPC with other AWS services to build solutions that meet your needs.

Contents

- Connect your VPC to services using AWS PrivateLink (p. 257)
- Filter network traffic using AWS Network Firewall (p. 258)
- Filter DNS traffic using Route 53 Resolver DNS Firewall (p. 258)

Connect your VPC to services using AWS PrivateLink

AWS PrivateLink establishes private connectivity between virtual private clouds (VPC) and supported AWS services, services hosted by other AWS accounts, and supported AWS Marketplace services. You do not need to use an internet gateway, NAT device, AWS Direct Connect connection, or AWS Site-to-Site VPN connection to communicate with the service.

To use AWS PrivateLink, create a VPC endpoint in your VPC, specifying the name of the service and a subnet. This creates an elastic network interface in the subnet that serves as an entry point for traffic destined to the service.

You can create your own VPC endpoint service, powered by AWS PrivateLink and enable other AWS customers to access your service.

The following diagram shows the common use cases for AWS PrivateLink. The VPC on the left has several EC2 instances in a private subnet and three interface VPC endpoints. The top-most VPC endpoint connects to an AWS service. The middle VPC endpoint connects to a service hosted by another AWS account (a VPC endpoint service). The bottom VPC endpoint connects to an AWS Marketplace partner service.
Filter network traffic using AWS Network Firewall

You can filter network traffic at the perimeter of your VPC using AWS Network Firewall. Network Firewall is a stateful, managed, network firewall and intrusion detection and prevention service. For more information, see the AWS Network Firewall Developer Guide.

You implement Network Firewall with the following AWS resources.

<table>
<thead>
<tr>
<th>Network Firewall resource</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firewall</td>
<td>A firewall connects a firewall policy's network traffic filtering behavior to the VPC that you want to protect. The firewall configuration includes specifications for the Availability Zones and subnets where the firewall endpoints are placed. It also defines high-level settings like the firewall logging configuration and tagging on the AWS firewall resource. For more information, see Firewalls in AWS Network Firewall.</td>
</tr>
<tr>
<td>Firewall policy</td>
<td>A firewall policy defines the monitoring and protection behavior for a firewall. The details of the behavior are defined in the rule groups that you add to your policy, and in some policy default settings. To use a firewall policy, you associate it with one or more firewalls. For more information, see Firewall policies in AWS Network Firewall.</td>
</tr>
<tr>
<td>Rule group</td>
<td>A rule group is a reusable set of criteria for inspecting and handling network traffic. You add one or more rule groups to a firewall policy as part of your policy configuration. You can define stateless rule groups to inspect each network packet in isolation. Stateless rule groups are similar in behavior and use to Amazon VPC network access control lists (ACLs). You can also define stateful rule groups to inspect packets in the context of their traffic flow. Stateful rule groups are similar in behavior and use to Amazon VPC security groups. For more information, see Rule groups in AWS Network Firewall.</td>
</tr>
</tbody>
</table>

You can also use AWS Firewall Manager to centrally configure and manage Network Firewall resources across your accounts and applications in AWS Organizations. You can manage firewalls for multiple accounts using a single account in Firewall Manager. For more information, see AWS Firewall Manager in the AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide.

Filter DNS traffic using Route 53 Resolver DNS Firewall

With DNS Firewall, you define domain name filtering rules in rule groups that you associate with your VPCs. You can specify lists of domain names to allow or block, and you can customize the responses for the DNS queries that you block. For more information, see the Route 53 Resolver DNS Firewall Documentation.
You implement DNS Firewall with the following AWS resources.

<table>
<thead>
<tr>
<th>DNS Firewall resource</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS Firewall rule group</td>
<td>A DNS Firewall rule group is a named, reusable collection of DNS Firewall rules for filtering DNS queries. You populate the rule group with the filtering rules, then associate the rule group with one or more VPCs from Amazon VPC. When you associate a rule group with a VPC, you enable DNS Firewall filtering for the VPC. Then, when Resolver receives a DNS query for a VPC that has a rule group associated with it, Resolver passes the query to DNS Firewall for filtering. Each rule within the rule group specifies one domain list and an action to take on DNS queries whose domains match the domain specifications in the list. You can allow, block, or alert on matching queries. You can also define custom responses for blocked queries. For more information, see Rule groups and rules in Route 53 Resolver DNS Firewall.</td>
</tr>
<tr>
<td>Domain list</td>
<td>A domain list is a reusable set of domain specifications that you use in a DNS Firewall rule, inside a rule group. For more information, see Domain lists in Route 53 Resolver DNS Firewall.</td>
</tr>
</tbody>
</table>

You can also use AWS Firewall Manager to centrally configure and manage DNS Firewall resources across your accounts and organizations in AWS Organizations. You can manage firewalls for multiple accounts using a single account in Firewall Manager. For more information, see AWS Firewall Manager in the AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide.
Scenarios

This section describes common VPC scenarios, their routing table configurations, and security recommendations.

Contents
- VPC with a single public subnet (p. 260)
- VPC with public and private subnets (NAT) (p. 269)
- VPC with public and private subnets and AWS Site-to-Site VPN access (p. 288)
- VPC with a private subnet only and AWS Site-to-Site VPN access (p. 307)

VPC with a single public subnet

The configuration for this scenario includes a virtual private cloud (VPC) with a single public subnet, and an internet gateway to enable communication over the internet. We recommend this configuration if you need to run a single-tier, public-facing web application, such as a blog or a simple website.

This scenario can also be optionally configured for IPv6. Instances launched into the public subnet can receive IPv6 addresses, and communicate using IPv6. For more information about IPv4 and IPv6 addressing, see IP addressing (p. 4).

For information about managing your EC2 instance software, see Managing software on your Linux instance in the Amazon EC2 User Guide for Linux Instances.

Contents
- Overview (p. 260)
- Routing (p. 262)
- Security (p. 262)

Overview

The following diagram shows the key components of the configuration for this scenario.
The configuration for this scenario includes the following:

- A virtual private cloud (VPC) with a size /16 IPv4 CIDR block (example: 10.0.0.0/16). This provides 65,536 private IPv4 addresses.
- A subnet with a size /24 IPv4 CIDR block (example: 10.0.0.0/24). This provides 256 private IPv4 addresses.
- An internet gateway. This connects the VPC to the internet and to other AWS services.
- An instance with a private IPv4 address in the subnet range (example: 10.0.0.6), which enables the instance to communicate with other instances in the VPC, and an Elastic IPv4 address (example: 198.51.100.2), which is a public IPv4 address that enables the instance to connect to the internet and to be reached from the internet.
- A custom route table associated with the subnet. The route table entries enable instances in the subnet to use IPv4 to communicate with other instances in the VPC, and to communicate directly over the internet. A subnet that's associated with a route table that has a route to an internet gateway is known as a public subnet.

For more information, see Subnets (p. 56). For more information about internet gateways, see Connect to the internet using an internet gateway (p. 128).

IPv6 configuration

You can optionally enable IPv6 for this scenario. In addition to the components listed above, the configuration includes the following:

- A size /56 IPv6 CIDR block associated with the VPC (example: 2001:db8:1234:1a00::/56). Amazon automatically assigns the CIDR; you cannot choose the range yourself.
- A size /64 IPv6 CIDR block associated with the public subnet (example: 2001:db8:1234:1a00::/64). You can choose the range for your subnet from the range allocated to the VPC. You cannot choose the size of the subnet IPv6 CIDR block.
- An IPv6 address assigned to the instance from the subnet range (example: 2001:db8:1234:1a00::123).
• Route table entries in the custom route table that enable instances in the VPC to use IPv6 to communicate with each other, and directly over the internet.

Routing

Your VPC has an implied router (shown in the configuration diagram above). In this scenario, Amazon VPC creates a custom route table that routes all traffic destined for an address outside the VPC to the internet gateway, and associates this route table with the subnet.

The following table shows the route table for the example in the configuration diagram above. The first entry is the default entry for local IPv4 routing in the VPC; this entry enables the instances in this VPC to communicate with each other. The second entry routes all other IPv4 subnet traffic to the internet gateway (for example, igw-1a2b3c4d).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-id</td>
</tr>
</tbody>
</table>

Routing for IPv6

If you associate an IPv6 CIDR block with your VPC and subnet, your route table must include separate routes for IPv6 traffic. The following table shows the custom route table for this scenario if you choose to enable IPv6 communication in your VPC. The second entry is the default route that's automatically added for local routing in the VPC over IPv6. The fourth entry routes all other IPv6 subnet traffic to the internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-id</td>
</tr>
<tr>
<td>::/0</td>
<td>igw-id</td>
</tr>
</tbody>
</table>

Security

AWS provides two features that you can use to increase security in your VPC: security groups and network ACLs. Security groups control inbound and outbound traffic for your instances, and network ACLs control inbound and outbound traffic for your subnets. In most cases, security groups can meet your needs; however, you can also use network ACLs if you want an additional layer of security for your VPC. For more information, see Internetwork traffic privacy in Amazon VPC (p. 224).

For this scenario, you use a security group but not a network ACL. If you'd like to use a network ACL, see Recommended network ACL rules for a VPC with a single public subnet (p. 265).

Your VPC comes with a default security group (p. 246). An instance that's launched into the VPC is automatically associated with the default security group if you don't specify a different security group during launch. You can add specific rules to the default security group, but the rules may not be suitable
for other instances that you launch into the VPC. Instead, we recommend that you create a custom security group for your web server.

For this scenario, create a security group named `WebServerSG`. When you create a security group, it has a single outbound rule that allows all traffic to leave the instances. You must modify the rules to enable inbound traffic and restrict the outbound traffic as needed. You specify this security group when you launch instances into the VPC.

The following are the inbound and outbound rules for IPv4 traffic for the `WebServerSG` security group.

<table>
<thead>
<tr>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>Allow inbound HTTP access to the web servers from any IPv4 address.</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>Allow inbound HTTPS access to the web servers from any IPv4 address.</td>
</tr>
<tr>
<td>Public IPv4 address range of your network</td>
<td>TCP</td>
<td>22</td>
<td>(Linux instances) Allow inbound SSH access from your network over IPv4. You can get the public IPv4 address of your local computer using a service such as <a href="http://checkip.amazonaws.com">http://checkip.amazonaws.com</a> or <a href="https://checkip.amazonaws.com">https://checkip.amazonaws.com</a>. If you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.</td>
</tr>
<tr>
<td>Public IPv4 address range of your network</td>
<td>TCP</td>
<td>3389</td>
<td>(Windows instances) Allow inbound RDP access from your network over IPv4.</td>
</tr>
<tr>
<td>The security group ID (sg-xxxxxxxx)</td>
<td>All</td>
<td>All</td>
<td>(Optional) Allow inbound traffic from other instances associated with this security group. This rule is automatically added to the default security group for the VPC; for any custom security group you create, you</td>
</tr>
</tbody>
</table>
Outbound (Optional)

<table>
<thead>
<tr>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>All</td>
<td>All</td>
<td>Default rule to allow all outbound access to any IPv4 address. If you remove this rule, your web server can't initiate outbound traffic, for example, to get software updates. If you remove this rule, your web server can still send response traffic to requests, because security groups are stateful.</td>
</tr>
</tbody>
</table>

Security group rules for IPv6

If you associate an IPv6 CIDR block with your VPC and subnet, you must add separate rules to your security group to control inbound and outbound IPv6 traffic for your web server instance. In this scenario, the web server will be able to receive all internet traffic over IPv6, and SSH or RDP traffic from your local network over IPv6.

The following are the IPv6-specific rules for the WebServerSG security group (which are in addition to the rules listed above).

<table>
<thead>
<tr>
<th>Inbound</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
</tr>
<tr>
<td>::/0</td>
</tr>
<tr>
<td>::/0</td>
</tr>
<tr>
<td>IPv6 address range of your network</td>
</tr>
<tr>
<td>IPv6 address range of your network</td>
</tr>
</tbody>
</table>
### Default rule to allow all outbound access to any IPv4 address.

If you remove this rule, your web server can’t initiate outbound traffic, for example, to get software updates. If you remove this rule, your web server can still send response traffic to requests, because security groups are stateful.

### Recommended network ACL rules for a VPC with a single public subnet

The following table shows the rules that we recommend. They block all traffic except that which is explicitly required.

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Rule #</th>
<th>Source IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>ALLOW</td>
<td>Allows inbound HTTP traffic from any IPv4 address.</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>ALLOW</td>
<td>Allows inbound HTTPS traffic from any IPv4 address.</td>
<td></td>
</tr>
<tr>
<td>120</td>
<td>Public IPv4 address range of your home network</td>
<td>TCP</td>
<td>22</td>
<td>ALLOW</td>
<td>Allows inbound SSH traffic from your home network (over the internet gateway).</td>
<td></td>
</tr>
<tr>
<td>130</td>
<td>Public IPv4 address range of your home network</td>
<td>TCP</td>
<td>3389</td>
<td>ALLOW</td>
<td>Allows inbound RDP traffic from your home network (over the internet gateway).</td>
<td></td>
</tr>
<tr>
<td>140</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>32768-65535</td>
<td>ALLOW</td>
<td>Allows inbound return traffic from hosts on</td>
<td></td>
</tr>
</tbody>
</table>
This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).

Denies all inbound IPv4 traffic not already handled by a preceding rule (not modifiable).

### Outbound

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Dest IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>ALLOW</td>
<td>Allows outbound HTTP traffic from the subnet to the internet.</td>
</tr>
<tr>
<td>110</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>ALLOW</td>
<td>Allows outbound HTTPS traffic from the subnet to the internet.</td>
</tr>
</tbody>
</table>
### Recommended network ACL rules for IPv6

If you implemented IPv6 support and created a VPC and subnet with associated IPv6 CIDR blocks, you must add separate rules to your network ACL to control inbound and outbound IPv6 traffic.

The following are the IPv6-specific rules for your network ACL (which are in addition to the preceding rules).

<table>
<thead>
<tr>
<th>Inbound</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Rule #</strong></td>
</tr>
<tr>
<td>150</td>
</tr>
<tr>
<td>160</td>
</tr>
</tbody>
</table>
### IPv6 address range of your home network

170 IPv6 address range of your home network TCP 22 ALLOW Allows inbound SSH traffic from your home network (over the internet gateway).

180 IPv6 address range of your home network TCP 3389 ALLOW Allows inbound RDP traffic from your home network (over the internet gateway).

190 ::/0 TCP 32768-65535 ALLOW Allows inbound return traffic from hosts on the internet that are responding to requests originating in the subnet. This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).

* ::/0 all all DENY Denies all inbound IPv6 traffic not already handled by a preceding rule (not modifiable).

### Outbound

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Dest IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>130</td>
<td>::/0</td>
<td>TCP</td>
<td>80</td>
<td>ALLOW</td>
<td>Allows outbound HTTP traffic from the subnet to the internet.</td>
</tr>
</tbody>
</table>
VPC with public and private subnets (NAT)

The configuration for this scenario includes a virtual private cloud (VPC) with a public subnet and a private subnet. We recommend this scenario if you want to run a public-facing web application, while maintaining back-end servers that aren't publicly accessible. A common example is a multi-tier website, with the web servers in a public subnet and the database servers in a private subnet. You can set up security and routing so that the web servers can communicate with the database servers.

The instances in the public subnet can send outbound traffic directly to the internet, whereas the instances in the private subnet can't. Instead, the instances in the private subnet can access the internet by using a network address translation (NAT) gateway that resides in the public subnet. The database servers can connect to the internet for software updates using the NAT gateway, but the internet cannot establish connections to the database servers.

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>

<tr>
<td>*</td>
<td>::/0</td>
<td>all</td>
<td>all</td>
<td>DENY</td>
</tr>
</tbody>
</table>

This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).
This scenario can also be optionally configured for IPv6. Instances launched into the subnets can receive IPv6 addresses, and communicate using IPv6. Instances in the private subnet can use an egress-only internet gateway to connect to the internet over IPv6, but the internet cannot establish connections to the private instances over IPv6. For more information about IPv4 and IPv6 addressing, see IP addressing (p. 4).

For information about managing your EC2 instance software, see Managing software on your Linux instance in the Amazon EC2 User Guide for Linux Instances.

Contents
- Overview (p. 270)
- Routing (p. 272)
- Security (p. 273)
- Implement this scenario (p. 277)
- Recommended network ACL rules (p. 278)

Overview

The following diagram shows the key components of the configuration for this scenario.

The configuration for this scenario includes the following:
- A VPC with a size /16 IPv4 CIDR block (example: 10.0.0.0/16). This provides 65,536 private IPv4 addresses.
- A public subnet with a size /24 IPv4 CIDR block (example: 10.0.0.0/24). This provides 256 private IPv4 addresses. A public subnet is a subnet that's associated with a route table that has a route to an internet gateway.
• A private subnet with a size /24 IPv4 CIDR block (example: 10.0.1.0/24). This provides 256 private IPv4 addresses.

• An internet gateway. This connects the VPC to the internet and to other AWS services.

• Instances with private IPv4 addresses in the subnet range (examples: 10.0.0.5, 10.0.1.5). This enables them to communicate with each other and other instances in the VPC.

• Instances in the public subnet with Elastic IPv4 addresses (example: 198.51.100.1), which are public IPv4 addresses that enable them to be reached from the internet. The instances can have public IP addresses assigned at launch instead of Elastic IP addresses. Instances in the private subnet are backend servers that don’t need to accept incoming traffic from the internet and therefore do not have public IP addresses; however, they can send requests to the internet using the NAT gateway (see the next bullet).

• A NAT gateway with its own Elastic IPv4 address. Instances in the private subnet can send requests to the internet through the NAT gateway over IPv4 (for example, for software updates).

• A custom route table associated with the public subnet. This route table contains an entry that enables instances in the subnet to communicate with other instances in the VPC over IPv4, and an entry that enables instances in the subnet to communicate directly with the internet over IPv4.

• The main route table associated with the private subnet. The route table contains an entry that enables instances in the subnet to communicate with other instances in the VPC over IPv4, and an entry that enables instances in the subnet to communicate with the internet through the NAT gateway over IPv4.

For more information, see Subnets (p. 56). For more information about internet gateways, see Connect to the internet using an internet gateway (p. 128). For more information about NAT gateways, see NAT gateways (p. 143).

**IPv6 configuration**

You can optionally enable IPv6 for this scenario. In addition to the components listed above, the configuration includes the following:

• A size /56 IPv6 CIDR block associated with the VPC (example: 2001:db8:1234:1a00::/56). Amazon automatically assigns the CIDR; you cannot choose the range yourself.

• A size /64 IPv6 CIDR block associated with the public subnet (example: 2001:db8:1234:1a00::/64). You can choose the range for your subnet from the range allocated to the VPC. You cannot choose the size of the VPC IPv6 CIDR block.

• A size /64 IPv6 CIDR block associated with the private subnet (example: 2001:db8:1234:1a01::/64). You can choose the range for your subnet from the range allocated to the VPC. You cannot choose the size of the subnet IPv6 CIDR block.

• IPv6 addresses assigned to the instances from the subnet range (example: 2001:db8:1234:1a00::1a).

• An egress-only internet gateway. You use the gateway to handle requests to the internet from instances in the private subnet over IPv6 (for example, for software updates). An egress-only internet gateway is necessary if you want instances in the private subnet to be able to initiate communication with the internet over IPv6. For more information, see Enable outbound IPv6 traffic using an egress-only internet gateway (p. 139).

• Route table entries in the custom route table that enable instances in the public subnet to use IPv6 to communicate with each other, and directly over the internet.

• Route table entries in the main route table that enable instances in the private subnet to use IPv6 to communicate with each other, and to communicate with the internet through an egress-only internet gateway.

The web servers in the public subnet have the following addresses.
The database servers in the private subnet have the following addresses.

<table>
<thead>
<tr>
<th>Server</th>
<th>IPv4 address</th>
<th>IPv6 address</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10.0.0.5</td>
<td>198.51.100.1</td>
</tr>
<tr>
<td>2</td>
<td>10.0.0.6</td>
<td>198.51.100.2</td>
</tr>
<tr>
<td>3</td>
<td>10.0.0.7</td>
<td>198.51.100.3</td>
</tr>
</tbody>
</table>

Routing

In this scenario, Amazon VPC updates the main route table used with the private subnet, and creates a custom route table and associates it with the public subnet.

In this scenario, all traffic from each subnet that is bound for AWS (for example, to the Amazon EC2 or Amazon S3 endpoints) goes over the internet gateway. The database servers in the private subnet can't receive traffic from the internet directly because they don't have Elastic IP addresses. However, the database servers can send and receive internet traffic through the NAT device in the public subnet.

Any additional subnets that you create use the main route table by default, which means that they are private subnets by default. If you want to make a subnet public, you can always change the route table that it's associated with.

The following tables describe the route tables for this scenario.

**Main route table**

The main route table is associated with the private subnet. The first entry is the default entry for local routing in the VPC; this entry enables the instances in the VPC to communicate with each other. The second entry sends all other subnet traffic to the NAT gateway (for example, nat-12345678901234567).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>nat-gateway-id</td>
</tr>
</tbody>
</table>

**Custom route table**

The custom route table is associated with the public subnet. The first entry is the default entry for local routing in the VPC; this entry enables the instances in this VPC to communicate with each other. The second entry routes all other subnet traffic to the internet over the internet gateway (for example, igw-1a2b3d4d).
Routing for IPv6

If you associate an IPv6 CIDR block with your VPC and subnets, your route tables must include separate routes for IPv6 traffic. The following tables show the route tables for this scenario if you choose to enable IPv6 communication in your VPC.

**Main route table**

The second entry is the default route that's automatically added for local routing in the VPC over IPv6. The fourth entry routes all other IPv6 subnet traffic to the egress-only internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>nat-gateway-id</td>
</tr>
<tr>
<td>::/0</td>
<td>egress-only-igw-id</td>
</tr>
</tbody>
</table>

**Custom route table**

The second entry is the default route that's automatically added for local routing in the VPC over IPv6. The fourth entry routes all other IPv6 subnet traffic to the internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-id</td>
</tr>
<tr>
<td>::/0</td>
<td>igw-id</td>
</tr>
</tbody>
</table>

**Security**

AWS provides two features that you can use to increase security in your VPC: security groups and network ACLs. Security groups control inbound and outbound traffic for your instances, and network ACLs control inbound and outbound traffic for your subnets. In most cases, security groups can meet your needs; however, you can also use network ACLs if you want an additional layer of security for your VPC. For more information, see *Internetwork traffic privacy in Amazon VPC* (p. 224).

For this scenario, you'll use security groups but not network ACLs. If you'd like to use a network ACL, see *Recommended network ACL rules* (p. 278).
Your VPC comes with a default security group (p. 246). An instance that's launched into the VPC is automatically associated with the default security group if you don't specify a different security group during launch. For this scenario, we recommend that you create the following security groups instead of using the default security group:

- **WebServerSG**: Specify this security group when you launch the web servers in the public subnet.
- **DBServerSG**: Specify this security group when you launch the database servers in the private subnet.

The instances assigned to a security group can be in different subnets. However, in this scenario, each security group corresponds to the type of role an instance plays, and each role requires the instance to be in a particular subnet. Therefore, in this scenario, all instances assigned to a security group are in the same subnet.

The following table describes the recommended rules for the WebServerSG security group, which allow the web servers to receive internet traffic, as well as SSH and RDP traffic from your network. The web servers can also initiate read and write requests to the database servers in the private subnet, and send traffic to the internet; for example, to get software updates. Because the web server doesn't initiate any other outbound communication, the default outbound rule is removed.

**Note**
These recommendations include both SSH and RDP access, and both Microsoft SQL Server and MySQL access. For your situation, you might only need rules for Linux (SSH and MySQL) or Windows (RDP and Microsoft SQL Server).

**WebServerSG: recommended rules**

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>Allow inbound HTTP access to the web servers from any IPv4 address.</td>
</tr>
<tr>
<td></td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>Allow inbound HTTPS access to the web servers from any IPv4 address.</td>
</tr>
<tr>
<td></td>
<td>Your home network's public IPv4 address range</td>
<td>TCP</td>
<td>22</td>
<td>Allow inbound SSH access to Linux instances from your home network (over the internet gateway). You can get the public IPv4 address of your local computer using a service such as <a href="http://checkip.amazonaws.com">http://checkip.amazonaws.com</a> or <a href="https://checkip.amazonaws.com">https://checkip.amazonaws.com</a>. If you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP</td>
</tr>
</tbody>
</table>
Your home network's public IPv4 address range | TCP | 3389 | Allow inbound RDP access to Windows instances from your home network (over the internet gateway).

### Outbound

<table>
<thead>
<tr>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>The ID of your DBServerSG security group</td>
<td>TCP</td>
<td>1433</td>
<td>Allow outbound Microsoft SQL Server access to the database servers assigned to the DBServerSG security group.</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>Allow outbound HTTP access to any IPv4 address.</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>Allow outbound HTTPS access to any IPv4 address.</td>
</tr>
</tbody>
</table>

The following table describes the recommended rules for the DBServerSG security group, which allow read or write database requests from the web servers. The database servers can also initiate traffic bound for the internet (the route table sends that traffic to the NAT gateway, which then forwards it to the internet over the internet gateway).

### DBServerSG: recommended rules

<table>
<thead>
<tr>
<th>Inbound</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
</tr>
<tr>
<td>The ID of your WebServerSG security group</td>
</tr>
<tr>
<td>The ID of your WebServerSG security group</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Outbound</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Security

<table>
<thead>
<tr>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>Allow outbound HTTP access to the internet over IPv4 (for example, for software updates).</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>Allow outbound HTTPS access to the internet over IPv4 (for example, for software updates).</td>
</tr>
</tbody>
</table>

(Optional) The default security group for a VPC has rules that automatically allow assigned instances to communicate with each other. To allow that type of communication for a custom security group, you must add the following rules:

**Inbound**

<table>
<thead>
<tr>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>The ID of the security group</td>
<td>All</td>
<td>All</td>
<td>Allow inbound traffic from other instances assigned to this security group.</td>
</tr>
</tbody>
</table>

**Outbound**

<table>
<thead>
<tr>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>The ID of the security group</td>
<td>All</td>
<td>All</td>
<td>Allow outbound traffic to other instances assigned to this security group.</td>
</tr>
</tbody>
</table>

(Optional) If you launch a bastion host in your public subnet to use as a proxy for SSH or RDP traffic from your home network to your private subnet, add a rule to the DBServerSG security group that allows inbound SSH or RDP traffic from the bastion instance or its associated security group.

Security group rules for IPv6

If you associate an IPv6 CIDR block with your VPC and subnets, you must add separate rules to your WebServerSG and DBServerSG security groups to control inbound and outbound IPv6 traffic for your instances. In this scenario, the web servers will be able to receive all internet traffic over IPv6, and SSH or RDP traffic from your local network over IPv6. They can also initiate outbound IPv6 traffic to the internet. The database servers can initiate outbound IPv6 traffic to the internet.

The following are the IPv6-specific rules for the WebServerSG security group (which are in addition to the rules listed above):

**Inbound**

<table>
<thead>
<tr>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>::/0</td>
<td>TCP</td>
<td>80</td>
<td>Allow inbound HTTP access to the web</td>
</tr>
</tbody>
</table>
Implement this scenario

You can use Amazon VPC to create the VPC, subnets, NAT gateway, and optionally, an egress-only internet gateway. You must specify an Elastic IP address for your NAT gateway; if you don’t have one, you must first allocate one to your account. If you want to use an existing Elastic IP address, ensure that it’s not currently associated with another instance or network interface. The NAT gateway is automatically created in the public subnet of your VPC.
**Recommended network ACL rules**

For this scenario, you can create a network ACL for the public subnet, and a separate network ACL for the private subnet. The following table shows the rules that we recommend for each network ACL. They block all traffic unless it is explicitly required. They mostly mimic the security group rules for the scenario.

**ACL rules for the public subnet**

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Source IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>ALLOW</td>
<td>Allows inbound HTTP traffic from any IPv4 address.</td>
</tr>
<tr>
<td>110</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>ALLOW</td>
<td>Allows inbound HTTPS traffic from any IPv4 address.</td>
</tr>
<tr>
<td>120</td>
<td>Public IP address range of your home network</td>
<td>TCP</td>
<td>22</td>
<td>ALLOW</td>
<td>Allows inbound SSH traffic from your home network (over the internet gateway).</td>
</tr>

<td>443</td>
<td>ALLOW</td>
<td>Allows outbound HTTPS traffic from the subnet to the internet.</td>
</tr>
<tr>
<td>120</td>
<td>10.0.0.0/24</td>
<td>TCP</td>
<td>32768-65535</td>
<td>ALLOW</td>
<td>Allows outbound responses to the public subnet (for example, responses to web servers in the public subnet that are communicating with DB servers in the private subnet). This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).</td>
</tr>
</tbody>
</table>
Recommended network ACL rules for IPv6

If you implemented IPv6 support and created a VPC and subnets with associated IPv6 CIDR blocks, you must add separate rules to your network ACLs to control inbound and outbound IPv6 traffic.

The following are the IPv6-specific rules for your network ACLs (which are in addition to the preceding rules).

**ACL rules for the public subnet**

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Source IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>150</td>
<td>::/0</td>
<td>TCP</td>
<td>80</td>
<td>ALLOW</td>
<td>Allows inbound HTTP traffic from any IPv6 address.</td>
</tr>
<tr>
<td>160</td>
<td>::/0</td>
<td>TCP</td>
<td>443</td>
<td>ALLOW</td>
<td>Allows inbound HTTPS traffic from any IPv6 address.</td>
</tr>
<tr>
<td>170</td>
<td>IPv6 address range of your home network</td>
<td>TCP</td>
<td>22</td>
<td>ALLOW</td>
<td>Allows inbound SSH traffic over IPv6 from your home network (over the internet gateway).</td>
</tr>
<tr>
<td>180</td>
<td>IPv6 address range of your home network</td>
<td>TCP</td>
<td>3389</td>
<td>ALLOW</td>
<td>Allows inbound RDP traffic over IPv6 from your home network (over the internet gateway).</td>
</tr>
<tr>
<td>190</td>
<td>::/0</td>
<td>TCP</td>
<td>1024-65535</td>
<td>ALLOW</td>
<td>Allows inbound return traffic from hosts on the internet that are responding to requests originating in the subnet.</td>
</tr>
</tbody>
</table>
This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).

| * | ::/0 | all | all | DENY |

### Outbound

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Dest IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>160</td>
<td>::/0</td>
<td>TCP</td>
<td>80</td>
<td>ALLOW</td>
<td>Allows outbound HTTP traffic from the subnet to the internet.</td>
</tr>
<tr>
<td>170</td>
<td>::/0</td>
<td>TCP</td>
<td>443</td>
<td>ALLOW</td>
<td>Allows outbound HTTPS traffic from the subnet to the internet.</td>
</tr>
<tr>
<td>Source</td>
<td>Destination</td>
<td>Protocol</td>
<td>Port Range</td>
<td>Action</td>
<td></td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>----------</td>
<td>------------</td>
<td>--------</td>
<td></td>
</tr>

VPC with public and private subnets and AWS Site-to-Site VPN access

The configuration for this scenario includes a virtual private cloud (VPC) with a public subnet and a private subnet, and a virtual private gateway to enable communication with your own network over an IPsec VPN tunnel. We recommend this scenario if you want to extend your network into the cloud and also directly access the internet from your VPC. This scenario enables you to run a multi-tiered application with a scalable web front end in a public subnet, and to house your data in a private subnet that is connected to your network by an IPsec AWS Site-to-Site VPN connection.

<table>
<thead>
<tr>
<th>140</th>
<th>::/0</th>

<td>32768-65535</td>
<td>ALLOW</td>
<td>Allows outbound responses to the public subnet (for example, responses to web servers in the public subnet that are communicating with DB servers in the private subnet). This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).</td>
</tr>
<tr>
<td></td>
<td>::/0</td>
<td>all</td>
<td>all</td>
<td>DENY</td>
<td>Denies all outbound IPv6 traffic not already handled by a preceding rule (not modifiable).</td>
</tr>
</tbody>
</table>
This scenario can also be optionally configured for IPv6. Instances launched into the subnets can receive IPv6 addresses. We do not support IPv6 communication over a Site-to-Site VPN connection on a virtual private gateway; however, instances in the VPC can communicate with each other via IPv6, and instances in the public subnet can communicate over the internet via IPv6. For more information about IPv4 and IPv6 addressing, see IP addressing (p. 4).

For information about managing your EC2 instance software, see Managing software on your Linux instance in the Amazon EC2 User Guide for Linux Instances.

Contents
• Overview (p. 289)
• Routing (p. 291)
• Security (p. 293)
• Implement this scenario (p. 296)
• Recommended network ACL rules (p. 297)

Overview
The following diagram shows the key components of the configuration for this scenario.

The configuration for this scenario includes the following:

• A virtual private cloud (VPC) with a size /16 IPv4 CIDR (example: 10.0.0.0/16). This provides 65,536 private IPv4 addresses.
• A public subnet with a size /24 IPv4 CIDR (example: 10.0.0.0/24). This provides 256 private IPv4 addresses. A public subnet is a subnet that's associated with a route table that has a route to an internet gateway.
• A VPN-only subnet with a size /24 IPv4 CIDR (example: 10.0.1.0/24). This provides 256 private IPv4 addresses.
• An internet gateway. This connects the VPC to the internet and to other AWS products.

• A Site-to-Site VPN connection between your VPC and your network. The Site-to-Site VPN connection consists of a virtual private gateway located on the Amazon side of the Site-to-Site VPN connection and a customer gateway located on your side of the Site-to-Site VPN connection.

• Instances with private IPv4 addresses in the subnet range (examples: 10.0.0.5 and 10.0.1.5), which enables the instances to communicate with each other and other instances in the VPC.

• Instances in the public subnet with Elastic IP addresses (example: 198.51.100.1), which are public IPv4 addresses that enable them to be reached from the internet. The instances can have public IPv4 addresses assigned at launch instead of Elastic IP addresses. Instances in the VPN-only subnet are back-end servers that don’t need to accept incoming traffic from the internet, but can send and receive traffic from your network.

• A custom route table associated with the public subnet. This route table contains an entry that enables instances in the subnet to communicate with other instances in the VPC, and an entry that enables instances in the subnet to communicate directly with the internet.

• The main route table associated with the VPN-only subnet. The route table contains an entry that enables instances in the subnet to communicate with other instances in the VPC, and an entry that enables instances in the subnet to communicate directly with your network.

For more information, see Subnets (p. 56). For more information about internet gateways, see Connect to the internet using an internet gateway (p. 128). For more information about NAT gateways, see NAT gateways (p. 143). For more information about your AWS Site-to-Site VPN connection, see the AWS Site-to-Site VPN User Guide.

IPv6 configuration

You can optionally enable IPv6 for this scenario. In addition to the components listed above, the configuration includes the following:

• A size /56 IPv6 CIDR block associated with the VPC (example: 2001:db8:1234:1a00::/56). AWS automatically assigns the CIDR; you cannot choose the range yourself.

• A size /64 IPv6 CIDR block associated with the public subnet (example: 2001:db8:1234:1a00::/64). You can choose the range for your subnet from the range allocated to the VPC. You cannot choose the size of the IPv6 CIDR.

• A size /64 IPv6 CIDR block associated with the VPN-only subnet (example: 2001:db8:1234:1a01::/64). You can choose the range for your subnet from the range allocated to the VPC. You cannot choose the size of the IPv6 CIDR.

• IPv6 addresses assigned to the instances from the subnet range (example: 2001:db8:1234:1a00::1a).

• Route table entries in the custom route table that enable instances in the public subnet to use IPv6 to communicate with each other, and directly over the internet.

• A route table entry in the main route table that enable instances in the VPN-only subnet to use IPv6 to communicate with each other.

The web servers in the public subnet have the following addresses.

<table>
<thead>
<tr>
<th>Server</th>
<th>IPv4 address</th>
<th>Elastic IP address</th>
<th>IPv6 address</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10.0.0.5</td>
<td>198.51.100.1</td>
<td>2001:db8:1234:1a00::1a</td>
</tr>
<tr>
<td>2</td>
<td>10.0.0.6</td>
<td>198.51.100.2</td>
<td>2001:db8:1234:1a00::2b</td>
</tr>
<tr>
<td>3</td>
<td>10.0.0.7</td>
<td>198.51.100.3</td>
<td>2001:db8:1234:1a00::3c</td>
</tr>
</tbody>
</table>
The database servers in the private subnet have the following addresses.

<table>
<thead>
<tr>
<th>Server</th>
<th>IPv4 address</th>
<th>IPv6 address</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10.0.1.5</td>
<td>2001:db8:1234:1a01::1a</td>
</tr>
<tr>
<td>2</td>
<td>10.0.1.6</td>
<td>2001:db8:1234:1a01::2b</td>
</tr>
<tr>
<td>3</td>
<td>10.0.1.7</td>
<td>2001:db8:1234:1a01::3c</td>
</tr>
</tbody>
</table>

**Routing**

Your VPC has an implied router (shown in the configuration diagram for this scenario). In this scenario, Amazon VPC updates the main route table used with the VPN-only subnet, and creates a custom route table and associates it with the public subnet.

The instances in the VPN-only subnet can't reach the internet directly; any internet-bound traffic must first traverse the virtual private gateway to your network, where the traffic is then subject to your firewall and corporate security policies. If the instances send any AWS-bound traffic (for example, requests to the Amazon S3 or Amazon EC2 APIs), the requests must go over the virtual private gateway to your network and then egress to the internet before reaching AWS.

**Tip**

Any traffic from your network going to an Elastic IP address for an instance in the public subnet goes over the internet, and not over the virtual private gateway. You could instead set up a route and security group rules that enable the traffic to come from your network over the virtual private gateway to the public subnet.

The Site-to-Site VPN connection is configured either as a statically-routed Site-to-Site VPN connection or as a dynamically-routed Site-to-Site VPN connection (using BGP). If you select static routing, you'll be prompted to manually enter the IP prefix for your network when you create the Site-to-Site VPN connection. If you select dynamic routing, the IP prefix is advertised automatically to the virtual private gateway for your VPC using BGP.

The following tables describe the route tables for this scenario.

### Main route table

The first entry is the default entry for local routing in the VPC; this entry enables the instances in the VPC to communicate with each other over IPv4. The second entry routes all other IPv4 subnet traffic from the private subnet to your network over the virtual private gateway (for example, vgw-1a2b3c4d).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>vgw-id</td>
</tr>
</tbody>
</table>

### Custom route table

The first entry is the default entry for local routing in the VPC; this entry enables the instances in the VPC to communicate with each other. The second entry routes all other IPv4 subnet traffic from the public subnet to the internet over the internet gateway (for example, igw-1a2b3c4d).
Alternate routing

Alternatively, if you want instances in the private subnet to access the internet, you can create a network address translation (NAT) gateway or instance in the public subnet, and set up the routing so that the internet-bound traffic for the subnet goes to the NAT device. This enables the instances in the VPN-only subnet to send requests over the internet gateway (for example, for software updates).

For more information about setting up a NAT device manually, see Connect to the internet or other networks using NAT devices (p. 142).

To enable the private subnet's internet-bound traffic to go to the NAT device, you must update the main route table as follows.

The first entry is the default entry for local routing in the VPC. The second entry routes the subnet traffic bound for your own local (customer) network to the virtual private gateway. In this example, assume your local network's IP address range is 172.16.0.0/12. The third entry sends all other subnet traffic to a NAT gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>172.16.0.0/12</td>
<td>vgw-id</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>nat-gateway-id</td>
</tr>
</tbody>
</table>

Routing for IPv6

If you associate an IPv6 CIDR block with your VPC and subnets, your route tables must include separate routes for IPv6 traffic. The following tables show the route tables for this scenario if you choose to enable IPv6 communication in your VPC.

Main route table

The second entry is the default route that's automatically added for local routing in the VPC over IPv6.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>vgw-id</td>
</tr>
</tbody>
</table>

Custom route table

The second entry is the default route that's automatically added for local routing in the VPC over IPv6. The fourth entry routes all other IPv6 subnet traffic to the internet gateway.
Security

AWS provides two features that you can use to increase security in your VPC: security groups and network ACLs. Security groups control inbound and outbound traffic for your instances, and network ACLs control inbound and outbound traffic for your subnets. In most cases, security groups can meet your needs; however, you can also use network ACLs if you want an additional layer of security for your VPC. For more information, see Internetwork traffic privacy in Amazon VPC (p. 224).

For this scenario, you'll use security groups but not network ACLs. If you'd like to use a network ACL, see Recommended network ACL rules (p. 297).

Your VPC comes with a default security group (p. 246). An instance that's launched into the VPC is automatically associated with the default security group if you don't specify a different security group during launch. For this scenario, we recommend that you create the following security groups instead of using the default security group:

- **WebServerSG**: Specify this security group when you launch web servers in the public subnet.
- **DBServerSG**: Specify this security group when you launch database servers in the VPN-only subnet.

The instances assigned to a security group can be in different subnets. However, in this scenario, each security group corresponds to the type of role an instance plays, and each role requires the instance to be in a particular subnet. Therefore, in this scenario, all instances assigned to a security group are in the same subnet.

The following table describes the recommended rules for the WebServerSG security group, which allow the web servers to receive internet traffic, as well as SSH and RDP traffic from your network. The web servers can also initiate read and write requests to the database servers in the VPN-only subnet, and send traffic to the internet; for example, to get software updates. Because the web server doesn't initiate any other outbound communication, the default outbound rule is removed.

**Note**
The group includes both SSH and RDP access, and both Microsoft SQL Server and MySQL access. For your situation, you might only need rules for Linux (SSH and MySQL) or Windows (RDP and Microsoft SQL Server).

### WebServerSG: recommended rules

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Source</th>
<th>Protocol</th>
<th>Port Range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>Allow inbound HTTP access to the web servers from any IPv4 address.</td>
</tr>
<tr>
<td></td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>Allow inbound HTTPS access to the web</td>
</tr>
</tbody>
</table>
Your network’s public IP address range  |  TCP  |  22  |  Allow inbound SSH access to Linux instances from your network (over the internet gateway).

Your network’s public IP address range  |  TCP  |  3389 |  Allow inbound RDP access to Windows instances from your network (over the internet gateway).

<table>
<thead>
<tr>
<th><strong>Outbound</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>The ID of your DBServerSG security group</td>
</tr>
<tr>
<td>The ID of your DBServerSG security group</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

The following table describes the recommended rules for the DBServerSG security group, which allow Microsoft SQL Server and MySQL read and write requests from the web servers and SSH and RDP traffic from your network. The database servers can also initiate traffic bound for the internet (your route table sends that traffic over the virtual private gateway).

**DBServerSG: recommended rules**

<table>
<thead>
<tr>
<th><strong>Inbound</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Source</strong></td>
</tr>
<tr>
<td>The ID of your WebServerSG security group</td>
</tr>
<tr>
<td>The ID of your WebServerSG security group</td>
</tr>
</tbody>
</table>
Your network's IPv4 address range  TCP  22  Allow inbound SSH traffic to Linux instances from your network (over the virtual private gateway).

Your network's IPv4 address range  TCP  3389  Allow inbound RDP traffic to Windows instances from your network (over the virtual private gateway).

<table>
<thead>
<tr>
<th>Outbound</th>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td></td>
<td>Allow outbound IPv4 HTTP access to the internet (for example, for software updates) over the virtual private gateway.</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td></td>
<td>Allow outbound IPv4 HTTPS access to the internet (for example, for software updates) over the virtual private gateway.</td>
</tr>
</tbody>
</table>

(Optional) The default security group for a VPC has rules that automatically allow assigned instances to communicate with each other. To allow that type of communication for a custom security group, you must add the following rules:

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>The ID of the security group</td>
<td>All</td>
<td>All</td>
<td>Allow inbound traffic from other instances assigned to this security group.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Outbound</th>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>The ID of the security group</td>
<td>All</td>
<td>All</td>
<td>Allow outbound traffic to other instances assigned to this security group.</td>
<td></td>
</tr>
</tbody>
</table>
Security group rules for IPv6

If you associate an IPv6 CIDR block with your VPC and subnets, you must add separate rules to your WebServerSG and DBServerSG security groups to control inbound and outbound IPv6 traffic for your instances. In this scenario, the web servers will be able to receive all internet traffic over IPv6, and SSH or RDP traffic from your local network over IPv6. They can also initiate outbound IPv6 traffic to the internet. The database servers cannot initiate outbound IPv6 traffic to the internet, so they do not require any additional security group rules.

The following are the IPv6-specific rules for the WebServerSG security group (which are in addition to the rules listed above).

<table>
<thead>
<tr>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>::/0</td>
<td>TCP</td>
<td>80</td>
<td>Allow inbound HTTP access to the web servers from any IPv6 address.</td>
</tr>
<tr>
<td>::/0</td>
<td>TCP</td>
<td>443</td>
<td>Allow inbound HTTPS access to the web servers from any IPv6 address.</td>
</tr>
<tr>
<td>IPv6 address range of</td>
<td>TCP</td>
<td>22</td>
<td>(Linux instances) Allow inbound SSH access over IPv6 from your network.</td>
</tr>
<tr>
<td>your network</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>IPv6 address range of</td>
<td>TCP</td>
<td>3389</td>
<td>(Windows instances) Allow inbound RDP access over IPv6 from your network.</td>
</tr>
<tr>
<td>your network</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Outbound

<table>
<thead>
<tr>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>::/0</td>
<td>TCP</td>
<td>HTTP</td>
<td>Allow outbound HTTP access to any IPv6 address.</td>
</tr>
<tr>
<td>::/0</td>
<td>TCP</td>
<td>HTTPS</td>
<td>Allow outbound HTTPS access to any IPv6 address.</td>
</tr>
</tbody>
</table>

Implement this scenario

To implement this scenario, get information about your customer gateway and create the VPC.

These procedures include optional steps for enabling and configuring IPv6 communication for your VPC. You do not have to perform these steps if you do not want to use IPv6 in your VPC.
To prepare your customer gateway

1. Determine the device you'll use as your customer gateway device. For more information, see Your customer gateway device in the AWS Site-to-Site VPN User Guide.

2. Obtain the internet-routable IP address for the customer gateway device's external interface. The address must be static and may be behind a device performing network address translation (NAT).

3. If you want to create a statically-routed Site-to-Site VPN connection, get the list of internal IP ranges (in CIDR notation) that should be advertised across the Site-to-Site VPN connection to the virtual private gateway. For more information, see Route tables and VPN route priority in the AWS Site-to-Site VPN User Guide.

For information about how to use Amazon VPC with IPv6, see the section called “VPC that supports IPv6 addressing” (p. 337).

Recommended network ACL rules

For this scenario, you can create a network ACL for the public subnet and a separate network ACL for the VPN-only subnet. The following table shows the rules that we recommend for each network ACL. They block all traffic unless it is explicitly required.

### ACL rules for the public subnet

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Rule #</th>
<th>Source IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>80</td>
<td>ALLOW</td>
<td>Allows inbound HTTP traffic to the web servers from any IPv4 address.</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>443</td>
<td>ALLOW</td>
<td>Allows inbound HTTPS traffic to the web servers from any IPv4 address.</td>
<td></td>
</tr>
<tr>
<td>120</td>
<td>Public IPv4 address range of your home network</td>
<td>TCP</td>
<td>22</td>
<td>ALLOW</td>
<td>Allows inbound SSH traffic to the web servers from your home network (over the internet gateway).</td>
<td></td>
</tr>
<tr>
<td>130</td>
<td>Public IPv4 address range of your home network</td>
<td>TCP</td>
<td>3389</td>
<td>ALLOW</td>
<td>Allows inbound RDP traffic to the web servers from your home network (over the internet gateway).</td>
<td></td>
</tr>
</tbody>
</table>
Recommended network ACL rules

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Dest IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>140</td>
<td>0.0.0.0/0</td>
<td>TCP</td>
<td>32768-65535</td>
<td>ALLOW</td>
<td>Allows inbound return traffic from hosts on the internet that are responding to requests originating in the subnet. This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).</td>
</tr>
<tr>
<td></td>
<td>*</td>
<td>all</td>
<td>all</td>
<td>DENY</td>
<td>Denies all inbound IPv4 traffic not already handled by a preceding rule (not modifiable).</td>
</tr>
</tbody>
</table>

Outbound

<table>
<thead>
<tr>
<th>Rule #</th>

<td>------------</td>
<td>--------</td>
<td></td>
</tr>
<tr>
<td>100</td>
<td>All outbound traffic from the subnet to your home network (over the virtual private gateway). This rule also covers rule 120. However, you can make this rule more restrictive by using a specific protocol type and port number. If you make this rule more restrictive, you must include rule 120 in your network ACL to ensure that outbound responses are not blocked.</td>
<td>All</td>
<td>All</td>
<td>ALLOW</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>Allows outbound responses to the web servers in the public subnet. This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).</td>
<td>TCP</td>
<td>32768-65535</td>
<td>ALLOW</td>
<td></td>
</tr>
</tbody>
</table>
Recommended network ACL rules

**Private IP address range of your home network**

TCP

32768-65535

ALLOW

Allows outbound responses to clients in the home network (over the virtual private gateway).

This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see **Ephemeral ports** (p. 120).

* 0.0.0.0/0 all all DENY

Denies all outbound traffic not already handled by a preceding rule (not modifiable).

**Recommended network ACL rules for IPv6**

If you implemented IPv6 support and created a VPC and subnets with associated IPv6 CIDR blocks, you must add separate rules to your network ACLs to control inbound and outbound IPv6 traffic.

The following are the IPv6-specific rules for your network ACLs (which are in addition to the preceding rules).

**ACL rules for the public subnet**

<table>

</tbody>
</table>

- **Rule 160**: Allows outbound HTTPS traffic from the subnet to the internet.
- **Rule 170**: Allows outbound MS SQL access to database servers in the private subnet.
- **Rule 190**: Allows outbound responses to clients on the internet (for example, serving webpages to people visiting the web servers in the subnet).

This port number is an example only. Other examples include 3306 for MySQL/Aurora access, 5432 for PostgreSQL access, 5439 for Amazon Redshift access, and 1521 for Oracle access.

For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).
### ACL rules for the VPN-only subnet

</table>
VPC with a private subnet only and AWS Site-to-Site VPN access

The configuration for this scenario includes a virtual private cloud (VPC) with a single private subnet, and a virtual private gateway to enable communication with your own network over an IPsec VPN tunnel. There is no internet gateway to enable communication over the internet. We recommend this scenario if you want to extend your network into the cloud using Amazon's infrastructure without exposing your network to the internet.

This scenario can also be optionally configured for IPv6. Instances launched into the subnet can receive IPv6 addresses. We do not support IPv6 communication over a AWS Site-to-Site VPN connection on a virtual private gateway; however, instances in the VPC can communicate with each other via IPv6. For more information about IPv4 and IPv6 addressing, see IP addressing (p. 4).

For information about managing your EC2 instance software, see Managing software on your Linux instance in the Amazon EC2 User Guide for Linux Instances.

Contents
- Overview (p. 308)
- Routing (p. 309)
- Security (p. 309)
Overview

The following diagram shows the key components of the configuration for this scenario.

The configuration for this scenario includes the following:

- A virtual private cloud (VPC) with a size /16 CIDR (example: 10.0.0.0/16). This provides 65,536 private IP addresses.
- A VPN-only subnet with a size /24 CIDR (example: 10.0.0.0/24). This provides 256 private IP addresses.
- A Site-to-Site VPN connection between your VPC and your network. The Site-to-Site VPN connection consists of a virtual private gateway located on the Amazon side of the Site-to-Site VPN connection and a customer gateway located on your side of the Site-to-Site VPN connection.
- Instances with private IP addresses in the subnet range (examples: 10.0.0.5, 10.0.0.6, and 10.0.0.7), which enables the instances to communicate with each other and other instances in the VPC.
- The main route table contains a route that enables instances in the subnet to communicate with other instances in the VPC. Route propagation is enabled, so a route that enables instances in the subnet to communicate directly with your network appears as a propagated route in the main route table.

For more information, see Subnets (p. 56). For more information about your Site-to-Site VPN connection, see the AWS Site-to-Site VPN User Guide. For more information about configuring a customer gateway device, see Your customer gateway device.

IPv6 configuration

You can optionally enable IPv6 for this scenario. In addition to the components listed above, the configuration includes the following:

- A size /56 IPv6 CIDR block associated with the VPC (example: 2001:db8:1234:1a00::/56). AWS automatically assigns the CIDR; you cannot choose the range yourself.
- A size /64 IPv6 CIDR block associated with the VPN-only subnet (example: 2001:db8:1234:1a00::/64). You can choose the range for your subnet from the range allocated to the VPC. You cannot choose the size of the IPv6 CIDR.
- IPv6 addresses assigned to the instances from the subnet range (example: 2001:db8:1234:1a00::1a).
- A route table entry in the main route table that enables instances in the private subnet to use IPv6 to communicate with each other.
Routing

Your VPC has an implied router (shown in the configuration diagram for this scenario). In this scenario, Amazon VPC creates a route table that routes all traffic destined for an address outside the VPC to the AWS Site-to-Site VPN connection, and associates the route table with the subnet.

The following describes the route table for this scenario. The first entry is the default entry for local routing in the VPC; this entry enables the instances in this VPC to communicate with each other. The second entry routes all other subnet traffic to the virtual private gateway (for example, vgw-1a2b3c4d).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>vgw-id</td>
</tr>
</tbody>
</table>

The AWS Site-to-Site VPN connection is configured either as a statically-routed Site-to-Site VPN connection or as a dynamically routed Site-to-Site VPN connection (using BGP). If you select static routing, you'll be prompted to manually enter the IP prefix for your network when you create the Site-to-Site VPN connection. If you select dynamic routing, the IP prefix is advertised automatically to your VPC through BGP.

The instances in your VPC can't reach the internet directly; any internet-bound traffic must first traverse the virtual private gateway to your network, where the traffic is then subject to your firewall and corporate security policies. If the instances send any AWS-bound traffic (for example, requests to Amazon S3 or Amazon EC2), the requests must go over the virtual private gateway to your network and then to the internet before reaching AWS.

Routing for IPv6

If you associate an IPv6 CIDR block with your VPC and subnets, your route table includes separate routes for IPv6 traffic. The following describes the custom route table for this scenario. The second entry is the default route that's automatically added for local routing in the VPC over IPv6.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>2001:db8:1234:1a00::/56</td>
<td>local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>vgw-id</td>
</tr>
</tbody>
</table>

Security

AWS provides two features that you can use to increase security in your VPC: security groups and network ACLs. Security groups control inbound and outbound traffic for your instances, and network ACLs control inbound and outbound traffic for your subnets. In most cases, security groups can meet your needs; however, you can also use network ACLs if you want an additional layer of security for your VPC. For more information, see Internetwork traffic privacy in Amazon VPC (p. 224).

For this scenario, you'll use the default security group for your VPC but not a network ACL. If you'd like to use a network ACL, see Recommended network ACL rules for a VPC with a private subnet only and AWS Site-to-Site VPN access (p. 310).
Your VPC comes with a default security group whose initial settings deny all inbound traffic, allow all outbound traffic, and allow all traffic between the instances assigned to the security group. For this scenario, we recommend that you add inbound rules to the default security group to allow SSH traffic (Linux) and Remote Desktop traffic (Windows) from your network.

**Important**
The default security group automatically allows assigned instances to communicate with each other, so you don’t have to add a rule to allow this. If you use a different security group, you must add a rule to allow this.

The following table describes the inbound rules that you should add to the default security group for your VPC.

## Default security group: recommended rules

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Source</th>
<th>Protocol</th>
<th>Port Range</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Private IPv4 address range of your network</td>
<td>TCP</td>
<td>22</td>
<td>(Linux instances) Allow inbound SSH traffic from your network.</td>
<td></td>
</tr>
<tr>
<td>Private IPv4 address range of your network</td>
<td>TCP</td>
<td>3389</td>
<td>(Windows instances) Allow inbound RDP traffic from your network.</td>
<td></td>
</tr>
</tbody>
</table>

### Security group rules for IPv6

If you associate an IPv6 CIDR block with your VPC and subnets, you must add separate rules to your security group to control inbound and outbound IPv6 traffic for your instances. In this scenario, the database servers cannot be reached over the Site-to-Site VPN connection using IPv6; therefore, no additional security group rules are required.

### Recommended network ACL rules for a VPC with a private subnet only and AWS Site-to-Site VPN access

The following table shows the rules that we recommend. They block all traffic except that which is explicitly required.

<table>
<thead>
<tr>
<th>Inbound</th>
<th>Rule #</th>
<th>Source IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>Private IP address range of your home network</td>
<td>TCP</td>
<td>22</td>
<td>ALLOW</td>
<td>Allows inbound SSH traffic to the subnet from your home network.</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>Private IP address range of your home network</td>
<td>TCP</td>
<td>3389</td>
<td>ALLOW</td>
<td>Allows inbound RDP traffic to the subnet from your home network.</td>
<td></td>
</tr>
</tbody>
</table>
### Security

#### Private IP address range of your home network

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Dest IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>120</td>
<td>Private IP address range of your home network</td>
<td>TCP</td>
<td>32768-65535</td>
<td>ALLOW</td>
<td>Allows inbound return traffic from requests originating in the subnet. This range is an example only. For information about choosing the correct ephemeral ports for your configuration, see Ephemeral ports (p. 120).</td>
</tr>
<tr>
<td></td>
<td>0.0.0.0/0</td>
<td>all</td>
<td>all</td>
<td>DENY</td>
<td>Denies all inbound traffic not already handled by a preceding rule (not modifiable).</td>
</tr>
</tbody>
</table>

#### Outbound

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Dest IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>Private IP address range of your home network</td>
<td>All</td>
<td>All</td>
<td>ALLOW</td>
<td>Allows all outbound traffic from the subnet to your home network. This rule also covers rule 120. However, you can make this rule more restrictive by using a specific protocol type and port number. If you make this rule more restrictive, you must include rule 120 in your network ACL to ensure that outbound responses are not blocked.</td>
</tr>
</tbody>
</table>
### Recommended network ACL rules for IPv6

If you implemented this scenario with IPv6 support and created a VPC and subnet with associated IPv6 CIDR blocks, you must add separate rules to your network ACL to control inbound and outbound IPv6 traffic.

In this scenario, the database servers cannot be reached over the VPN communication via IPv6, therefore no additional network ACL rules are required. The following are the default rules that deny IPv6 traffic to and from the subnet.

#### ACL rules for the VPN-only subnet

<table>
<thead>
<tr>
<th>Rule #</th>
<th>Source IP</th>
<th>Protocol</th>
<th>Port</th>
<th>Allow/Deny</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>

</thead>
<tbody>
<tr>
<td>*</td>
<td>::/0</td>
<td>all</td>
<td>all</td>
<td>DENY</td>
<td>Denies all outbound</td>
</tr>
</tbody>
</table>
IPv6 traffic not already handled by a preceding rule (not modifiable).
Tutorials

The following tutorials show you how to create VPCs using step-by-step tutorials based on use cases.

Contents
- Tutorials using the AWS CLI (p. 314)
- Tutorials using the AWS Management Console (p. 336)

Tutorials using the AWS CLI

The following tutorials show you how to create VPCs using the AWS CLI.

Prerequisites
Before you begin, install and configure the AWS CLI. For more information, see Installing or updating the AWS CLI and Configuring the AWS CLI.

Contents
- Create an IPv4-enabled VPC and subnets using the AWS CLI (p. 314)
- Create a dual-stack VPC and subnets using the AWS CLI (p. 319)
- Create an IPv6-enabled VPC and IPv6-only subnets using the AWS CLI (p. 328)

Create an IPv4-enabled VPC and subnets using the AWS CLI

The following example uses AWS CLI commands to create a nondefault VPC with an IPv4 CIDR block, and a public and private subnet in the VPC. After you've created the VPC and subnets, you can launch an instance in the public subnet and connect to it.

You will create the following AWS resources:
- A VPC
- Two subnets
- An internet gateway
- A route table
- An EC2 instance

Tasks
- Prerequisites (p. 315)
- Step 1: Create a VPC and subnets (p. 315)
- Step 2: Make your subnet public (p. 315)
- Step 3: Launch an instance into your subnet (p. 317)
- Step 4: Clean up (p. 318)
Prerequisites

Before you begin, install and configure the AWS CLI. When you configure the AWS CLI, you specify your AWS credentials. The examples in this tutorial assume you configured a default Region. Otherwise, add the --region option to each command. For more information, see Installing or updating the AWS CLI and Configuring the AWS CLI.

Step 1: Create a VPC and subnets

The first step is to create a VPC and two subnets. This example uses the CIDR block 10.0.0.0/16 for the VPC, but you can choose a different CIDR block. For more information, see VPC CIDR blocks (p. 14).

To create a VPC and subnets using the AWS CLI

1. Create a VPC with a 10.0.0.0/16 CIDR block using the following create-vpc command.

   ```bash
   aws ec2 create-vpc --cidr-block 10.0.0.0/16 --query Vpc.VpcId --output text
   ```

   The command returns the ID of the new VPC. The following is an example.

   ```bash
   vpc-2f09a348
   ```

2. Using the VPC ID from the previous step, create a subnet with a 10.0.1.0/24 CIDR block using the following create-subnet command.

   ```bash
   aws ec2 create-subnet --vpc-id vpc-2f09a348 --cidr-block 10.0.1.0/24
   ```

3. Create a second subnet in your VPC with a 10.0.0.0/24 CIDR block.

   ```bash
   aws ec2 create-subnet --vpc-id vpc-2f09a348 --cidr-block 10.0.0.0/24
   ```

Step 2: Make your subnet public

After you've created the VPC and subnets, you can make one of the subnets a public subnet by attaching an internet gateway to your VPC, creating a custom route table, and configuring routing for the subnet to the internet gateway.

To make your subnet a public subnet

1. Create an internet gateway using the following create-internet-gateway command.

   ```bash
   aws ec2 create-internet-gateway --query InternetGateway.InternetGatewayId --output text
   ```

   The command returns the ID of the new internet gateway. The following is an example.

   ```bash
   igw-1ff7a07b
   ```

2. Using the ID from the previous step, attach the internet gateway to your VPC using the following attach-internet-gateway command.

   ```bash
   aws ec2 attach-internet-gateway --vpc-id vpc-2f09a348 --internet-gateway-id igw-1ff7a07b
   ```

3. Create a custom route table for your VPC using the following create-route-table command.
aws ec2 create-route-table --vpc-id vpc-2f09a348 --query RouteTable.RouteTableId --output text

The command returns the ID of the new route table. The following is an example.

rtn-c1c8faa6

4. Create a route in the route table that points all traffic (0.0.0.0/0) to the internet gateway using the following create-route command.

aws ec2 create-route --route-table-id rtb-c1c8faa6 --destination-cidr-block 0.0.0.0/0 --gateway-id igw-1ff7a07b

5. (Optional) To confirm that your route has been created and is active, you can describe the route table using the following describe-route-tables command.

aws ec2 describe-route-tables --route-table-id rtb-c1c8faa6

```
{
  "RouteTables": [
    {
      "Associations": [],
      "RouteTableId": "rtb-c1c8faa6",
      "VpcId": "vpc-2f09a348",
      "PropagatingVgws": [],
      "Tags": [],
      "Routes": [
        {
          "GatewayId": "local",
          "DestinationCidrBlock": "10.0.0.0/16",
          "State": "active",
          "Origin": "CreateRouteTable"
        },
        {
          "GatewayId": "igw-1ff7a07b",
          "DestinationCidrBlock": "0.0.0.0/0",
          "State": "active",
          "Origin": "CreateRoute"
        }
      ]
    }
  ]
}
```

6. The route table is currently not associated with any subnet. You need to associate it with a subnet in your VPC so that traffic from that subnet is routed to the internet gateway. Use the following describe-subnets command to get the subnet IDs. The --filter option restricts the subnets to your new VPC only, and the --query option returns only the subnet IDs and their CIDR blocks.

aws ec2 describe-subnets --filter Name=vpc-id,Values=vpc-2f09a348 --query "Subnets[*].{ID:SubnetId,CIDR:CidrBlock}

```
[
  {
    "CIDR": "10.0.1.0/24",
    "ID": "subnet-b46032ec"
  },
  {
```
7. You can choose which subnet to associate with the custom route table, for example, subnet-b46032ec, and associate it using the `associate-route-table` command. This subnet is your public subnet.

```bash
aws ec2 associate-route-table --subnet-id subnet-b46032ec --route-table-id rtb-c1c8faa6
```

8. (Optional) You can modify the public IP addressing behavior of your subnet so that an instance launched into the subnet automatically receives a public IP address using the following `modify-subnet-attribute` command. Otherwise, associate an Elastic IP address with your instance after launch so that the instance is reachable from the internet.

```bash
aws ec2 modify-subnet-attribute --subnet-id subnet-b46032ec --map-public-ip-on-launch
```

**Step 3: Launch an instance into your subnet**

To test that your subnet is public and that instances in the subnet are accessible over the internet, launch an instance into your public subnet and connect to it. First, you must create a security group to associate with your instance, and a key pair with which you'll connect to your instance. For more information about security groups, see [Control traffic to resources using security groups](p. 245). For more information about key pairs, see [Amazon EC2 Key Pairs](p. 245) in the [Amazon EC2 User Guide for Linux Instances](p. 245).

**To launch and connect to an instance in your public subnet**

1. Create a key pair and use the `--query` option and the `--output text` option to pipe your private key directly into a file with the `.pem` extension.

   ```bash
   aws ec2 create-key-pair --key-name MyKeyPair --query "KeyMaterial" --output text > MyKeyPair.pem
   ```

   In this example, you launch an Amazon Linux instance. If you use an SSH client on a Linux or Mac OS X operating system to connect to your instance, use the following command to set the permissions of your private key file so that only you can read it.

   ```bash
   chmod 400 MyKeyPair.pem
   ```

2. Create a security group in your VPC using the `create-security-group` command.

   ```bash
   aws ec2 create-security-group --group-name SSHAccess --description "Security group for SSH access" --vpc-id vpc-2f09a348
   ```

   ```json
   {
   "GroupId": "sg-e1fb8c9a"
   }
   ```

   Add a rule that allows SSH access from anywhere using the `authorize-security-group-ingress` command.
Note
If you use 0.0.0.0/0, you enable all IPv4 addresses to access your instance using SSH. This is acceptable for this short exercise, but in production, authorize only a specific IP address or range of addresses.

3. Launch an instance into your public subnet, using the security group and key pair you've created. In the output, take note of the instance ID for your instance.

```bash
aws ec2 run-instances --image-id ami-a4827dc9 --count 1 --instance-type t2.micro --key-name MyKeyPair --security-group-ids sg-e1fb8c9a --subnet-id subnet-b46032ec
```

Note
In this example, the AMI is an Amazon Linux AMI in the US East (N. Virginia) Region. If you're in a different Region, you'll need the AMI ID for a suitable AMI in your Region. For more information, see Finding a Linux AMI in the Amazon EC2 User Guide for Linux Instances.

4. Your instance must be in the running state in order to connect to it. Use the following command to describe the state and IP address of your instance.

```bash
aws ec2 describe-instances --instance-id i-0146854b7443af453 --query "Reservations[*].Instances[*].{State:State.Name,Address:PublicIpAddress}"
```

The following is example output.

```
[ 
  { 
    "State": "running", 
    "Address": "52.87.168.235"
  }
]
```

5. When your instance is in the running state, you can connect to it using an SSH client on a Linux or Mac OS X computer by using the following command:

```bash
ssh -i "MyKeyPair.pem" ec2-user@52.87.168.235
```

If you're connecting from a Windows computer, use the following instructions: Connecting to your Linux instance from Windows using PuTTY.

**Step 4: Clean up**

After you've verified that you can connect to your instance, you can terminate it if you no longer need it. To do this, use the `terminate-instances` command. To delete the other resources you've created in this example, use the following commands in their listed order:

1. Delete your security group:

```bash
aws ec2 delete-security-group --group-id sg-e1fb8c9a
```

2. Delete your subnets:
Create a dual-stack VPC and subnets using the AWS CLI

The following example uses AWS CLI commands to create a nondefault VPC with an IPv6 CIDR block, a public subnet, and a private subnet with outbound internet access only. After you've created the VPC and subnets, you can launch an instance in the public subnet and connect to it. You can launch an instance in your private subnet and verify that it can connect to the internet.

You will create the following AWS resources:

- A VPC
- Two subnets
- An internet gateway
- A route table
- An EC2 instance

Tasks

- Prerequisites (p. 320)
- Step 1: Create a VPC and subnets (p. 320)
- Step 2: Configure a public subnet (p. 321)
- Step 3: Configure an egress-only private subnet (p. 323)
- Step 4: Modify the IPv6 addressing behavior of the subnets (p. 323)
- Step 5: Launch an instance into your public subnet (p. 324)
- Step 6: Launch an instance into your private subnet (p. 325)
- Step 7: Clean up (p. 327)
Prerequisites

Before you begin, install and configure the AWS CLI. When you configure the AWS CLI, you specify your AWS credentials. The examples in this tutorial assume you configured a default Region. Otherwise, add the --region option to each command. For more information, see Installing or updating the AWS CLI and Configuring the AWS CLI.

Step 1: Create a VPC and subnets

The first step is to create a VPC and two subnets. This example uses the IPv4 CIDR block 10.0.0.0/16 for the VPC, but you can choose a different CIDR block. For more information, see VPC CIDR blocks (p. 14).

To create a VPC and subnets using the AWS CLI

1. Create a VPC with a 10.0.0.0/16 CIDR block and associate an IPv6 CIDR block with the VPC.

   ```bash
   aws ec2 create-vpc --cidr-block 10.0.0.0/16 --amazon-provided-ipv6-cidr-block
   ```

   In the output that's returned, take note of the VPC ID.

   ```json
   {
     "Vpc": {
       "VpcId": "vpc-2f09a348",
       ...
     }
   }
   ```

2. Describe your VPC to get the IPv6 CIDR block that's associated with the VPC.

   ```bash
   aws ec2 describe-vpcs --vpc-id vpc-2f09a348
   ```

   ```json
   {
     "Vpcs": [
       {
         "Vpc": {
           "VpcId": "vpc-2f09a348",
           ...
         }
       },
       ...
     ]
   }
   ```

3. Create a subnet with a 10.0.0.0/24 IPv4 CIDR block and a 2001:db8:1234:1a00::/64 IPv6 CIDR block (from the ranges that were returned in the previous step).

   ```bash
   aws ec2 create-subnet --vpc-id vpc-2f09a348 --cidr-block 10.0.0.0/24 --ipv6-cidr-block 2001:db8:1234:1a00::/64
   ```

4. Create a second subnet in your VPC with a 10.0.1.0/24 IPv4 CIDR block and a 2001:db8:1234:1a01::/64 IPv6 CIDR block.
aws ec2 create-subnet --vpc-id vpc-2f09a348 --cidr-block 10.0.1.0/24 --ipv6-cidr-block 2001:db8:1234:1a01::/64

Step 2: Configure a public subnet

After you've created the VPC and subnets, you can make one of the subnets a public subnet by attaching an internet gateway to your VPC, creating a custom route table, and configuring routing for the subnet to the internet gateway. In this example, a route table is created that routes all IPv4 traffic and IPv6 traffic to an internet gateway.

To make your subnet a public subnet
1. Create an internet gateway.

```bash
aws ec2 create-internet-gateway
```

In the output that's returned, take note of the internet gateway ID.

```json
{
  "InternetGateway": {
    ...
    "InternetGatewayId": "igw-1ff7a07b",
    ...
  }
}
```

2. Using the ID from the previous step, attach the internet gateway to your VPC.

```bash
aws ec2 attach-internet-gateway --vpc-id vpc-2f09a348 --internet-gateway-id igw-1ff7a07b
```

3. Create a custom route table for your VPC.

```bash
aws ec2 create-route-table --vpc-id vpc-2f09a348
```

In the output that's returned, take note of the route table ID.

```json
{
  "RouteTable": {
    ...
    "RouteTableId": "rtb-c1c8faa6",
    ...
  }
}
```

4. Create a route in the route table that points all IPv6 traffic (:/0) to the internet gateway.

```bash
aws ec2 create-route --route-table-id rtb-c1c8faa6 --destination-ipv6-cidr-block ::/0 --gateway-id igw-1ff7a07b
```

Note
If you intend to use your public subnet for IPv4 traffic too, you need to add another route for 0.0.0.0/0 traffic that points to the internet gateway.
5. To confirm that your route has been created and is active, you can describe the route table and view the results.

```bash
aws ec2 describe-route-tables --route-table-id rtb-c1c8faa6
```

```json
{
  "RouteTables": [
    {
      "Associations": [],
      "RouteTableId": "rtb-c1c8faa6",
      "VpcId": "vpc-2f09a348",
      "PropagatingVgws": [],
      "Tags": [],
      "Routes": [
        {
          "GatewayId": "local",
          "DestinationCidrBlock": "10.0.0.0/16",
          "State": "active",
          "Origin": "CreateRouteTable"
        },
        {
          "GatewayId": "local",
          "Origin": "CreateRouteTable",
          "State": "active",
          "DestinationIpv6CidrBlock": "2001:db8:1234:1a00::/56"
        },
        {
          "GatewayId": "igw-1ff7a07b",
          "Origin": "CreateRoute",
          "State": "active",
          "DestinationIpv6CidrBlock": "::/0"
        }
      ]
    }
  ]
}
```

6. The route table is not currently associated with any subnet. Associate it with a subnet in your VPC so that traffic from that subnet is routed to the internet gateway. First, describe your subnets to get their IDs. You can use the `--filter` option to return the subnets for your new VPC only, and the `--query` option to return only the subnet IDs and their IPv4 and IPv6 CIDR blocks.

```bash
aws ec2 describe-subnets --filters "Name=vpc-id,Values=vpc-2f09a348" --query "Subnets[*].{ID:SubnetId,IPv4CIDR:CidrBlock,IPv6CIDR:Ipv6CidrBlockAssociationSet[*].Ipv6CidrBlock}"
```

```json
[
  {
    "IPv6CIDR": [
      "2001:db8:1234:1a00::/64"
    ],
    "ID": "subnet-b46032ec",
    "IPv4CIDR": "10.0.0.0/24"
  },
  {
    "IPv6CIDR": [
      "2001:db8:1234:1a01::/64"
    ],
    "ID": "subnet-a46032fc",
    "IPv4CIDR": "10.0.1.0/24"
  }
]```
7. You can choose which subnet to associate with the custom route table, for example, subnet-b46032ec. This subnet will be your public subnet.

```bash
aws ec2 associate-route-table --subnet-id subnet-b46032ec --route-table-id rtb-c1c8faa6
```

### Step 3: Configure an egress-only private subnet

You can configure the second subnet in your VPC to be an IPv6 egress-only private subnet. Instances that are launched in this subnet are able to access the internet over IPv6 (for example, to get software updates) through an egress-only internet gateway, but hosts on the internet cannot reach your instances.

**To make your subnet an egress-only private subnet**

1. Create an egress-only internet gateway for your VPC. In the output that's returned, take note of the gateway ID.

```bash
aws ec2 create-egress-only-internet-gateway --vpc-id vpc-2f09a348
```

```json
{
  "EgressOnlyInternetGateway": {
    "EgressOnlyInternetGatewayId": "eigw-015e0e244e24dfe8a",
    "Attachments": [
      {
        "State": "attached",
        "VpcId": "vpc-2f09a348"
      }
    ]
  }
}
```

2. Create a custom route table for your VPC. In the output that's returned, take note of the route table ID.

```bash
aws ec2 create-route-table --vpc-id vpc-2f09a348
```

3. Create a route in the route table that points all IPv6 traffic (::/0) to the egress-only internet gateway.

```bash
aws ec2 create-route --route-table-id rtb-abc123ab --destination-ipv6-cidr-block ::/0 --egress-only-internet-gateway-id eigw-015e0e244e24dfe8a
```

4. Associate the route table with the second subnet in your VPC (you described the subnets in the previous section). This subnet will be your private subnet with egress-only IPv6 internet access.

```bash
aws ec2 associate-route-table --subnet-id subnet-a46032fc --route-table-id rtb-abc123ab
```

### Step 4: Modify the IPv6 addressing behavior of the subnets

You can modify the IP addressing behavior of your subnets so that instances launched into the subnets automatically receive IPv6 addresses. When you launch an instance into the subnet, a single IPv6 address is assigned from the range of the subnet to the primary network interface (eth0) of the instance.
Step 5: Launch an instance into your public subnet

To test that your public subnet is public and that instances in the subnet are accessible from the internet, launch an instance into your public subnet and connect to it. First, you must create a security group to associate with your instance, and a key pair with which you'll connect to your instance. For more information about security groups, see Control traffic to resources using security groups (p. 245). For more information about key pairs, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

To launch and connect to an instance in your public subnet

1. Create a key pair and use the --query option and the --output text option to pipe your private key directly into a file with the .pem extension.

   ```bash
   aws ec2 create-key-pair --key-name MyKeyPair --query "KeyMaterial" --output text > MyKeyPair.pem
   ```

   In this example, launch an Amazon Linux instance. If you use an SSH client on a Linux or OS X operating system to connect to your instance, use the following command to set the permissions of your private key file so that only you can read it.

   ```bash
   chmod 400 MyKeyPair.pem
   ```

2. Create a security group for your VPC using the create-security-group command.

   ```bash
   aws ec2 create-security-group --group-name SSHAccess --description "Security group for SSH access" --vpc-id vpc-2f09a348
   ```

   ```json
   {
     "GroupId": "sg-e1fb8c9a"
   }
   ```

   Add a rule that allows SSH access from any IPv6 address using the authorize-security-group-ingress command. Note that the following syntax works only on Linux and macOS. For syntax that works on Windows, see the examples section in the AWS CLI Command Reference.

   ```bash
   aws ec2 authorize-security-group-ingress --group-id sg-e1fb8c9a --ip-permissions '[{"IpProtocol": "tcp", "FromPort": 22, "ToPort": 22, "Ipv6Ranges": [{"CidrIpv6": ":/0"}]}]'
   ```

   Note

   If you use :/0, you enable all IPv6 addresses to access your instance using SSH. This is acceptable for this short exercise, but in production, authorize only a specific IP address or range of addresses to access your instance.

3. Launch an instance into your public subnet, using the security group and key pair that you've created. In the output, take note of the instance ID for your instance.
aws ec2 run-instances --image-id ami-0de53d8956e8dcf80 --count 1 --instance-type t2.micro --key-name MyKeyPair --security-group-ids sg-e1fb8c9a --subnet-id subnet-b46032ec

**Note**
In this example, the AMI is an Amazon Linux AMI in the US East (N. Virginia) Region. If you're in a different Region, you need the AMI ID for a suitable AMI in your Region. For more information, see Find a Linux AMI in the Amazon EC2 User Guide for Linux Instances.

4. Your instance must be in the running state in order to connect to it. Describe your instance and confirm its state, and take note of its IPv6 address.

```bash
aws ec2 describe-instances --instance-id i-0146854b7443af453
```

The following is example output.

```json
{
  "Reservations": [
    {
      "Instances": [
        {
          "State": {
            "Code": 16,
            "Name": "running"
          },
          "NetworkInterfaces": {
            "Ipv6Addresses": {
              "Ipv6Address": "2001:db8:1234:1a00::123"
            }
          }
        }
      ]
    }
  ]
}
```

5. When your instance is in the running state, you can connect to it using an SSH client on a Linux or OS X computer by using the following command. Your local computer must have an IPv6 address configured.

```bash
ssh -i "MyKeyPair.pem" ec2-user@2001:db8:1234:1a00::123
```

If you're connecting from a Windows computer, use the following instructions: Connecting to your Linux instance from Windows using PuTTY.

**Step 6: Launch an instance into your private subnet**

To test that instances in your egress-only private subnet can access the internet, launch an instance in your private subnet and connect to it using a bastion instance in your public subnet (you can use the instance you launched in the previous section). First, you must create a security group for the instance. The security group must have a rule that allows your bastion instance to connect using SSH, and a rule that allows the ping6 command (ICMPv6 traffic) to verify that the instance is not accessible from the internet.
1. Create a security group in your VPC using the `create-security-group` command.

   ```
   aws ec2 create-security-group --group-name SSHAccessRestricted --description "Security group for SSH access from bastion" --vpc-id vpc-2f09a348
   ```

   Add a rule that allows inbound SSH access from the IPv6 address of the instance in your public subnet, and a rule that allows all ICMPv6 traffic using the `authorize-security-group-ingress` command. Note that the following syntax works only on Linux and macOS. For syntax that works on Windows, see the examples section in the AWS CLI Command Reference.

   ```
   
   
   ```

   

   ```
   aws ec2 authorize-security-group-ingress --group-id sg-aabb1122 --ip-permissions 
   
   
   ```

   

   ```
   aws ec2 authorize-security-group-ingress --group-id sg-aabb1122 --ip-permissions 
   
   
   ```

   2. Launch an instance into your private subnet, using the security group you've created and the same key pair you used to launch the instance in the public subnet.

   ```
   aws ec2 run-instances --image-id ami-a4827dc9 --count 1 --instance-type t2.micro --key-name MyKeyPair --security-group-ids sg-aabb1122 --subnet-id subnet-a46032fc
   ```

   Use the `describe-instances` command to verify that your instance is running, and to get its IPv6 address.

   3. Configure SSH agent forwarding on your local machine, and then connect to your instance in the public subnet.

   For Linux, use the following commands:

   ```
   ssh-add MyKeyPair.pem
   ssh -A ec2-user@2001:db8:1234:1a00::123
   ```

   For OS X, use the following commands:

   ```
   ssh-add -K MyKeyPair.pem
   ssh -A ec2-user@2001:db8:1234:1a00::123
   ```

   For Windows, use the following instructions: To configure SSH agent forwarding for Windows (PuTTY) (p. 149). Connect to the instance in the public subnet by using its IPv6 address.

   4. From your instance in the public subnet (the bastion instance), connect to your instance in the private subnet by using its IPv6 address:

   ```
   ssh ec2-user@2001:db8:1234:1a01::456
   ```

   5. From your private instance, test that you can connect to the internet by running the `ping6` command for a website that has ICMP enabled, for example:

   ```
   ping6 example.com
   ```
To test that hosts on the internet cannot reach your instance in the private subnet, use the `ping6` command from a computer that's enabled for IPv6. You should get a timeout response. If you get a valid response, then your instance is accessible from the internet—check the route table that's associated with your private subnet and verify that it does not have a route for IPv6 traffic to an internet gateway.

```
ping6 2001:db8:1234:1a01::456
```

**Step 7: Clean up**

After you've verified that you can connect to your instance in the public subnet and that your instance in the private subnet can access the internet, you can terminate the instances if you no longer need them. To do this, use the `terminate-instances` command. To delete the other resources you've created in this example, use the following commands in their listed order:

1. Delete your security groups:
   ```
   aws ec2 delete-security-group --group-id sg-e1fb8c9a
   aws ec2 delete-security-group --group-id sg-aabb1122
   ```

2. Delete your subnets:
   ```
   aws ec2 delete-subnet --subnet-id subnet-b46032ec
   aws ec2 delete-subnet --subnet-id subnet-a46032fc
   ```

3. Delete your custom route tables:
   ```
   aws ec2 delete-route-table --route-table-id rtb-c1c8faa6
   aws ec2 delete-route-table --route-table-id rtb-abc123ab
   ```

4. Detach your internet gateway from your VPC:
   ```
   aws ec2 detach-internet-gateway --internet-gateway-id igw-1ff7a07b --vpc-id vpc-2f09a348
   ```

5. Delete your internet gateway:
   ```
   aws ec2 delete-internet-gateway --internet-gateway-id igw-1ff7a07b
   ```

6. Delete your egress-only internet gateway:
Create an IPv6-enabled VPC and IPv6-only subnets using the AWS CLI

The following example uses AWS CLI commands to create a nondefault VPC with an IPv6 CIDR block, a public IPv6-only subnet, and a private IPv6-only subnet with outbound internet access only. After you've created the VPC and subnets, you can launch an instance in the public subnet and connect to it. You can launch an instance in your private subnet and verify that it can connect to the internet.

You will create the following AWS resources:

- A VPC
- Two subnets
- An internet gateway
- A route table
- An EC2 instance

Tasks

- Prerequisites (p. 328)
- Step 1: Create a VPC and subnets (p. 328)
- Step 2: Configure a public subnet (p. 329)
- Step 3: Configure an egress-only private subnet (p. 331)
- Step 4: Modify the subnets (p. 332)
- Step 5: Launch an instance into your public subnet (p. 332)
- Step 6: Launch an instance into your private subnet (p. 334)
- Step 7: Clean up (p. 336)

Prerequisites

Before you begin, install and configure the AWS CLI. When you configure the AWS CLI, you specify your AWS credentials. The examples in this tutorial assume you configured a default Region. Otherwise, add the --region option to each command. For more information, see Installing or updating the AWS CLI and Configuring the AWS CLI.

Step 1: Create a VPC and subnets

The first step is to create a VPC. You are required to define an IPv4 CIDR block for the VPC even though we are primarily focussed on IPv6 in this example. This example uses the IPv4 CIDR block 10.0.0.0/16 for the VPC, but you can choose a different CIDR block. For more information, see VPC CIDR blocks (p. 14).
To create a VPC and subnets using the AWS CLI

1. Create a VPC with a 10.0.0.0/16 CIDR block and associate an IPv6 CIDR block with the VPC.

```bash
aws ec2 create-vpc --cidr-block 10.0.0.0/16 --amazon-provided-ipv6-cidr-block
```

In the output that's returned, take note of the VPC ID.

```json
{  
  "Vpc": {  
    "VpcId": "vpc-2f09a348"  
  }  
}
```

2. Describe your VPC to get the IPv6 CIDR block that's associated with the VPC.

```bash
aws ec2 describe-vpcs --vpc-id vpc-2f09a348
```

```json
{  
  "Vpcs": [  
    {  
      "Ipv6CidrBlockAssociationSet": [  
        {  
          "Ipv6CidrBlock": "2001:db8:1234:1a00::/56",  
          "AssociationId": "vpc-cidr-assoc-17a5407e",  
          "Ipv6CidrBlockState": {  
            "State": "ASSOCIATED"  
          }  
        }  
      ]  
    }  
  ]  
}
```

3. Create an IPv6-only subnet in your VPC with a 2001:db8:1234:1a00::/64 IPv6 CIDR block (from the ranges that were returned in the previous step). For more information about the IPv6-only option, see the section called “Create a subnet in your VPC” (p. 59) or create-subnet in the AWS CLI Command Reference.

```bash
aws ec2 create-subnet --vpc-id vpc-2f09a348 --ipv6-cidr-block 2001:db8:1234:1a00::/64 --ipv6-native
```

4. Create a second IPv6-only subnet in your VPC with a 2001:db8:1234:1a01::/64 IPv6 CIDR block.

```bash
aws ec2 create-subnet --vpc-id vpc-2f09a348 --ipv6-cidr-block 2001:db8:1234:1a01::/64 --ipv6-native
```

**Step 2: Configure a public subnet**

After you've created the VPC and subnets, you can make one of the IPv6 subnets a public subnet by attaching an internet gateway to your VPC, creating a custom route table, and configuring routing for the subnet to the internet gateway. In this example, a route table is created that routes all IPv6 traffic to an internet gateway.

**To make your subnet a public subnet**

1. Create an internet gateway.
aws ec2 create-internet-gateway

In the output that's returned, take note of the internet gateway ID.

```
{
   "InternetGateway": {
      ...
      "InternetGatewayId": "igw-1ff7a07b",
      ...
   }
}
```

2. Using the ID from the previous step, attach the internet gateway to your VPC.

```
aws ec2 attach-internet-gateway --vpc-id vpc-2f09a348 --internet-gateway-id igw-1ff7a07b
```

3. Create a custom route table for your VPC.

```
aws ec2 create-route-table --vpc-id vpc-2f09a348
```

In the output that's returned, take note of the route table ID.

```
{
   "RouteTable": {
      ...
      "RouteTableId": "rtb-c1c8faa6",
      ...
   }
}
```

4. Create a route in the route table that points all IPv6 traffic (::/0) to the internet gateway.

```
aws ec2 create-route --route-table-id rtb-c1c8faa6 --destination-ipv6-cidr-block ::/0 --gateway-id igw-1ff7a07b
```

5. To confirm that your route has been created and is active, you can describe the route table and view the results.

```
aws ec2 describe-route-tables --route-table-id rtb-c1c8faa6
```

```
{
   "RouteTables": [
      {
         "Associations": [],
         "RouteTableId": "rtb-c1c8faa6",
         "VpcId": "vpc-2f09a348",
         "PropagatingVgws": [],
         "Tags": [],
         "Routes": [
            {
               "GatewayId": "local",
               "DestinationCidrBlock": "10.0.0.0/16",
               "State": "active",
               "Origin": "CreateRouteTable"
            },
            {
               "GatewayId": "local",
               "DestinationCidrBlock": "10.0.0.0/16",
               "State": "active",
               "Origin": "CreateRouteTable"
            }
```
IPv6-enabled VPC and IPv6-only subnets

6. The route table is not currently associated with any subnet. Associate it with a subnet in your VPC so that traffic from that subnet is routed to the internet gateway. First, describe your subnets to get their IDs. You can use the --filter option to return the subnets for your new VPC only, and the --query option to return only the subnet IDs and their IPv6 CIDR blocks.

```bash
aws ec2 describe-subnets --filters "Name=vpc-id,Values=vpc-2f09a348" --query "Subnets[*].{ID:SubnetId,IPv6CIDR:Ipv6CidrBlockAssociationSet[*].Ipv6CidrBlock}"
```

```
[{
  "ID": "subnet-b46032ec",
  "IPv6CIDR": [ "2001:db8:1234:1a01::/64"
  ],
  "ID": "subnet-a46032fc",
  "IPv6CIDR": [ "2001:db8:1234:1a01::/64"
  ]
}
]
```

7. You can choose which subnet to associate with the custom route table, for example, subnet-b46032ec. This subnet will be your public subnet.

```bash
aws ec2 associate-route-table --subnet-id subnet-b46032ec --route-table-id rtb-c1c8faa6
```

**Step 3: Configure an egress-only private subnet**

You can configure the second subnet in your VPC to be an IPv6 egress-only private subnet. Instances that are launched in this subnet are able to access the internet over IPv6 (for example, to get software updates) through an egress-only internet gateway, but hosts on the internet cannot reach your instances.

**To make your subnet an egress-only private subnet**

1. Create an egress-only internet gateway for your VPC. In the output that's returned, take note of the gateway ID.

```bash
aws ec2 create-egress-only-internet-gateway --vpc-id vpc-2f09a348
```

```json
{
  "EgressOnlyInternetGateway": {
    "EgressOnlyInternetGatewayId": "eigw-015e0e244e24dfe8a",
  }
}
```
2. Create a custom route table for your VPC. In the output that's returned, take note of the route table ID.

   ```bash
   aws ec2 create-route-table --vpc-id vpc-2f09a348
   ```

3. Create a route in the route table that points all IPv6 traffic (::/0) to the egress-only Internet gateway.

   ```bash
   aws ec2 create-route --route-table-id rtb-abc123ab --destination-ipv6-cidr-block ::/0 --egress-only-internet-gateway-id eigw-015e0e244e24dfe8a
   ```

4. Associate the route table with the second subnet in your VPC (you described the subnets in the previous section). This subnet will be your private subnet with egress-only IPv6 internet access.

   ```bash
   aws ec2 associate-route-table --subnet-id subnet-a46032fc --route-table-id rtb-abc123ab
   ```

**Step 4: Modify the subnets**

Once you've created the subnets, you can modify the following:

- The IP addressing behavior of your subnets so that instances launched into the subnets automatically receive IPv6 addresses. As a result, when you launch an instance into the subnet, a single IPv6 address is assigned from the range of the subnet to the primary network interface (eth0) of the instance.

- Resource-based Name (RBN) settings for the subnet and instances launched into the subnet. For more information on RBN, see [Amazon EC2 instance hostname types](https://docs.aws.amazon.com/ec2/latest/userguide/amazon-ec2-instance-hostname-types.html) in the Amazon EC2 User Guide. For details on the RBN options used in this section, see [modify-subnet-attribute](https://docs.aws.amazon.com/cli/latest/reference/ec2/modify-subnet-attribute.html) in the AWS CLI Command Reference or [Modifying RBN configurations](https://docs.aws.amazon.com/ec2/latest/userguide/modify-subnet-attribute.html) in the Amazon EC2 User Guide.

   ```bash
   aws ec2 modify-subnet-attribute --subnet-id subnet-b46032ec --assign-ipv6-address-on-creation --private-dns-hostname-type-on-launch resource-name --enable-resource-name-dns-aaaa-record-on-launch --enable-resource-name-dns-a-record-on-launch
   ```

   ```bash
   aws ec2 modify-subnet-attribute --subnet-id subnet-a46032fc --assign-ipv6-address-on-creation --private-dns-hostname-type-on-launch resource-name --enable-resource-name-dns-aaaa-record-on-launch --enable-resource-name-dns-a-record-on-launch
   ```

**Step 5: Launch an instance into your public subnet**

To test that your public subnet is public and that instances in the subnet are accessible from the internet, launch an instance into your public subnet and connect to it. First, you must create a security group to associate with your instance, and a key pair with which you'll connect to your instance. For more information about security groups, see [Control traffic to resources using security groups](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/using-network-security.html) (p. 245). For more information about key pairs, see [Amazon EC2 key pairs](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/using-network-security.html) in the Amazon EC2 User Guide for Linux Instances.
IPv6-enabled VPC and IPv6-only subnets

For details on the options available when you run an instance, see run-instances in the AWS CLI Command Reference or Launch an instance using the Launch Instance Wizard in the Amazon EC2 User Guide.

To launch and connect to an instance in your public subnet

1. Create a key pair and use the --query option and the --output text option to pipe your private key directly into a file with the .pem extension.

   ```bash
   aws ec2 create-key-pair --key-name MyKeyPair --query "KeyMaterial" --output text > MyKeyPair.pem
   ```

   In this example, launch an Amazon Linux instance. If you use an SSH client on a Linux or OS X operating system to connect to your instance, use the following command to set the permissions of your private key file so that only you can read it.

   ```bash
   chmod 400 MyKeyPair.pem
   ```

2. Create a security group for your VPC using the create-security-group command.

   ```bash
   aws ec2 create-security-group --group-name SSHAccess --description "Security group for SSH access" --vpc-id vpc-2f09a348
   ```

   Add a rule that allows SSH access from any IPv6 address using the authorize-security-group-ingress command. Note that the following syntax works only on Linux and macOS. For syntax that works on Windows, see the examples section in the AWS CLI Command Reference.

   ```bash
   aws ec2 authorize-security-group-ingress --group-id sg-e1fb8c9a --ip-permissions '[{"IpProtocol": "tcp", "FromPort": 22, "ToPort": 22, "Ipv6Ranges": [{"CidrIpv6": ":/0"}]}]'
   ```

   **Note**
   If you use ::/0, you enable all IPv6 addresses to access your instance using SSH. This is acceptable for this short exercise, but in production, authorize only a specific IP address or range of addresses to access your instance.

3. Launch an IPv6-only EC2 instance into your public subnet using the security group and key pair that you've created. To launch an IPv6-only EC2 instance, you must use EC2 instances built on the Nitro System. For more information, see Amazon DNS server (p. 37). In the output, take note of the instance ID for your instance.

   ```bash
   aws ec2 run-instances --image-id ami-0de53d8956e8dcf80 --count 1 --instance-type t3.micro --key-name MyKeyPair --security-group-ids sg-e1fb8c9a --subnet-id subnet-b46032ec
   ```

   **Note**
   In this example, the AMI is an Amazon Linux AMI in the US East (N. Virginia) Region. If you're in a different Region, you need the AMI ID for a suitable AMI in your Region. For more information, see Find a Linux AMI in the Amazon EC2 User Guide for Linux Instances.

4. Your instance must be in the running state in order to connect to it. Describe your instance and confirm its state, and take note of its IPv6 address.
aws ec2 describe-instances --instance-id i-0146854b7443af453

The following is example output.

```json
{
  "Reservations": [
    {
      "Instances": [
        {
          "State": {
            "Code": 16,
            "Name": "running"
          },
          "NetworkInterfaces": {
            "Ipv6Addresses": {
              "Ipv6Address": "2001:db8:1234:1a00::123"
            }
          }
        }
      ]
    }
  ]
}
```

5. When your instance is in the running state, you can connect to it using an SSH client on a Linux or OS X computer by using the following command. Your local computer must have an IPv6 address configured.

```bash
ssh -i "MyKeyPair.pem" ec2-user@2001:db8:1234:1a00::123
```

If you're connecting from a Windows computer, use the following instructions: Connecting to your Linux instance from Windows using PuTTY.

**Step 6: Launch an instance into your private subnet**

To test that instances in your egress-only private subnet can access the internet, launch an instance in your private subnet and connect to it using a bastion instance in your public subnet (you can use the instance you launched in the previous section). First, you must create a security group for the instance. The security group must have a rule that allows your bastion instance to connect using SSH, and a rule that allows the ping6 command (ICMPv6 traffic) to verify that the instance is not accessible from the internet.

1. **Create a security group in your VPC using the `create-security-group` command.**

   ```bash
   aws ec2 create-security-group --group-name SSHAccessRestricted --description "Security group for SSH access from bastion" --vpc-id vpc-2f09a348
   ```

   Add a rule that allows inbound SSH access from the IPv6 address of the instance in your public subnet, and a rule that allows all ICMPv6 traffic using the `authorize-security-group-ingress` command. Note that the following syntax works only on Linux and macOS. For syntax that works on Windows, see the examples section in the *AWS CLI Command Reference*.

   ```json
   {
   }
   ```
IPv6-enabled VPC and IPv6-only subnets

aws ec2 authorize-security-group-ingress --group-id sg-aabb1122 --ip-permissions '[["IpProtocol": "tcp", "FromPort": 22, "ToPort": 22, "Ipv6Ranges": ["2001:db8:1234:1a00::123/128"]]]'

aws ec2 authorize-security-group-ingress --group-id sg-aabb1122 --ip-permissions '[["IpProtocol": "58", "FromPort": -1, "ToPort": -1, "Ipv6Ranges": ["::/0"]]]'

2. Launch an IPv6-only instance into your private subnet, using the security group you've created and the same key pair you used to launch the instance in the public subnet. To launch an IPv6-only EC2 instance, you must use EC2 instances built on the Nitro System.

aws ec2 run-instances --image-id ami-a4827dc9 --count 1 --instance-type t3.micro --key-name MyKeyPair --security-group-ids sg-aabb1122 --subnet-id subnet-a46032fc

Use the describe-instances command to verify that your instance is running, and to get its IPv6 address.

3. Configure SSH agent forwarding on your local machine, and then connect to your instance in the public subnet.

   For Linux, use the following commands:
   
   ```bash
   ssh-add MyKeyPair.pem
   ssh -A ec2-user@2001:db8:1234:1a00::123
   ```

   For OS X, use the following commands:
   
   ```bash
   ssh-add -K MyKeyPair.pem
   ssh -A ec2-user@2001:db8:1234:1a00::123
   ```

   For Windows, use the following instructions: To configure SSH agent forwarding for Windows (PuTTY) (p. 149). Connect to the instance in the public subnet by using its IPv6 address.

4. From your instance in the public subnet (the bastion instance), connect to your instance in the private subnet by using its IPv6 address:

   ```bash
   ssh ec2-user@2001:db8:1234:1a01::456
   ```

5. From your private instance, test that you can connect to the internet by running the ping6 command for a website that has ICMP enabled, for example:

   ```bash
   ping6 -n ietf.org
   ```

   ```bash
   PING ietf.org(2001:1900:3001:11::2c) 56 data bytes
   64 bytes from 2001:1900:3001:11::2c: icmp_seq=1 ttl=46 time=73.9 ms
   64 bytes from 2001:1900:3001:11::2c: icmp_seq=2 ttl=46 time=73.8 ms
   64 bytes from 2001:1900:3001:11::2c: icmp_seq=3 ttl=46 time=73.9 ms
   ...
   ```

6. To test that hosts on the internet cannot reach your instance in the private subnet, use the ping6 command from a computer that's enabled for IPv6. You should get a timeout response. If you get a valid response, then your instance is accessible from the internet—check the route table that's
associated with your private subnet and verify that it does not have a route for IPv6 traffic to an internet gateway.

```
    ping6 2001:db8:1234:1a01::456
```

**Step 7: Clean up**

After you've verified that you can connect to your instance in the public subnet and that your instance in the private subnet can access the internet, you can terminate the instances if you no longer need them. To do this, use the `terminate-instances` command. To delete the other resources you've created in this example, use the following commands in their listed order:

1. Delete your security groups:

   ```
   aws ec2 delete-security-group --group-id sg-e1fb8c9a
   aws ec2 delete-security-group --group-id sg-aabb1122
   ```

2. Delete your subnets:

   ```
   aws ec2 delete-subnet --subnet-id subnet-b46032ec
   aws ec2 delete-subnet --subnet-id subnet-a46032fc
   ```

3. Delete your custom route tables:

   ```
   aws ec2 delete-route-table --route-table-id rtb-c1c8faa6
   aws ec2 delete-route-table --route-table-id rtb-abc123ab
   ```

4. Detach your internet gateway from your VPC:

   ```
   aws ec2 detach-internet-gateway --internet-gateway-id igw-1ff7a07b --vpc-id vpc-2f09a348
   ```

5. Delete your internet gateway:

   ```
   aws ec2 delete-internet-gateway --internet-gateway-id igw-1ff7a07b
   ```

6. Delete your egress-only internet gateway:

   ```
   aws ec2 delete-egress-only-internet-gateway  --egress-only-internet-gateway-id eigw-015e0e244e24dfe8a
   ```

7. Delete your VPC:

   ```
   aws ec2 delete-vpc --vpc-id vpc-2f09a348
   ```

**Tutorials using the AWS Management Console**

The following tutorials show you how to create VPCs using the AWS Management console in Amazon Virtual Private Cloud.
VPC that supports IPv6 addressing

The following steps describe how to create a nondefault VPC that supports IPv6 addressing.

To complete this exercise, do the following:

• Create a nondefault VPC with an IPv6 CIDR block and a single public subnet. Subnets enable you to group instances based on your security and operational needs. A public subnet is a subnet that has access to the internet through an internet gateway.
• Create a security group for your instance that allows traffic only through specific ports.
• Launch an Amazon EC2 instance into your subnet, and associate an IPv6 address with your instance during launch. An IPv6 address is globally unique, and allows your instance to communicate with the internet.
• You can request an IPv6 CIDR block for the VPC. When you select this option, you can set the network border group, which is the location from which we advertise the IPv6 CIDR block. Setting the network border group limits the CIDR block to this group.

For more information about IPv4 and IPv6 addressing, see IP addressing in your VPC.

Tasks

• Step 1: Create the VPC (p. 337)
• Step 2: Create a security group (p. 338)
• Step 3: Launch an instance (p. 339)

Step 1: Create the VPC

Follow the steps in this section to create a VPC.

To create a VPC:

1. Follow the steps in Create a VPC (p. 18) to create the VPC and additional resources. When you create the VPC, do the following:
   • For Number of Availability Zones (AZs), choose 1.
   • For Number of public subnets, choose 1.
   • For Number of private subnets, choose 0.
   • For NAT gateways, choose None.
   • For VPC endpoints, choose None.
   • For DNS options, choose Enable DNS hostnames and Enable DNS resolution.
2. Choose Create VPC.
3. The Your VPCs page displays your default VPC and the VPC that you just created.

View information about your VPC

After you've created the VPC, you can view information about the subnet, internet gateway, and route tables. The VPC that you created has two route tables — a main route table that all VPCs have by default, and a custom route table that was created by Amazon VPC. The custom route table is associated
with your subnet, which means that the routes in that table determine how the traffic for the subnet flows. If you add a new subnet to your VPC, it uses the main route table by default.

To view information about your VPC

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Your VPCs. Take note of the name and the ID of the VPC that you created (look in the Name and VPC ID columns). You use this information to identify the components that are associated with your VPC.
3. In the navigation pane, choose Subnets. The console displays the subnet that was created when you created your VPC. You can identify the subnet by its name in Name column, or you can use the VPC information that you obtained in the previous step and look in the VPC column.
4. In the navigation pane, choose Internet Gateways. You can find the internet gateway that's attached to your VPC by looking at the VPC column, which displays the ID and the name (if applicable) of the VPC.
5. In the navigation pane, choose Route Tables. There are two route tables associated with the VPC. Select the custom route table (the Main column displays No), and then choose the Routes tab to display the route information in the details pane:
   - The first two rows in the table are the local routes, which enable instances within the VPC to communicate over IPv4 and IPv6. You can't remove these routes.
   - The next row shows the route that enables traffic destined for an IPv4 address outside the VPC (0.0.0.0/0) to flow from the subnet to the internet gateway.
   - The next row shows the route that enables traffic destined for an IPv6 address outside the VPC (::/0) to flow from the subnet to the internet gateway.
6. Select the main route table. The main route table has a local route, but no other routes.

Step 2: Create a security group

A security group controls the traffic for its associated resources, such as EC2 instances. To use a security group, add inbound rules to control the incoming traffic and outbound rules to control the outgoing traffic. To associate a security group with an instance, specify the security group when you launch the instance. You can also associate and disassociate security groups with your instances after you launch them.

Your VPC comes with a default security group. Any instance not associated with another security group during launch is associated with the default security group. In this exercise, you create a new security group, WebServerSG, and specify this security group when you launch an instance into your VPC.

Create your WebServerSG security group

You can create your security group using the Amazon VPC console.

To create the WebServerSG security group and add rules

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups, Create Security Group.
3. For Group name, enter WebServerSG as the name of the security group and provide a description. You can optionally use the Name tag field to create a tag for the security group with a key of Name and a value that you specify.
4. Select the ID of your VPC from the VPC menu and choose Yes, Create.
5. Select the WebServerSG security group that you just created (you can view its name in the Group Name column).
6. On the Inbound Rules tab, choose Edit and add rules for inbound traffic as follows:
a. For Type, choose HTTP and enter :/:0 in the Source field.

b. Choose Add another rule, For Type, choose HTTPS, and then enter :/:0 in the Source field.

c. Choose Add another rule. If you're launching a Linux instance, choose SSH for Type, or if you're launching a Windows instance, choose RDP. Enter your network's public IPv6 address range in the Source field. If you don't know this address range, you can use :/:0 for this exercise.

    Important
    If you use :/:0, you enable all IPv6 addresses to access your instance using SSH or RDP. This is acceptable for the short exercise, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instance.

d. Choose Save.

Step 3: Launch an instance

When you launch an EC2 instance into a VPC, you must specify the subnet in which to launch the instance. In this case, you'll launch an instance into the public subnet of the VPC you created. Use the Amazon EC2 launch wizard in the Amazon EC2 console to launch your instance. Not all of the Amazon EC2 launch wizard options are detailed here. For more information, see Launching an instance in the Amazon EC2 User Guide for Linux Instances.

To ensure that your instance is accessible from the internet, assign an IPv6 address from the subnet range to the instance during launch. This ensures that your instance can communicate with the internet over IPv6.

To launch an EC2 instance into a VPC

Before you launch the EC2 instance into the VPC, configure the subnet of the VPC to automatically assign IPv6 IP addresses. For more information, see the section called “Modify the IPv6 addressing attribute for your subnet” (p. 62).

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar, on the top-right, ensure that you select the same Region in which you created your VPC and security group.
3. From the dashboard, choose Launch Instance.
4. On the first page of the wizard, choose the AMI to use. For this exercise, we recommend that you choose an Amazon Linux AMI or a Windows AMI.
5. On the Choose an Instance Type page, you can select the hardware configuration and size of the instance to launch. By default, the wizard selects the first available instance type based on the AMI that you selected. You can leave the default selection and choose Next: Configure Instance Details.
6. On the Configure Instance Details page, select the VPC that you created from the Network list and the subnet from the Subnet list.
7. For Auto-assign IPv6 IP, choose Enable.
8. Leave the rest of the default settings, and go through the next pages of the wizard until you get to the Add Tags page.
9. On the Add Tags page, you can tag your instance with a Name tag; for example Name=MyWebServer. This helps you to identify your instance in the Amazon EC2 console after you've launched it. Choose Next: Configure Security Group when you are done.
10. On the Configure Security Group page, the wizard automatically defines the launch-wizard-x security group to allow you to connect to your instance. Instead, choose the Select an existing security group option, select the WebServerSG group that you created previously, and then choose Review and Launch.
11. On the Review Instance Launch page, check the details of your instance and choose Launch.
12. In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. If you create a new key pair, ensure that you download the file and store it in a secure location. You need the contents of the private key to connect to your instance after it's launched.

To launch your instance, select the acknowledgment check box and choose **Launch Instances**.

13. On the confirmation page, choose **View Instances** to view your instance on the **Instances** page. Select your instance, and view its details in the **Description** tab. The **Private IPs** field displays the private IPv4 address that's assigned to your instance from the range of IPv4 addresses in your subnet. The **IPv6 IPs** field displays the IPv6 address that's assigned to your instance from the range of IPv6 addresses in your subnet.

You can connect to your instance through its IPv6 address using SSH or Remote Desktop from your home network. Your local computer must have an IPv6 address and must be configured to use IPv6. For more information about how to connect to an instance, see Connecting to an instance in the Amazon EC2 User Guide for Linux Instances. For more information about how to connect to a Windows instance, see Connect to your Windows instance using RDP in the Amazon EC2 User Guide for Windows Instances.

**Note**

If you also want your instance to be accessible via an IPv4 address over the internet, SSH, or RDP, you must associate an Elastic IP address (a static public IPv4 address) to your instance, and you must adjust your security group rules to allow access over IPv4. For more information, see Get started with Amazon VPC (p. 10).

## Migrate existing VPCs from IPv4 to IPv6

If you have an existing VPC that supports IPv4 only, and resources in your subnet that are configured to use IPv4 only, you can enable IPv6 support for your VPC and resources. Your VPC can operate in dual-stack mode — your resources can communicate over IPv4, or IPv6, or both. IPv4 and IPv6 communication are independent of each other.

You cannot disable IPv4 support for your VPC and subnets; this is the default IP addressing system for Amazon VPC and Amazon EC2.

**Note**

- There is no migration path currently from IPv4-only subnets to IPv6-only subnets. For information about creating IPv6-only subnets, see the section called "Create a subnet in your VPC" (p. 59).
- This section assumes that you have an existing VPC with public and private subnets. For information about setting up a new VPC for use with IPv6, see the section called "IPv6 configuration" (p. 261).

The following table provides an overview of the steps to enable your VPC and subnets to use IPv6.

<table>
<thead>
<tr>
<th>Step</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1: Associate an IPv6 CIDR block with your VPC and subnets (p. 343)</strong></td>
<td>Associate an Amazon-provided or BYOIP IPv6 CIDR block with your VPC and with your subnets.</td>
</tr>
<tr>
<td><strong>Step 2: Update your route tables (p. 344)</strong></td>
<td>Update your route tables to route your IPv6 traffic. For a public subnet, create a route that routes all IPv6 traffic from the subnet to the internet gateway. For a private subnet, create a route that routes all internet-bound IPv6 traffic</td>
</tr>
</tbody>
</table>
### Step 3: Update your security group rules (p. 344)
Update your security group rules to include rules for IPv6 addresses. This enables IPv6 traffic to flow to and from your instances. If you've created custom network ACL rules to control the flow of traffic to and from your subnet, you must include rules for IPv6 traffic.

### Step 4: Change your instance type (p. 345)
If your instance type does not support IPv6, change the instance type.

### Step 5: Assign IPv6 addresses to your instances (p. 346)
Assign IPv6 addresses to your instances from the IPv6 address range of your subnet.

### Step 6: (Optional) Configure IPv6 on your instances (p. 346)
If your instance was launched from an AMI that is not configured to use DHCPv6, you must manually configure your instance to recognize an IPv6 address assigned to the instance.

Before you migrate to using IPv6, ensure that you have read the features of IPv6 addressing for Amazon VPC: Compare IPv4 and IPv6 (p. 4).

**Contents**
- Example: Enable IPv6 in a VPC with a public and private subnet (p. 341)
- Step 1: Associate an IPv6 CIDR block with your VPC and subnets (p. 343)
- Step 2: Update your route tables (p. 344)
- Step 3: Update your security group rules (p. 344)
- Step 4: Change your instance type (p. 345)
- Step 5: Assign IPv6 addresses to your instances (p. 346)
- Step 6: (Optional) Configure IPv6 on your instances (p. 346)

**Example: Enable IPv6 in a VPC with a public and private subnet**

In this example, your VPC has a public and a private subnet. You have a database instance in your private subnet that has outbound communication with the internet through a NAT gateway in your VPC. You have a public-facing web server in your public subnet that has internet access through the internet gateway. The following diagram represents the architecture of your VPC.
The security group for your web server (for example with the security group ID sg-11aa22bb11aa22bb1) has the following inbound rules:

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>All traffic</td>
<td>All</td>
<td>All</td>
<td>sg-33cc44dd33cc44dd3</td>
<td>Allows inbound access for all traffic from instances associated with sg-33cc44dd33cc44dd3 (the database instance).</td>
</tr>
<tr>
<td>HTTP</td>
<td>TCP</td>
<td>80</td>
<td>0.0.0.0/0</td>
<td>Allows inbound traffic from the internet over HTTP.</td>
</tr>
<tr>
<td>HTTPS</td>
<td>TCP</td>
<td>443</td>
<td>0.0.0.0/0</td>
<td>Allows inbound traffic from the internet over HTTPS.</td>
</tr>
</tbody>
</table>
The security group for your database instance (for example with the security group ID sg-33cc44dd33cc44dd3) has the following inbound rule:

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL</td>
<td>TCP</td>
<td>3306</td>
<td>sg-11aa22bb11aa22bb1</td>
<td>Allows inbound access for MySQL traffic from instances associated with sg-11aa22bb11aa22bb1 (the web server instance).</td>
</tr>
</tbody>
</table>

Both security groups have the default outbound rule that allows all outbound IPv4 traffic, and no other outbound rules.

Your web server is t2.medium instance type. Your database server is an m3.large.

You want your VPC and resources to be enabled for IPv6, and you want them to operate in dual-stack mode; in other words, you want to use both IPv6 and IPv4 addressing between resources in your VPC and resources over the internet.

**Step 1: Associate an IPv6 CIDR block with your VPC and subnets**

You can associate an IPv6 CIDR block with your VPC, and then associate a /64 CIDR block from that range with each subnet.

**To associate an IPv6 CIDR block with a VPC**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Your VPCs**.
3. Select your VPC, choose **Actions, Edit CIDRs**.
4. Choose **Add IPv6 CIDR**, choose one of the following options, and then choose **Select CIDR**:
   - **Amazon-provided IPv6 CIDR block**: Requests an IPv6 CIDR block from Amazon’s pool of IPv6 addresses. For **Network Border Group**, select the group from which AWS advertises IP addresses.
   - **IPv6 CIDR owned by me: (BYOIP)** Allocates an IPv6 CIDR block from your IPv6 address pool. For **Pool**, choose the IPv6 address pool from which to allocate the IPv6 CIDR block.
To associate an IPv6 CIDR block with a subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select your subnet, choose Subnet Actions, Edit IPv6 CIDRs.
4. Choose Add IPv6 CIDR. Specify the hexadecimal pair for the subnet (for example, 00) and confirm the entry by choosing the tick icon.
5. Choose Close. Repeat the steps for the other subnets in your VPC.

For more information, see IPv6 VPC CIDR blocks (p. 18).

Step 2: Update your route tables

For a public subnet, you must update the route table to enable instances (such as web servers) to use the internet gateway for IPv6 traffic.

For a private subnet, you must update the route table to enable instances (such as database instances) to use an egress-only internet gateway for IPv6 traffic.

To update your route table for a public subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Route Tables and select the route table that's associated with the public subnet.
3. On the Routes tab, choose Edit routes.
4. Choose Add route. Specify ::/0 for Destination, select the ID of the internet gateway for Target, and then choose Save changes.

To update your route table for a private subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. If you're using a NAT device in your private subnet, it does not support IPv6 traffic. Instead, create an egress-only internet gateway for your private subnet to enable outbound communication to the internet over IPv6 and prevent inbound communication. An egress-only internet gateway supports IPv6 traffic only. For more information, see Enable outbound IPv6 traffic using an egress-only internet gateway (p. 139).
3. In the navigation pane, choose Route Tables and select the route table that's associated with the private subnet.
4. On the Routes tab, choose Edit routes.
5. Choose Add route. For Destination, specify ::/0. For Target, select the ID of the egress-only internet gateway, and then choose Save changes.

For more information, see Example routing options (p. 84).

Step 3: Update your security group rules

To enable your instances to send and receive traffic over IPv6, you must update your security group rules to include rules for IPv6 addresses.

For example, in the example above, you can update the web server security group (sg-11aa22bb11aa22bb1) to add rules that allow inbound HTTP, HTTPS, and SSH access from IPv6 addresses. You do not need to make any changes to the inbound rules for your database security group;
the rule that allows all communication from sg-11aa22bb11aa22bb1 includes IPv6 communication by default.

To update your security group rules

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups and select your web server security group.
3. In the Inbound Rules tab, choose Edit.
4. For each rule, choose Add another rule, and choose Save when you're done. For example, to add a rule that allows all HTTP traffic over IPv6, for Type, select HTTP and for Source, enter ::/0.

By default, an outbound rule that allows all IPv6 traffic is automatically added to your security groups when you associate an IPv6 CIDR block with your VPC. However, if you modified the original outbound rules for your security group, this rule is not automatically added, and you must add equivalent outbound rules for IPv6 traffic. For more information, see Control traffic to resources using security groups (p. 245).

Update your network ACL rules

If you associate an IPv6 CIDR block with your VPC, we automatically add rules to the default network ACL to allow IPv6 traffic, provided you haven’t modified its default rules. If you’ve modified your default network ACL or if you’ve created a custom network ACL with rules to control the flow of traffic to and from your subnet, you must manually add rules for IPv6 traffic. For more information, see Control traffic to subnets using Network ACLs (p. 108).

Step 4: Change your instance type

All current generation instance types support IPv6. For more information, see Instance types.

If your instance type does not support IPv6, you must resize the instance to a supported instance type. In the example above, the database instance is an m3.1large instance type, which does not support IPv6. You must resize the instance to a supported instance type, for example, m4.1large.

To resize your instance, be aware of the compatibility limitations. For more information, see Compatibility for resizing instances in the Amazon EC2 User Guide for Linux Instances. In this scenario, if your database instance was launched from an AMI that uses HVM virtualization, you can resize it to an m4.1large instance type by using the following procedure.

Important
To resize your instance, you must stop it. Stopping and starting an instance changes the public IPv4 address for the instance, if it has one. If you have any data stored on instance store volumes, the data is erased.

To resize your instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select the database instance.
3. Choose Actions, Instance State, Stop.
4. In the confirmation dialog box, choose Yes, Stop.
5. With the instance still selected, choose Actions, Instance Settings, Change Instance Type.
6. For Instance Type, choose the new instance type, and then choose Apply.
7. To restart the stopped instance, select the instance and choose Actions, Instance State, Start. In the confirmation dialog box, choose Yes, Start.

If your instance is an instance store-backed AMI, you can't resize your instance using the earlier procedure. Instead, you can create an instance store-backed AMI from your instance, and launch a new
instance from your AMI using a new instance type. For more information, see Creating an instance store-backed Linux AMI in the Amazon EC2 User Guide for Linux Instances, and Creating an instance store-backed Windows AMI in the Amazon EC2 User Guide for Windows Instances.

You may not be able to migrate to a new instance type if there are compatibility limitations. For example, if your instance was launched from an AMI that uses PV virtualization, the only instance type that supports both PV virtualization and IPv6 is C3. This instance type may not be suitable for your needs. In this case, you may have to reinstall your software on a base HVM AMI, and launch a new instance.

If you launch an instance from a new AMI, you can assign an IPv6 address to your instance during launch.

Step 5: Assign IPv6 addresses to your instances

After you've verified that your instance type supports IPv6, you can assign an IPv6 address to your instance using the Amazon EC2 console. The IPv6 address is assigned to the primary network interface (eth0) for the instance.

To assign an IPv6 address to your instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance, and choose Actions, Networking, Manage IP Addresses.
4. Under IPv6 Addresses, choose Assign new IP. You can enter a specific IPv6 address from the range of your subnet, or you can leave the default Auto-Assign value to let Amazon choose one for you.
5. Choose Yes, Update.

Alternatively, if you launch a new instance (for example, if you were unable to change the instance type and you created a new AMI instead), you can assign an IPv6 address during launch.

To assign an IPv6 address to an instance during launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Select your AMI and an IPv6-compatible instance type, and choose Next: Configure Instance Details.
4. Follow the remaining steps in the wizard to launch your instance.

You can connect to an instance using its IPv6 address. If you're connecting from a local computer, ensure that your local computer has an IPv6 address and is configured to use IPv6. For more information, see Connect to Your Linux Instance in the Amazon EC2 User Guide for Linux Instances and Connecting to Your Windows Instance in the Amazon EC2 User Guide for Windows Instances.

Step 6: (Optional) Configure IPv6 on your instances

If you launched your instance using Amazon Linux 2016.09.0 or later, Windows Server 2008 R2 or later, or Ubuntu Server 2018 or later, your instance is configured for IPv6 and no additional steps are required.

If you launched your instance from a different AMI, it might not be configured for IPv6 and DHCPv6, which means that any IPv6 address that you assign to the instance is not automatically recognized on the primary network interface.

To verify DHCPv6 on Linux

Use the ping6 command as follows.
$ ping6 ipv6.google.com

To verify DHCPv6 on Windows

Use the ping command as follows.

C:\> ping -6 ipv6.google.com

If your instance is not configured already, you can configure it manually, as shown in the following procedures.

Manual configuration, by operating system

- Amazon Linux (p. 347)
- Ubuntu (p. 348)
- RHEL/CentOS (p. 350)
- Windows (p. 351)

Amazon Linux

To configure your Amazon Linux instance

1. Connect to your instance using the instance's public IPv4 address.
2. Get the latest software packages for your instance:

   ```
sudo yum update -y
   ```
3. Using a text editor of your choice, open `/etc/sysconfig/network-scripts/ifcfg-eth0` and locate the following line:

   ```
   IPV6INIT=no
   ```
   Replace that line with the following:

   ```
   IPV6INIT=yes
   ```
   Add the following two lines, and save your changes:

   ```
   DHCPV6C=yes
   DHCPV6C_OPTIONS=-nw
   ```
4. Open `/etc/sysconfig/network`, remove the following lines, and save your changes:

   ```
   NETWORKING_IPV6=no
   IPV6INIT=no
   IPV6_ROUTER=no
   IPV6_AUTOCONF=no
   IPV6FORWARDING=no
   IPV6TO4INIT=no
   IPV6_CONTROL_RADVD=no
   ```
5. Open `/etc/hosts`, replace the contents with the following, and save your changes:

   ```
   127.0.0.1 localhost localhost.localdomain localhost4 localhost6.localdomain4
   ```
6. Reboot your instance. Reconnect to your instance and use the `ifconfig` command to verify that the IPv6 address is recognized on the primary network interface.

### Ubuntu

You can configure your Ubuntu instance to dynamically recognize any IPv6 address assigned to the network interface. If your instance does not have an IPv6 address, this configuration may cause the boot time of your instance to be extended by up to 5 minutes.

**Contents**

- Ubuntu Server 16 (p. 348)
- Ubuntu Server 14 (p. 349)
- Start the DHCPv6 client (p. 349)

#### Ubuntu Server 16

These steps must be performed as the root user.

**To configure an Ubuntu Server 16 instance**

1. Connect to your instance using the instance's public IPv4 address.
2. View the contents of the `/etc/network/interfaces.d/50-cloud-init.cfg` file:
   ```bash
   cat /etc/network/interfaces.d/50-cloud-init.cfg
   ```

   ```
   # This file is generated from information provided by
   # the datasource. Changes to it will not persist across an instance.
   # To disable cloud-init's network configuration capabilities, write a file
   # /etc/cloud/cloud.cfg.d/99-disable-network-config.cfg with the following:
   # network: {config: disabled}
   auto lo
   iface lo inet loopback
   auto eth0
   iface eth0 inet dhcp
   ```

   Verify that the loopback network device (`lo`) is configured, and take note of the name of the network interface. In this example, the network interface name is `eth0`; the name may be different depending on the instance type.

3. Create the file `/etc/network/interfaces.d/60-default-with-ipv6.cfg` and add the following line. If required, replace `eth0` with the name of the network interface that you retrieved in the step above.
   ```bash
   iface eth0 inet6 dhcp
   ```

4. Reboot your instance, or restart the network interface by running the following command. If required, replace `eth0` with the name of your network interface.
   ```bash
   sudo ifdown eth0 ; sudo ifup eth0
   ```

5. Reconnect to your instance and use the `ifconfig` command to verify that the IPv6 address is configured on the network interface.
To configure IPv6 using user data

- You can launch a new Ubuntu instance and ensure that any IPv6 address assigned to the instance is automatically configured on the network interface by specifying the following user data during launch:

```bash
#!/bin/bash
echo "iface eth0 inet6 dhcp" >> /etc/network/interfaces.d/60-default-with-ipv6.cfg
dhcclient -6
```

In this case, you do not have to connect to the instance to configure the IPv6 address.

For more information, see Running Commands on Your Linux Instance at Launch in the Amazon EC2 User Guide for Linux Instances.

Ubuntu Server 14

If you're using Ubuntu Server 14, you must include a workaround for a known issue that occurs when restarting a dual-stack network interface (the restart results in an extended timeout during which your instance is unreachable).

These steps must be performed as the root user.

To configure an Ubuntu Server 14 instance

1. Connect to your instance using the instance's public IPv4 address.
2. Edit the `/etc/network/interfaces.d/eth0.cfg` file so that it contains the following:

   ```
   auto lo
   iface lo inet loopback
   auto eth0
   iface eth0 inet dhcp
   up dhclient -6 $IFACE
   ```

3. Reboot your instance:

   ```
sudo reboot
   ```

4. Reconnect to your instance and use the `ifconfig` command to verify that the IPv6 address is configured on the network interface.

Start the DHCPv6 client

Alternatively, to bring up the IPv6 address for the network interface immediately without performing any additional configuration, you can start the DHCPv6 client for the instance. However, the IPv6 address does not persist on the network interface after reboot.

To start the DHCPv6 client on Ubuntu

1. Connect to your instance using the instance's public IPv4 address.
2. Start the DHCPv6 client:

   ```
sudo dhclient -6
   ```

3. Use the `ifconfig` command to verify that the IPv6 address is recognized on the primary network interface.
RHEL/CentOS

RHEL 7.4 and CentOS 7 and later use cloud-init to configure your network interface and generate the /etc/sysconfig/network-scripts/ifcfg-eth0 file. You can create a custom cloud-init configuration file to enable DHCPv6, which generates an ifcfg-eth0 file with settings that enable DHCPv6 after each reboot.

**Note**
Due to a known issue, if you're using RHEL/CentOS 7.4 with the latest version of cloud-init-0.7.9, these steps might result in you losing connectivity to your instance after reboot. As a workaround, you can manually edit the /etc/sysconfig/network-scripts/ifcfg-eth0 file.

**To configure a RHEL/CentOS instance using cloud-init**

1. Connect to your instance using the instance's public IPv4 address.
2. Using a text editor of your choice, create a custom file, for example:

   ```
   /etc/cloud/cloud.cfg.d/99-custom-networking.cfg
   ```

3. Add the following lines to your file, and save your changes:

   ```
   network:
       version: 1
       config:
           - type: physical
             name: eth0
             subnets:
                 - type: dhcp
                 - type: dhcp6
   ```

4. Using a text editor of your choice, add the following line to the interface-specific file under /etc/sysctl.d. If you disabled Consistent Network Device Naming, the network-interface-name is ethX or the secondary interface.

   ```
   net.ipv6.conf.network-interface-name.accept_ra=1
   ```

   In the following example, the network interface is en5.

   ```
   net.ipv6.conf.en5.accept_ra=1
   ```

5. Reboot your instance.
6. Reconnect to your instance and use the `ifconfig` command to verify that the IPv6 address is configured on the network interface.

Alternatively, you can use the following procedure to modify the /etc/sysconfig/network-scripts/ifcfg-eth0 file directly. You must use this method with earlier version of RHEL and CentOS that don't support cloud-init.

**To configure a RHEL/CentOS instance**

1. Connect to your instance using the instance's public IPv4 address.
2. Using a text editor of your choice, open /etc/sysconfig/network-scripts/ifcfg-eth0 and locate the following line:

   ```
   IPV6INIT="no"
   ```
Replace that line with the following:

```
IPV6INIT="yes"
```

Add the following two lines, and save your changes:

```
DHCPV6C=yes
NM_CONTROLLED=no
```

3. Open `/etc/sysconfig/network`, add or amend the following line as follows, and save your changes:

```
NETWORKING_IPV6=yes
```

4. Restart networking on your instance by running the following command:

```
sudo service network restart
```

You can use the `ifconfig` command to verify that the IPv6 address is recognized on the primary network interface.

**To troubleshoot RHEL 6 or CentOS 6**

If you restart networking and you get an error that an IPv6 address cannot be obtained, open `/etc/sysconfig/network-scripts/ifup-eth` and locate the following line (by default, it's line 327):

```
if /sbin/dhclient "$DHCLIENTARGS"; then
```

Remove the quotes that surround `$DHCLIENTARGS` and save your changes. Restart networking on your instance:

```
sudo service network restart
```

**Windows**

Use the following procedures to configure IPv6 on Windows Server 2003 and Windows Server 2008 SP2.

To ensure that IPv6 is preferred over IPv4, download the fix named [Prefer IPv6 over IPv4 in prefix policies](https://support.microsoft.com/en-us/help/929852/how-to-disable-ipv6-or-its-components-in-windows) from the following Microsoft support page:

**To enable and configure IPv6 on Windows Server 2003**

1. Get the IPv6 address of your instance by using the `describe-instances` AWS CLI command, or by checking the IPv6 IPs field for the instance in the Amazon EC2 console.
2. Connect to your instance using the instance's public IPv4 address.
3. From within your instance, choose **Start**, **Control Panel**, **Network Connections**, **Local Area Connection**.
4. Choose **Properties**, and then choose **Install**.
5. Choose **Protocol**, and choose **Add**. In the **Network Protocol** list, choose **Microsoft TCP/IP version 6**, and then choose **OK**.
6. Open the command prompt and open the network shell.
Migrate existing VPCs from IPv4 to IPv6

1. Get the IPv6 address of your instance by using the describe-instances AWS CLI command, or by checking the IPv6 IPs field for the instance in the Amazon EC2 console.
2. Connect to your Windows instance using the instance's public IPv4 address.
3. Choose Start, Control Panel.
4. Open the Network and Sharing Center, then open Network Connections.
5. Right-click Local Area Network (for the network interface) and choose Properties.
6. Choose the Internet Protocol Version 6 (TCP/IPv6) check box, and choose OK.
7. Open the properties dialog box for Local Area Network again. Choose Internet Protocol Version 6 (TCP/IPv6) and choose Properties.
8. Choose Use the following IPv6 address and do the following:
   • For IPv6 Address, enter the IPv6 address you obtained in step 1.
   • For Subnet prefix length, enter 64.
9. Choose OK and close the properties dialog box.
10. Open the command prompt. Use the ipconfig command to verify that the IPv6 address is recognized for the Local Area Connection.
Amazon VPC quotas

The following tables list the quotas, formerly referred to as limits, for Amazon VPC resources per Region for your AWS account. Unless indicated otherwise, you can request an increase for these quotas. For some of these quotas, you can view your current quota using the Limits page of the Amazon EC2 console.

If you request a quota increase that applies per resource, we increase the quota for all resources in the Region.

VPC and subnets

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>

<td>Yes</td>
<td></td>
</tr>
<tr>
<td>IPv4 CIDR blocks per VPC</td>
<td>5</td>
<td>Yes</td>
<td>This primary CIDR block and all secondary CIDR blocks count toward this quota. (up to 50)</td>
</tr>
<tr>
<td>IPv6 CIDR blocks per VPC</td>
<td>5</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

DNS

Each EC2 instance can send 1024 packets per second per network interface to Route 53 Resolver (specifically the .2 address, such as 10.0.0.2 and 169.254.169.253). This quota cannot be increased. The number of DNS queries per second supported by Route 53 Resolver varies by the type of query, the size of the response, and the protocol in use. For more information and recommendations for a scalable DNS architecture, see the AWS Hybrid DNS with Active Directory Technical Guide.

Elastic IP addresses (IPv4)

<tr>
<td>Carrier gateways per VPC</td>
<td>1</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

Customer-managed prefix lists

**Note**
While the default quotas for customer-managed prefix lists are adjustable, you cannot adjust the quotas using the Service Quotas console. You must contact the AWS Support Center as described in [AWS service quotas](https://docs.aws.amazon.com/quotas/latest/sg.html) in the [AWS General Reference](https://docs.aws.amazon.com/.general/latest/gr/aws-General-Reference.html).

<table>
<thead>
<tr>

</tr>
<tr>
<td>VPC endpoint policy size</td>
<td>20,480 characters</td>
<td>No</td>
<td>This quota includes white space.</td>
</tr>
</tbody>
</table>

The following maximum transmission unit (MTU) rules apply to traffic that passes through a VPC endpoint.

- The maximum transmission unit (MTU) of a network connection is the size, in bytes, of the largest permissible packet that can be passed through the VPC endpoint. The larger the MTU, the more data that can be passed in a single packet. A VPC endpoint supports an MTU of 8500 bytes.
- Packets with a size larger than 8500 bytes that arrive at the VPC endpoint are dropped.
- The VPC endpoint does not generate the FRAG_NEEDEDICMP packet, so Path MTU Discovery (PMTUD) is not supported.
- The VPC endpoint enforces Maximum Segment Size (MSS) clamping for all packets. For more information, see RFC879.

VPC sharing

All standard VPC quotas apply to a shared VPC.

To increase these quota, contact AWS Support. AWS recommends that you paginate your DescribeSecurityGroups and DescribeSubnets API calls before requesting an increase.
Network Address Usage

Network Address Usage (NAU) is comprised of IP addresses, network interfaces, and CIDRs in managed prefix lists. NAU is a metric applied to resources in a VPC to help you plan for and monitor the size of your VPC. For more information, see Network Address Usage (p. 42).

The resources that make up the NAU count have their own individual service quotas. Even if a VPC has NAU capacity available, you won’t be able to launch resources into the VPC if the resources have exceeded their service quotas.

Amazon EC2 API throttling

For information about Amazon EC2 throttling, see API Request Throttling in the Amazon EC2 API Reference.

Additional quota resources

For more information, see the following:

- Transit gateway quotas in Amazon VPC Transit Gateways
- AWS Client VPN quotas in the AWS Client VPN Administrator Guide
- Site-to-Site VPN quotas in the AWS Site-to-Site VPN User Guide
- AWS Direct Connect quotas in the AWS Direct Connect User Guide
## Document history

The following table describes the important changes in each release of the *Amazon VPC User Guide*.

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network Address Usage metrics</td>
<td>You can enable Network Address Usage metrics for your VPC to help you plan for and monitor the size of your VPC.</td>
<td>October 4, 2022</td>
</tr>
<tr>
<td>Publish Flow Logs to Amazon Kinesis Data Firehose</td>
<td>You can specify a Kinesis Data Firehose delivery stream as a destination for flow log data.</td>
<td>September 8, 2022</td>
</tr>
<tr>
<td>NAT gateway bandwidth</td>
<td>NAT gateways now support bandwidth up to 100 Gbps (an increase from 45 Gbps) and can process up to ten million packets per second (up from four million packets).</td>
<td>June 15, 2022</td>
</tr>
<tr>
<td>Multiple IPv6 CIDR blocks</td>
<td>You can associate up to five IPv6 CIDR blocks to a VPC.</td>
<td>May 12, 2022</td>
</tr>
<tr>
<td>Reorganization (p. 359)</td>
<td>General reorganization of this Amazon Virtual Private Cloud User Guide.</td>
<td>January 2, 2022</td>
</tr>
<tr>
<td>NAT gateway IPv6 to IPv4</td>
<td>NAT gateway supports network address translation from IPv6 to IPv4, popularly known as NAT64.</td>
<td>November 24, 2021</td>
</tr>
<tr>
<td>IPv6-only subnets in VPCs</td>
<td>You can create IPv6-only subnets into which you can launch IPv6-only EC2 instances.</td>
<td>November 23, 2021</td>
</tr>
<tr>
<td>VPC Flow Logs delivery options to Amazon S3</td>
<td>You can specify the Apache Parquet log file format, hourly partitions, and Hive-compatible S3 prefixes.</td>
<td>October 13, 2021</td>
</tr>
<tr>
<td>Amazon EC2 Global View</td>
<td>Amazon EC2 Global View enables you to view VPCs, subnets, instances, security groups, and volumes across multiple AWS Regions in a single console.</td>
<td>September 1, 2021</td>
</tr>
<tr>
<td>More specific routes (p. 359)</td>
<td>You can add a route to your route tables that is more specific than the local route. You can use more specific routes to redirect traffic between subnets within a VPC (East-West traffic) to a middlebox appliance. You can</td>

<tr>
<td>Resource IDs and tagging support for security group rules (p. 359)</td>
<td>You can refer to security group rules by resource ID. You can also add tags to your security group rules.</td>
<td>July 7, 2021</td>
</tr>
<tr>
<td>Private NAT gateways</td>
<td>You can use a private NAT gateway for outbound-only private communication between VPCs or between a VPC and your on-premises network.</td>
<td>June 10, 2021</td>
</tr>
<tr>
<td>Carrier gateways</td>
<td>You can create carrier gateways to allow inbound traffic from a carrier network in a specific location, and to allow outbound traffic to the carrier network and internet.</td>
<td>August 6, 2020</td>
</tr>
<tr>
<td>Tag on create (p. 359)</td>
<td>You can add tags when you create a VPC, DHCP options, internet gateway, egress-only gateway, network ACL, and security group.</td>
<td>June 30, 2020</td>
</tr>
<tr>
<td>Managed prefix lists</td>
<td>You can create and manage a set of CIDR blocks in prefix list.</td>
<td>June 29, 2020</td>
</tr>
<tr>
<td>Flow logs enhancements</td>
<td>New flow log fields are available, and you can specify a custom format for flow logs that publish to CloudWatch Logs.</td>
<td>May 4, 2020</td>
</tr>
<tr>
<td>Tagging support for flow logs</td>
<td>You can add tags to your flow logs.</td>
<td>March 16, 2020</td>
</tr>
<tr>
<td>Tag on NAT gateway creation</td>
<td>You can add a tag when you create a NAT gateway.</td>
<td>March 9, 2020</td>
</tr>
<tr>
<td>Maximum aggregation interval for flow logs</td>
<td>You can specify the maximum period of time during which a flow is captured and aggregated into a flow log record.</td>
<td>February 4, 2020</td>
</tr>
<tr>
<td>Network border group configuration</td>
<td>You can configure network border groups for your VPCs from the Amazon Virtual Private Cloud Console.</td>
<td>January 22, 2020</td>
</tr>
<tr>
<td>Private DNS name</td>
<td>You can access AWS PrivateLink based services privately from within your VPC using Private DNS names.</td>
<td>January 6, 2020</td>
</tr>
