What are AWS WAF, AWS Shield, and AWS Firewall Manager?

AWS WAF is a web application firewall that lets you monitor the HTTP and HTTPS requests that are forwarded to your protected web application resources. You can protect the following resource types:

- Amazon CloudFront distribution
- Amazon API Gateway REST API
- Application Load Balancer
- AWS AppSync GraphQL API
- Amazon Cognito user pool

AWS WAF also lets you control access to your content. Based on conditions that you specify, such as the IP addresses that requests originate from or the values of query strings, your protected resource responds to requests either with the requested content, with an HTTP 403 status code (Forbidden), or with a custom response.

At the simplest level, AWS WAF lets you choose one of the following behaviors:

- **Allow all requests except the ones that you specify** – This is useful when you want Amazon CloudFront, Amazon API Gateway, Application Load Balancer, AWS AppSync, or Amazon Cognito to serve content for a public website, but you also want to block requests from attackers.
- **Block all requests except the ones that you specify** – This is useful when you want to serve content for a restricted website whose users are readily identifiable by properties in web requests, such as the IP addresses that they use to browse to the website.
- **Count requests that match your criteria** – You can use the Count action to track your web traffic without modifying how you handle it. You can use this for general monitoring and also to test your new web request handling rules. When you want to allow or block requests based on new properties in the web requests, you can first configure AWS WAF to count the requests that match those properties. This lets you confirm your new configuration settings before you switch your rules to allow or block matching requests.
- **Run CAPTCHA or challenge checks against requests that match your criteria** – You can implement CAPTCHA and silent challenge controls against requests to help reduce bot traffic to your protected resources.

Using AWS WAF has several benefits:

- Additional protection against web attacks using criteria that you specify. You can define criteria using characteristics of web requests such as the following:
  - IP addresses that requests originate from.
  - Country that requests originate from.
  - Values in request headers.
  - Strings that appear in requests, either specific strings or strings that match regular expression (regex) patterns.
  - Length of requests.
  - Presence of SQL code that is likely to be malicious (known as SQL injection).
  - Presence of a script that is likely to be malicious (known as cross-site scripting).
AWS Shield

You can use AWS WAF web access control lists (web ACLs) to help minimize the effects of a Distributed Denial of Service (DDoS) attack. For additional protection against DDoS attacks, AWS also provides AWS Shield Standard and AWS Shield Advanced. AWS Shield Standard is automatically included at no extra cost beyond what you already pay for AWS WAF and your other AWS services. AWS Shield Advanced provides expanded DDoS attack protection for your Amazon EC2 instances, Elastic Load Balancing load balancers, CloudFront distributions, Route 53 hosted zones, and AWS Global Accelerator standard accelerators. AWS Shield Advanced incurs additional charges.

For more information about AWS Shield Standard and AWS Shield Advanced, see AWS Shield (p. 460).

AWS Firewall Manager

AWS Firewall Manager simplifies your administration and maintenance tasks across multiple accounts and resources for a variety of protections, including AWS WAF, AWS Shield Advanced, Amazon VPC security groups, AWS Network Firewall, and Amazon Route 53 Resolver DNS Firewall. With Firewall Manager, you set up your protections just once and the service automatically applies them across your accounts and resources, even as you add new accounts and resources.

For more information about Firewall Manager, see AWS Firewall Manager (p. 358).

Which should I choose?

You can use AWS WAF (p. 6), AWS Firewall Manager (p. 358), and AWS Shield (p. 460) together to create a comprehensive security solution.

It all starts with AWS WAF. You can automate and then simplify AWS WAF management using AWS Firewall Manager. Shield Advanced adds additional features on top of AWS WAF, such as dedicated support from the Shield Response Team (SRT) and advanced reporting.

If you want granular control over the protection that is added to your resources, AWS WAF alone is the right choice. If you want to use AWS WAF across accounts, accelerate your AWS WAF configuration, or automate protection of new resources, use Firewall Manager with AWS WAF.

Finally, if you own high visibility websites or are otherwise prone to frequent DDoS attacks, you should consider purchasing the additional features that Shield Advanced provides.

Note

To use the services of the SRT, you must be subscribed to the Business Support plan or the Enterprise Support plan.
Setting up

This topic describes preliminary steps, such as creating an AWS account, to prepare you to use AWS WAF, AWS Firewall Manager, and AWS Shield Advanced. You are not charged to set up this account and other preliminary items. You are charged only for AWS services that you use.

After you complete these steps, see Getting started with AWS WAF (p. 8) to continue getting started with AWS WAF.

Note
AWS Shield Standard is included with AWS WAF and does not require additional setup. For more information, see How AWS Shield works (p. 461).

Before you use AWS WAF or AWS Shield Advanced for the first time, complete the following tasks:

- Step 1: Sign up for an AWS account (p. 3)
- Step 2: Create an IAM user (p. 3)
- Step 3: Download tools (p. 5)

Step 1: Sign up for an AWS account

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all services in AWS, including AWS WAF. You are charged only for the services that you use.

If you have an AWS account already, skip to the next task. If you don't have an AWS account, use the following procedure to create one.

To sign up for AWS

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

Note your AWS account number, because you'll need it for the next task.

Step 2: Create an IAM user

To use the AWS WAF console, you must sign in to confirm that you have permission to perform AWS WAF operations. You can use the root credentials for your AWS account, but we don't recommend it. For greater security and control of your account, we recommend that you use AWS Identity and Access Management (IAM) to do the following:

- Create an IAM user account for yourself or your business.
• Either add the IAM user account to an IAM group that has administrative permissions, or grant administrative permissions directly to the IAM user account.
• Verify that the account has full access to AWS WAF and related services, for general use and for console access. For information, see AWS managed (predefined) policies for AWS WAF (p. 230).

You then can sign in to the AWS WAF console (and other service consoles) by using a special URL and the credentials for the IAM user. You also can add other users to the IAM user account, and control their level of access to AWS services and to your resources.

**Note**
For information about creating access keys to access AWS WAF by using the AWS Command Line Interface (AWS CLI), Tools for Windows PowerShell, the AWS SDKs, or the AWS WAF API, see Managing Access Keys for IAM Users.

If you signed up for AWS but have not created an IAM user for yourself, you can create one using the IAM console. If you aren't familiar with using the console, see Working with the AWS Management Console for an overview.

To create an administrator user, choose one of the following options.

<table>
<thead>
<tr>
<th>Choose one way to manage your administra</th>
<th>To</th>
<th>By</th>
<th>You can also</th>
</tr>
</thead>
<tbody>
<tr>
<td>In IAM Identity Center (Recommended)</td>
<td>Use short-term credentials to access AWS.</td>
<td>Following the instructions in Getting started in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.</td>
<td>Configure programmatic access by Configuring the AWS CLI to use AWS IAM Identity Center (successor to AWS Single Sign-On) in the AWS Command Line Interface User Guide.</td>
</tr>
<tr>
<td>In IAM Identity Center (Not recommended)</td>
<td>Use long-term credentials to access AWS.</td>
<td>Following the instructions in Creating your first IAM admin user and user group in the IAM User Guide.</td>
<td>Configure programmatic access by Managing access keys for IAM users in the IAM User Guide.</td>
</tr>
</tbody>
</table>

To sign in as this new IAM user, first sign out of the AWS Management Console. Then use the following URL, where `your_aws_account_id` is your AWS account number without the hyphens. For example, if your AWS account number is 1234-5678-9012, your AWS account ID is 123456789012:

https://your_aws_account_id.signin.aws.amazon.com/console/

Enter the IAM user name and password that you just created. When you’re signed in, the navigation bar displays “your_user_name @ your_aws_account_id”.

If you don’t want the URL for your sign-in page to contain your AWS account ID, you can create an account alias. From the IAM dashboard, choose Customize and enter an alias, such as your company name. To sign in after you create an account alias, use the following URL:
To verify the sign-in link for IAM users for your account, open the IAM console and check under the IAM users sign-in link on the dashboard.

After you complete these steps, you can stop here and go to Getting started with AWS WAF (p. 8) to continue getting started with AWS WAF using the console. If you want to access AWS WAF programmatically using the AWS WAF API, continue on to the next step, Step 3: Download tools (p. 5).

Step 3: Download tools

The AWS Management Console includes a console for AWS WAF, but if you want to access AWS WAF programmatically, the following documentation and tools will help you:

- If you want to call the AWS WAF API without having to handle low-level details like assembling raw HTTP requests, you can use an AWS SDK. The AWS SDKs provide functions and data types that encapsulate the functionality of AWS WAF and other AWS services. To download an AWS SDK, see the applicable page, which also includes prerequisites and installation instructions:
  - Java
  - JavaScript
  - .NET
  - Node.js
  - PHP
  - Python
  - Ruby

For a complete list of AWS SDKs, see Tools for Amazon Web Services.

- If you’re using a programming language for which AWS doesn’t provide an SDK, the AWS WAF API Reference documents the operations that AWS WAF supports.

- The AWS Command Line Interface (AWS CLI) supports AWS WAF. The AWS CLI lets you control multiple AWS services from the command line and automate them through scripts. For more information, see AWS Command Line Interface.

- AWS Tools for Windows PowerShell supports AWS WAF. For more information, see AWS Tools for PowerShell Cmdlet Reference.
AWS WAF

AWS WAF is a web application firewall that lets you monitor the HTTP(S) requests that are forwarded to your protected web application resources. You can protect the following resource types:

- Amazon CloudFront distribution
- Amazon API Gateway REST API
- Application Load Balancer
- AWS AppSync GraphQL API
- Amazon Cognito user pool

AWS WAF also lets you control access to your content. Based on criteria that you specify, such as the IP addresses that requests originate from or the values of query strings, the service associated with your protected resource responds to requests either with the requested content, with an HTTP 403 status code (Forbidden), or with a custom response.

Note
You can also use AWS WAF to protect your applications that are hosted in Amazon Elastic Container Service (Amazon ECS) containers. Amazon ECS is a highly scalable, fast container management service that makes it easy to run, stop, and manage Docker containers on a cluster. To use this option, you configure Amazon ECS to use an Application Load Balancer that is enabled for AWS WAF to route and protect HTTP(S) layer 7 traffic across the tasks in your service. For more information, see Service Load Balancing in the Amazon Elastic Container Service Developer Guide.

How AWS WAF works

You use AWS WAF to control how your protected resources respond to HTTP(S) web requests. You do this by defining a web access control list (ACL) and then associating it with one or more web application resources that you want to protect.
AWS WAF components

The following are the central components of AWS WAF:

- **Web ACLs** – You use a web access control list (ACL) to protect a set of AWS resources. You create a web ACL and define its protection strategy by adding rules. Rules define criteria for inspecting web requests and they specify the action to take on requests that match their criteria. You also set a default action for the web ACL that indicates whether to block or allow through any requests that the rules haven't already blocked or allowed.

- **Rules** – Each rule contains a statement that defines the inspection criteria, and an action to take if a web request meets the criteria. When a web request meets the criteria, that's a match. You can configure rules to block matching requests, allow them through, count them, or run bot controls against them that use CAPTCHA puzzles or silent client browser challenges.

- **Rules groups** – You can use rules individually or in reusable rule groups. AWS Managed Rules and AWS Marketplace sellers provide managed rule groups for your use. You can also define your own rule groups.

AWS WAF Web ACL capacity units (WCU)

AWS WAF uses web ACL capacity units (WCU) to calculate and control the operating resources that are required to run your rules, rule groups, and web ACLs. AWS WAF enforces WCU limits when you configure your rule groups and web ACLs. WCUs don't affect how AWS WAF inspects web traffic.

AWS WAF calculates capacity differently for each rule type, to reflect each rule's relative cost. Simple rules that cost little to run use fewer WCUs than more complex rules that use more processing power. For example, a size constraint rule statement uses fewer WCUs than a statement that inspects against a regex pattern set.

AWS WAF manages capacity for rules, rule groups, and web ACLs:

- **Rule capacity** – AWS WAF calculates rule capacity when you create or update a rule. For some basic guidelines for rule capacity requirements, see the listings for the various rule statements at AWS WAF rule statements (p. 85). You can also get an idea of the capacity required for the various rule types in the AWS WAF console by creating a web ACL or rule group and adding individual rules to it. The console displays the capacity units used as you add the rules.

- **Rule group capacity** – AWS WAF requires that each rule group is assigned an immutable capacity at creation. This is true for managed rule groups and rule groups that you create through AWS WAF. When you modify a rule group, your changes must keep the rule group's WCU within its capacity. This ensures that web ACLs that are using the rule group remain within their maximum capacity.

- **Web ACL capacity** – The maximum capacity for a web ACL is 1,500, which is sufficient for most use cases. If you need more capacity, contact the AWS Support Center.

Resources that you can protect with AWS WAF

You can use an AWS WAF web ACL to protect global or regional resource types. You do this by associating the web ACL with the resources that you want to protect.

**Amazon CloudFront distribution**

You can associate an AWS WAF web ACL with a CloudFront distribution using the AWS WAF console or APIs. You can also associate a web ACL with a CloudFront distribution when you create or update the distribution itself. To configure an association in AWS CloudFormation, you must use the CloudFront
AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide
Getting started with AWS WAF

Getting started with AWS WAF

This tutorial shows how to use AWS WAF to perform the following tasks:

- Set up AWS WAF.
- Create a web access control list (web ACL) using the wizard in the AWS WAF console.
- Choose the AWS resources that you want AWS WAF to inspect web requests for. This tutorial covers the steps for Amazon CloudFront. The process is essentially the same for an Amazon API Gateway REST API, an Application Load Balancer, an AWS AppSync GraphQL API, or an Amazon Cognito user pool.
- Add the rules and rule groups that you want to use to filter web requests. For example, you can specify the IP addresses that the requests originate from and specify values in the request that are used only by attackers. For each rule, you specify how to handle matching web requests. You can do things like block or count them and you can run bot challenges like CAPTCHA. You define an action for each rule that you define inside a web ACL and for each rule that you define inside a rule group.
- Specify a default action for the web ACL, either Block or Allow. This is the action that AWS WAF takes on a request when the rules in the web ACL don't explicitly allow or block it.

Note
AWS typically bills you less than US $0.25 per day for the resources that you create during this tutorial. When you're finished with the tutorial, we recommend that you delete the resources to prevent incurring unnecessary charges.
Step 1: Set up AWS WAF

If you already signed up for an AWS account and created an IAM user as described in Setting up (p. 3), go to Step 2: Create a Web ACL (p. 9).

If not, go to Setting up (p. 3) and perform at least the first two steps. (You can skip downloading tools for now because this Getting Started topic focuses on using the AWS WAF console.)

Step 2: Create a Web ACL

The AWS WAF console guides you through the process of configuring AWS WAF to block or allow web requests based on criteria that you specify, such as the IP addresses that the requests originate from or values in the requests. In this step, you create a web ACL. For more information about AWS WAF web ACLs, see Web access control lists (web ACLs) (p. 12).

To create a web ACL

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. From the AWS WAF home page, choose Create web ACL.
3. For Name, enter the name that you want to use to identify this web ACL.
   
   Note
   You can't change the name after you create the web ACL.
4. (Optional) For Description - optional, enter a longer description for the web ACL if you want to.
5. For CloudWatch metric name, change the default name if applicable. Follow the guidance on the console for valid characters. The name can't contain special characters, white space, or metric names reserved for AWS WAF, including "All" and "Default_Action."
   
   Note
   You can't change the CloudWatch metric name after you create the web ACL.
6. For Resource type, choose CloudFront distributions. The Region automatically populates to Global (CloudFront) for CloudFront distributions.
7. (Optional) For Associated AWS resources - optional, choose Add AWS resources. In the dialog box, choose the resources that you want to associate, and then choose Add. AWS WAF returns you to the Describe web ACL and associated AWS resources page.
8. Choose Next.

Step 3: Add a string match rule

In this step, you create a rule with a string match statement and indicate what to do with matching requests. A string match rule statement identifies strings that you want AWS WAF to search for in a
request. Usually, a string consists of printable ASCII characters, but you can specify any character from hexadecimal 0x00 to 0xFF (decimal 0 to 255). In addition to specifying the string to search for, you specify the web request component that you want to search, such as a header, a query string, or the request body.

This statement type operates on a web request component, and requires the following request component settings:

- **Request components** – The part of the web request to inspect, for example, a query string or the body.

  **Warning**
  If you inspect the request components **Body**, **JSON body**, **Headers**, or **Cookies**, read about the limitations on how much content AWS WAF can inspect at [Oversize handling for request components](p. 113).

  For information about web request components, see [Web request components](p. 108).

- **Optional text transformations** – Transformations that you want AWS WAF to perform on the request component before inspecting it. For example, you could transform to lowercase or normalize white space. If you specify more than one transformation, AWS WAF processes them in the order listed. For information, see [Text transformations](p. 114).

  For additional information about AWS WAF rules, see [Rules](p. 83).

### To create a string match rule statement

1. On the **Add rules and rule groups** page, choose **Add rules**, **Add my own rules and rule groups**, **Rule builder**, then **Rule visual editor**.

   **Note**
   The console provides the **Rule visual editor** and also a **Rule JSON editor**. The JSON editor makes it easy for you to copy configurations between web ACLs and is required for more complex rule sets, like those with multiple levels of nesting. This procedure uses the **Rule visual editor**.

2. For **Name**, enter the name that you want to use to identify this rule.

3. For **Type** choose **Regular rule**.

4. For **If a request** choose **matches the statement**.

   The other options are for the logical rule statement types. You can use them to combine or negate the results of other rule statements.

5. On **Statement**, for **Inspect**, open the dropdown and choose the web request component that you want AWS WAF to inspect. For this example, choose **Header**.

   When you choose **Header**, you also specify which header you want AWS WAF to inspect. Enter **User-Agent**. This value isn’t case sensitive.

6. For **Match type** choose where the specified string must appear in the **User-Agent** header.

   For this example, choose **Exactly matches string**. This indicates that AWS WAF inspects the user-agent header in each web request for a string that is identical to the string that you specify.

7. For **String to match**, specify a string that you want AWS WAF to search for. The maximum length of **String to match** is 200 characters. If you want to specify a base64-encoded value, you can specify up to 200 characters before encoding.

   For this example, enter **MyAgent**. AWS WAF will inspect the **User-Agent** header in web requests for the value MyAgent.

8. Leave **Text transformation** set to **None**.
9. For **Action**, select the action that you want the rule to take when it matches a web request. For this example, choose **Count** and leave the other choices as they are. The count action creates metrics for web requests that match the rule, but doesn't affect whether the request is allowed or blocked. For more information about action choices, see *AWS WAF rule action* (p. 84) and *Web ACL rule and rule group evaluation* (p. 13).

10. Choose **Add rule**.

### Step 4: Add an AWS Managed Rules rule group

AWS Managed Rules offers a set of managed rule groups for your use, most of which are free of charge to AWS WAF customers. For more information about rule groups, see *Rule groups* (p. 25). We'll add an AWS Managed Rules rule group to this web ACL.

**To add an AWS Managed Rules rule group**

1. On the **Add rules and rule groups** page, choose **Add rules**, and then choose **Add managed rule groups**.

2. On the **Add managed rule groups** page, expand the listing for the **AWS managed rule groups**. (You'll also see listings offered for AWS Marketplace sellers. You can subscribe to their offerings and then use them in the same way as for AWS Managed Rules rule groups.)

3. For the rule group that you want to add, do the following:
   
   a. In the **Action** column, turn on the **Add to web ACL** toggle.
   
   b. Select **Edit** and, in the rule group's **Rules** listing, open the **Override all rule actions** dropdown and select **Count**. This sets the action for all rules in the rule group to count only. This allows you to see how all of the rules in the rule group behave with your web requests before you put any of them to use.

   c. Choose **Save rule**.

4. In the **Add managed rule groups** page, choose **Add rules**. This returns you to the **Add rules and rule groups** page.

### Step 5: Finish your web ACL configuration

When you're done adding rules and rule groups to your web ACL configuration, finish up by managing the priority of the rules in the web ACL and configuring settings like metrics, tagging, and logging.

**To finish your web ACL configuration**

1. On the **Add rules and rule groups** page, choose **Next**.

2. On the **Set rule priority** page, you can see the processing order for the rules and rule groups in the web ACL. AWS WAF processes them starting from the top of the list. You can change the processing order by moving the rules up or down. To do this, select one in the list and choose **Move up** or **Move down**. For more information about rule priority, see *Processing order of rules and rule groups in a web ACL* (p. 14).

3. Choose **Next**.

4. On the **Configure metrics** page, for **Amazon CloudWatch metrics**, you can see the planned metrics for your rules and rule groups and you can see the web request sampling options. For information about Amazon CloudWatch metrics, see *Monitoring with Amazon CloudWatch* (p. 541). For information about viewing sampled requests, see *Viewing a sample of web requests* (p. 219).

5. Choose **Next**.

6. On the **Review and create web ACL** page, review your settings, then choose **Create web ACL**.
Step 6: Clean up your resources

You've now successfully completed the tutorial. To prevent your account from accruing additional AWS WAF charges, clean up the AWS WAF objects that you created. Alternatively, you can change the configuration to match the web requests that you really want to manage using AWS WAF.

**Note**
AWS typically bills you less than US $0.25 per day for the resources that you create during this tutorial. When you're finished, we recommend that you delete the resources to prevent incurring unnecessary charges.

To delete the objects that AWS WAF charges for:

1. In the **Web ACL** page, select your web ACL from the list and choose **Edit**.
2. On the **Associated AWS resources** tab, for each associated resource, select the radio button next to the resource name and then choose **Disassociate**. This disassociates the web ACL from your AWS resources.
3. In each of the following screens, choose **Next** until you return to the **Web ACL** page.
   - In the **Web ACL** page, select your web ACL from the list and choose **Delete**.

Rules and rule statements don't exist outside of rule group and web ACL definitions. If you delete a web ACL, this deletes all individual rules that you've defined in the web ACL. When you remove a rule group from a web ACL, you just remove the reference to it.

Web access control lists (web ACLs)

A web access control list (web ACL) gives you fine-grained control over all of the HTTP(S) web requests that your protected resource responds to. You can protect Amazon CloudFront, Amazon API Gateway, Application Load Balancer, AWS AppSync, and Amazon Cognito resources.

You can use criteria like the following to allow or block requests:

- IP address origin of the request
- Country of origin of the request
- String match or regular expression (regex) match in a part of the request
- Size of a particular part of the request
- Detection of malicious SQL code or scripting

You can also test for any combination of these conditions. You can block or count web requests that not only meet the specified conditions, but also exceed a specified number of requests in any 5-minute period. You can combine conditions using logical operators. You can also run CAPTCHA puzzles and silent client session challenges against requests.

You provide your matching criteria and the action to take on matches in AWS WAF rule statements. You can define rule statements directly inside your web ACL and in reusable rule groups that you use in your web ACL. For a full list of the options, see [AWS WAF rule statements](p. 85) and [AWS WAF rule action](p. 84).

To specify your web request inspection and handling criteria, perform the following tasks:
1. Choose the web ACL default action, either Allow or Block, for web requests that don't match any of the rules that you specify. For more information, see Deciding on the default action for a web ACL (p. 16).

2. Add any rule groups that you want to use in your web ACL. Managed rule groups usually contain rules that block web requests. For information about rule groups, see Rule groups (p. 25).

3. Specify additional matching criteria and handling instructions in one or more rules. To add more than one rule, start with AND or OR rule statements and nest the rules that you want to combine under those. If you want to negate a rule option, nest the rule in a NOT statement. You can optionally use a rate-based rule instead of a regular rule to limit the number of requests from any single IP address that meets the conditions. For information about rules, see Rules (p. 83).

If you add more than one rule to a web ACL, AWS WAF evaluates the rules in the order that they're listed for the web ACL. For more information, see Web ACL rule and rule group evaluation (p. 13).

When you create a web ACL, you specify the types of resources that you want to use it with. For information, see Creating a web ACL (p. 18). After you define a web ACL, you can associate it with your resources to begin providing protection for them. For more information, see Associating or disassociating a web ACL with an AWS resource (p. 23).

How AWS resources handle response delays from AWS WAF

On some occasions, AWS WAF might encounter an internal error that delays the response to associated AWS resources about whether to allow or block a request. On those occasions, CloudFront typically allows the request or serves the content, while the Regional services typically deny the request and don't serve the content.

Topics

- Web ACL rule and rule group evaluation (p. 13)
- Deciding on the default action for a web ACL (p. 16)
- CAPTCHA, challenge, and token domain configuration for a web ACL (p. 17)
- Working with web ACLs (p. 18)

Web ACL rule and rule group evaluation

The way a web ACL handles a web request depends on the following:

- The numeric priority settings of the rules in the web ACL and inside rule groups
- The action settings on the rules and web ACL
- Any overrides that you place on the rules in the rule groups that you add

For a list of the rule action settings, see AWS WAF rule action (p. 84).

You can customize request and response handling in your rule action settings and default web ACL action settings. For information, see Customized web requests and responses in AWS WAF (p. 126).

Topics

- Processing order of rules and rule groups in a web ACL (p. 14)
- Basic handling of the rule and rule group actions in a web ACL (p. 14)
- Action overrides in rule groups (p. 15)
Processing order of rules and rule groups in a web ACL

In a web ACL and inside any rule group, you determine the evaluation order of the rules using numeric priority settings. You must give each rule in a web ACL a unique priority setting within that web ACL, and you must give each rule in a rule group a unique priority setting within that rule group.

Note
When you manage rule groups and web ACLs through the console, AWS WAF assigns unique numeric priority settings for you based on the order of the rules in the list. AWS WAF assigns the lowest numeric priority to the rule at the top of the list, and the highest numeric priority to the rule at the bottom.

When AWS WAF evaluates any web ACL or rule group against a web request, it evaluates the rules from the lowest numeric priority setting on up until it either finds a match that terminates the evaluation or exhausts all of the rules.

For example, say you have the following rules and rule groups in your web ACL, prioritized as shown:

- Rule1 – priority 0
- RuleGroupA – priority 100
  - RuleA1 – priority 10,000
  - RuleA2 – priority 20,000
- Rule2 – priority 200
- RuleGroupB – priority 300
  - RuleB1 – priority 0
  - RuleB2 – priority 1

AWS WAF would evaluate the rules for this web ACL in the following order:

- Rule1
- RuleGroupA RuleA1
- RuleGroupA RuleA2
- Rule2
- RuleGroupB RuleB1
- RuleGroupB RuleB2

Basic handling of the rule and rule group actions in a web ACL

When you configure your rules and rule groups, you choose how you want AWS WAF to handle matching web requests:

- **Allow and Block are terminating actions** – Allow and Block actions stop all other processing of the web ACL on the matching web request. If a rule in a web ACL finds a match for a request and the rule action is Allow or Block, that match determines the final disposition of the web request for the web ACL. AWS WAF doesn't process any other rules in the web ACL that come after the matching one. This is true for rules that you add directly to the web ACL and rules that are inside an added rule group. With the Block action, the protected resource doesn't receive or process the web request.

- **Count is a non-terminating action** – When a rule with a Count action matches a request, AWS WAF counts the request, then continues processing the rules that follow in the web ACL rule set.

- **Count and Challenge can be non-terminating or terminating actions** – When a rule with one of these actions matches a request, AWS WAF checks its token status. If the request has a valid token, AWS WAF treats the match similar to a Count match, and then continues processing the rules that follow in the
web ACL rule set. If the request doesn't have a valid token, AWS WAF terminates the evaluation and sends the client a CAPTCHA puzzle or silent background client session challenge to solve.

If the rule evaluation doesn't result in any terminating action, then AWS WAF applies the web ACL default action to the request.

The actions that AWS WAF applies to a web request are affected by the numeric priority settings of the rules in the web ACL. For example, say that your web ACL has a rule that has Allow action and a numeric priority of 50 and another rule that has Count action and a numeric priority of 100. AWS WAF evaluates the rules in a web ACL in the order of their priority, starting from the lowest setting, so it will evaluate the allow rule before the count rule. If you have a web request that matches both rules, it will match the allow rule first. Since Allow is a terminating action, AWS WAF will stop the evaluation at this match and won't evaluate the request against the count rule. If you want count metrics from the count rule even for requests that match the allow rule, you'd need to give the count rule a lower numeric priority setting than the allow rule, so that it runs first. For more information about priority settings, see Processing order of rules and rule groups in a web ACL (p. 14).

In your web ACL, you can override the action settings for rules inside a rule group and you can override the action that's returned by a rule group. For information, see Action overrides in rule groups (p. 15).

**Action overrides in rule groups**

When you add a rule group to your web ACL, you can override the actions it takes on matching web requests. Overriding the actions for a rule group inside your web ACL configuration doesn't alter the rule group itself. It only alters how AWS WAF uses the rule group in the context of the web ACL.

**Rule action overrides**

You can override the actions of the rules inside a rule group to any valid rule action. For a list of actions, see AWS WAF rule action (p. 84). When you do this, matching requests are handled exactly as if the configured rule's action were the override setting.

For information about how to use this option, see Overriding rule actions in a rule group (p. 22).

**Overriding the rule action to Count**

The most common use case for rule action overrides is overriding some or all of the rule actions to Count, in order to test and monitor a rule group's behavior before putting it into production.

You can also use this to troubleshoot a rule group that's generating false positives. False positives occur when a rule group blocks traffic that you aren't expecting it to block. If you identify a rule within a rule group that would block requests that you want to allow through, you can keep the count action override on that rule, to exclude it from acting on your requests.

For more information about using the rule action override in testing, see Testing and tuning your AWS WAF protections (p. 212).

**JSON listing: RuleActionOverrides replaces ExcludedRules**

If you set rule group rule actions to Count in your web ACL configuration prior to October 27, 2022, AWS WAF saved your overrides in the web ACL JSON as ExcludedRules. Now, the JSON setting for overriding a rule to Count is in the RuleActionOverrides settings.

When you use the AWS WAF console to edit the existing rule group settings, the console automatically converts any ExcludedRules settings in the JSON to RuleActionOverrides settings, with the override action set to Count.

- Current setting example:

```
"ManagedRuleGroupStatement": {
```

Deciding on the default action for a web ACL

When you create and configure a web ACL, you set the web ACL default action, which determines how AWS WAF handles web requests that don't match any rules in the web ACL. The default action must be a terminating action.

We recommend that you update all of your ExcludedRules settings in your JSON listings to RuleActionOverrides settings with the action set to Count. The API accepts either setting, but you'll get consistency in your JSON listings, between your console work and your API work, if you only use the new RuleActionOverrides setting.

Rule group action override to Count

You can override the action that the rule group returns, setting it to Count.

Note
This is not a good option for testing the rules in a rule group, because it doesn't alter how AWS WAF evaluates the rule group itself. It only affects how AWS WAF handles results that are returned to the web ACL from the rule group evaluation. If you want to test the rules in a rule group, use the option described in the preceding section, Rule action overrides (p. 15).

When you override the rule group action to Count, AWS WAF processes the rule group evaluation normally.

If no rules in the rule group match or if all matching rules have a Count action, then this override has no effect on the processing of the rule group or the web ACL.

The first rule in the rule group that matches a web request and that has a terminating rule action causes AWS WAF to stop evaluating the rule group and return the terminating action result to the web ACL evaluation level. At this point, in the web ACL evaluation, this override takes effect. AWS WAF overrides the terminating action so that the result of the rule group evaluation is only a Count action. AWS WAF then continues processing the rest of the rules in the web ACL.

For information about how to use this option, see Overriding a rule group's evaluation result to Count (p. 23).
• **Allow** – If you want to allow most users to access your website, but you want to block access to attackers whose requests originate from specified IP addresses, or whose requests appear to contain malicious SQL code or specified values, choose Allow for the default action. Then, when you add rules to your web ACL, add rules that identify and block the specific requests that you want to block. With this action, you can insert custom headers into the request before forwarding it to the protected resource.

• **Block** – If you want to prevent most users from accessing your website, but you want to allow access to users whose requests originate from specified IP addresses, or whose requests contain specified values, choose Block for the default action. Then when you add rules to your web ACL, add rules that identify and allow the specific requests that you want to allow in. By default, for the Block action, the AWS resource responds with an HTTP 403 (Forbidden) status code, but you can customize the response.

For information about customizing requests and responses, see Customized web requests and responses in AWS WAF (p. 126).

Your configuration of your own rules and rule groups depends in part on whether you want to allow or block most web requests. For example, if you want to allow most requests, you would set the web ACL default action to Allow, and then add rules that identify web requests that you want to block, such as the following:

• Requests that originate from IP addresses that are making an unreasonable number of requests
• Requests that originate from countries that either you don't do business in or are the frequent source of attacks
• Requests that include fake values in the User-agent header
• Requests that appear to include malicious SQL code

Managed rule group rules usually use the Block action, but not all do. For examples, some rules used for Bot Control use the CAPTCHA and Challenge action settings. For information about managed rule groups, see Managed rule groups (p. 26).

**CAPTCHA, challenge, and token domain configuration for a web ACL**

You can configure options in your web ACL for the rules that use the CAPTCHA or Challenge rule actions and for the application integration SDKs that manage silent client challenges for AWS WAF managed protections.

These features mitigate bot activity by challenging end users with CAPTCHA puzzles and by presenting client sessions with silent challenges. When the client responds successfully, AWS WAF provides a token for them to use in their web request, timestamped with the last successful puzzle and challenge responses. For more information, see AWS WAF intelligent threat mitigation (p. 139).

In your web ACL configuration, you can configure how AWS WAF manages these tokens:

• **CAPTCHA and challenge immunity times** – These specify how long a CAPTCHA or challenge timestamp remains valid. The web ACL settings are inherited by all rules that don't have their own immunity time settings configured and also by the application integration SDKs. For more information, see Timestamp expiration: token immunity times (p. 145).

• **Token domains** – By default, AWS WAF accepts tokens only for the domain of the resource that the web ACL is associated with. If you configure a token domain list, AWS WAF accepts tokens for all domains in the list and for the domain of the associated resource. For more information, see Token domains and domain lists (p. 146).
Working with web ACLs

This section provides procedures for creating, managing, and using web ACLs through the AWS console.

Temporary inconsistencies during updates

When you create or change a web ACL or other AWS WAF resources, the changes take a small amount of time to propagate to all areas where the resources are stored. The propagation time can be from a few seconds to a number of minutes.

The following are examples of the temporary inconsistencies that you might notice during change propagation:

- After you create a web ACL, if you try to associate it with a resource, you might get an exception indicating that the web ACL is unavailable.
- After you add a rule group to a web ACL, the new rule group rules might be in effect in one area where the web ACL is used and not in another.
- After you change a rule action setting, you might see the old action in some places and the new action in others.
- After you add an IP address to an IP set that is in use in a blocking rule, the new address might be blocked in one area while still allowed in another.

Topics

- Creating a web ACL (p. 18)
- Editing a web ACL (p. 21)
- Managing rule group behavior in a web ACL (p. 22)
- Associating or disassociating a web ACL with an AWS resource (p. 23)
- Deleting a web ACL (p. 25)

Creating a web ACL

To create a web ACL

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. Choose Web ACLs in the navigation pane, and then choose Create web ACL.
3. For Name, enter the name that you want to use to identify this web ACL.
   
   Note
   
   You can't change the name after you create the web ACL.
4. (Optional) For Description - optional, enter a longer description for the web ACL if you want to.
5. For CloudWatch metric name, change the default name if applicable. Follow the guidance on the console for valid characters. The name can't contain special characters, white space, or metric names reserved for AWS WAF, including "All" and "Default_Action."
   
   Note
   
   You can't change the CloudWatch metric name after you create the web ACL.
6. For Resource type, choose the category of AWS resource that you want to associate with this web ACL. For more information, see Associating or disassociating a web ACL with an AWS resource (p. 23).
7. For Region, if you've chosen a Regional resource type, choose the Region where you want AWS WAF to store the web ACL.
You only need to choose this option for Regional resource types. For CloudFront distributions, the Region is hard-coded to the US East (N. Virginia) Region, us-east-1, for Global (CloudFront) applications.

8. (Optional) For Associated AWS resources - optional, choose Add AWS resources. In the dialog box, choose the resources that you want to associate, and then choose Add. AWS WAF returns you to the Describe web ACL and associated AWS resources page.

9. Choose Next.

10. (Optional) If you want to add managed rule groups, on the Add rules and rule groups page, choose Add rules, and then choose Add managed rule groups. Do the following for each managed rule group that you want to add:

   a. On the Add managed rule groups page, expand the listing for AWS managed rule groups or for the AWS Marketplace seller of your choice.

   b. For the rule group that you want to add, in the Action column, turn on the Add to web ACL toggle.

   To customize how your web ACL uses the rule group, choose Edit. The following are common customization settings:

      • Override the rule actions for some or all rules. If you don't define an override action for a rule, the evaluation uses the rule action that's defined inside the rule group. For information about this option, see Action overrides in rule groups (p. 15).

      • Reduce the scope of the web requests that the rule group inspects by adding a scope-down statement. For information about this option, see Scope-down statements (p. 117).

      • Some managed rule groups require you to provide additional configuration. See the documentation from your managed rule group provider. For information specific to the AWS Managed Rules rule groups, see AWS Managed Rules for AWS WAF (p. 34).

   When you're finished with your settings, choose Save rule.

Choose Add rules to finish adding managed rules and return to the Add rules and rule groups page.

11. (Optional) If you want to add your own rule group, on the Add rules and rule groups page, choose Add rules, and then choose Add my own rules and rule groups. Do the following for each rule group that you want to add:

   a. On the Add my own rules and rule groups page, choose Rule group.

   b. For Name, enter the name that you want to use for the rule group rule in this web ACL.

   c. Choose your rule group from the list, and then choose Add rule.

12. (Optional) If you want to add your own rule, on the Add rules and rule groups page, choose Add rules, Add my own rules and rule groups, Rule builder, then Rule visual editor.

   **Note**
   The console Rule visual editor supports one level of nesting. For example, you can use a single logical AND or OR statement and nest one level of other statements inside it, but you can't nest logical statements within logical statements. To manage more complex rule statements, use the Rule JSON editor. For information about all options for rules, see Rules (p. 83).
   This procedure covers the Rule visual editor.

   a. For Name, enter the name that you want to use to identify this rule.

   b. Enter your rule definition, according to your needs. You can combine rules inside logical AND and OR rule statements. The wizard guides you through the options for each rule, according to context. For information about your rules options, see Rules (p. 83).
c. For **Action**, select the action you want the rule to take when it matches a web request. For information on your choices, see [AWS WAF rule action](#) and [Web ACL rule and rule group evaluation](#).

If you are using the **CAPTCHA** or **Challenge** action, adjust the **Immunity time** configuration as needed for the rule. If you don't specify the setting, the rule inherits it from the web ACL. For more information, see [Timestamp expiration: token immunity times](#).

**Note**
You are charged additional fees when you use the CAPTCHA or Challenge rule action in one of your rules or as a rule action override in a rule group. For more information, see [AWS WAF Pricing](#).

If you want to customize the request or response, choose the options for that and fill in the details of your customization. For more information, see [Customized web requests and responses in AWS WAF](#).

If you want to have your rule add labels to matching web requests, choose the options for that and fill in your label details. For more information, see [Labels on web requests](#).

**d. Choose Add rule.**

13. Choose the default action for the web ACL, either **Block** or **Allow**. This is the action that AWS WAF takes on a request when the rules in the web ACL don't explicitly allow or block it. For more information, see [Deciding on the default action for a web ACL](#).

If you want to customize the default action, choose the options for that and fill in the details of your customization. For more information, see [Customized web requests and responses in AWS WAF](#).

14. You can define a **Token domain list** to enable token sharing between protected applications. Tokens are used by the CAPTCHA and Challenge actions and by the application integration SDKs that you implement when you use the AWS Managed Rules rule groups for AWS WAF Fraud Control account takeover prevention (ATP) and AWS WAF Bot Control.

Public suffixes aren't allowed. For example, you can't use **usa.gov** or **co.uk** as a token domain.

By default, AWS WAF accepts tokens only for the domain of the protected resource. If you add token domains in this list, AWS WAF accepts tokens for all domains in the list and for the domain of the associated resource. For more information, see [Token domains and domain lists](#).

15. Choose **Next**.

16. In the **Set rule priority** page, select and move your rules and rule groups to the order that you want AWS WAF to process them. AWS WAF processes rules starting from the top of the list. When you save the web ACL AWS WAF assigns numeric priority settings to the rules, in the order that you have them listed. For more information, see [Processing order of rules and rule groups in a web ACL](#).

17. Choose **Next**.

18. In the **Configure metrics** page, review the options and apply any updates that you need. You can combine metrics from multiple sources by providing the same **CloudWatch metric name** for them.

19. Choose **Next**.

20. In the **Review and create web ACL** page, check over your definitions. If you want to change any area, choose **Edit** for the area. This returns you to the page in the web ACL wizard. Make any changes, then choose **Next** through the pages until you come back to the **Review and create web ACL** page.

21. Choose **Create web ACL**. Your new web ACL is listed in the **Web ACLs** page.
Editing a web ACL

To add or remove rules from a web ACL or change configuration settings, access the web ACL using the procedure on this page. While updating a web ACL, AWS WAF provides continuous coverage to the resources that you have associated with the web ACL.

**Production traffic risk**

Before you deploy changes in your web ACL for production traffic, test and tune them in a staging or testing environment until you are comfortable with the potential impact to your traffic. Then test and tune your updated rules in count mode with your production traffic before enabling them. For guidance, see *Testing and tuning your AWS WAF protections (p. 212).*

To edit a web ACL

2. In the navigation pane, choose Web ACLs.
3. Choose the name of the web ACL that you want to edit. The console takes you to the web ACL’s description, where you can edit it.

   **Note**
   
   Web ACLs that are managed by AWS Firewall Manager have names that start with FMManagedWebACLV2-. The Firewall Manager administrator manages these in Firewall Manager AWS WAF policies. These web ACLs might contain rule group sets that are designated to run first and last in the web ACL, on either side of any rules or rule groups that you add and manage. The first and last rule groups have names that start with PREFFMManaged- and POSTFMManaged-, respectively. For more information about these policies, see *AWS WAF policies (p. 404).*

4. Page through the web ACL definitions, and make your changes. This is similar to the procedure that you use to create the web ACL in *Creating a web ACL (p. 18)*, with the following exceptions.
   - Some fields that you set at creation aren’t modifiable. For example, you can’t change the name of a web ACL, and for web ACLs that are managed by Firewall Manager, you can’t change any first and last rule group specifications.
   - You can only change the web ACL’s CAPTCHA and challenge immunity times when you edit an existing web ACL. You can find these settings under the web ACL’s Rules tab. For information about these settings, see *Timestamp expiration: token immunity times (p. 145).*

**Temporary inconsistencies during updates**

When you create or change a web ACL or other AWS WAF resources, the changes take a small amount of time to propagate to all areas where the resources are stored. The propagation time can be from a few seconds to a number of minutes.

The following are examples of the temporary inconsistencies that you might notice during change propagation:

- After you create a web ACL, if you try to associate it with a resource, you might get an exception indicating that the web ACL is unavailable.
- After you add a rule group to a web ACL, the new rule group rules might be in effect in one area where the web ACL is used and not in another.
- After you change a rule action setting, you might see the old action in some places and the new action in others.
- After you add an IP address to an IP set that is in use in a blocking rule, the new address might be blocked in one area while still allowed in another.
Managing rule group behavior in a web ACL

This section describes your options for modifying how you use a rule group in your web ACL. This information applies to all rule group types. After you add a rule group to a web ACL, you can override the actions of the individual rules in the rule group to Count or to any other valid rule action setting. You can also override the rule group's resulting action to Count, which has no effect on how the rules are evaluated inside the rule group.

For information about these options, see Action overrides in rule groups (p. 15).

Overriding rule actions in a rule group

For each rule group in a web ACL, you can override the contained rule's actions for some or all of the rules.

The most common use case for this is overriding the rule actions to Count in order to test new or updated rules. If you have metrics enabled, you receive count metrics for each rule that you override to count. For more information about testing, see Testing and tuning your AWS WAF protections (p. 212).

To override rule actions in a rule group

You can make these changes when you're adding the rule group to the web ACL or later. These instructions are for a rule group that has already been added to the web ACL. See the additional information about this option at Rule action overrides (p. 15).

1. Edit the web ACL.
2. In the web ACL page Rules tab, select the rule group, then choose Edit.
3. In the Rules section for the rule group, manage the action settings as needed.
   - All rules – To set an override action for all rules in the rule group, open the Override all rule actions dropdown and select the override action. To remove the overrides for all rules, select Remove all overrides.
   - Single rule – To set an override action for a single rule, open the rule's dropdown and select the override action. To remove an override for a rule, open the rule's dropdown and select Remove override.
4. When you are finished making your changes, choose Save rule. The rule action and override action settings are listed in the rule group page.

The following example JSON listing shows a rule group declaration inside a web ACL that overrides the rule actions to Count for the rules CategoryVerifiedSearchEngine and CategoryVerifiedSocialMedia. In the JSON, you override all rule actions by providing a RuleActionOverrides entry for each individual rule.

```json
{
    "Name": "AWS-AWSBotControl-Example",
    "Priority": 5,
    "Statement": {
        "ManagedRuleGroupStatement": {
            "VendorName": "AWS",
            "Name": "AWSManagedRulesBotControlRuleSet",
            "RuleActionOverrides": [
                {
                    "ActionToUse": {
                        "Count": {}
                    },
                    "Name": "CategoryVerifiedSearchEngine"
                }
            ]
        }
    }
}
```
Overriding a rule group's evaluation result to Count

You can override the action that results from a rule group evaluation, without altering how the rules in the rule group are configured or evaluated. This option is not commonly used. If any rule in the rule group results in a match, this override sets the resulting action from the rule group to Count.

You can override the rule group's resulting action in the web ACL when you add or edit the rule group. In the console, open the rule group's **Override rule group action - optional** pane and enable the override. In the JSON set `OverrideAction` in the rule group statement, as shown in the following example listing:

```json
{
  "Name": "AWS-AWSBotControl-Example",
  "Priority": 5,
  "Statement": {
    "ManagedRuleGroupStatement": {
      "VendorName": "AWS",
      "Name": "AWSManagedRulesBotControlRuleSet"
    }
  },
  "OverrideAction": {
    "Count": {}
  },
  "VisibilityConfig": {
    "SampledRequestsEnabled": true,
    "CloudWatchMetricsEnabled": true,
    "MetricName": "AWS-AWSBotControl-Example"
  }
}
```

Associating or disassociating a web ACL with an AWS resource

You can use AWS WAF to create the following associations between web ACLs and your resources:

- Associate a regional web ACL with any of the regional resources listed below. For this option, the web ACL must be in the same region as your resource.
  - Amazon API Gateway REST API
  - Application Load Balancer
  - AWS AppSync GraphQL API
  - Amazon Cognito user pool
- Associate a global web ACL with a Amazon CloudFront distribution. The global web ACL will have a hard-coded Region of US East (N. Virginia) Region.
You can also associate a web ACL with a CloudFront distribution when you create or update the distribution itself. For information, see Using AWS WAF to Control Access to Your Content in the Amazon CloudFront Developer Guide.

Restrictions on multiple associations

You can associate a single web ACL with one or more AWS resources, according to the following restrictions:

- You can associate each AWS resource with only one web ACL. The relationship between web ACL and AWS resources is one-to-many.
- You can associate a web ACL with one or more CloudFront distributions. You cannot associate a web ACL that you have associated with a CloudFront distribution with any other AWS resource type.

Additional restrictions

The following additional restrictions apply to web ACL associations:

- You can only associate a web ACL to an Application Load Balancer within AWS Regions. For example, you cannot associate a web ACL to an Application Load Balancer that is on AWS Outposts.
- You can't associate an Amazon Cognito user pool with a web ACL that uses the AWS WAF Fraud Control account takeover prevention (ATP) managed rule group AWSManagedRulesATPRuleSet. For information about account takeover prevention, see AWS WAF Fraud Control account takeover prevention (ATP) (p. 165).

Production traffic risk

Before you deploy your web ACL for production traffic, test and tune it in a staging or testing environment until you are comfortable with the potential impact to your traffic. Then test and tune your rules in count mode with your production traffic before enabling them. For guidance, see Testing and tuning your AWS WAF protections (p. 212).

To associate a web ACL with an AWS resource

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Web ACLs.
3. Choose the name of the web ACL that you want to associate with a resource. The console takes you to the web ACL's description, where you can edit it.
4. On the Associated AWS resources tab, choose Add AWS resources.
5. When prompted, choose the resource type, select the radio button next to the resource that you want to associate, and then choose Add.

To disassociate a web ACL from an AWS resource

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Web ACLs.
3. Choose the name of the web ACL that you want to disassociate from your resource. The console takes you to the web ACL's description, where you can edit it.
4. On the Associated AWS resources tab, select the resource that you want to disassociate this web ACL from and then choose Disassociate. The console opens a confirmation dialogue. Confirm your choice to disassociate the web ACL from the AWS resource.
Rule groups

A rule group is a reusable set of rules that you can add to a web ACL. For more information about web ACLs, see Web access control lists (web ACLs) (p. 12).

Rule groups fall into the following main categories:

- Managed rule groups, which AWS Managed Rules and AWS Marketplace sellers create and maintain for you
- Your own rule groups, which you create and maintain
- Rule groups that are owned and managed by other services, like AWS Firewall Manager and Shield Advanced.

Differences between rule groups and web ACLs

Rule groups and web ACLs both contain rules, which are defined in the same manner in both places. Rule groups differ from web ACLs in the following ways:

- Rule groups can't contain rule group reference statements.
- You can reuse a single rule group in multiple web ACLs by adding a rule group reference statement to each web ACL. You can't reuse a web ACL.
- Rule groups don't have default actions. In a web ACL, you set a default action for each rule or rule group that you include. Each individual rule inside a rule group or web ACL has an action defined.
- You don't directly associate a rule group with an AWS resource. To protect resources using a rule group, you use the rule group in a web ACL.
- Web ACLs have a system-defined maximum capacity of 1,500 web ACL capacity units (WCUs). Each rule group has a WCU setting that must be set at creation. You can use this setting to calculate the additional capacity requirements that using a rule group would add to your web ACL. For more information about WCUs, see AWS WAF Web ACL capacity units (WCU) (p. 7).

For information about rules, see Rules (p. 83).

This section provides guidance for creating and managing your own rule groups, describes the managed rule groups that are available to you, and provides guidance for using managed rule groups.
Managed rule groups

Managed rule groups are collections of predefined, ready-to-use rules that AWS and AWS Marketplace sellers write and maintain for you:

- **AWS Managed Rules rule groups** are mostly available for free to AWS WAF customers. The AWS WAF Bot Control and AWS WAF Fraud Control account takeover prevention (ATP) rule groups have additional fees. For more information, see [AWS WAF Pricing](#).

- **AWS Marketplace managed rule groups** are available by subscription through AWS Marketplace. Each of these rule groups is owned and managed by the AWS Marketplace seller.

Some managed rule groups are designed to help protect specific types of web applications like WordPress, Joomla, or PHP. Others offer broad protection against known threats or common web application vulnerabilities, including some of the ones listed in the [OWASP Top 10](#). If you're subject to regulatory compliance like PCI or HIPAA, you might be able to use managed rule groups to satisfy web application firewall requirements.

**Automatic updates**

Keeping up to date on the constantly changing threat landscape can be time consuming and expensive. Managed rule groups can save you time when you implement and use AWS WAF. Many AWS and AWS Marketplace sellers automatically update managed rule groups and provide new versions of rule groups when new vulnerabilities and threats emerge.

In some cases, AWS is notified of new vulnerabilities before public disclosure, due to its participation in a number of private disclosure communities. In those cases, AWS can update the AWS Managed Rules rule groups and deploy them for you even before a new threat is widely known.

**Restricted access to rules in a managed rule group**

Each managed rule group provides a comprehensive description of the types of attacks and vulnerabilities that it's designed to protect against. To protect the intellectual property of the rule group providers, you can’t view all of the details for the individual rules within a rule group. This restriction also helps to keep malicious users from designing threats that specifically circumvent published rules.

Topics
- Managed rule groups (p. 26)
- Managing your own rule groups (p. 81)
- Rule groups provided by other services (p. 83)
When you add a managed rule group to your web ACL, if the rule group supports versioning, you can choose to let the provider manage which version you use or you can manage the version setting yourself.

**Can't find the version you want?**

If you don't see a version in a rule group's version listing, the version is probably scheduled for expiration or already expired. After a version is scheduled for expiration, AWS WAF no longer lets you to choose it for the rule group.

**Versioning and SNS notifications for AWS Managed Rules rule groups**

The AWS Managed Rules rule groups all provide versioning and SNS update notifications except for the rule groups for IP reputation, Bot Control, and account takeover prevention.

The AWS Managed Rules rule groups that provide notifications all use the same SNS topic Amazon Resource Name (ARN).

**Topics**

- Version lifecycle for managed rule groups (p. 27)
- Best practices for handling managed rule group versions (p. 27)

**Version lifecycle for managed rule groups**

Providers handle the following lifecycle stages of a managed rule group static version:

- **Release and updates** – A managed rule group provider announces upcoming and new static versions of their managed rule groups through notifications to an Amazon Simple Notification Service (Amazon SNS) topic. Providers might also use the topic to communicate other important information about their rule groups, such as urgent required updates.

  You can subscribe to the rule group's topic and configure how you want to receive notifications. For more information see [Getting notified of new versions and updates](p. 31).

- **Expiration scheduling** – A managed rule group provider schedules older versions of a rule group for expiration. A version that's scheduled to expire cannot be added to your web ACL rules. After expiration is scheduled for a version, AWS WAF tracks the expiration with a countdown metric in Amazon CloudWatch.

  You can set an alarm on the metric in CloudWatch to track the expiration of a version that you're using. This gives you time to test a new version and move off of the expiring one before the countdown completes. For more information, see [Tracking version expiration](p. 33).

- **Version expiration** – When a version expires, the rule group provider determines how to manage the expiration for web ACLs that are still using the expired version:
  - For AWS Managed Rules rule groups, AWS WAF moves any web ACL that's using the expired version to the rule group's default version.
  - For AWS Marketplace rule groups, the provider determines how to handle the expiration. Ask your managed rule group provider for information.

**Best practices for handling managed rule group versions**

Follow this versioning best practice guidance when you use a managed rule group.

When you use a managed rule group in your web ACL, you can choose to use a specific, static version of the rule group, or you can choose to use the default version:

- **Default version** – AWS WAF always sets the default version to the static version that's currently recommended by the provider. When the provider updates their recommended static version, AWS WAF automatically updates the default version setting for the rule group in your web ACL.
When you use the default version of a managed rule group, do the following as best practice:

- **Subscribe to notifications** – Subscribe to notifications for changes to the rule group and keep an eye on those. Most providers send advanced notification of new static versions and of default version changes. These let you check the effects of a new static version before AWS switches the default version to it. For more information see [Getting notified of new versions and updates](p. 31).

- **Review the effects of static version settings and make adjustments as needed before your default is set to it** – Before your default is set to a new static version, review the effects of the static version on the monitoring and management of your web requests. The new static version might have new rules to review. Look for false positives or other unexpected behavior, in case you need to modify how you use the rule group. You can set rules to count, for example, to stop them from blocking traffic while you figure out how you want to handle the new behavior. For more information, see [Testing and tuning your AWS WAF protections](p. 212).

- **Static version** – If you choose to use a static version, you must manually update the version setting when you're ready to adopt a new version of the rule group.

When you use a static version of a managed rule group, do the following as best practice:

- **Keep your version up to date** – Keep your managed rule group as close as you can to the latest version. When a new version is released, test it, adjust settings as needed, and implement it in a timely manner. For information about testing, see [Testing and tuning your AWS WAF protections](p. 212).

- **Subscribe to notifications** – Subscribe to notifications for changes to the rule group, so you know when your provider releases new static versions. Most providers give advanced notification of version changes. Additionally, your provider might need to update the static version that you're using to close a security loophole or for other urgent reasons. You'll know what's happening if you're subscribed to the provider's notifications. For more information, see [Getting notified of new versions and updates](p. 31).

- **Avoid version expiration** – Don't allow a static version to expire while you're using it. Provider handling of expired versions can vary and might include forcing an upgrade to an available version or other changes that can have unexpected consequences. Track the AWS WAF expiry metric and set an alarm that gives you a sufficient number of days to successfully upgrade to a supported version. For more information, see [Tracking version expiration](p. 33).

### Working with managed rule groups

This section provides guidance for accessing and managing your managed rule groups.

When you add a managed rule group to your web ACL, you can choose the same configuration options as you can your own rule groups, plus additional settings.

Through the console, you access managed rule group information during the process of adding and editing the rules in your web ACLs. Through the APIs and the command line interface (CLI), you can directly request managed rule group information.

When you use a managed rule group in your web ACL, you can edit the following settings:

- **Version** – This is available only if the rule group is versioned. For more information, see [Version management with managed rule groups](p. 26).

- **Override rule actions** – You can override the actions for rules in the rule group to any action. Setting them to Count is useful for testing a rule group before using it to manage your web requests. For more information, see [Rule action overrides](p. 15).

- **Scope-down statement** – You can add a scope-down statement, to filter out web requests that you don't want to evaluate with the rule group. For more information, see [Scope-down statements](p. 117).
• **Override rule group action** – You can override the action that results from the rule group evaluation, and set it to Count only. This option isn’t commonly used. It doesn’t alter how AWS WAF evaluates the rules in the rule group. For more information, see Rule group action override to Count (p. 16).

**To edit the managed rule group settings in your web ACL**

- **Console**
  - (Option) When you add the managed rules group to your web ACL, you can choose **Edit** to view and edit the settings.
  - (Option) After you’ve added the managed rule group into your web ACL, from the **Web ACLs** page, choose the web ACL you just created. This takes you to the web ACL edit page.
    - Choose **Rules**.
    - Select the rule group, then choose **Edit** to view and edit the settings.
  - **APIs and CLI** – Outside of the console, you can manage the managed rule group settings when you create and update the web ACL.

**Retrieving the list of managed rule groups**

The managed rule groups that are available for you to use in your web ACLs are the following:

- All AWS Managed Rules rule groups.
- The AWS Marketplace rule groups that you have subscribed to.

  **Note**
  For information about subscribing to AWS Marketplace rule groups, see AWS Marketplace managed rule groups (p. 79).

When you retrieve the list of managed rule groups, the list you get back depends on the interface that you’re using:

- **Console** – Through the console, you can see all managed rule groups, including the AWS Marketplace rule groups that you haven’t subscribed to yet. For the ones that you haven’t subscribed to yet, the interface provides links that you can follow to subscribe.
- **APIs and CLI** – Outside of the console, your request returns only the rule groups that are available for you to use.

**To retrieve the list of managed rule groups**

- **Console** – During the process of creating a web ACL, on the **Add rules and rule groups** page, choose **Add managed rule groups**. At the top level, the provider names are listed. Expand each provider listing to see the list of managed rule groups. For versioned rule groups, the information shown at this level is for the default version. When you add a managed rule group to your web ACL, the console lists it based on the naming scheme `<Vendor Name>-<Managed Rule Group Name>`.

- **API**
  - `ListAvailableManagedRuleGroups`

- **CLI**
  - `aws wafv2 list-available-managed-rule-groups --scope=<CLOUDFRONT|REGIONAL>`

**Retrieving the rules in a managed rule group**

You can retrieve a list of the rules in a managed rule group. The API and CLI calls return the rules specifications that you can reference in the JSON model or through AWS CloudFormation.
To retrieve the list of rules in a managed rule group

- **Console**
  - (Option) When you add the managed rules group to your web ACL, you can choose **Edit** to view the rules.
  - (Option) After you've added the managed rule group into your web ACL, from the **Web ACLs** page, choose the web ACL you just created. This takes you to the web ACL edit page.
    - Choose **Rules**.
    - Select the rule group you want to see a rules list for, then choose **Edit**. AWS WAF shows the list of rules in the rule group.
  - **API** – **DescribeManagedRuleGroup**
  - **CLI** – `aws wafv2 describe-managed-rule-group --scope=<CLOUDFRONT|REGIONAL> --vendor-name <vendor> --name <managedrule_name>`

Retrieving the available versions for a managed rule group

The available versions of a managed rule group are versions that haven't yet been scheduled to expire. The list indicates which version is the current default version for the rule group.

To retrieve a list of the available versions of a managed rule group

- **Console**
  - (Option) When you add the managed rule group to your web ACL, choose **Edit** to see the rule group's information. Expand the **Version** dropdown to see the list of available versions.
  - (Option) After you've added the managed rule group into your web ACL, choose **Edit** on the web ACL, and then select and edit the rule group rule. Expand the **Version** dropdown to see the list of available versions.
  - **API** – **ListAvailableManagedRuleGroupVersions**
  - **CLI** – `aws wafv2 list-available-managed-rule-group-versions --scope=<CLOUDFRONT|REGIONAL> --vendor-name <vendor> --name <managedrule_name>`

Adding a managed rule group to a web ACL through the console

This guidance applies to all AWS Managed Rules rule groups and to the AWS Marketplace rule groups that you're subscribed to.

**Production traffic risk**

Before you deploy changes in your web ACL for production traffic, test and tune them in a staging or testing environment until you are comfortable with the potential impact to your traffic. Then test and tune your updated rules in count mode with your production traffic before enabling them. For guidance, see Testing and tuning your AWS WAF protections (p. 212).

To add a managed rule group to a web ACL through the console

2. Choose **Web ACLs** in the navigation pane.
3. In the **Web ACLs** page, from the list of web ACLs, select the one that you want to add the rule group to. This takes you to the page for the single web ACL.
4. In your web ACL's page, choose the **Rules** tab.
5. In the **Rules** pane, choose **Add rules**, then choose **Add managed rule groups**.
6. In the Add managed rule groups page, expand the selection for your rule group vendor, to see the list of available rule groups.

7. For each rule group that you want to add, choose Add to web ACL. If you want to change the web ACL's configuration for the rule group, choose Edit, make your changes, and then choose Save rule. For information about the options, see the versioning guidance at Version management with managed rule groups (p. 26) and the guidance for using a managed rule group in a web ACL at Managed rule group statement (p. 97).

8. At the bottom of the Add managed rule groups page, choose Add rules.

9. In the Set rule priority page, adjust the order that the rules run as needed, then choose Save. For more information, see Processing order of rules and rule groups in a web ACL (p. 14).

In your web ACL's page, the managed rule groups that you've added are listed under the Rules tab.

Test and tune any changes to your AWS WAF protections before you use them for production traffic. For information, see Testing and tuning your AWS WAF protections (p. 212).

Temporary inconsistencies during updates

When you create or change a web ACL or other AWS WAF resources, the changes take a small amount of time to propagate to all areas where the resources are stored. The propagation time can be from a few seconds to a number of minutes.

The following are examples of the temporary inconsistencies that you might notice during change propagation:

- After you create a web ACL, if you try to associate it with a resource, you might get an exception indicating that the web ACL is unavailable.
- After you add a rule group to a web ACL, the new rule group rules might be in effect in one area where the web ACL is used and not in another.
- After you change a rule action setting, you might see the old action in some places and the new action in others.
- After you add an IP address to an IP set that is in use in a blocking rule, the new address might be blocked in one area while still allowed in another.

Getting notified of new versions and updates to a managed rule group

A managed rule group provider uses SNS notifications to announce rule group changes, like upcoming new versions and urgent security updates.

How to subscribe to SNS notifications

To subscribe to notifications for a rule group, you create an Amazon SNS subscription for the rule group's Amazon SNS topic ARN in the US East (N. Virginia) Region us-east-1.

For information about how to subscribe, see the Amazon Simple Notification Service Developer Guide.

Note

Create your subscription for the SNS topic only in the us-east-1 Region.

Where to find the Amazon SNS topic ARN for a managed rule group

AWS Managed Rules rule groups use a single SNS topic ARN, so you can retrieve the topic ARN from one of the rule groups and subscribe to it to get notifications for all of the AWS Managed Rules rule groups that provide SNS notifications.

- Console
Managed rule groups

- (Option) When you add the managed rule group to your web ACL, choose Edit to see the rule group's information, which includes the rule group's Amazon SNS topic ARN.
- (Option) After you've added the managed rule group into your web ACL, choose Edit on the web ACL, and then select and edit the rule group rule to see the rule group's Amazon SNS topic ARN.
- API – DescribeManagedRuleGroup
- CLI – aws wafv2 describe-managed-rule-group --scope=<CLOUDFRONT|REGIONAL> --vendor-name <vendor> --name <managedrule_name>

Versioning and SNS notifications for AWS Managed Rules rule groups

The AWS Managed Rules rule groups all provide versioning and SNS update notifications except for the rule groups for IP reputation, Bot Control, and account takeover prevention.

The AWS Managed Rules rule groups that provide notifications all use the same SNS topic Amazon Resource Name (ARN).

For deployments that affect your protections, such as changes to the default version, AWS provides SNS notifications to inform you of planned deployments and to let you know when a deployment is completed. For deployments that don't affect your protections, such as release candidate and static version deployments, AWS might notify you after the deployment has started or even after it's completed. At the completion of the deployment of a new static version, AWS updates this guide, in the changelog at AWS Managed Rules changelog (p. 70) and in the document history page at Document history (p. 566). For more information about the notifications provided for each type of deployment, see Deployments for versioned AWS Managed Rules rule groups (p. 63).

To receive all updates that AWS provides for the AWS Managed Rules rule groups, subscribe to the RSS feed from any HTML page of this guide, and subscribe to the SNS topic for the AWS Managed Rules rule groups.

The fields in the Amazon SNS notifications always include the Subject, Message, and MessageAttributes. Additional fields depend on the type of message and which managed rule group the notification is for. The following shows an example notification listing for AWSManagedRulesCommonRuleSet.

```
{
  "Type": "Notification",
  "MessageId": "4286b830-a463-5e61-bd15-e1ae72303868",
  "Subject": "New version available for rule group AWSManagedRulesCommonRuleSet",
  "Message": "Welcome to AWSManagedRulesCommonRuleSet version 1.5! We’ve updated the regex specification in this version to improve protection coverage, adding protections against insecure deserialization. For details about this change, see http://updatedPublicDocs.html. Look for more exciting updates in the future! ",
  "Timestamp": "2021-08-24T11:12:19.810Z",
  "SignatureVersion": "1",
  "Signature": "EXAMPLEHXgJm...",
  "SigningCertURL": "https://sns.us-west-2.amazonaws.com/SimpleNotificationService-f3ecfb7224c7235f7b7b5f9f96de52f.pem",
  "MessageAttributes": {
    "major_version": {
      "Type": "String",
      "Value": "v1"
    },
    "managed_rule_group": {
      "Type": "String",
      "Value": "AWSManagedRulesCommonRuleSet"
    }
  }
}
```
For general information about Amazon SNS notification formats and how to filter the notifications that you receive, see Parsing message formats and Amazon SNS subscription filter policies in the Amazon Simple Notification Service Developer Guide.

**Tracking a rule group's version expiration**

If you use a specific version of a rule group, make sure that you don't keep using a version past its expiration date.

**Tip**

If you track upcoming changes for the managed rule group through Amazon SNS, you'll receive notifications about new and recommended versions. If you regularly test and move to a newer version, you'll stay ahead of any expiration activities on the older versions. You'll also benefit from the most current protections from the rule group. For information about notifications, see Getting notified of new versions and updates (p. 31).

If a version that you're using is expired, AWS WAF blocks modifications to the web ACL where you're using the rule group. The block remains until you update the rule group to an available version or remove it from your web ACL.

Expiration handling for a managed rule group depends on the rule group provider. For AWS Managed Rules rule groups, the version is automatically changed to the rule group's default version. For AWS Marketplace rule groups, ask the provider how they handle expiration.

To monitor expiration scheduling for a managed rule group, track the Amazon CloudWatch expiry metrics from AWS WAF:

- Metric name: DaysToExpiry
- Metric dimensions: Region, ManagedRuleGroup, Vendor, and Version

Locate the metric for your managed rule group in Amazon CloudWatch and set an alarm on it so that you're notified in time to switch to a newer version of your rule group. For information about using Amazon CloudWatch metrics and configuring alarms, see the Amazon CloudWatch User Guide.

When the provider creates a new version of the rule group, it sets the version's forecasted lifetime. While the version isn't scheduled to expire, the metric value is set to the forecasted lifetime setting, and in CloudWatch, you'll see a flat value for the metric. After the provider schedules the metric to expire, the metric value diminishes each day until it reaches zero on the day of expiration.

If you have a managed rule group in your web ACL that's evaluating traffic, you will get a metric for it. The metric isn't available for unused rule groups.

**Example managed rule group configurations in JSON and YAML**

The API and CLI calls return a list of all rules in the managed rule group that you can reference in the JSON model or through AWS CloudFormation.

**JSON**

You can reference and modify managed rule groups within a rule statement using JSON. The following listing shows the AWS Managed Rules rule group, AWSManagedRulesCommonRuleSet, in JSON format. The RuleActionOverrides specification lists a rule whose action has been overridden to Count.

```json
{
  "Name": "AWS-AWSManagedRulesCommonRuleSet",
  "Priority": 0,
  "Statement": {
    "ManagedRuleGroupStatement": {
```
You can reference and modify managed rule groups within a rule statement using the AWS CloudFormation YAML template. The following listing shows the AWS Managed Rules rule group, AWSManagedRulesCommonRuleSet, in AWS CloudFormation template. The RuleActionOverrides specification lists a rule whose action has been overridden to Count.

```yaml
Name: AWS-AWSManagedRulesCommonRuleSet
Priority: 0
Statement:
  ManagedRuleGroupStatement:
    VendorName: AWS
    Name: AWSManagedRulesCommonRuleSet
    RuleActionOverrides:
      - ActionToUse:
          Count: {}
        Name: NoUserAgent_HEADER
      ExcludedRules: []
    OverrideAction:
      None: {}
    VisibilityConfig:
      SampledRequestsEnabled: true,
      CloudWatchMetricsEnabled: true,
      MetricName: AWS-AWSManagedRulesCommonRuleSet
```

**AWS Managed Rules for AWS WAF**

AWS Managed Rules for AWS WAF is a managed service that provides protection against common application vulnerabilities or other unwanted traffic, without having to write your own rules. You have the option of selecting one or more rule groups from AWS Managed Rules for each web ACL, up to the maximum web ACL capacity unit (WCU) limit. You can choose whether to count (monitor) or block requests that are matched by the managed rules.
Mitigating false positives and testing rule group changes

Before using any managed rule group in production, test it in a non-production environment according to the guidance at Testing and tuning your AWS WAF protections (p. 212). Follow the testing and tuning guidance when you add a rule group to your web ACL, to test a new version of a rule group, and whenever a rule group isn't handling your web traffic as you need it to.

Shared security responsibilities

AWS Managed Rules are designed to protect you from common web threats. When used in accordance with the documentation, AWS Managed Rules rule groups add another layer of security for your applications. However, AWS Managed Rules rule groups aren't intended as a replacement for your security responsibilities, which are determined by the AWS resources that you select. Refer to the Shared Responsibility Model to ensure that your resources in AWS are properly protected.

AWS Managed Rules rule groups list

This section describes the most recent versions of the AWS Managed Rules rule groups. You see these on the console when you add a managed rule group to your web ACL. Through the API, you can retrieve this list along with the AWS Marketplace managed rule groups that you're subscribed to by calling ListAvailableManagedRuleGroups.

Note

For information about retrieving an AWS Managed Rules rule group's versions, see Retrieving the available versions for a managed rule group (p. 30).

All AWS Managed Rules rule groups support labeling, and the rule listings in this section include label specifications. You can retrieve the labels for a managed rule group through the API by calling DescribeManagedRuleGroup. The labels are listed in the AvailableLabels property in the response. For information about labeling, see Labels on web requests (p. 131).

The information that we publish for the AWS Managed Rules rule group rules is intended to provide you with enough information to use the rules while not providing information that bad actors could use to circumvent the rules. If you need more information than you find in this documentation, contact the AWS Support Center.

Test and tune any changes to your AWS WAF protections before you use them for production traffic. For information, see Testing and tuning your AWS WAF protections (p. 212).

AWS Managed Rules rule groups

- Baseline rule groups (p. 36)
  - Core rule set (CRS) managed rule group (p. 36)
  - Admin protection managed rule group (p. 41)
  - Known bad inputs managed rule group (p. 42)
- Use-case specific rule groups (p. 45)
  - SQL database managed rule group (p. 45)
  - Linux operating system managed rule group (p. 46)
  - POSIX operating system managed rule group (p. 47)
  - Windows operating system managed rule group (p. 48)
  - PHP application managed rule group (p. 50)
  - WordPress application managed rule group (p. 51)
- IP reputation rule groups (p. 51)
  - Amazon IP reputation list managed rule group (p. 52)
  - Anonymous IP list managed rule group (p. 52)
- AWS WAF Bot Control rule group (p. 53)
- AWS WAF Fraud Control account takeover prevention (ATP) rule group (p. 60)
Baseline rule groups

Baseline managed rule groups provide general protection against a wide variety of common threats. Choose one or more of these rule groups to establish baseline protection for your resources.

Core rule set (CRS) managed rule group

VendorName: AWS, Name: AWSManagedRulesCommonRuleSet, WCU: 700

The Core rule set (CRS) rule group contains rules that are generally applicable to web applications. This provides protection against exploitation of a wide range of vulnerabilities, including some of the high risk and commonly occurring vulnerabilities described in OWASP publications such as OWASP Top 10. Consider using this rule group for any AWS WAF use case.

Note
This table describes the latest static version of this rule group. For other versions, use the API command DescribeManagedRuleGroup.

<table>
<thead>
<tr>
<th>Rule name</th>

# Managed rule groups

## CrossSiteScripting_BODY

- **Description and label**: Inspects the request body for common cross-site scripting (XSS) patterns using the built-in AWS WAF Cross-site scripting attack rule statement (p. 107). Example patterns include scripts like `<script>alert("hello")</script>.

  - **Note**: The rule match details in the AWS WAF logs is not populated for version 2.0 of this rule group.

  - **Warning**: This rule only inspects the first 8 KB of the request body. For information, see Inspection of the request body, headers, and cookies (p. 120).

- **Rule action**: Block
- **Label**: awswaf:managed:aws:core-rule-set:CrossSiteScripting_Body

## CrossSiteScripting_URIPATH

- **Description and label**: Inspects the value of the URI path for common cross-site scripting (XSS) patterns using the built-in AWS WAF Cross-site scripting attack rule statement (p. 107). Example patterns include scripts like `<script>alert("hello")</script>.

  - **Note**: The rule match details in the AWS WAF logs is not populated for version 2.0 of this rule group.

- **Rule action**: Block
- **Label**: awswaf:managed:aws:core-rule-set:CrossSiteScripting_URIPATH

## Admin protection managed rule group

**VendorName**: AWS, **Name**: AWSManagedRulesAdminProtectionRuleSet, **WCU**: 100

The Admin protection rule group contains rules that allow you to block external access to exposed administrative pages. This might be useful if you run third-party software or want to reduce the risk of a malicious actor gaining administrative access to your application.

- **Note**: This table describes the latest static version of this rule group. For other versions, use the API command DescribeManagedRuleGroup.

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>
</tr>
</thead>
<tbody>
<tr>
<td>AdminProtection_URIPATH</td>
<td>Inspects for URI paths that are generally reserved for administration of a web server or application. Example patterns include sqlmanager.</td>
</tr>
</tbody>
</table>
### Known bad inputs managed rule group

**VendorName:** AWS, **Name:** AWSManagedRulesKnownBadInputsRuleSet, **WCU:** 200

The Known bad inputs rule group contains rules to block request patterns that are known to be invalid and are associated with exploitation or discovery of vulnerabilities. This can help reduce the risk of a malicious actor discovering a vulnerable application.

**Note**
This table describes the latest static version of this rule group. For other versions, use the API command `DescribeManagedRuleGroup`.

<table>
<thead>
<tr>

#### Use-case specific rule groups

Use-case specific rule groups provide incremental protection for many diverse AWS WAF use cases. Choose the rule groups that apply to your application.

**SQL database managed rule group**

VendorName: AWS, Name: AWSManagedRulesSQLiRuleSet, WCU: 200

The SQL database rule group contains rules to block request patterns associated with exploitation of SQL databases, like SQL injection attacks. This can help prevent remote injection of unauthorized queries. Evaluate this rule group for use if your application interfaces with an SQL database.

**Note**

This table describes the latest static version of this rule group. For other versions, use the API command DescribeManagedRuleGroup.

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLi_QUERYARGUMENTS</td>
<td>Uses the built-in AWS WAF SQL injection attack rule statement (p. 105), with sensitivity level set to Low, to inspect the values of all query parameters for patterns that match malicious SQL code.</td>
</tr>
<tr>
<td></td>
<td>Rule action: Block</td>
</tr>
<tr>
<td>SQLiExtendedPatterns_QUERYARGUMENTS</td>
<td>Inspects the values of all query parameters for patterns that match malicious SQL code. The patterns this rule inspects for aren't covered by the rule SQLi_QUERYARGUMENTS.</td>
</tr>
<tr>
<td></td>
<td>Rule action: Block</td>
</tr>
<tr>
<td></td>
<td>awswaf:managed:aws:sql-database:SQLiExtendedPatterns_QueryArguments</td>
</tr>
<tr>
<td>SQLi_BODY</td>

### Linux operating system managed rule group

**VendorName:** AWS, **Name:** AWSManagedRulesLinuxRuleSet, **WCU:** 200

The Linux operating system rule group contains rules that block request patterns associated with the exploitation of vulnerabilities specific to Linux, including Linux-specific Local File Inclusion (LFI) attacks. This can help prevent attacks that expose file contents or run code for which the attacker should not have had access. You should evaluate this rule group if any part of your application runs on Linux. You should use this rule group in conjunction with the POSIX operating system (p. 47) rule group.

**Note**

This table describes the latest static version of this rule group. For other versions, use the API command `DescribeManagedRuleGroup`.
<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>
</tr>
</thead>
<tbody>
<tr>
<td>LFI_URIPATH</td>
<td>Inspects the request path for attempts to exploit Local File Inclusion (LFI) vulnerabilities in web applications. Example patterns include files like <code>/proc/version</code>, which could provide operating system information to attackers.</td>
</tr>
<tr>
<td></td>
<td>Rule action: Block</td>
</tr>
<tr>
<td></td>
<td>Label: <code>awswaf:managed:aws:linux-os:LFI_URIPath</code></td>
</tr>
<tr>
<td>LFI_QUERYSTRING</td>
<td>Inspects the values of querystring for attempts to exploit Local File Inclusion (LFI) vulnerabilities in web applications. Example patterns include files like <code>/proc/version</code>, which could provide operating system information to attackers.</td>
</tr>
<tr>
<td></td>
<td>Rule action: Block</td>
</tr>
<tr>
<td></td>
<td>Label: <code>awswaf:managed:aws:linux-os:LFI_QueryString</code></td>
</tr>
<tr>
<td>LFI_COOKIE</td>
<td>Inspects the request cookie headers for attempts to exploit Local File Inclusion (LFI) vulnerabilities in web applications. Example patterns include files like <code>/proc/version</code>, which could provide operating system information to attackers.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning</strong></td>
</tr>
<tr>
<td></td>
<td>This rule only inspects the first 8 KB of the request cookies or the first 200 cookies, whichever limit is reached first. For information, see <code>Inspection of the request body, headers, and cookies (p. 120)</code>.</td>
</tr>
<tr>
<td></td>
<td>Rule action: Block</td>
</tr>
<tr>
<td></td>
<td>Label: <code>awswaf:managed:aws:linux-os:LFI_Cookie</code></td>
</tr>
</tbody>
</table>

**POSIX operating system managed rule group**

VendorName: AWS, Name: AWSManagedRulesUnixRuleSet, WCU: 100

The POSIX operating system rule group contains rules that block request patterns associated with the exploitation of vulnerabilities specific to POSIX and POSIX-like operating systems, including Local File Inclusion (LFI) attacks. This can help prevent attacks that expose file contents or run code for which the attacker should not have had access. You should evaluate this rule group if any part of your application runs on a POSIX or POSIX-like operating system, including Linux, AIX, HP-UX, macOS, Solaris, FreeBSD, and OpenBSD.

**Note**

This table describes the latest static version of this rule group. For other versions, use the API command `DescribeManagedRuleGroup`.

<td>UNIXShellCommandsVariables_QUERYARGUMENTS</td>
<td>Inspects the values of all query parameters for attempts to exploit command injection, LFI, and path traversal vulnerabilities in web applications that run on Unix systems. Examples include patterns like <code>echo $HOME</code> and <code>echo $PATH</code>.</td>
</tr>
<tr>
<td>UNIXShellCommandsVariables_BODY</td>
<td>Inspects the request body for attempts to exploit command injection, LFI, and path traversal vulnerabilities in web applications that run on Unix systems. Examples include patterns like <code>echo $HOME</code> and <code>echo $PATH</code>. <strong>Warning</strong> This rule only inspects the first 8 KB of the request body. For information, see <strong>Inspection of the request body, headers, and cookies</strong> (p. 120).</td>
</tr>
</tbody>
</table>

**Windows operating system managed rule group**

VendorName: AWS, Name: AWSManagedRulesWindowsRuleSet, WCU: 200

The Windows operating system rule group contains rules that block request patterns associated with the exploitation of vulnerabilities specific to Windows, like remote execution of PowerShell commands. This can help prevent exploitation of vulnerabilities that permit an attacker to run unauthorized commands or run malicious code. Evaluate this rule group if any part of your application runs on a Windows operating system.

**Note**
This table describes the latest static version of this rule group. For other versions, use the API command DescribeManagedRuleGroup.

<table>
<thead>
<tr>

### PHP application managed rule group

**VendorName:** AWS, **Name:** AWSManagedRulesPHPRuleSet, **WCU:** 100

The PHP application rule group contains rules that block request patterns associated with the exploitation of vulnerabilities specific to the use of the PHP programming language, including injection of unsafe PHP functions. This can help prevent exploitation of vulnerabilities that permit an attacker to remotely run code or commands for which they are not authorized. Evaluate this rule group if PHP is installed on any server with which your application interfaces.

**Note**

This table describes the latest static version of this rule group. For other versions, use the API command DescribeManagedRuleGroup.

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>

</tbody>
</table>

**WordPress application managed rule group**

VendorName: AWS, Name: AWSManagedRulesWordPressRuleSet, WCU: 100

The WordPress application rule group contains rules that block request patterns associated with the exploitation of vulnerabilities specific to WordPress sites. You should evaluate this rule group if you are running WordPress. This rule group should be used in conjunction with the SQL database (p. 45) and PHP application (p. 50) rule groups.

**Note**

This table describes the latest static version of this rule group. For other versions, use the API command DescribeManagedRuleGroup.

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>
</tr>
</thead>
<tbody>
<tr>
<td>WordPressExploitableCommands_QUERYSTRING</td>
<td>Inspects the request query string for high risk WordPress commands that can be exploited in vulnerable installations or plugins. Examples patterns include commands like do-reset-wordpress.</td>
</tr>
<tr>
<td>Rule action: Block</td>
<td></td>
</tr>
<tr>
<td>WordPressExploitablePaths_URIPATH</td>
<td>Inspects the request URI path for WordPress files like xmlrpc.php, which are known to have easily exploitable vulnerabilities.</td>
</tr>
<tr>
<td>Rule action: Block</td>
<td></td>
</tr>
</tbody>
</table>

**IP reputation rule groups**

IP reputation rule groups block requests based on their source IP address.

Choose one or more of these rule groups if you want to reduce your exposure to bot traffic or exploitation attempts, or if you are enforcing geographic restrictions on your content. For bot management, see also AWS WAF Bot Control rule group (p. 53).
The rule groups in this category don’t provide versioning or SNS update notifications.

**Amazon IP reputation list managed rule group**

VendorName: AWS, Name: AWSManagedRulesAmazonIpReputationList, WCU: 25

The Amazon IP reputation list rule group contains rules that are based on Amazon internal threat intelligence. This is useful if you would like to block IP addresses typically associated with bots or other threats. Blocking these IP addresses can help mitigate bots and reduce the risk of a malicious actor discovering a vulnerable application.

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWSManagedIPReputationList</td>
<td>Inspects for IP addresses that have been identified as bots. Rule action: Block</td>
</tr>
<tr>
<td></td>
<td>Label: awswaf:managed:aws:amazon-ip-list:AWSManagedIPReputationList</td>
</tr>
<tr>
<td>AWSManagedReconnaissanceList</td>
<td>Inspects for connections from IP addresses that are performing reconnaissance against AWS resources. Rule action: Block</td>
</tr>
<tr>
<td></td>
<td>Label: awswaf:managed:aws:amazon-ip-list:AWSManagedReconnaissanceList</td>
</tr>
<tr>
<td>AWSManagedIPDDoSList</td>
<td>Inspects for IP addresses that have been identified as actively engaging in DDoS activities. Rule action: Count</td>
</tr>
<tr>
<td></td>
<td>Label: awswaf:managed:aws:amazon-ip-list:AWSManagedIPDDoSList</td>
</tr>
</tbody>
</table>

**Anonymous IP list managed rule group**

VendorName: AWS, Name: AWSManagedRulesAnonymousIpList, WCU: 50

The Anonymous IP list rule group contains rules to block requests from services that permit the obfuscation of viewer identity. These include requests from VPNs, proxies, Tor nodes, and hosting providers. This rule group is useful if you want to filter out viewers that might be trying to hide their identity from your application. Blocking the IP addresses of these services can help mitigate bots and evasion of geographic restrictions.

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>
</tr>
</thead>
<tbody>
<tr>
<td>AnonymousIPList</td>
<td>Inspects for a list of IP addresses of sources known to anonymize client information, like TOR nodes, temporary proxies, and other masking services. Rule action: Block</td>
</tr>
</tbody>
</table>
### Rule name

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostingProviderIPList</td>
<td>Inspects for a list of IP addresses from hosting and cloud providers, which are less likely to source end-user traffic. The IP list does not include AWS IP addresses.</td>
</tr>
<tr>
<td></td>
<td>Rule action: Block</td>
</tr>
<tr>
<td></td>
<td>Label: awswaf:managed:aws:anonymous-ip-list:HostingProviderIPList</td>
</tr>
</tbody>
</table>

### AWS WAF Bot Control rule group

VendorName: AWS, Name: AWSManagedRulesBotControlRuleSet, WCU: 50

The Bot Control managed rule group provides rules to block and manage requests from bots. Bots can consume excess resources, skew business metrics, cause downtime, and perform malicious activities.

**Note**

You are charged additional fees when you use this managed rule group. For more information, see [AWS WAF Pricing](#).

In order to keep your costs down and to be sure you're managing your bot traffic as you want, use this rule group in accordance with the guidance at [AWS WAF Bot Control](#) (p. 151).

The Bot Control rule group doesn't provide versioning or SNS update notifications.

### Protection levels

The Bot Control managed rule group provides two levels of protection that you can choose from:

- **Common** – Detects a variety of self-identifying bots, such as web scraping frameworks, search engines, and automated browsers. Bot Control protections at this level identify common bots using traditional bot detection techniques, such as static request data analysis. The rules label traffic from these bots and block the ones that they cannot verify.

- **Targeted** – Includes the common-level protections and adds detection for advanced bots that do not self identify. Targeted protections use advanced detection techniques such as browser interrogation, fingerprinting, and behavior heuristics to identify bad bot traffic. The protections target these bots using a combination of rate limiting and CAPTCHA and background browser challenges. The rules that provide targeted protection have names that begin with `TGT_`.

### Token labels

This rule group uses AWS WAF token management to inspect and label web requests according to the status of their AWS WAF tokens. AWS WAF uses tokens for client session tracking and verification.

AWS WAF applies one of the following labels when it inspects a web request's token and challenge timestamp. AWS WAF doesn't add labeling about the status of the CAPTCHA timestamp.

- `awswaf:managed:token:accepted` – The request token is present and has an unexpired challenge timestamp.
- `awswaf:managed:token:rejected` – The request token is present but is either corrupt or has an expired challenge timestamp.
- `awswaf:managed:token:absent` – The request doesn't have a token.

For more information, see [AWS WAF tokens](#) (p. 144).
Bot Control labels

The Bot Control managed rule group generates labels with the namespace prefix `awswaf:managed:aws:bot-control:` followed by the custom namespace. The rule group might add more than one label to a request.

Each label reflects the Bot Control rule findings:

- `awswaf:managed:aws:bot-control:bot:name:<name>` – The bot name, if one is available, for example the custom namespaces `bot:name:slurp`, `bot:name:googlebot`, and `bot:name:pocket_parser`.
- `awswaf:managed:aws:bot-control:bot:verified` – Used to indicate a verified bot. This is used for common desirable bots, and can be useful when combined with category labels like `bot:category:search_engine` or name labels like `bot:name:googlebot`.

**Note**
Bot Control uses the IP address from the web request origin and can't be configured to use the AWS WAF forwarded IP configuration to inspect using a different IP address source. If you have verified bots that route through a proxy or load balancer, you can add a rule to your web ACL before the Bot Control rule group that does use the forwarded IP address and that explicitly allows those requests. For information about using the forwarded IP addresses, see Forwarded IP address (p. 117).

- `awswaf:managed:aws:bot-control:signal:<signal-details>` – Used for attributes of the request that are indicative of bots that are not more commonly used or verified.

You can retrieve the labels through the API by calling `DescribeManagedRuleGroup`. The labels are listed in the `AvailableLabels` property in the response.

The Bot Control managed rule group applies labels to a set of verifiable bots that are commonly allowed. The rule group doesn't block these verified bots and doesn't apply any `signal:` labels. If you want, you can block them, or a subset of them, by writing a custom rule that uses the labels applied by the Bot Control managed rule group. For more information about this and examples, see AWS WAF Bot Control (p. 151).

**Rule listing**

The following table lists the Bot Control rules.

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CategoryAdvertising</td>
<td>Inspects for bots that are used for advertising purposes.</td>
</tr>
<tr>
<td></td>

### AWS WAF Fraud Control account takeover prevention (ATP) rule group

VendorName: AWS, Name: AWSManaged Rules ATP Rule Set, WCU: 50

The AWS WAF Fraud Control account takeover prevention (ATP) managed rule group provides rules to block, label, and manage requests that might be part of malicious account takeover attempts.

**Note**
You are charged additional fees when you use this managed rule group. For more information, see [AWS WAF Pricing](#).

**Using this rule group**

This rule group requires specific configuration. To configure and implement this rule group, see the guidance at [AWS WAF Fraud Control account takeover prevention (ATP)](#) (p. 165).

To make full use of the capabilities of this rule group, implement the AWS WAF client application integration SDKs. The SDKs enable client session tracking through the use of AWS WAF tokens. When you use the SDKs, you enable this rule group to use client tokens for client session tracking and management. A number of the rules only run if the tokens are available. For information about tokens and the SDKs, see [AWS WAF client application integration](#) (p. 175) and [AWS WAF tokens](#) (p. 144).

You can't use this rule group with Amazon Cognito user pools. You can't associate a web ACL that uses this rule group with a user pool, and you can't add this rule group to a web ACL that's already associated with a user pool.

This rule group doesn't provide versioning or SNS update notifications.

**Token labels**

This rule group uses AWS WAF token management to inspect and label web requests according to the status of their AWS WAF tokens. AWS WAF uses tokens for client session tracking and verification.

AWS WAF applies one of the following labels when it inspects a web request's token and challenge timestamp. AWS WAF doesn't add labeling about the status of the CAPTCHA timestamp.

- `awswaf:managed:token:accepted`—The request token is present and has an unexpired challenge timestamp.

---

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description</th>
</tr>
</thead>
</table>
| TGT_SignalBrowserInconsistency | Inspects for inconsistent browser interrogation data. This inspection only applies when the web request has a token. Tokens are added to requests by the application integration SDKs and by the rule actions CAPTCHA and Challenge. For more information, see [AWS WAF tokens](#) (p. 144). Rule action, applied only to clients that are not verified bots: CAPTCHA  
For verified bots, the rule group takes no action, but it adds the rule labeling plus the label `awswaf:managed:aws:bot-control:bot:verified`. |
Managed rule groups

- `awswaf:managed:token:rejected` – The request token is present but is either corrupt or has an expired challenge timestamp.
- `awswaf:managed:token:absent` – The request doesn't have a token.

For more information, see [AWS WAF tokens](p. 144).

**ATP labels**

The ATP managed rule group generates labels with the namespace prefix `awswaf:managed:aws:atp:` followed by the custom namespace.

The following table lists the ATP rules in `AWSManagedRulesATPRuleSet` and the labels that the rule group adds to web requests.

<table>
<thead>
<tr>
<th>Rule name</th>
<th>Description and label</th>
</tr>
</thead>
<tbody>
<tr>
<td>UnsupportedCognitoIDP</td>
<td>Inspects for web traffic going to an Amazon Cognito user pool. ATP isn't available for use with Amazon Cognito user pools, and this rule helps to ensure that the other ATP rule group rules are not used to evaluate user pool traffic. Rule action: Block</td>
</tr>
<tr>
<td>VolumetricIpHigh</td>
<td>Inspects for high volumes of requests sent from individual IP addresses. A high volume is more than 20 requests in a 10 minute window. Rule action: Block</td>
</tr>
</tbody>
</table>

The rule group applies the following labels to requests with medium volumes (16-20 requests per 10 minute window) and low volumes (11-15 requests per 10 minute window), but takes no action on them:

<table>
<thead>
<tr>
<th>VolumetricSession</th>
<th>Inspects for high volumes of requests sent from individual client sessions.</th>
</tr>
</thead>
<tbody>

</table>

### Deployments for versioned AWS Managed Rules rule groups

AWS deploys changes to its versioned AWS Managed Rules rule groups in three standard deployments: release candidate, static version, and default version. Additionally, AWS might sometimes need to release an exception deployment or roll back a default version deployment.

**Note**

This section applies only to AWS Managed Rules rule groups that are versioned. The rule groups that are not versioned are IP reputation, Bot Control, and ATP rule groups.

### Sign up for deployment notifications

For every deployment of a versioned rule group, AWS provides at least one SNS notification. In some cases, we also update the managed rule group description in this guide, the changelog for the AWS Managed Rules rule groups, and the document history page. To sign up for notifications, see [Getting notified of new versions and updates to a managed rule group](p. 31).

### Topics

- Overview of the standard deployments for AWS Managed Rules (p. 64)
- Typical version states for AWS Managed Rules (p. 64)
- Release candidate deployments for AWS Managed Rules (p. 65)
- Static version deployments for AWS Managed Rules (p. 67)
- Default version deployments for AWS Managed Rules (p. 68)
- Exception deployments for AWS Managed Rules (p. 69)
Overview of the standard deployments for AWS Managed Rules

AWS rolls out new AWS Managed Rules functionality using three standard deployment stages: release candidate, static version, and default version.

The following diagram depicts these standard deployments. Each is described in more detail in the sections that follow.

**Typical version states for AWS Managed Rules**

Normally, a versioned managed rule group has a number of unexpired static versions, and the default version points to the static version that AWS recommends. The following figure shows an example of the typical set of static versions and default version setting.
Managed rule group: Version settings

The production action for most rules in a static version is Block, but it might be set to something different. For detailed information about rule action settings, see the rule listings for each rule group at AWS Managed Rules rule groups list (p. 35).

Release candidate deployments for AWS Managed Rules

When AWS has a candidate set of rule changes for a managed rule group, it tests them in a temporary release candidate deployment. AWS evaluates the candidate rules in count mode against production traffic, and performs final tuning activities, including mitigating false positives. AWS tests release candidate rules in this way for all customers who use the default version of the rule group. Release candidate deployments don't apply to customers who use a static version of the rule group.

If you use the default version, a release candidate deployment won't alter how your web traffic is managed by the rule group. You might notice the following while the candidate rules are being tested:

- Default version name change from Default (using Version_X.Y) to Default (using Version_X.Y_PLUS_RC_COUNT).
- Additional count metrics in Amazon CloudWatch with RC_COUNT in their names. These are generated by the release candidate rules.

AWS tests a release candidate for about a week, then removes it and resets the default version to the current recommended static version.

AWS performs the following steps for a release candidate deployment:

1. **Create the release candidate** – AWS adds a release candidate based on the current recommended static version, which is the version that the default is pointing to.

   The name of the release candidate is the static version name appended with _PLUS_RC_COUNT. For example, if the current recommended static version is Version_2.1, then the release candidate would be named Version_2.1_PLUS_RC_COUNT.

   The release candidate contains the following rules:

   - Rules copied exactly from the current recommended static version, with no changes to rule configurations.
   - Candidate new rules with rule action set to Count and with names that end with _RC_COUNT.

   Most candidate rules provide proposed improvements to rules that exist already in the rule group. The name for each of these rules is the existing rule's name appended with _RC_COUNT.
2. **Set the default version to the release candidate and test** – AWS sets the default version to point to the new release candidate, to perform testing against your production traffic. Testing usually takes about a week.

You'll see the default version's name change from the one that indicates only the static version, such as Default (using Version_1.4), to one that indicates the static version plus the release candidate rules, such as Default (using Version_1.4_PLUS_RC_COUNT). This naming scheme lets you identify which static version you're using to manage your web traffic.

The following diagram shows the state of the example rule group versions at this point.

![Diagram showing version states](image)

The release candidate rules are always configured with Count action, so they don't alter how the rule group manages your web traffic.

The release candidate rules generate Amazon CloudWatch count metrics that AWS uses to verify behavior and to identify false positives. AWS makes adjustments as needed, to tune the behavior of the release candidate count rules.

The release candidate version isn't a static version, and it's not available for you to choose from the list of static rule group versions. You can only see the name of the release candidate version in the default version specification.

3. **Return the default version to the recommended static version** – After testing the release candidate rules, AWS sets the default version back to the current recommended static version. The default version name setting drops the _PLUS_RC_COUNT ending, and the rule group stops generating CloudWatch count metrics for the release candidate rules. This is a silent change, and is not the same as a deployment of a default version rollback.
The following diagram shows the state of the example rule group versions after the testing of the release candidate is complete.

![Managed rule group: Release candidate testing complete](image)

### Timing and notifications

AWS deploys release candidate versions on an as-needed basis, to test improvements to a rule group.

- **SNS** – AWS sends an SNS notification at the start of the deployment. The notification indicates the estimated time that the release candidate will be tested. When testing is complete, AWS silently returns the default to the static version setting, without a second notification.

- **Change log** – AWS doesn't update the change log or other parts of this guide for this type of deployment.

### Static version deployments for AWS Managed Rules

When AWS determines that a release candidate provides valuable changes to the rule group, AWS deploys a new static version for the rule group based on the release candidate. This deployment doesn't change the default version of the rule group.

The new static version contains the following rules from the release candidate:

- Rules from the prior static version that don't have a replacement candidate among the release candidate rules.
- Release candidate rules, with the following changes:
  - AWS changes the rule name by removing the release candidate suffix `_RC_COUNT`.
  - AWS changes the rule actions from Count to their production rule actions.

For release candidate rules that are replacements of prior existing rules, this replaces the functionality of the prior rules in the new static version.

The following diagram depicts the creation of the new static version from the release candidate.
After deployment, the new static version is available for you to test and to use in your protections if you want to. You can review new and updated rule actions and descriptions in the rule group's rule listings at AWS Managed Rules rule groups list (p. 35).

A static version is immutable after deployment, and only changes when AWS expires it. For information about version lifecycles, see Version management with managed rule groups (p. 26).

**Timing and notifications**

AWS deploys a new static version as needed, in order to deploy improvements to rule group functionality. The deployment of a static version doesn't impact the default version setting.

- **SNS** – AWS sends an SNS notification at the start of the deployment.
- **Change log** – After the deployment is complete everywhere that AWS WAF is available, AWS updates the rule group definition in this guide as needed, and then announces the release in the AWS Managed Rules rule group change log and in the documentation history page.

**Default version deployments for AWS Managed Rules**

When AWS determines that a new static version provides improved protections for the rule group compared to the current default, AWS updates the default version to the new static version. AWS might release multiple static versions before promoting one to the rule group's default version.

The following diagram shows the state of the example rule group versions after AWS moves the default version setting to the new static version.
Before deploying this change to the default version, AWS provides notifications so that you can test and prepare for the upcoming changes. If you use the default version, you can take no action and remain on it through the update. If instead you want to delay switching to the new version, before the planned start of the default version deployment, you can explicitly configure your rule group to use the static version that the default is set to.

**Timing and notifications**

AWS updates the default version when it recommends a different static version for the rule group than the one that's currently in use.

- **SNS** – AWS sends an SNS notification at least one week prior to the targeted deployment day and then another on the deployment day, at the start of the deployment. Each notification includes the rule group name, the static version that the default version is being updated to, and the deployment date. The notification sent on the deployment day also provides the scheduled timing of the deployment for each AWS Region where the update is being performed.
- **Change log** – AWS doesn't update the change log or other parts of this guide for this type of deployment.

**Exception deployments for AWS Managed Rules**

AWS might bypass the standard deployment stages in order to quickly deploy updates that address critical security risks. An exception deployment might involve any of the standard deployment types, and it might be rolled out quickly across the AWS Regions.

AWS provides as much advance notification as possible for exception deployments.

**Timing and notifications**

AWS performs exception deployments only when required.

- **SNS** – AWS sends an SNS notification as far ahead of the targeted deployment day as possible and then another one at the start of the deployment. Each notification includes the rule group name, the change that's being made, and the deployment date.
- **Change log** – If the deployment is for a static version, after the deployment is complete everywhere that AWS WAF is available, AWS updates the rule group definition in this guide as needed, and then announces the release in the AWS Managed Rules rule group change log and in the documentation history page.
Default deployment rollbacks for AWS Managed Rules

Under certain conditions, AWS might roll back the default version to its prior setting. A rollback usually takes less than ten minutes for all AWS Regions.

AWS performs a rollback only to mitigate a significant issue in a static version, such as an unacceptably high level of false positives.

After the rollback of the default version setting, AWS expedites both the expiration of the static version that has the issue and the release of a new static version to address the issue.

Timing and notifications

AWS performs default version rollbacks only when required.

- **SNS** – AWS sends a single SNS notification at the time of the rollback. The notification includes the rule group name, the version that the default version is being set to, and the deployment date. This deployment type is very quick, so the notification doesn't provide timing information for Regions.

- **Change log** – AWS doesn't update the change log or other parts of this guide for this type of deployment.

AWS Managed Rules disclaimer

AWS Managed Rules are designed to protect you from common web threats. When used in accordance with the documentation, AWS Managed Rules rule groups add another layer of security for your applications. However, AWS Managed Rules rule groups aren't intended as a replacement for your security responsibilities, which are determined by the AWS resources that you select. Refer to the Shared Responsibility Model to ensure that your resources in AWS are properly protected.

AWS Managed Rules changelog

This section lists changes to the AWS Managed Rules for AWS WAF since their release in November, 2019.

**Note**

This changelog reports changes to the rules and rule groups in AWS Managed Rules for AWS WAF.

For the IP reputation rule groups (p. 51), this changelog reports changes to the rules and rule group, but it doesn't report changes to the IP address lists that are used by the rules, due to the dynamic nature of those lists.

### Known bad inputs

- **Log4JRCE**
  - Released version 1.4 of the rule Log4JRCE to tune the matching criteria and to inspect additional headers. Released version 1.5 to tune the matching criteria.

- **BadAuthToken_COOKIE_AUTHORIZATION**
  - Added the rule Log4JRCE version 1.2 in response to the recently disclosed security issue within Log4j. For information see [CVE-2021-44228](#). This rule inspects common URI paths, query strings, the first 8KB of the request body, and common headers. The rule uses double URL DECODE UNI text transformations. Released version 1.3 of Log4JRCE to tune the matching criteria and to inspect additional headers. Removed the rule BadAuthToken_COOKIE_AUTHORIZATION.

The following table lists changes prior to December, 2021.

### AWS Marketplace managed rule groups

AWS Marketplace managed rule groups are available by subscription through the AWS Marketplace console at [AWS Marketplace](https://aws.amazon.com/marketplace). After you subscribe to a AWS Marketplace managed rule group, you can use it in AWS WAF. To use an AWS Marketplace rule group in an AWS Firewall Manager AWS WAF policy, each account in your organization must subscribe to it.

Test and tune any changes to your AWS WAF protections before you use them for production traffic. For information, see [Testing and tuning your AWS WAF protections](p. 212).

**AWS Marketplace Rule Group Pricing**

AWS Marketplace rule groups are available with no long-term contracts, and no minimum commitments. When you subscribe to a rule group, you are charged a monthly fee (prorated hourly) and ongoing request fees based on volume. For more information, see [AWS WAF Pricing](https://aws.amazon.com/waf-pricing/) and the description for each AWS Marketplace rule group at [AWS Marketplace](https://aws.amazon.com/marketplace).

**Have questions about an AWS Marketplace rule group?**

For questions about a rule group that's managed by an AWS Marketplace seller and to request changes in functionality, contact the provider's customer support team. To find contact information, see the provider's listing at [AWS Marketplace](https://aws.amazon.com/marketplace).

The AWS Marketplace rule group provider determines how to manage the rule group, for example how to update the rule group and whether the rule group is versioned. The provider also determines the details of the rule group, including the rules, rule actions, and any labels that the rules add to matching web requests.

**Subscribing to AWS Marketplace managed rule groups**

You can subscribe to and unsubscribe from AWS Marketplace rule groups on the AWS WAF console.

**Important**

To use an AWS Marketplace rule group in an AWS Firewall Manager policy, each account in your organization must first subscribe to that rule group.

**To subscribe to an AWS Marketplace managed rule group**

2. In the navigation pane, choose **AWS Marketplace**.
3. In the **Available marketplace products** section, choose the name of a rule group to view the details and pricing information.
4. If you want to subscribe to the rule group, choose **Continue**.

   **Note**

   If you don’t want to subscribe to this rule group, simply close this page in your browser.
5. Choose **Set up your account**.
6. Add the rule group to a web ACL, similar to how you add an individual rule. For more information, see Creating a web ACL (p. 18) or Editing a web ACL (p. 21).

**Note**
When adding a rule group to a web ACL, you can override the actions of rules in the rule group and of the rule group result. For more information, see Action overrides in rule groups (p. 15).

After you’re subscribed to an AWS Marketplace rule group, you use it in your web ACLs as you do other managed rule groups. For information, see Creating a web ACL (p. 18).

### Unsubscribing from AWS Marketplace managed rule groups

You can unsubscribe from AWS Marketplace rule groups on the AWS WAF console.

**Important**
To stop the subscription charges for an AWS Marketplace managed rule group, you must remove it from all web ACLs in AWS WAF and in any Firewall Manager AWS WAF policies, in addition to unsubscribing from it. If you unsubscribe from an AWS Marketplace managed rule group but don’t remove it from your web ACLs, you will continue to be charged for the subscription.

To unsubscribe from an AWS Marketplace managed rule group

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. Remove the rule group from all web ACLs. For more information, see Editing a web ACL (p. 21).
3. In the navigation pane, choose AWS Marketplace.
4. Choose Manage your subscriptions.
5. Choose Cancel subscription next to the name of the rule group that you want to unsubscribe from.
6. Choose Yes, cancel subscription.

### Troubleshooting AWS Marketplace rule groups

If you find that an AWS Marketplace rule group is blocking legitimate traffic, you can troubleshoot the problem by performing the following steps.

To troubleshoot an AWS Marketplace rule group

1. Override the actions to count for the rules that are blocking specific requests. You can identify which rules are blocking specific requests using either the AWS WAF sampled requests or AWS WAF logs. You can identify the rules by looking at the ruleGroupId field in the log or the RuleWithinRuleGroup in the sampled request. You can identify the rule in the pattern `<Seller Name>#<RuleGroup Name>#<Rule Name>`.
2. If setting specific rules to only count requests doesn’t solve the problem, you can override all of the rule actions or change the action for the AWS Marketplace rule group itself from No override to Override to count. This allows the web request to pass through, regardless of the individual rule actions within the rule group.
3. After overriding either the individual rule action or the entire AWS Marketplace rule group action, contact the rule group provider’s customer support team to further troubleshoot the issue. For contact information, see the rule group listing on the product listing pages on AWS Marketplace.

### Contacting AWS support

For problems with AWS WAF or a rule group that is managed by AWS, contact AWS Support. For problems with a rule group that is managed by an AWS Marketplace seller, contact the provider’s customer support team. To find contact information, see the provider’s listing on AWS Marketplace.
Managing your own rule groups

You can create your own rule group to reuse collections of rules that you either don't find in the managed rule group offerings or that you prefer to handle on your own.

Rule groups that you create hold rules just like a web ACL does, and you add rules to a rule group in the same way as you do to a web ACL. When you create your own rule group, you must set an immutable maximum capacity for it.

You can share a rule group that you own with another AWS account, for use by that account. This option is available through the AWS WAF API. For more information, see PutPermissionPolicy in the AWS WAF API Reference.

Topics

• Creating a rule group (p. 81)
• Using your rule group in a web ACL (p. 81)
• Deleting a rule group (p. 82)

Creating a rule group

To create a rule group

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Rule groups, and then Create rule group.
3. Enter a name and description for the rule group. You'll use these to identify the set to manage it and use it.

   Note
   You can't change the name after you create the rule group.

4. For Region, choose the Region where you want to store the rule group. To use a rule group in web ACLs that protect Amazon CloudFront distributions, you must use the global setting. You can use the global setting for regional applications, too.
5. Choose Next.
6. Add rules to the rule group using the Rule builder wizard, the same as you do in web ACL management. The only difference is that you can't add a rule group to another rule group.
7. For Capacity, set the maximum for the rule group's use of web ACL capacity units (WCUs). This is an immutable setting. For information about WCUs, see AWS WAF Web ACL capacity units (WCU) (p. 7).

   As you add rules to the rule group, the Add rules and set capacity pane displays the minimum required capacity, which is based on the rules that you've already added. You can use this and your future plans for the rule group to help estimate the capacity that the rule group will require.
8. Review the settings for the rule group, and choose Create.

Using your rule group in a web ACL

To use a rule group in a web ACL, you add it to the web ACL in a rule group reference statement.

Production traffic risk
Before you deploy changes in your web ACL for production traffic, test and tune them in a staging or testing environment until you are comfortable with the potential impact to your
traffic. Then test and tune your updated rules in count mode with your production traffic before enabling them. For guidance, see Testing and tuning your AWS WAF protections (p. 212).

On the console, when you add or update the rules in your web ACL, on the Add rules and rule groups page, choose Add rules, and then choose Add my own rules and rule groups. Then choose Rule group and select your rule group from the list.

In your web ACL, you can alter the behavior of a rule group and its rules by setting the individual rule actions to count or any other action and by overriding the resulting rule group action to count. This can help you do things like test a rule group, identify false positives from rules in a rule group, and customize how a managed rule group handles your requests. For more information about these options, see Action overrides in rule groups (p. 15).

If your rule group contains a rate-based statement, each web ACL where you use the rule group has its own separate rate tracking and management for the rate-based rule, independent of any other web ACL where you use the rule group. For more information, see Rate-based rule statement (p. 100).

Temporary inconsistencies during updates

When you create or change a web ACL or other AWS WAF resources, the changes take a small amount of time to propagate to all areas where the resources are stored. The propagation time can be from a few seconds to a number of minutes.

The following are examples of the temporary inconsistencies that you might notice during change propagation:

- After you create a web ACL, if you try to associate it with a resource, you might get an exception indicating that the web ACL is unavailable.
- After you add a rule group to a web ACL, the new rule group rules might be in effect in one area where the web ACL is used and not in another.
- After you change a rule action setting, you might see the old action in some places and the new action in others.
- After you add an IP address to an IP set that is in use in a blocking rule, the new address might be blocked in one area while still allowed in another.

Deleting a rule group

Follow the guidance in this section to delete a rule group.

Deleting referenced sets and rule groups

When you delete an entity that you can use in a web ACL, like an IP set, regex pattern set, or rule group, AWS WAF checks to see if the entity is currently being used in a web ACL. If it finds that it is in use, AWS WAF warns you. AWS WAF is almost always able to determine if an entity is being referenced by a web ACL. However, in rare cases it might not be able to do so. If you need to be sure that nothing is currently using the entity, check for it in your web ACLs before deleting it. If the entity is a referenced set, also check that no rule groups are using it.

To delete a rule group

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Rule groups.
3. Choose the rule group that you want to delete, and then choose Delete.
Rule groups provided by other services

If you or an administrator in your organization uses AWS Firewall Manager or AWS Shield Advanced to manage resource protections using AWS WAF, you might see rule group reference statements added to web ACLs in your account.

The names of these rule groups begin with the following strings:

- **ShieldMitigationRuleGroup** – These rule groups are managed by AWS Shield Advanced. Shield Advanced adds them to the web ACLs that you use for Shield Advanced application layer (layer 7) protections, when you enable automatic application layer DDoS mitigation for the associated resource. For more information about these rule groups, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

  **Warning**
  Don't manually delete this rule group reference statement from your web ACL. Doing this could have unintended consequences for all resources that are associated with the web ACL. Instead, use Shield Advanced to disable automatic mitigation for the resources that are associated with the web ACL. Shield Advanced will remove the rule group when it's no longer needed for automatic mitigation.

- **PREFMManaged** and **POSTFMManaged** – These rule groups are managed by AWS Firewall Manager. Firewall Manager provides them inside web ACLs that Firewall Manager creates and manages. The names of the web ACLs begin with **FMManagedWebACLV2**. For information about these web ACLs and rule groups, see AWS WAF policies (p. 404).

Rules

An AWS WAF rule defines how to inspect HTTP(S) web requests and the action to take on a request when it matches the inspection criteria. You define rules only in the context of a rule group or web ACL.

You can define rules that inspect for criteria like the following:

- Scripts that are likely to be malicious. Attackers embed scripts that can exploit vulnerabilities in web applications. This is known as cross-site scripting (XSS).
- IP addresses or address ranges that requests originate from.
- Country or geographical location that requests originate from.
- Length of a specified part of the request, such as the query string.
- SQL code that is likely to be malicious. Attackers try to extract data from your database by embedding malicious SQL code in a web request. This is known as SQL injection.
- Strings that appear in the request, for example, values that appear in the User-Agent header or text strings that appear in the query string. You can also use regular expressions (regex) to specify these strings.
- Labels that prior rules in the web ACL have added to the request.

Each rule requires one top-level statement, which might contain nested statements at any depth, depending on the rule and statement type. Some rule types take sets of criteria. For example, you can specify up to 10,000 IP addresses or IP address ranges in an IP address rule.

In addition to statements with web request inspection criteria, like the ones in the preceding list, AWS WAF supports logical statements for **AND**, **OR**, and **NOT** that you use to combine statements in a rule.

For example, based on recent requests that you've seen from an attacker, you might create a rule with a logical **AND** statement that combines the following nested statements:
• The requests come from 192.0.2.44.
• They contain the value BadBot in the User-Agent header.
• They appear to include SQL-like code in the query string.

In this case, the web request needs to match all of the statements to result in a match for the top-level AND.

Rules don't exist in AWS WAF on their own. They aren't AWS resources, and they don't have Amazon Resource Names (ARNs). You can access a rule by name in the rule group or web ACL where it's defined. You can manage rules and copy them to other web ACLs by using the JSON format of the rule group or web ACL that contains the rule. Or you can manage them through the AWS WAF console Rule Builder, which is available for web ACLs and rule groups.

Topics
• AWS WAF rule name (p. 84)
• AWS WAF rule action (p. 84)
• AWS WAF rule statements (p. 85)

AWS WAF rule name

You must assign a unique name to every rule in your web ACL or rule group.

The name can contain only the characters A-Z, a-z, 0-9, - (hyphen), and _ (underscore). You can't change the name of a rule after you create it in your rule group or web ACL.

AWS WAF rule action

The rule action tells AWS WAF what to do with a web request when it matches the criteria defined in the rule. You can optionally add custom behavior to each rule action.

Here are the rule action options:

• **Count** – AWS WAF counts the request but doesn't determine whether to allow it or block it. With this action, AWS WAF continues processing the remaining rules in the web ACL. You can insert custom headers into the request and you can add labels that other rules can match against.

• **Allow** – AWS WAF allows the request to be forwarded to the protected AWS resource for processing and response. This action terminates the web ACL evaluation of the request. You can insert custom headers into the request before forwarding it to the protected resource.

• **Block** – AWS WAF blocks the request. This action terminates the web ACL evaluation of the request. By default, the AWS resource responds with an HTTP 403 (Forbidden) status code, but you can customize the response. When AWS WAF blocks a request, the Block action settings determine the response that the protected resource sends back to the client.

• **CAPTCHA and Challenge** – AWS WAF uses CAPTCHA puzzles and silent challenges to verify that the request isn't coming from a bot, and AWS WAF uses tokens to track recent successful client responses.

  **Note**
  You are charged additional fees when you use the CAPTCHA or Challenge rule action in one of your rules or as a rule action override in a rule group. For more information, see **AWS WAF Pricing**.

With these rule action options, AWS WAF might handle the request in a terminating or non-terminating manner, depending on the state of the token in the request:

• **Non-terminating for valid, unexpired token** – If the token is valid and unexpired according to the configured CAPTCHA or challenge immunity time, AWS WAF handles the request similar to the
Count action. AWS WAF continues to inspect the web request based on the remaining rules in the web ACL. Similar to the Count configuration, you can optionally configure these actions with custom headers to insert into the request, and you can add labels that other rules can match against.

- **Terminating with blocked request for invalid or expired token** – If the token isn’t valid or the indicated timestamp is expired, AWS WAF terminates the inspection of the web request and blocks the request, similar to the Block action. AWS WAF then responds to the client with an error. For CAPTCHA, if the request contents indicate that the client browser can handle it, AWS WAF sends a CAPTCHA puzzle in a JavaScript interstitial, which is designed to distinguish human clients from bots. For the Challenge action, AWS WAF sends a JavaScript interstitial with a silent challenge that's designed to distinguish normal browsers from sessions that are being run by bots.

For additional information, see [CAPTCHA and Challenge actions in AWS WAF](p. 186).

For information about customizing requests and responses, see [Customized web requests and responses in AWS WAF](p. 126).

For information about adding labels to matching requests, see [Labels on web requests](p. 131).

For information about how web ACL and rule settings interact, see [Web ACL rule and rule group evaluation](p. 13).

## AWS WAF rule statements

Rule statements are the part of a rule that tells AWS WAF how to inspect a web request. When AWS WAF finds the inspection criteria in a web request, we say that the web request matches the statement. Every rule statement specifies what to look for and how, according to the statement type.

Every rule in AWS WAF has a single top-level rule statement, which can contain other statements. Rule statements can be very simple. For example, you could have a statement that provides a set of originating countries to check your web requests for. Rule statements can also be very complex. For example, you could have a statement that combines many other statements with logical AND, OR, and NOT statements.

Web ACLs can also contain rule statements that just reference rule groups. On the console, you don’t see these represented as rule statements, but every web ACL has a JSON format representation. In the JSON, you can see these special types of rule statements. For rules of any complexity, managing your web ACL using the JSON editor is the easiest way to go. You can retrieve the complete configuration for a web ACL in JSON format, modify it as you need, and then provide it to AWS WAF through the console, API, or CLI. The same is true for rule groups that you manage on your own.

### Nesting rule statements

AWS WAF supports nesting for many rule statements, but not for all. For example, you can't nest a rule group statement inside of another statement. You need to use nesting for some scenarios, such as scope-down statements and logical statements. The rule statement lists and rule details that follow describe the nesting capabilities and requirements for each category and rule.

The visual editor for rules in the console supports only one level of nesting for rule statements. For example, you can nest many types of statements inside a logical AND or OR rule, but you can't nest another AND or OR rule, because that requires a second level of nesting. To implement multiple levels of nesting, you need to provide the rule definition in JSON, either through the JSON rule editor in the console or through the APIs.

### Topics

- Rule statements list (p. 86)
- Web request components (p. 108)
- Statements that reference a set or a rule group (p. 116)
• Scope-down statements (p. 117)
• Forwarded IP address (p. 117)

Rule statements list

This section describes the statements that you can add to a rule and provides some guidelines for calculating web ACL capacity units (WCU) usage for each. For information about WCUs, see AWS WAF Web ACL capacity units (WCU) (p. 7).

This page groups the rule statements by category, provides a high-level description for each, and provides a link to a section with more information for the statement type.

Match statements

Match statements compare the web request or its origin against criteria that you provide. For many statements of this type, AWS WAF compares a specific component of the request for matching content.

Match statements are nestable. You can nest them inside logical rule statements and use them in scope-down statements.

<table>
<thead>
<tr>
<th>Match Statement</th>
<th>Description</th>
<th>WCUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geographic match (p. 91)</td>
<td>Inspects the request's country of origin and applies labels for the country and region of origin.</td>
<td>1</td>
</tr>
<tr>
<td>IP set match (p. 96)</td>
<td>Inspects the request against a set of IP addresses and address ranges.</td>
<td>1 for most cases. If you configure the statement to use a header with forwarded IP addresses and specify a position in the header of Any, then the WCUs are 5.</td>
</tr>
<tr>
<td>Label match rule statement (p. 97)</td>
<td>Inspects the request for labels that have been added by other rules in the same web ACL.</td>
<td>1</td>
</tr>
<tr>
<td>Regex match rule statement (p. 102)</td>
<td>Compares a regex pattern against a specified request component.</td>
<td>3, as a base cost. If you use the request component All query parameters, add 10 WCUs. If you use the request component JSON body, double the base cost WCUs. For each Text transformation that you apply, add 10 WCUs.</td>
</tr>
<tr>
<td>Regex pattern set (p. 103)</td>
<td>Compares regex patterns against a specified request component.</td>
<td>25 per pattern set, as a base cost. If you use the request component All query parameters, add 10 WCUs. If you use the request component JSON body, double the base cost WCUs. For each Text transformation that you apply, add 10 WCUs.</td>
</tr>
<tr>
<td>Match Statement</td>
<td>Description</td>
<td>WCUs</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>

<tr>
<td>Size constraint (p. 104)</td>
<td>Checks size constraints against a specified request component.</td>
<td>1, as a base cost. If you use the request component <strong>All query parameters</strong>, add 10 WCUs. If you use the request component <strong>JSON body</strong>, double the base cost WCUs. For each <strong>Text transformation</strong> that you apply, add 10 WCUs.</td>
</tr>
<tr>
<td>SQLi attack (p. 105)</td>
<td>Inspects for malicious SQL code in a specified request component.</td>
<td>20, as a base cost. If you use the request component <strong>All query parameters</strong>, add 10 WCUs. If you use the request component <strong>JSON body</strong>, double the base cost WCUs. For each <strong>Text transformation</strong> that you apply, add 10 WCUs.</td>
</tr>
<tr>
<td>String match (p. 106)</td>
<td>Compares a string to a specified request component.</td>
<td>The base cost depends on the type of string match and is between 1 and 10. If you use the request component <strong>All query parameters</strong>, add 10 WCUs. If you use the request component <strong>JSON body</strong>, double the base cost WCUs. For each <strong>Text transformation</strong> that you apply, add 10 WCUs.</td>
</tr>
<tr>
<td>XSS scripting attack (p. 107)</td>
<td>Inspects for cross-site scripting attacks in a specified request component.</td>
<td>40, as a base cost. If you use the request component <strong>All query parameters</strong>, add 10 WCUs. If you use the request component <strong>JSON body</strong>, double the base cost WCUs. For each <strong>Text transformation</strong> that you apply, add 10 WCUs.</td>
</tr>
</tbody>
</table>

**Logical rules statements**

Use logical rules statements to combine other statements or negate their results. Every logical rule statement takes at least one nested statement.

To logically combine or negate rule statement results, you nest the statements under logical rule statements.
Note
The visual editor on the console supports one level of rule statement nesting, which works for many needs. To nest more levels, edit the JSON representation of the rule on the console or use the APIs.

Logical rules statements are nestable. You can nest them inside other logical rule statements and use them in scope-down statements. For information about scope-down statements, see Scope-down statements (p. 117).

<table>
<thead>
<tr>
<th>Logical Statement</th>
<th>Description</th>
<th>WCUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND logic (p. 89)</td>
<td>Combines nested statements with AND logic.</td>
<td>Based on nested statements</td>
</tr>
<tr>
<td>NOT logic (p. 98)</td>
<td>Negates the results of a nested statement.</td>
<td>Based on nested statement</td>
</tr>
<tr>
<td>OR logic (p. 98)</td>
<td>Combines nested statements with OR logic.</td>
<td>Based on nested statements</td>
</tr>
</tbody>
</table>

Complex statements
AWS WAF supports rate-based and rule group statements. You can't nest these statement types inside other rule statements. For some of these statements, you can narrow the scope of the requests that they inspect by adding a scope-down statement.

<table>
<thead>
<tr>
<th>Statement</th>
<th>Description</th>
<th>WCUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Managed rule group (p. 97)</td>
<td>Runs the rules that are defined in the specified managed rule group.</td>
<td>Defined by the rule group, plus any additional WCUs for a scope-down statement.</td>
</tr>
<tr>
<td></td>
<td>You can narrow the scope of requests that you evaluate with the rule group by adding a scope-down statement.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>You cannot nest a managed rule group statement inside any other statement type.</td>
<td></td>
</tr>
<tr>
<td>Rule group (p. 104)</td>
<td>Runs the rules that are defined in a rule group that you manage.</td>
<td>You define the WCU limit for the rule group when you create it.</td>
</tr>
<tr>
<td></td>
<td>You cannot nest a rule group statement inside any other statement type.</td>
<td></td>
</tr>
<tr>
<td>Rate-based (p. 100)</td>
<td>Tracks the rate of requests from individual IP addresses and temporarily blocks addresses while they are sending too many requests.</td>
<td>2, plus any additional WCUs for a scope-down statement.</td>
</tr>
</tbody>
</table>
AND rule statement

The AND rule statement combines nested statements with a logical AND operation, so all nested statements must match for the AND statement to match. This requires at least one nested statement.

Nestable – You can nest this statement type.

WCUs – Depends on the nested statements.

Where to find this rule statement

• Rule builder on the console – For a request, choose matches all the statements (AND), and then fill in the nested statements.
• API – AndStatement

Examples

The following listing shows the use of AND and NOT logical rule statements to eliminate false positives from the matches for an SQL injection attack statement. For this example, suppose we can write a single byte match statement to match the requests that are resulting in false positives.

The AND statement matches for requests that do not match the byte match statement and that do match the SQL injection attack statement.

```json
{
    "Name": "SQLiExcludeFalsePositives",
    "Priority": 0,
    "Statement": {
        "AndStatement": {
            "Statements": [
                {
                    "NotStatement": {
                        "Statement": {
                            "ByteMatchStatement": {
                                "SearchString": "string identifying a false positive",
                                "FieldToMatch": {
                                    "Body": {
                                        "OversizeHandling": "MATCH"
                                    }
                                },
                                "TextTransformations": [
                                    {
                                        "Priority": 0,
                                        "Type": "NONE"
                                    }
                                ],
                                "PositionalConstraint": "CONTAINS"
                            }
                        }
                    }
                }
            ]
        }
    }
}
```
Using the console rule visual editor, you can nest a non-logical statement or a NOT statement under an OR or AND statement. The nesting of the NOT statement is shown in the prior example.

Using the console rule visual editor, you can nest most nestable statements under a logical rule statement, such as the one shown in the prior example. You can't use the visual editor to nest OR or AND statements. To configure this type of nesting, you need to provide your rule statement in JSON. For example, the following JSON rule listing includes an OR statement nested inside an AND statement.

```json
{
  "Name": "match_rule",
  "Priority": 0,
  "Statement": {
    "AndStatement": {
      "Statements": [
        {
          "LabelMatchStatement": {
            "Scope": "LABEL",
            "Key": "awsfw:managed:aws:bot-control:bot:category:monitoring"
          }
        },
        {
          "NotStatement": {
            "Statement": {
              "LabelMatchStatement": {
                "Scope": "LABEL",
                "Key": "awsfw:managed:aws:bot-control:bot:name:pingdom"
              }
            }
          }
        }
      ]
    }
  }
}
```
Geographic match rule statement

Use geographical or geo match statements to manage web requests based on country and region of origin.

**Note**

For CloudFront distributions, if you use the CloudFront geo restriction feature, the feature doesn't forward blocked requests to AWS WAF. The feature does forward allowed requests to AWS WAF. If you want to block requests based on geography and other AWS WAF criteria, use the AWS WAF geo match statement and do not use the CloudFront geo restriction feature.

You can use the geo match statement for country and region matching, as follows:

- **Country** — Use a geo match rule by itself to manage requests based on their country of origin.
- **Region** — Use a geo match rule followed by a label match rule to manage requests based on their country and region of origin. For information about using label match rules, see Label match rule statement (p. 97) and Labels on web requests (p. 131).

With the geo match statement, AWS WAF manages each web request as follows:

1. **Determines the request's country and region codes** — AWS WAF determines the country and region of a request based on its IP address. By default, AWS WAF uses the IP address of the web request’s
You can instruct AWS WAF to use an IP address from an alternate request header, like X-Forwarded-For, by enabling forwarded IP configuration in the rule statement settings.

AWS WAF uses the alpha-2 country and region codes from the International Organization for Standardization (ISO) 3166 standard. You can find the codes at the following locations:

- At the ISO website, you can search the country codes at ISO Online Browsing Platform (OBP).
- On Wikipedia, the country codes are listed at ISO 3166-2.

The region codes for a country are listed at the URL https://en.wikipedia.org/wiki/ISO_3166-2:<ISO country code>. For example, the regions for the United States are at ISO 3166-2:US and for Ukraine they’re at ISO 3166-2:UA.

2. **Determines the country label and region label to add to the request** — The labels indicate whether the geo match statement uses the origin IP or a forwarded IP configuration.

   - **Origin IP**

   - **Forwarded IP**

     If the country or region code isn't available for a request's specified IP address, AWS WAF uses XX in the labels, in the place of the value. For example, the following label is for a client IP whose country code isn't available: awswaf:clientip:geo:country:XX and the following is for a forwarded IP whose country is the United States, but whose region code isn't available: awswaf:forwardedip:geo:region:US-XX.

3. **Evaluates the request's country code against the rule criteria**

   The geo match statement adds country and region labels to all requests that it inspects, regardless of whether it finds a match. AWS WAF adds any labels at the end of a rule's web request evaluation. Because of this, any label matching that you use against the labels from a geo match statement must be defined in a separate rule from the geo match statement rule.

   If you want to inspect only region values, you can write a geo match rule with Count action and with a single country code match, followed by a label match rule for the region labels. You are required to supply a country code for the geo match rule to evaluate, even for this approach. You can reduce logging and count metrics by specifying a country that's very unlikely to be a source of traffic to your site.

   **Nestable** – You can nest this statement type.

   **WCUs** – 1 WCU.

   **Settings** – This statement uses the following settings:

   - **Country codes** – An array of country codes to compare for a geo match. These must be two-character country codes from the alpha-2 country ISO codes of the ISO 3166 international standard, for example, ["US", "CN"].

   - **(Optional) Forwarded IP configuration** – By default, AWS WAF uses the IP address in the web request origin to determine country of origin. Alternatively, you can configure the rule to use a forwarded
Rule statements

IP in an HTTP header like X-Forwarded-For instead. AWS WAF uses the first IP address in the header. With this configuration, you also specify a fallback behavior to apply to a web request with a malformed IP address in the specified header. The fallback behavior sets the matching result for the request, to match or no match. For more information, see Forwarded IP address (p. 117).

Where to find this rule statement

- Rule builder on the console – For Request option, choose Originates from a country in.
- API – GeoMatchStatement

Examples

You can use the geo match statement to manage requests from specific countries or regions. For example, if you want to block requests from certain countries, but still allow requests from a specific set of IP addresses in those countries, you could create a rule with the action set to Block and the following nested statements, shown in pseudocode:

- AND statement
  - Geo match statement listing the countries that you want to block
  - NOT statement
    - IP set statement that specifies the IP addresses that you want to allow through

Or, if you want to block some regions in certain countries, but still allow requests from other regions in those countries, you could first define a geo match rule with the action set to Count. Then, define a label match rule that matches against the added geo match labels and handles the requests as you need.

The following pseudo code describes an example of this approach:

1. Geo match statement listing the countries with regions that you want to block, but with the action set to Count. This labels every web request regardless of match status, and it also gives you count metrics for the countries of interest.
2. AND statement with Block action
   - Label match statement that specifies the labels for the countries that you want to block
   - NOT statement
     - Label match statement that specifies the labels of the regions in those countries that you want to allow through

The following JSON listing shows an implementation of the two rules described in the prior pseudocode. These rules block all traffic from the United States except for traffic from Oregon and Washington. The geo match statement adds country and region labels to all requests that it inspects. The label match rule runs after the geo match rule, so it can match against the country and region labels that the geo match rule has just added. The geo match statement uses a forwarded IP address, so the label matching also specifies forwarded IP labels.

```json
{
  "Name": "geoMatchForLabels",
  "Priority": 10,
  "Statement": {
    "GeoMatchStatement": {
      "CountryCodes": ["US"],
      "ForwardedIPConfig": {
        "HeaderName": "X-Forwarded-For",
      }
    },
    "Not": {
      "LabelMatchStatement": {
        "LabelNames": ["Oregon", "Washington"]
      }
    }
  }
}
```
"FallbackBehavior": "MATCH"
},
"Action": {
"Count": {}
},
"VisibilityConfig": {
"SampledRequestsEnabled": true,
"CloudWatchMetricsEnabled": true,
"MetricName": "geoMatchForLabels"
}
},
"Name": "blockUSButNotOROrWA",
"Priority": 11,
"Statement": {
  "AndStatement": {
    "Statements": [
      {"LabelMatchStatement": {
        "Scope": "LABEL",
        "Key": "awswaf:forwardedip:geo:country:US"
      }},
      {"NotStatement": {
        "Statement": {
          "OrStatement": {
            "Statements": [
              {"LabelMatchStatement": {
                "Scope": "LABEL",
                "Key": "awswaf:forwardedip:geo:region:US-OR"
              }},
              {"LabelMatchStatement": {
                "Scope": "LABEL",
                "Key": "awswaf:forwardedip:geo:region:US-WA"
              }}
            ]
          }
        }
      }
    ]
  }
},
"Action": {
"Block": {}
},
"VisibilityConfig": {
"SampledRequestsEnabled": true,
"CloudWatchMetricsEnabled": true,
"MetricName": "blockUSButNotOROrWA"
}
}

As another example, you can combine geo matching with rate-based rules to prioritize resources for users in a particular country or region. You create a different rate-based statement for each geo match or label match statement that you use to differentiate your users. Set a higher rate limit for users in the preferred country or region and set a lower rate limit for other users.
The following JSON listing shows a geo match rule followed by rate-based rules that limit the rate of traffic from the United States. The rules allow traffic from Oregon to come in at a higher rate than traffic from anywhere else in the country.

```json
{
  "Name": "geoMatchForLabels",
  "Priority": 190,
  "Statement": {
    "GeoMatchStatement": {
      "CountryCodes": ["US"]
    },
    "Action": {
      "Count": {}
    },
    "VisibilityConfig": {
      "SampledRequestsEnabled": true,
      "CloudWatchMetricsEnabled": true,
      "MetricName": "geoMatchForLabels"
    }
  },
  "Name": "rateLimitOregon",
  "Priority": 195,
  "Statement": {
    "RateBasedStatement": {
      "Limit": 3000,
      "AggregateKeyType": "IP",
      "ScopeDownStatement": {
        "LabelMatchStatement": {
          "Scope": "LABEL",
          "Key": "awswaf:clientip:geo:region:US-OR"
        }
      },
      "Action": {
        "Block": {}
      },
      "VisibilityConfig": {
        "SampledRequestsEnabled": true,
        "CloudWatchMetricsEnabled": true,
        "MetricName": "rateLimitOregon"
      }
    }
  },
  "Name": "rateLimitUSNotOR",
  "Priority": 200,
  "Statement": {
    "RateBasedStatement": {
      "Limit": 100,
      "AggregateKeyType": "IP",
      "ScopeDownStatement": {
        "AndStatement": {
          "Statements": [
            {
              "LabelMatchStatement": {
                "Scope": "LABEL",
                "Key": "awswaf:clientip:geo:country:US"
              }
            }
          ],
          "NotStatement": {
            "Statements": []
          }
        }
      },
      "Action": {
        "Block": {}
      },
      "VisibilityConfig": {
        "SampledRequestsEnabled": true,
        "CloudWatchMetricsEnabled": true,
        "MetricName": "rateLimitUSNotOR"
      }
    }
  }
}
```
IP set match rule statement

The IP set match statement inspects the IP address of a web request against a set of IP addresses and address ranges. Use this to allow or block web requests based on the IP addresses that the requests originate from. By default, AWS WAF uses the IP address from the web request origin, but you can configure the rule to use an HTTP header like `X-Forwarded-For` instead.

AWS WAF supports all IPv4 and IPv6 CIDR ranges except for /0. For more information about CIDR notation, see the Wikipedia entry [Classless Inter-Domain Routing](https://en.wikipedia.org/wiki/Classless_Inter-Domain_Routing). An IP set can hold up to 10,000 IP addresses or IP address ranges to check.

**Note**
Each IP set match rule references an IP set, which you create and maintain independent of your rules. You can use a single IP set in multiple rules, and when you update the referenced set, AWS WAF automatically updates all rules that reference it.

For information about creating and managing an IP set, see Creating and managing an IP set (p. 122).

When you add or update the rules in your rule group or web ACL, choose the option **IP set** and select the name of the IP set that you want to use.

**Nestable** – You can nest this statement type.

**WCUs** – 1 WCU for most. If you configure the statement to use forwarded IP addresses and specify a position of ANY, the WCU usage is 5.

This statement uses the following settings:

- **IP set specification** – Choose the IP set that you want to use from the list or create a new one.

- **(Optional) Forwarded IP configuration** – An alternate forwarded IP header name to use in place of the request origin. You specify whether to match against the first, last, or any address in the header. You also specify a fallback behavior to apply to a web request with a malformed IP address in the specified header. The fallback behavior sets the matching result for the request, to match or no match. For more information, see Forwarded IP address (p. 117).
Where to find this rule statement

- **Rule builder** on the console – For **Request option**, choose **Originates from an IP address in**.
- **Add my own rules and rule groups** page on the console – Choose the **IP set** option.
- **API** – **IPSetReferenceStatement**

**Label match rule statement**

The label match statement inspects the labels that are on the web request against a string specification. The labels that are available to a rule for inspection are those that have already been added to the web request by other rules in the same web ACL evaluation. Labels don't persist outside of the web ACL evaluation.

**Note**

A label match statement can only see labels from rules that are evaluated earlier in the web ACL. For information about how AWS WAF evaluates the rules and rule groups in a web ACL, see **Processing order of rules and rule groups in a web ACL** (p. 14).

For more information about labels, see **Labels on web requests** (p. 131).

**Nestable** – You can nest this statement type.

**WCUs** – 1 WCU

This statement uses the following settings:

- **Match scope** – Set this to **Label** to match against the label name and, optionally, the preceding namespaces and prefix. Set this to **Namespace** to match against some or all of the namespace specifications and, optionally, the preceding prefix.
- **Key** – The string that you want to match against. If you specify a namespace match scope, this should only specify namespaces and optionally the prefix, with an ending colon. If you specify a label match scope, this must include the label name and can optionally include preceding namespaces and prefix.

For more information about these settings, see **Matching against a label** (p. 135) and **Label match examples** (p. 136).

**Where to find this rule statement**

- **Rule builder** on the console – For **Request option**, choose **Has label**.
- **API** – **LabelMatchStatement**

**Managed rule group statement**

The managed rule group rule statement adds a reference in your web ACL rules list to a managed rule group. You don’t see this option under your rule statements on the console, but when you work with the JSON format of your web ACL, any managed rule groups that you’ve added show up under the web ACL rules as this type.

A managed rule group is either an AWS Managed Rules rule group, most of which are free for AWS WAF customers, or a AWS Marketplace managed rule group. You automatically subscribe to the paid AWS Managed Rules rule groups when you add them to your web ACL. You can subscribe to AWS Marketplace managed rule groups through AWS Marketplace. For more information, see **Managed rule groups** (p. 26).

When you add a rule group to a web ACL, you can override the actions of rules in the group to Count or to another rule action. For more information, see **Action overrides in rule groups** (p. 15).
You can narrow the scope of the requests that AWS WAF evaluates with the rule group. To do this, you add a scope-down statement inside the rule group statement. For information about scope-down statements, see Scope-down statements (p. 117). This can help you manage how the rule group affects your traffic and can help you contain costs associated with traffic volume when you use the rule group. For information and examples for using scope-down statements with the AWS WAF Bot Control managed rule group, see AWS WAF Bot Control (p. 151).

**Not nestable** – You can't nest this statement type inside other statements, and you can't include it in a rule group. You can include it directly in a web ACL.

**Optional** Scope-down statement – This rule type takes an optional scope-down statement, to narrow the scope of the requests that the rule group evaluates. For more information, see Scope-down statements (p. 117).

**WCUs** – Set for the rule group at creation.

**Where to find this rule statement**

- **Console** – During the process of creating a web ACL, on the Add rules and rule groups page, choose Add managed rule groups, and then find and select the rule group that you want to use.
- **API** – ManagedRuleGroupStatement

**NOT rule statement**

The NOT rule statement logically negates the results of a single nested statement, so the nested statements must not match for the NOT statement to match, and vice versa. This requires one nested statement.

For example, if you want to block requests that don't originate in a specific country, create a NOT statement with action set to block, and nest a geographic match statement that specifies the country.

**Nestable** – You can nest this statement type.

**WCUs** – Depends on the nested statement.

**Where to find this rule statement**

- **Rule builder** on the console – For If a request, choose doesn't match the statement (NOT), and then fill in the nested statement.
- **API** – NotStatement

**OR rule statement**

The OR rule statement combines nested statements with OR logic, so one of the nested statements must match for the OR statement to match. This requires at least one nested statement.

For example, if you want to block requests that come from a specific country or that contain a specific query string, you could create an OR statement and nest in it a geographic match statement for the country and a string match statement for the query string.

If instead you want to block requests that don't come from a specific country or that contain a specific query string, you would modify the previous OR statement to nest the geographics match statement one level lower, inside a NOT statement. This level of nesting requires you to use the JSON formatting, because the console supports only one level of nesting.

**Nestable** – You can nest this statement type.

**WCUs** – Depends on the nested statements.
Where to find this rule statement

- **Rule builder** on the console – For If a request, choose **matches at least one of the statements (OR)**, and then fill in the nested statements.
- **API** – **OrStatement**

**Examples**

The following listing shows the use of OR to combine two other statements. The OR statement is a match if either of the nested statements match.

```json
{
  "Name": "neitherOfTwo",
  "Priority": 1,
  "Action": {
    "Block": {}
  },
  "VisibilityConfig": {
    "SampledRequestsEnabled": true,
    "CloudWatchMetricsEnabled": true,
    "MetricName": "neitherOfTwo"
  },
  "Statement": {
    "OrStatement": {
      "Statements": [
        {
          "GeoMatchStatement": {
            "CountryCodes": ["CA"
          ]
        },
        {
          "IPSetReferenceStatement": {
          }
        }
      ]
    }
  }
}
```

Using the console rule visual editor, you can nest most nestable statements under a logical rule statement, but you can’t use the visual editor to nest OR or AND statements. To configure this type of nesting, you need to provide your rule statement in JSON. For example, the following JSON rule listing includes an OR statement nested inside an AND statement.

```json
{
  "Name": "match_rule",
  "Priority": 0,
  "Statement": {
    "AndStatement": {
      "Statements": [
        {
          "LabelMatchStatement": {
            "Scope": "LABEL",
            "Key": "awswaf:managed:aws:bot-control:bot:category:monitoring"
          }
        },
        {
          "NotStatement": {
```

99
"Statement": {
  "LabelMatchStatement": {
    "Scope": "LABEL",
    "Key": "awswaf:managed:aws:bot-control:bot:name:pingdom"
  }
},
"OrStatement": {
  "Statements": [
    {
      "GeoMatchStatement": {
        "CountryCodes": ["JM", "JP"
      }
    },
    {
      "ByteMatchStatement": {
        "SearchString": "JCountryString",
        "FieldToMatch": {
          "Body": {}
        },
        "TextTransformations": [
          {
            "Priority": 0,
            "Type": "NONE"
          }
        ],
        "PositionalConstraint": "CONTAINS"
      }
    }
  ]
},
"Action": {
  "Block": {}
},
"VisibilityConfig": {
  "SampledRequestsEnabled": true,
  "CloudWatchMetricsEnabled": true,
  "MetricName": "match_rule"
}

Rate-based rule statement

A rate-based rule tracks the rate of requests for each originating IP address, and triggers the rule action on IPs with rates that go over a limit. You set the limit as the number of requests per 5-minute time span. You can use this type of rule to put a temporary block on requests from an IP address that's sending excessive requests. By default, AWS WAF aggregates requests based on the IP address from the web request origin, but you can configure the rule to use an IP address from an HTTP header, like X-Forwarded-For, instead.

AWS WAF tracks and manages web requests separately for each instance of a rate-based rule that you use. For example, if you provide the same rate-based rule settings in two web ACLs, each of the two rule statements represents a separate instance of the rate-based rule and gets its own tracking and management by AWS WAF. If you define a rate-based rule inside a rule group, and then use that rule...
group in multiple places, each use creates a separate instance of the rate-based rule that gets its own tracking and management by AWS WAF.

When the rule action triggers, AWS WAF applies the action to additional requests from the IP address until the request rate falls below the limit. It can take a minute or two for the action change to go into effect.

You can retrieve the list of IP addresses that are currently blocked due to rate limiting. For information, see Listing IP addresses blocked by rate-based rules (p. 212).

The following caveats apply to AWS WAF rate-based rules:

- The minimum rate that you can set is 100.
- AWS WAF checks the rate of requests every 30 seconds, and counts requests for the prior five minutes each time. Because of this, it's possible for an IP address to send requests at too high a rate for 30 seconds before AWS WAF detects and blocks it.
- AWS WAF can block up to 10,000 IP addresses. If more than 10,000 IP addresses send high rates of requests at the same time, AWS WAF will only block 10,000 of them.

You can narrow the scope of the requests that AWS WAF tracks and counts. To do this, you nest another, scope-down statement inside the rate-based statement. Then, AWS WAF only counts requests that match the scope-down statement. For information about scope-down statements, see Scope-down statements (p. 117).

For example, based on recent requests that you've seen from an attacker in the United States, you might create a rate-based rule with the following scope-down statement:

- AND rule statement that contains the following, second level of nested statements:
  - A geo match statement that specifies requests originating in the United States.
  - A string match statement that searches in the User-Agent header for the string BadBot.

Let's say that you also set a rate limit of 1,000. For each IP address, AWS WAF counts requests that meet the criteria for both of the nested statements. Requests that don't meet both aren't counted. If the count for an IP address exceeds 1,000 requests in any 5-minute time span, the rule's action triggers against that IP address.

As another example, you might want to limit requests to the login page on your website. To do this, you could create a rate-based rule with the following nested string match statement:

- The Inspect Request component is URI path.
- The Match type is Starts with string.
- The String to match is /login.

By adding this rate-based rule to a web ACL, you could limit requests to your login page without affecting the rest of your site.

Not nestable – You can’t nest this statement type inside other statements. You can include it directly in a web ACL and in a rule group.

(Optional) Scope-down statement – This rule type takes an optional scope-down statement, to narrow the scope of the requests that the rate-based statement tracks. For more information, see Scope-down statements (p. 117).

WCUs – 2 plus any additional WCUs for a nested statement.

This statement uses the following optional setting:
• **(Optional) Forwarded IP configuration** – By default, AWS WAF aggregates on the IP address in the web request origin, but you can instead configure the rule to use a forwarded IP address in an HTTP header like `X-Forwarded-For`. AWS WAF uses the first IP address in the header. With this configuration, you also specify a fallback behavior to apply to a web request with a malformed IP address in the specified header. The fallback behavior sets the matching result for the request, to match or no match. For more information, see Forwarded IP address (p. 117).

Where to find this rule statement

• **Rule builder** in your web ACL, on the console – Under **Rule**, for **Type**, choose Rate-based rule.
• **API** – `RateBasedStatement`

**Regex match rule statement**

A regex match statement instructs AWS WAF to match a request component against a single regular expression (regex). A web request matches the statement if the request component matches the regex that you specify.

This statement type is a good alternative to the [Regex pattern set match rule statement (p. 103)](#) for situations where you want to combine your matching criteria using mathematical logic. For example, if you want a request component to match against some regex patterns and to not match against others, you can combine the regex match statements using the [AND rule statement (p. 89)](#) and the [NOT rule statement (p. 98)](#).

AWS WAF supports the pattern syntax used by the PCRE library `libpcre`. The library is documented at [PCRE - Perl Compatible Regular Expressions](#).

**Regex pattern use limitations**

AWS WAF does not support all constructs of the PCRE library. For example, it supports some zero-width assertions, but not all. We do not have comprehensive list of the constructs that are supported. However, if you provide a regex pattern that is not valid or use unsupported constructs, the AWS WAF API reports a failure.

AWS WAF does not support the following PCRE patterns:

• Backreferences and capturing subexpressions
• Subroutine references and recursive patterns
• Conditional patterns
• Backtracking control verbs
• The `\C` single-byte directive
• The `\R` newline match directive
• The `\K` start of match reset directive
• Callouts and embedded code
• Atomic grouping and possessive quantifiers

**Nestable** – You can nest this statement type.

**WCUs** – 3 WCUs, as a base cost. If you use the request component **All query parameters**, add 10 WCUs. If you use the request component **JSON body**, double the base cost WCUs. For each **Text transformation** that you apply, add 10 WCUs.

This statement type operates on a web request component, and requires the following request component settings:
• **Request components** – The part of the web request to inspect, for example, a query string or the body.

  **Warning**
  If you inspect the request components **Body**, **JSON body**, **Headers**, or **Cookies**, read about the limitations on how much content AWS WAF can inspect at [Oversize handling for request components](p. 113).

For information about web request components, see [Web request components](p. 108).

• **Optional text transformations** – Transformations that you want AWS WAF to perform on the request component before inspecting it. For example, you could transform to lowercase or normalize white space. If you specify more than one transformation, AWS WAF processes them in the order listed. For information, see [Text transformations](p. 114).

### Where to find this rule statement

• **Rule builder** on the console – For **Match type**, choose **Matches regular expression**.

• **API** – `RegexMatchStatement`

#### Regex pattern set match rule statement

The regex pattern set match inspects the part of the web request that you specify for the regular expression patterns that you've specified inside a regex pattern set.

  **Note**
  Each regex pattern set match rule references a regex pattern set, which you create and maintain independent of your rules. You can use a single regex pattern set in multiple rules, and when you update the referenced set, AWS WAF automatically updates all rules that reference it.
  For information about creating and managing a regex pattern set, see [Creating and managing a regex pattern set](p. 124).

A regex pattern set match statement instructs AWS WAF to search for any of the patterns in the set inside the request component that you choose. A web request will match the pattern set rule statement if the request component matches any of the patterns in the set.

If you want to combine your regex pattern matches using logic, for example to match against some regular expressions and not match against others, consider using [Regex match rule statement](p. 102).

**Nestable** – You can nest this statement type.

**WCUs** – 25 WCUs, as a base cost. If you use the request component **All query parameters**, add 10 WCUs. If you use the request component **JSON body**, double the base cost WCUs. For each **Text transformation** that you apply, add 10 WCUs.

This statement type operates on a web request component, and requires the following request component settings:

• **Request components** – The part of the web request to inspect, for example, a query string or the body.

  **Warning**
  If you inspect the request components **Body**, **JSON body**, **Headers**, or **Cookies**, read about the limitations on how much content AWS WAF can inspect at [Oversize handling for request components](p. 113).

For information about web request components, see [Web request components](p. 108).

• **Optional text transformations** – Transformations that you want AWS WAF to perform on the request component before inspecting it. For example, you could transform to lowercase or normalize white
space. If you specify more than one transformation, AWS WAF processes them in the order listed. For information, see Text transformations (p. 114).

This statement requires the following settings:

- **Regex pattern set specification** – Choose the regex pattern set that you want to use from the list or create a new one.

**Where to find this rule statement**

- **Rule builder** on the console – For **Match type**, choose **String match condition > Matches pattern from regular expression set**.
- **API** – `RegexPatternSetReferenceStatement`

**Rule group statement**

The rule group rule statement adds a reference to your web ACL rules list to a rule group that you manage. You don't see this option under your rule statements on the console, but when you work with the JSON format of your web ACL, any of your own rule groups that you've added show up under the web ACL rules as this type. For information about using your own rule groups, see Managing your own rule groups (p. 81).

When you add a rule group to a web ACL, you can override the actions of rules in the group to Count or to another rule action. For more information, see Action overrides in rule groups (p. 15).

**Not nestable** – You can't nest this statement type inside other statements, and you can't include it in a rule group. You can include it directly in a web ACL. You can narrow the scope of the requests that the rule group evaluates by adding one of the nestable statements within the rule group statement, as a scope-down statement.

**WCUs** – Set for the rule group at creation.

**Where to find this rule statement**

- **Console** – During the process of creating a web ACL, on the Add rules and rule groups page, choose Add my own rules and rule groups, Rule group, and then add the rule group that you want to use.
- **API** – `RuleGroupReferenceStatement`

**Size constraint rule statement**

A size constraint statement compares a number of bytes against the size of a request component, using a comparison operator, such as greater than (>) or less than (<). For example, you can use a size constraint statement to look for query strings that are longer than 100 bytes.

**Note**

If you choose **URI** for the value of Part of the request to filter on, the / in the URI counts as one character. For example, the URI /logo.jpg is nine characters long.

**Nestable** – You can nest this statement type.

**WCUs** – 1 WCU, as a base cost. If you use the request component All query parameters, add 10 WCUs. If you use the request component **JSON body**, double the base cost WCUs. For each **Text transformation** that you apply, add 10 WCUs.

This statement type operates on a web request component, and requires the following request component settings:
• **Request components** – The part of the web request to inspect, for example, a query string or the body.

  **Warning**
  If you inspect the request components **Body**, **JSON body**, **Headers**, or **Cookies**, read about the limitations on how much content AWS WAF can inspect at [Oversize handling for request components](p. 113).

For information about web request components, see [Web request components](p. 108).

• **Optional text transformations** – Transformations that you want AWS WAF to perform on the request component before inspecting it. For example, you could transform to lowercase or normalize white space. If you specify more than one transformation, AWS WAF processes them in the order listed. For information, see [Text transformations](p. 114).

Additionally, this statement requires the following settings:

• **Size match condition** – This indicates the numerical comparison operator to use to compare the size that you provide with the request component that you've chosen. Choose the operator from the list.

• **Size** – The size setting, in bytes, to use in the comparison.

**Where to find this rule statement**

• **Rule builder** on the console – For **Match type**, under **Size match condition**, choose the condition that you want to use.

• **API** – `SizeConstraintStatement`

**SQL injection attack rule statement**

An SQL injection rule statement inspects for malicious SQL code. Attackers insert malicious SQL code into web requests in order to do things like modify your database or extract data from it.

**Nestable** – You can nest this statement type.

**WCUs** – The base cost depends on the sensitivity level setting for the rule statement: Low costs 20 and High costs 30.

If you use the request component **All query parameters**, add 10 WCUs. If you use the request component **JSON body**, double the base cost WCUs. For each **Text transformation** that you apply, add 10 WCUs.

This statement type operates on a web request component, and requires the following request component settings:

• **Request components** – The part of the web request to inspect, for example, a query string or the body.

  **Warning**
  If you inspect the request components **Body**, **JSON body**, **Headers**, or **Cookies**, read about the limitations on how much content AWS WAF can inspect at [Oversize handling for request components](p. 113).

For information about web request components, see [Web request components](p. 108).

• **Optional text transformations** – Transformations that you want AWS WAF to perform on the request component before inspecting it. For example, you could transform to lowercase or normalize white space. If you specify more than one transformation, AWS WAF processes them in the order listed. For information, see [Text transformations](p. 114).
Additionally, this statement requires the following setting:

- **Sensitivity level** – This setting tunes the sensitivity of the SQL injection match criteria. The options are LOW and HIGH. The default setting is LOW.

The HIGH setting detects more SQL injection attacks, and is the recommended setting. Due to the higher sensitivity, this setting generates more false positives, especially if your web requests typically contain unusual strings. During your web ACL testing and tuning, you might need to do more work to mitigate false positives. For information, see Testing and tuning your AWS WAF protections (p. 212).

The lower setting provides less stringent SQL injection detection, which also results in fewer false positives. LOW can be a better choice for resources that have other protections against SQL injection attacks or that have a low tolerance for false positives.

**Where to find this rule statement**

- **Rule builder** on the console – For **Match type**, choose **Attack match condition > Contains SQL injection attacks**.
- **API** – SqliMatchStatement

**String match rule statement**

A string match statement indicates the string that you want AWS WAF to search for in a request, where in the request to search, and how. For example, you can look for a specific string at the start of any query string in the request or as an exact match for the request's User-agent header. Usually, the string consists of printable ASCII characters, but you can use any character from hexadecimal 0x00 to 0xFF (decimal 0 to 255).

**Nestable** – You can nest this statement type.

**WCUs** – The base cost depends on the type of match that you use.

- Exactly matches string – 2
- Starts with string – 2
- Ends with string – 2
- Contains string – 10
- Contains words – 10

If you use the request component **All query parameters**, add 10 WCUs. If you use the request component **JSON body**, double the base cost WCUs. For each **Text transformation** that you apply, add 10 WCUs.

This statement type operates on a web request component, and requires the following request component settings:

- **Request components** – The part of the web request to inspect, for example, a query string or the body.

  **Warning**
  If you inspect the request components **Body**, **JSON body**, **Headers**, or **Cookies**, read about the limitations on how much content AWS WAF can inspect at Oversize handling for request components (p. 113).

  For information about web request components, see Web request components (p. 108).

- **Optional text transformations** – Transformations that you want AWS WAF to perform on the request component before inspecting it. For example, you could transform to lowercase or normalize white
space. If you specify more than one transformation, AWS WAF processes them in the order listed. For information, see Text transformations (p. 114).

Additionally, this statement requires the following settings:

- **String to match** – This is the string that you want AWS WAF to compare to the specified request component. Usually, the string consists of printable ASCII characters, but you can use any character from hexadecimal 0x00 to 0xFF (decimal 0 to 255).
- **String match condition** – This indicates the search type that you want AWS WAF to perform.
  - **Exactly matches string** – The string and the value of the request component are identical.
  - **Starts with string** – The string appears at the beginning of the request component.
  - **Ends with string** – The string appears at the end of the request component.
  - **Contains string** – The string appears anywhere in the request component.
  - **Contains word** – The string that you specify must appear in the request component. For this option, the string that you specify must contain only alphanumeric characters or underscore (A-Z, a-z, 0-9, or _).

One of the following must be true for the request to match:

- The string exactly matches the value of the request component, such as the value of a header.
- The string is at the beginning of the request component and is followed by a character other than an alphanumeric character or underscore (_), for example, BadBot;.
- The string is at the end of the request component and is preceded by a character other than an alphanumeric character or underscore (_), for example, ;BadBot.
- The string is in the middle of the request component and is preceded and followed by characters other than alphanumeric characters or underscore (_), for example, -BadBot;.

**Where to find this rule statement**

- **Rule builder** on the console – For Match type, choose String match condition, and then fill in the strings that you want to match against.
- **API** – ByteMatchStatement

**Cross-site scripting attack rule statement**

An XSS (cross-site scripting) attack statement inspects for malicious scripts in a web request component. In an XSS attack, the attacker uses vulnerabilities in a benign website as a vehicle to inject malicious client-site scripts into other legitimate web browsers.

**Nestable** – You can nest this statement type.

**WCUs** – 40 WCUs, as a base cost. If you use the request component All query parameters, add 10 WCUs. If you use the request component JSON body, double the base cost WCUs. For each Text transformation that you apply, add 10 WCUs.

This statement type operates on a web request component, and requires the following request component settings:

- **Request components** – The part of the web request to inspect, for example, a query string or the body.

  **Warning**
  If you inspect the request components Body, JSON body, Headers, or Cookies, read about the limitations on how much content AWS WAF can inspect at Oversize handling for request components (p. 113).
For information about web request components, see Web request components (p. 108).

- **Optional text transformations** – Transformations that you want AWS WAF to perform on the request component before inspecting it. For example, you could transform to lowercase or normalize white space. If you specify more than one transformation, AWS WAF processes them in the order listed. For information, see Text transformations (p. 114).

**Where to find this rule statement**

- Rule builder on the console – For Match type, choose Attack match condition > Contains XSS injection attacks.
- API – XssMatchStatement

**Web request components**

This section describes the settings that you can specify for rule statements that inspect a component of the web request. For information on usage, see the individual rule statements.

For the request component settings, you need to specify the component type itself, and additional options that depend on the type. For example, if you choose a component type that contains text to be inspected, you can specify text transformations that you want AWS WAF to apply before evaluating your inspection criteria.

Unless otherwise noted, if a web request doesn't have the request component that's specified in the rule statement, the request results as not matching the rule.

**Contents**

- Request component options (p. 108)
  - Single header (p. 109)
  - All headers (p. 109)
  - Cookies (p. 110)
  - Single query parameter (p. 110)
  - All query parameters (p. 110)
  - URI path (p. 110)
  - Query string (p. 111)
  - Body (p. 111)
  - JSON body (p. 111)
  - HTTP method (p. 113)
- Oversize handling for request components (p. 113)
- Text transformations (p. 114)

**Request component options**

This section describes the components of the web request that you can specify for inspection. You specify the request component for match rule statements that look for patterns inside the web request. These types of statements include string match, regex match, size constraint, and SQL injection attack statements. For information on how to use these request component settings, see the individual rule statements. For more information about the rule statements, see Rule statements list (p. 86)

Unless otherwise noted, if a web request doesn't contain the request component that's specified in the rule statement, the request results as not matching the rule.
Note
You specify a single request component for each rule statement that requires it. To inspect more than one component of a request, create a rule statement for each component.

The AWS WAF console and API documentation provide guidance for the request component settings in the following locations:

- **Rule builder** on the console – In the **Statement** settings for a regular rule type, choose the component that you want to inspect in the **Inspect** dialogue under **Request components**.
- **API statement contents** – **FieldToMatch**

The rest of this section describes the options for the part of the web request to inspect.

Topics
- Single header (p. 109)
- All headers (p. 109)
- Cookies (p. 110)
- Single query parameter (p. 110)
- All query parameters (p. 110)
- URI path (p. 110)
- Query string (p. 111)
- Body (p. 111)
- JSON body (p. 111)
- HTTP method (p. 113)

Single header

Inspects a single named header in the request. For this option, you specify the header key in the **Header field name**, for example, User-Agent or Referer. The string match for the key is not case sensitive.

All headers

Inspects all of the request headers, including cookies. You can apply a filter to inspect a subset of all headers. For this option, you provide the following specifications:

- **Match patterns** – The filter to use to obtain a subset of headers for inspection. AWS WAF looks for these patterns in the headers keys.

  The match patterns setting can be one of the following:
  - **All** – Match all keys. Evaluate the rule inspection criteria for all headers.
  - **Excluded headers** – Inspect only the headers whose keys don’t match any of the strings that you specify here. The string match for a key is not case sensitive.
  - **Included headers** – Inspect only the headers that have a key that matches one of the strings that you specify here. The string match for a key is not case sensitive.
  - **Match scope** – The parts of the headers that AWS WAF should inspect with the rule inspection criteria. You can specify **Keys, Values**, or **All** for both keys and values.

- **Oversize handling** – How AWS WAF should handle requests that have header data that is larger than AWS WAF can inspect. You can inspect at most the first 8 KB (8,192 bytes) of the request headers and at most the first 200 headers. The content is available for inspection by AWS WAF up to the first limit reached. You can choose to continue the inspection, or to skip inspection and mark the request as matching or not matching the rule. For more information about handling oversize content, see [Oversize handling for request components](p. 113).
Cookies

Inspects all of the request cookies. You can apply a filter to inspect a subset of all cookies. For this option, you provide the following specifications:

- **Match patterns** – The filter to use to obtain a subset of cookies for inspection. AWS WAF looks for these patterns in the cookie keys.

  The match patterns setting can be one of the following:
  - **All** – Match all keys. Evaluate the rule inspection criteria for all cookies.
  - **Excluded cookies** – Inspect only the cookies whose keys don't match any of the strings that you specify here. The string match for a key is case sensitive and must be exact.
  - **Included cookies** – Inspect only the cookies that have a key that matches one of the strings that you specify here. The string match for a key is case sensitive and must be exact.

- **Match scope** – The parts of the cookies that AWS WAF should inspect with the rule inspection criteria. You can specify **Keys**, **Values**, or **All** for both keys and values.

- **Oversize handling** – How AWS WAF should handle requests that have cookie data that is larger than AWS WAF can inspect. You can inspect at most the first 8 KB (8,192 bytes) of the request cookies and at most the first 200 cookies. The content is available for inspection by AWS WAF up to the first limit reached. You can choose to continue the inspection, or to skip inspection and mark the request as matching or not matching the rule. For more information about handling oversize content, see [Oversize handling for request components](p. 113).

Single query parameter

Inspects a single query parameter that you have defined as part of the query string. AWS WAF inspects the value of the parameter that you specify.

For this option, you also specify a **Query argument**. For example, if the URL is `www.xyz.com?UserName=abc&SalesRegion=seattle`, you can specify `UserName` or `SalesRegion` for the query argument. The maximum length for the name of the argument is 30 characters. The name is not case sensitive, so if you specify `UserName`, AWS WAF matches all variations of `UserName`, including `username` and `USERName`.

If the query string contains more than one instance of the query argument that you've specified, AWS WAF inspects all the values for a match, using OR logic. For example, in the URL `www.xyz.com?SalesRegion=boston&SalesRegion=seattle`, AWS WAF evaluates the name that you've specified against `boston` and `seattle`. If either is a match, the inspection is a match.

All query parameters

Inspects all query parameters in the request. This is similar to the single query parameter component choice, but AWS WAF inspects the values of all arguments within the query string. For example, if the URL is `www.xyz.com?UserName=abc&SalesRegion=seattle`, AWS WAF triggers a match if either the value of `UserName` or `SalesRegion` match the inspection criteria.

Choosing this option adds 10 WCUs to the base cost.

URI path

Inspects the part of a URL that identifies a resource, for example, `/images/daily-ad.jpg`. For information, see [Uniform Resource Identifier (URI): Generic Syntax](p. 114).

If you don't use a text transformation with this option, AWS WAF doesn't normalize the URI and inspects it just as it receives it from the client in the request. For information about text transformations, see [Text transformations](p. 114).
Query string

Inspects the part of the URL that appears after a ? character, if any.

**Note**

For cross-site scripting match statements, we recommend that you choose *All query parameters* instead of *Query string*. Choosing *All query parameters* adds 10 WCUs to the base cost.

Body

Inspects the request body, evaluated as plain text. You can also evaluate the body as JSON using the JSON content type.

The request body is the part of the request that immediately follows the request headers. It contains any additional data that is needed for the web request, for example, data from a form.

- In the console, you select this under the **Request option** choice **Body**, by selecting the **Content type** choice **Plain text**.
- In the API, in the rule's **FieldToMatch** specification, you specify Body to inspect the request body as plain text.

You must specify oversize handling for this component type. You can inspect the first 8 KB (8,192 bytes) of the body of a request. Oversize handling defines how AWS WAF handles requests that have body data that is larger than AWS WAF can inspect. You can choose to continue the inspection, or to skip inspection and mark the request as matching or not matching the rule. For more information about handling oversize content, see [Oversize handling for request components](p. 113).

You can also evaluate the body as parsed JSON. For information about this, see the section that follows.

**JSON body**

Inspects the request body, evaluated as JSON. You can also evaluate the body as plain text.

The request body is the part of the request that immediately follows the request headers. It contains any additional data that is needed for the web request, for example, data from a form.

- In the console, you select this under the **Request option** choice **Body**, by selecting the **Content type** choice **JSON**.
- In the API, in the rule's **FieldToMatch** specification, you specify JsonBody.

You must specify oversize handling for this component type. You can inspect the first 8 KB (8,192 bytes) of the body of a request. Oversize handling defines how AWS WAF handles requests that have body data that is larger than AWS WAF can inspect. You can choose to continue the inspection, or to skip inspection and mark the request as matching or not matching the rule. For more information about handling oversize content, see [Oversize handling for request components](p. 113).

When AWS WAF inspects the web request body as parsed JSON, it parses and extracts the elements from the JSON and inspects the parts that you indicate using the rule's match statement criteria.

Choosing this option doubles the match statement's base cost WCUs. For example, if the match statement base cost is 5 WCUs without JSON parsing, using JSON parsing doubles the cost to 10 WCUs.

With this option, AWS WAF runs two match patterns against the web request body. The output of the first match pattern is used as input to the second match pattern:

1. AWS WAF parses and extracts the JSON content and identifies the elements to inspect. To do this, AWS WAF uses the criteria that you provide in the rule's JSON body specification.
2. AWS WAF applies any text transformations to the extracted elements and then matches the resulting JSON element set against the rule statement's match criteria. If any of the elements match, the web request is a match for the rule.

You specify the following criteria for AWS WAF to use for the first pattern matching step, to identify the JSON elements to inspect:

- **Body parsing fallback behavior** – What AWS WAF should do if it fails to completely parse the JSON body. The options are the following:
  - **None (default behavior)** - AWS WAF evaluates the content only up to the point where it encountered a parsing error.
  - **Evaluate as string** - Inspect the body as plain text. AWS WAF applies the text transformations and inspection criteria that you defined for the JSON inspection to the body text string.
  - **Match** - Treat the web request as matching the rule statement. AWS WAF applies the rule action to the request.
  - **No match** - Treat the web request as not matching the rule statement.

AWS WAF does its best to parse the entire JSON body, but might be forced to stop for reasons such as invalid characters, duplicate keys, truncation, and any content whose root node isn't an object or an array.

AWS WAF parses the JSON in the following examples as two valid key:value pairs:

- Missing comma: "key1":"value1","key2":"value2"
- Missing colon: "key1":"value1","key2""value2"
- Extra colons: "key1":"value1","key2""value2"

- **JSON match scope** – The types of elements in the JSON that AWS WAF should inspect. You can specify **Keys**, **Values**, or **All** for both keys and values.

- **Content to inspect** – The elements in the parsed and extracted JSON that you want AWS WAF to inspect.

You must specify one of the following:

- **Full JSON content** - Evaluate all elements in the parsed JSON.
- **Only included elements** - Evaluate only elements in the JSON that match the JSON Pointer criteria that you provide. For information about the JSON Pointer syntax, see the Internet Engineering Task Force (IETF) documentation *JavaScript Object Notation (JSON) Pointer*.

Don't use this option to include all paths in the JSON. Use **Full JSON content** instead.

For example, in the console, you can provide the following:

```
/dogs/0/name
/dogs/1/name
```

In the API or CLI, you can provide the following:

```
"IncludedPaths": ["/dogs/0/name", "/dogs/1/name"]
```

**Example JSON body inspection scenario**

If the included elements setting is /a/b, then for the following JSON body:

```
{
  "a": {
```
The following list describes what AWS WAF would evaluate for each match scope setting. The key b, which is part of the included elements path, isn't evaluated.

- For a match scope set to all: e, f, and g.
- For a match scope set to keys: e and f.
- For a match scope set to values: g.

**HTTP method**

Inspects the HTTP method for the request. The HTTP method indicates the type of operation that the web request is asking your protected resource to perform.

**Oversize handling for request components**

AWS WAF does not support inspecting very large contents for the body, headers, or cookies request components. The underlying host service has count and size limits on what it forwards to AWS WAF for inspection. For example, the host service does not send more than 200 headers to AWS WAF, so for a web request with 205 headers, AWS WAF cannot inspect the last 5 headers. When AWS WAF allows a web request to proceed to your protected resource, the entire web request is sent, including any contents that are outside of the count and size limits that AWS WAF was able to inspect.

The limitations are as follows:

- **Body and JSON Body** – You can inspect the first 8 KB (8,192 bytes) of the body of a request.
- **Headers** – You can inspect at most the first 8 KB (8,192 bytes) of the request headers and at most the first 200 headers. The content is available for inspection by AWS WAF up to the first limit reached.
- **Cookies** – You can inspect at most the first 8 KB (8,192 bytes) of the request cookies and at most the first 200 cookies. The content is available for inspection by AWS WAF up to the first limit reached.

For these components, you provide oversize handling instructions when you define your rule statement. Oversize handling tells AWS WAF what to do with a web request when the request component that the rule inspects is over the limits.

The options for oversize handling are the following:

- **Continue** – Inspect the request component normally according to the rule inspection criteria. AWS WAF will inspect the request component contents that are within the size limitations.
- **Match** – Treat the web request as matching the rule statement. AWS WAF applies the rule action to the request without evaluating it against the rule's inspection criteria.
- **No match** – Treat the web request as not matching the rule statement, without evaluating it against the rule's inspection criteria. AWS WAF continues its inspection of the web request using the rest of the rules in the web ACL, like it would do for any non-matching rule.

In the AWS WAF console, you're required to choose one of these handling options. Outside the console, the default is Continue.
If you use the Match option in a rule with the action set to Block, the rule will block a request where the component type is oversized. With other configurations, the final disposition of the request depends on various factors, such as the configuration of the other rules in your web ACL and the web ACL’s default action setting.

The size and count limitations apply to all rules that you use. This includes any rules that you use but don’t manage, in managed rule groups and in rule groups that are shared with you by another account. For information about managing oversize components in those cases, see Inspection of the request body, headers, and cookies (p. 120).

**Text transformations**

In statements that look for patterns or set constraints, you can provide transformations for AWS WAF to apply before inspecting the request. A transformation reformat a web request to eliminate some of the unusual formatting that attackers use in an effort to bypass AWS WAF.

When you use this with the JSON body request component selection, AWS WAF applies your transformations after parsing and extracting the elements to inspect from the JSON. For more information, see the prior section, JSON body (p. 111).

If you provide more than one transformation, you also set the order for AWS WAF to apply them.

**WCUs** – Each text transformation is 10 WCUs.

The AWS WAF console and API documentation also provide guidance for these settings in the following locations:

- **Rule builder** on the console – Text transformation. This option is available when you use request components.
- **API statement contents** – TextTransformations

**Options for text transformations**

**Base64 decode**

AWS WAF decodes a Base64-encoded string.

**Base64 decode ext**

AWS WAF decodes a Base64-encoded string, but uses a forgiving implementation that ignores characters that aren't valid.

**Command line**

This option mitigates situations where attackers might be injecting an operating system command line command and are using unusual formatting to disguise some or all of the command.

Use this option to perform the following transformations:

- Delete the following characters: \ " ' ^
- Delete spaces before the following characters: / ( 
- Replace the following characters with a space: , ;
- Replace multiple spaces with one space
- Convert uppercase letters, A-Z, to lowercase, a-z

**Compress white space**

AWS WAF replaces multiple spaces with one space and replaces the following characters with a space character (decimal 32):
Rule statements

- \f, formfeed, decimal 12
- \t, tab, decimal 9
- \n, newline, decimal 10
- \r, carriage return, decimal 13
- \v, vertical tab, decimal 11
- non-breaking space, decimal 160

CSS decode

AWS WAF decodes characters that were encoded using CSS 2.x escape rules. This function uses up to two bytes in the decoding process, so it can help to uncover ASCII characters that were encoded using CSS encoding that wouldn't typically be encoded. It's also useful in countering evasion, which is a combination of a backslash and non-hexadecimal characters. For example, ja\vascript for javascript.

Escape sequence decode

AWS WAF decodes the following ANSI C escape sequences: \a, \b, \f, \n, \r, \t, \v, \ , ?, , , , \xHH (hexadecimal), \0OOO (octal). Encodings that aren't valid remain in the output.

Hex decode

AWS WAF decodes a string of hexadecimal characters into a binary.

HTML entity decode

AWS WAF replaces HTML-encoded characters with unencoded characters:
- Replaces &quot; with "
- Replaces &nbsp; with a non-breaking space, decimal 160
- Replaces &lt; with <
- Replaces &gt; with >
- Replaces characters that are represented in hexadecimal format, &\xhhhh;, with the corresponding characters
- Replaces characters that are represented in decimal format, &\nnnn;, with the corresponding characters

JS decode

AWS WAF decodes JavaScript escape sequences. If a \uHHHH code is in the full-width ASCII code range of FF01-FF5E, then the higher byte is used to detect and adjust the lower byte. If not, only the lower byte is used and the higher byte is zeroed, causing a possible loss of information.

Lowercase

AWS WAF converts uppercase letters (A-Z) to lowercase (a-z).

MD5

AWS WAF calculates an MD5 hash from the data in the input. The computed hash is in a raw binary form.

None

AWS WAF inspects the web request as received, without any text transformations.

Normalize path

AWS WAF removes multiple slashes, directory self-references, and directory back-references that are not at the beginning of the input from an input string.
Normalize path win

AWS WAF processes this like NORMALIZE_PATH, but first converts backslash characters to forward slashes.

Remove nulls

AWS WAF removes all NULL bytes from the input.

Replace comments

AWS WAF replaces each occurrence of a C-style comment (/\* ... */\*) with a single space. It doesn't compress multiple consecutive occurrences. It replaces unterminated comments with a space (ASCII 0x20). It doesn't change a standalone termination of a comment (*/).

Replace nulls

AWS WAF replaces NULL bytes in the input with space characters (ASCII 0x20).

SQL hex decode

AWS WAF decodes SQL hex data. For example, (0x414243) is decoded to (ABC).

URL decode

AWS WAF decodes a URL-encoded value.

URL decode uni

Like URL_DECODE, but with support for Microsoft-specific %u encoding. If the code is in the full-width ASCII code range of FF01-FF5E, the higher byte is used to detect and adjust the lower byte. Otherwise, only the lower byte is used and the higher byte is zeroed.

UTF8 to Unicode

AWS WAF converts all UTF-8 character sequences to Unicode. This helps input normalization, and minimizes false-positives and false-negatives for non-English languages.

Statements that reference a set or a rule group

Some rules use entities that are reusable and that are managed outside of your web ACLs, either by you, AWS, or an AWS Marketplace seller. When the reusable entity is updated, AWS WAF propagates the update to your rule. For example, if you use an AWS Managed Rules rule group in a web ACL, when AWS updates the rule group, AWS propagates the change to your web ACL, to update its behavior. If you use an IP set statement in a rule, when you update the set, AWS WAF propagates the change to all rules that reference it, so any web ACLs that use those rules are kept up-to-date with your changes.

The following are the reusable entities that you can use in a rule statement.

- **IP sets** – You create and manage your own IP sets. On the console, you can access these from the navigation pane. For information about managing IP sets, see IP sets and regex pattern sets (p. 121).
- **Regex match sets** – You create and manage your own regex match sets. On the console, you can access these from the navigation pane. For information about managing regex pattern sets, see IP sets and regex pattern sets (p. 121).
- **AWS Managed Rules rule groups** – AWS manages these rule groups. On the console, these are available for your use when you add a managed rule group to your web ACL. For more information about these, see AWS Managed Rules rule groups list (p. 35).
- **AWS Marketplace managed rule groups** – AWS Marketplace sellers manage these rule groups and you can subscribe to them to use them. To manage your subscriptions, on the navigation pane of the console, choose AWS Marketplace. The AWS Marketplace managed rule groups are listed when you add a managed rule group to your web ACL. For rule groups that you haven't yet subscribed to, you can find a link to AWS Marketplace on that page as well. For more information about AWS Marketplace seller managed rule groups, see AWS Marketplace managed rule groups (p. 79).
• **Your own rule groups** – You manage your own rule groups, usually when you need some behavior that isn't available through the managed rule groups. On the console, you can access these from the navigation pane. For more information, see Managing your own rule groups (p. 81).

**Deleting a referenced set or rule group**

When you delete a referenced entity, AWS WAF checks to see if it's currently being used in a web ACL. If AWS WAF finds that it's in use, it warns you. AWS WAF is almost always able to determine if an entity is being referenced by a web ACL. However, in rare cases, it might not be able to do so. If you need to be sure that the entity that you want to delete isn't in use, check for it in your web ACLs before deleting it.

**Scope-down statements**

You can add a scope-down statement inside some rules. The scope-down statement narrows the scope of the requests that the rule evaluates. If a rule has a scope-down statement, traffic is first evaluated using the scope-down statement. If it matches that, then it's evaluated using the rule's standard criteria. Traffic that doesn't match the scope-down statement results as not matching the rule. AWS WAF performs no further evaluation.

You can define a scope-down statement inside the following statement types:

• **Managed rule group statement** – If you add a scope-down statement to a managed rule group statement, any request that doesn't match the scope-down statement results as not matching the rule group. Only those requests that match the scope-down statement are evaluated against the rule group. For managed rule groups with pricing that's based on the number of requests evaluated, scope-down statements can help contain costs. For more information about managed rule group statements, see Managed rule group statement (p. 97).

• **Rate-based rule statement** – A rate-based rule without a scope-down statement controls the rate of all requests that come in to your applications. If you want to only control the rate for a specific category of requests, you add a scope-down statement to the rate-based rule. For example, to only track and control the rate of requests from a specific geographical area, you specify that geographical areas in a geographic match rule as the scope-down statement. For more information about rate-based rule statements, see Rate-based rule statement (p. 100).

You can use any nestable rule in a scope-down statement. The WCUs for the scope-down statement are calculated as the WCUs required for the rule statements that you use in it. For a list of available statements, see Rule statements list (p. 86).

**Forwarded IP address**

This section applies to rule statements that use the IP address of a web request. By default, AWS WAF uses the IP address from the web request origin. However, if a web request goes through one or more proxies or load balancers, the web request origin will contain the address of the last proxy, and not the originating address of the client. In this case, the originating client address is usually forwarded in another HTTP header. This header is typically X-Forwarded-For (XFF), but it can be a different one.

**Rule statements that use IP addresses**

The rule statements that use IP addresses are the following:

• **IP set match** (p. 96) - Inspects the IP address for a match with the addresses that are defined in an IP set.

• **Geographic match** (p. 91) - Uses the IP address to determine country and region of origin and matches the country of origin against a list of countries.

• **Rate-based** (p. 100) - Aggregates requests by their IP addresses to ensure that no individual IP address sends requests at too high a rate.
You can instruct AWS WAF to use a forwarded IP address for any of these rule statements, either from the `X-Forwarded-For` header or from another HTTP header, instead of using the web request's origin. For details on how to provide the specifications, see the guidance for the individual rule statement types.

**IP addresses used in AWS WAF Bot Control**

The Bot Control managed rule group verifies bots using the IP addresses from AWS WAF. If you use Bot Control and you have verified bots that route through a proxy or load balancer, you need to explicitly allow them using a custom rule. For example, you can configure a custom IP set match rule that uses forwarded IP addresses to detect and allow your verified bots. You can use the rule to customize your bot management in a number of ways. For information and examples, see [AWS WAF Bot Control](p. 151).

**General considerations for using forwarded IP addresses**

Before you use a forwarded IP address, note the following general caveats:

- A header can be modified by proxies along the way, and the proxies might handle the header in different ways.
- Attackers might alter the contents of the header in an attempt to bypass AWS WAF inspections.
- The IP address inside the header can be malformed or invalid.
- The header that you specify might not be present at all in a request.

**Considerations for using forwarded IP addresses with AWS WAF**

The following list describes requirements and caveats for using forwarded IP addresses in AWS WAF:

- For any single rule, you can specify one header for the forwarded IP address. The header specification is case insensitive.
- For rate-based rule statements, any nested scoping statements do not inherit the forwarded IP configuration. Specify the configuration for each statement that uses a forwarded IP address.
- For geo match and rate-based rules, AWS WAF uses the first address in the header. For example, if a header contains “10.1.1.1, 127.0.0.0, 10.10.10.10”, AWS WAF uses “10.1.1.1”.
- For IP set match, you indicate whether to match against the first, last, or any address in the header. If you specify any, AWS WAF inspects all addresses in the header for a match, up to 10 addresses. If the header contains more than 10 addresses, AWS WAF inspects the last 10.
- Headers that contain multiple addresses must use a comma separator between the addresses. If a request uses a separator other than a comma, AWS WAF considers the IP addresses in the header malformed.
- If the IP addresses inside the header are malformed or invalid, AWS WAF designates the web request as matching the rule or not matching, according to the fallback behavior that you specify in the forwarded IP configuration.
- If the header that you specify isn't present in a request, AWS WAF doesn't apply the rule to the request at all. This means that AWS WAF doesn't apply the rule action and doesn't apply the fallback behavior.
- A rule statement that uses a forwarded IP header for the IP address won't use the IP address that's reported by the web request origin.

**Best practices for using forwarded IP addresses with AWS WAF**

When you use forwarded IP addresses, use the following best practices:

- Carefully consider all possible states of your request headers before enabling forwarded IP configuration. You might need to use more than one rule to get the behavior you want.
- To inspect multiple forwarded IP headers or to inspect the web request origin and a forwarded IP header, use one rule for each IP address source.
- To block web requests that have an invalid header, set the rule action to block and set the fallback behavior for the forwarded IP configuration to match.

**Example JSON for forwarded IP addresses**

The following geo match statement matches only if the X-Forwarded-For header contains an IP whose country of origin is US:

```json
{
  "Name": "XFFTestGeo",
  "Priority": 0,
  "Action": {
    "Block": {}
  },
  "VisibilityConfig": {
    "SampledRequestsEnabled": true,
    "CloudWatchMetricsEnabled": true,
    "MetricName": "XFFTestGeo"
  },
  "Statement": {
    "GeoMatchStatement": {
      "CountryCodes": ["US"],
      "ForwardedIPConfig": {
        "HeaderName": "x-forwarded-for",
        "FallbackBehavior": "MATCH"
      }
    }
  }
}
```

The following rate-based rule aggregates requests based on the first IP in the X-Forwarded-For header. The rule counts only requests that match the nested geo match statement. The nested geo match statement also uses the X-Forwarded-For header to determine whether the IP address indicates a country of origin of US. If it does, or if the header is present but malformed, the geo match statement returns a match.

```json
{
  "Name": "XFFTestRateGeo",
  "Priority": 0,
  "Action": {
    "Block": {}
  },
  "VisibilityConfig": {
    "SampledRequestsEnabled": true,
    "CloudWatchMetricsEnabled": true,
    "MetricName": "XFFTestRateGeo"
  },
  "Statement": {
    "RateBasedStatement": {
      "Limit": "100",
      "AggregateKeyType": "FORWARDED_IP",
      "ScopeDownStatement": {
        "GeoMatchStatement": {
          "CountryCodes": ["US"],
          "ForwardedIPConfig": {
            "HeaderName": "x-forwarded-for",
            "FallbackBehavior": "MATCH"
          }
        }
      }
    }
  }
}
```
Inspection of the request body, headers, and cookies

AWS WAF does not support inspecting very large contents for the body, headers, or cookies request components. The underlying host service has count and size limits on what it forwards to AWS WAF for inspection. For example, the host service does not send more than 200 headers to AWS WAF, so for a web request with 205 headers, AWS WAF cannot inspect the last 5 headers. When AWS WAF allows a web request to proceed to your protected resource, the entire web request is sent, including any contents that are outside of the count and size limits that AWS WAF was able to inspect.

The limitations are as follows:

- **Body and JSON Body** – You can inspect the first 8 KB (8,192 bytes) of the body of a request.
- **Headers** – You can inspect at most the first 8 KB (8,192 bytes) of the request headers and at most the first 200 headers. The content is available for inspection by AWS WAF up to the first limit reached.
- **Cookies** – You can inspect at most the first 8 KB (8,192 bytes) of the request cookies and at most the first 200 cookies. The content is available for inspection by AWS WAF up to the first limit reached.

When you add or update a rule that inspects any of the limited request components, you specify oversize content handling in the component specification. For information, see Oversize handling for request components (p. 113).

When you use a managed rule group or a rule group that another account has shared with you, the rule group might have a rule that inspects a limited request component but that doesn’t handle oversized contents the way you need them to be handled. For information about AWS Managed Rules, see AWS Managed Rules rule groups list (p. 35). For information about other rule groups, ask your rule group provider.

The way you handle oversize components in your web ACL can depend on a number of factors such as the expected size of your request component contents, your web ACL’s default request handling, and how other rules in your web ACL match and handle requests.

The following are general guidelines for managing oversized web request components:

- If you need to allow some requests with oversize component contents, if possible, add rules to explicitly allow only those requests. Prioritize those rules so that they run before any other rules in the web ACL that inspect the same component types. With this approach, you won’t be able to use AWS WAF to inspect the entire contents of the oversize components that you allow to pass to your protected resource.
- For all other requests, you can prevent any additional bytes from passing through by blocking requests that go over the limit:
  - **Your rules and rule groups** – In your rules that inspect size limited components, configure oversize handling so that you block requests that go over the limit. For example, if your rule blocks requests with specific header contents, you can set the oversize handling to match on any request that has
oversize header content. As another example, if your web ACL blocks requests by default and your rule allows specific header contents, then you can configure your rule's oversize handling so that it doesn't match on any request that has oversize header content. For information about the handling options, see Oversize handling for request components (p. 113).

- **Rule groups that you don't manage** – To prevent rule groups that you don't manage from allowing oversize request components, you can add a separate rule that inspects the request component type and blocks requests that go over the limits. Prioritize the rule in your web ACL so that it runs before the rule groups. For example, you can block requests with oversize body content before any of your body inspection rules run in the web ACL. The following procedure describes how to add this type of rule.

**To add a rule that blocks oversized contents**

1. When you create or edit your web ACL, in the rules settings, choose Add rules, Add my own rules and rule groups, Rule builder, then Rule visual editor. For guidance creating or editing a web ACL, see Working with web ACLs (p. 18).
2. Enter a name for your rule, and leave the Type setting at Regular rule.
3. Change the following match settings from their defaults:
   a. On Statement, for Inspect, open the dropdown and choose the web request component that you need, either Body, Headers, or Cookies.
   b. For Match type, choose Size greater than.
   c. For Size, type a number that's at least 8192.
   d. For Oversize handling, select Match.
4. For Action, select Block.
5. Choose Add rule.
6. After you add the rule, on the Set rule priority page, move it above any rules or rule groups in your web ACL that inspect the same component type. This gives it a lower numeric priority setting, which causes AWS WAF to evaluate it first. For more information, see Processing order of rules and rule groups in a web ACL (p. 14).

**IP sets and regex pattern sets**

AWS WAF stores some more complex information in sets that you use by referencing them in your rules. Each of these sets has a name and is assigned an Amazon Resource Name (ARN) at creation. You can manage these sets from inside your rule statements and you can access and manage them on their own, through the console navigation pane.

**Temporary inconsistencies during updates**

When you create or change a web ACL or other AWS WAF resources, the changes take a small amount of time to propagate to all areas where the resources are stored. The propagation time can be from a few seconds to a number of minutes.

The following are examples of the temporary inconsistencies that you might notice during change propagation:

- After you create a web ACL, if you try to associate it with a resource, you might get an exception indicating that the web ACL is unavailable.
- After you add a rule group to a web ACL, the new rule group rules might be in effect in one area where the web ACL is used and not in another.
- After you change a rule action setting, you might see the old action in some places and the new action in others.
Creating and managing an IP set

An IP set provides a collection of IP addresses and IP address ranges that you want to use together in a rule statement. IP sets are AWS resources.

To use an IP set in a web ACL or rule group, you first create an AWS resource, IPSet with your address specifications. Then you reference the set when you add an IP set rule statement to a web ACL or rule group.

Creating an IP set

Follow the procedure in this section to create a new IP set.

**Note**
In addition to the procedure in this section, you have the option to add a new IP set when you add an IP match rule to your web ACL or rule group. Choosing that option requires you to provide the same settings as those required by this procedure.

**To create an IP set**

2. In the navigation pane, choose **IP sets** and then **Create IP set**.
3. Enter a name and description for the IP set. You’ll use these to identify the set when you want to use it.

   **Note**
   You can’t change the name after you create the IP set.

4. For **Region**, choose Global (CloudFront) or choose the Region where you want to store the IP set. You can use regional IP sets only in web ACLs that protect regional resources. To use an IP set in web ACLs that protect Amazon CloudFront distributions, you must use Global (CloudFront).
5. For **IP version**, select the version you want to use.
6. In the **IP addresses** text box, enter one IP address or IP address range per line, in CIDR notation. AWS WAF supports all IPv4 and IPv6 CIDR ranges except for /0. For more information about CIDR notation, see the Wikipedia article **Classless Inter-Domain Routing**.

Here are some examples:

- To specify the IPv4 address 192.0.2.44, type `192.0.2.44/32`.
- To specify the IPv6 address 2620:0:2d0:200:0:0:0:0, type `2620:0:2d0:200:0:0:0:0/128`.
Creating and managing an IP set

• To specify the range of IPv4 addresses from 192.0.2.0 to 192.0.2.255, type **192.0.2.0/24**.
• To specify the range of IPv6 addresses from 2620:0:2d0:200:0:0:0:0 to 2620:0:2d0:200:ffff:ffff:ffff:ffff, enter **2620:0:2d0:200::/64**.

7. Review the settings for the IP set, and choose Create IP set.

Using an IP set in a rule group or Web ACL

To use an IP set, add a rule statement that references it to the rule group or web ACL where you need it. For information, see IP set match rule statement (p. 96).

Editing an IP set

To add or remove IP addresses or IP address ranges from an IP set or change its description, perform the following procedure.

To edit an IP set

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose IP sets.
3. Select the IP set that you want to edit and choose Edit.
4. Modify the IP version and addresses as needed. In the IP addresses text box, you must have one IP address or IP address range per line, in CIDR notation. AWS WAF supports all IPv4 and IPv6 CIDR ranges except for /0. For more information about CIDR notation, see the Wikipedia article Classless Inter-Domain Routing. For addresses, enter one IP address or IP address range per line, in CIDR notation.

Here are some examples:

• To specify the IPv4 address 192.0.2.44, type **192.0.2.44/32**.
• To specify the IPv6 address 2620:0:2d0:200:0:0:0:0, type **2620:0:2d0:200::/128**.
• To specify the range of IPv4 addresses from 192.0.2.0 to 192.0.2.255, type **192.0.2.0/24**.
• To specify the range of IPv6 addresses from 2620:0:2d0:200:0:0:0:0 to 2620:0:2d0:200:ffff:ffff:ffff:ffff, enter **2620:0:2d0:200::/64**.

5. Choose Save changes.

Deleting an IP set

Follow the guidance in this section to delete a referenced set.

Deleting referenced sets and rule groups

When you delete an entity that you can use in a web ACL, like an IP set, regex pattern set, or rule group, AWS WAF checks to see if the entity is currently being used in a web ACL. If it finds that it is in use, AWS WAF warns you. AWS WAF is almost always able to determine if an entity is being referenced by a web ACL. However, in rare cases it might not be able to do so. If you need to be sure that nothing is currently using the entity, check for it in your web ACLs before deleting it. If the entity is a referenced set, also check that no rule groups are using it.

To delete an IP set

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose IP sets.
3. Select the IP set that you want to delete and choose Delete.

Creating and managing a regex pattern set

A regex pattern set provides a collection of regular expressions that you want to use together in a rule statement. Regex pattern sets are AWS resources.

To use a regex pattern set in a web ACL or rule group, you first create an AWS resource, RegexPatternSet with your regex pattern specifications. Then you reference the set when you add a regex pattern set rule statement to a web ACL or rule group. A regex pattern set must contain at least one regex pattern.

If your regex pattern set contains more than one regex pattern, when it's used in a rule, the pattern matching is combined with OR logic. That is, a web request will match the pattern set rule statement if the request component matches any of the patterns in the set.

AWS WAF supports the pattern syntax used by the PCRE library libpcre. The library is documented at PCRE - Perl Compatible Regular Expressions.

Regex pattern use limitations

AWS WAF does not support all constructs of the PCRE library. For example, it supports some zero-width assertions, but not all. We do not have comprehensive list of the constructs that are supported. However, if you provide a regex pattern that is not valid or use unsupported constructs, the AWS WAF API reports a failure.

AWS WAF does not support the following PCRE patterns:

- Backreferences and capturing subexpressions
- Subroutine references and recursive patterns
- Conditional patterns
- Backtracking control verbs
- The \C single-byte directive
- The \R newline match directive
- The \K start of match reset directive
- Callouts and embedded code
- Atomic grouping and possessive quantifiers

Topics

- Creating a regex pattern set (p. 124)
- Using a regex pattern set in a rule group or Web ACL (p. 125)
- Deleting a regex pattern set (p. 125)

Creating a regex pattern set

Follow the procedure in this section to create a new regex pattern set.

To create a regex pattern set

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Regex pattern sets and then Create regex pattern set.
3. Enter a name and description for the regex pattern set. You'll use these to identify it when you want to use the set.

   **Note**
   You can't change the name after you create the regex pattern set.

4. For **Region**, choose Global (CloudFront) or choose the Region where you want to store the regex pattern set. You can use regional regex pattern sets only in web ACLs that protect regional resources. To use a regex pattern set in web ACLs that protect Amazon CloudFront distributions, you must use Global (CloudFront).

5. In the **Regular expressions** text box, enter one regex pattern per line.

   For example, the regular expression \[a@\]mAB[a@]dRequest matches the following strings:
   IamABadRequest, IamAB@dRequest, I@mABadRequest, and I@mAB@dRequest.

   AWS WAF supports the pattern syntax used by the PCRE library *libpcre*. The library is documented at [PCRE - Perl Compatible Regular Expressions](https://www.regular-expressions.info/).

   AWS WAF doesn't support all constructs of the library. For example, it supports some zero-width assertions, but not all. We do not have a comprehensive list of the constructs that are supported. However, if you provide a regex pattern that isn't valid or use unsupported constructs, the AWS WAF API reports a failure.

   AWS WAF does not support the following PCRE patterns:
   - Backreferences and capturing subexpressions
   - Subroutine references and recursive patterns
   - Conditional patterns
   - Backtracking control verbs
   - The \C single-byte directive
   - The \R newline match directive
   - The \K start of match reset directive
   - Callouts and embedded code
   - Atomic grouping and possessive quantifiers

6. Review the settings for the regex pattern set, and choose **Create regex pattern set**.

### Using a regex pattern set in a rule group or Web ACL

To use a regex pattern set in a rule group or web ACL, in the console, when you add or update the rules in your rule group or web ACL, in the **Rule builder** interface, for **Request option**, choose the request component that you want to compare to your pattern set. Choose **Match type > String match condition** > **Matches pattern from regular expression**, and then choose the name of the regex pattern set that you want to use.

### Deleting a regex pattern set

Follow the guidance in this section to delete a referenced set.

#### Deleting referenced sets and rule groups

When you delete an entity that you can use in a web ACL, like an IP set, regex pattern set, or rule group, AWS WAF checks to see if the entity is currently being used in a web ACL. If it finds that it is in use, AWS WAF warns you. AWS WAF is almost always able to determine if an entity is being referenced by a web ACL. However, in rare cases it might not be able to do so. If you need to be sure that nothing is currently using the entity, check for it in your web ACLs before deleting it. If the entity is a referenced set, also check that no rule groups are using it.
To delete a regex pattern set

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Regex pattern sets.
3. Select the regex pattern set that you want to delete and choose Delete.

Customized web requests and responses in AWS WAF

You can add custom web request and response handling behavior to your AWS WAF rule actions and default web ACL actions. Your custom settings apply whenever the action they’re attached to applies.

You can customize web requests and responses in the following ways:

- With Allow, Count, CAPTCHA, and Challenge actions, you can insert custom headers into the web request. When AWS WAF forwards the web request to the protected resource, the request contains the entire original request plus the custom headers that you’ve inserted. For the CAPTCHA and Challenge actions, AWS WAF only applies the customization if the request passes the CAPTCHA or challenge token inspection.

- With Block actions, you can define a complete custom response, with response code, headers, and body. The protected resource responds to the request using the custom response provided by AWS WAF. Your custom response replaces the default Block action response of 403 (Forbidden).

Action settings that you can customize

You can specify a custom request or response when you define the following action settings:

- Rule action. For information, see AWS WAF rule action (p. 84).
- Default action for a web ACL. For information, see Deciding on the default action for a web ACL (p. 16).

Action settings that you cannot customize

You cannot specify custom request handling in the override action for a rule group that you use in a web ACL. See Web ACL rule and rule group evaluation (p. 13). Also see Managed rule group statement (p. 97) and Rule group statement (p. 104).

Temporary inconsistencies during updates

When you create or change a web ACL or other AWS WAF resources, the changes take a small amount of time to propagate to all areas where the resources are stored. The propagation time can be from a few seconds to a number of minutes.

The following are examples of the temporary inconsistencies that you might notice during change propagation:

- After you create a web ACL, if you try to associate it with a resource, you might get an exception indicating that the web ACL is unavailable.
- After you add a rule group to a web ACL, the new rule group rules might be in effect in one area where the web ACL is used and not in another.
• After you change a rule action setting, you might see the old action in some places and the new action in others.
• After you add an IP address to an IP set that is in use in a blocking rule, the new address might be blocked in one area while still allowed in another.

Limits on your use of custom requests and responses

AWS WAF defines maximum settings for your use of custom requests and responses. For example, a maximum number of request headers per web ACL or rule group, and a maximum number of custom headers for a single custom response definition. For information, see AWS WAF quotas (p. 243).

Topics

• Custom request header insertions for non-blocking actions (p. 127)
• Custom responses for Block actions (p. 128)
• Supported status codes for custom response (p. 130)

Custom request header insertions for non-blocking actions

You can instruct AWS WAF to insert custom headers into the original HTTP request when a rule action doesn't block the request. With this option, you only add to the request. You can't modify or replace any part of the original request. Use cases for custom header insertion include signaling a downstream application to process the request differently based on the inserted headers, and flagging the request for analysis.

This option applies to the rule actions Allow, Count, CAPTCHA, and Challenge and to web ACL default actions that are set to Allow. For more information about rule actions, see AWS WAF rule action (p. 84). For more information about default web ACL actions, see Deciding on the default action for a web ACL (p. 16).

Custom request header names

AWS WAF prefixes all request headers that it inserts with x-amzn-waf-, to avoid confusion with the headers that are already in the request. For example, if you specify the header name sample, AWS WAF inserts the header x-amzn-waf-sample.

Headers with the same name

If the request already has a header with the same name that AWS WAF is inserting, AWS WAF overwrites the header. So, if you define headers in multiple rules with identical names, the last rule to inspect the request and find a match would have its header added, and any previous rules would not.

Custom headers with non-terminating rule actions

Unlike the Allow action, the Count action doesn't stop AWS WAF from processing the web request using the rest of the rules in the web ACL. Similarly, when CAPTCHA and Challenge determine that the request token is valid, these actions don't stop AWS WAF from processing the web request. So, if you insert custom headers using a rule with one of these actions, subsequent rules might also insert custom headers. For more information about rule action behavior, see AWS WAF rule action (p. 84).

For example, suppose you have the following rules, prioritized in the order shown:

1. RuleA with a Count action and a customized header named RuleAHeader.
2. RuleB with an Allow action and a customized header named RuleBHeader.
If a request matches both RuleA and RuleB, AWS WAF inserts the headers `x-amzn-waf-RuleAHeader` and `x-amzn-waf-RuleBHeader`, and then forwards the request to the protected resource.

AWS WAF inserts custom headers into a web request when it finishes inspecting the request. So if you use custom request handling with a rule that has the action set to Count, the custom headers that you add are not inspected by subsequent rules.

**Example custom request handling**

You define custom request handling for a rule's action or for a web ACL's default action. The following listing shows the JSON for custom handling added to the default action for a web ACL.

```json
{
  "Name": "SampleWebACL",
  "Scope": "REGIONAL",
  "DefaultAction": {
    "Allow": {
      "CustomRequestHandling": {
        "InsertHeaders": [
          {
            "Name": "fruit",
            "Value": "watermelon"
          },
          {
            "Name": "pie",
            "Value": "apple"
          }
        ]
      }
    }
  },
  "Description": "Sample web ACL with custom request handling configured for default action.",
  "Rules": [],
  "VisibilityConfig": {
    "SampledRequestsEnabled": true,
    "CloudWatchMetricsEnabled": true,
    "MetricName": "SampleWebACL"
  }
}
```

**Custom responses for Block actions**

You can instruct AWS WAF to send a custom HTTP response back to the client for rule actions or web ACL default actions that are set to Block. For more information about rule actions, see [AWS WAF rule action](p. 84). For more information about default web ACL actions, see [Deciding on the default action for a web ACL](p. 16).

When you define custom response handling for a Block action, you define the status code, headers, and response body. For a list of status codes that you can use with AWS WAF, see [Supported status codes for custom response](p. 130).

**Use cases**

The use cases for custom responses include the following:

- Sending a non-default status code back to the client.
- Sending a static error page back to the client.
- Redirecting the client to a different URL. To do this, you specify one of the 3xx redirection status codes, like 301 (Moved Permanently) or 302 (Found), and then specify a new header named Location with the new URL.
Interaction with responses that you define in your protected resource

Custom responses that you specify for the AWS WAF Block action take precedence over any response specifications that you define in your protected resource.

The host service for the AWS resource that you protect with AWS WAF might permit custom response handling for web requests. Examples include the following:

- With Amazon CloudFront, you can customize the error page based on status code. For information, see Generating custom error responses in the Amazon CloudFront Developer Guide.
- With Amazon API Gateway you can define the response and status code for your gateway. For information, see Gateway responses in API Gateway in the Amazon API Gateway Developer Guide.

You can't combine AWS WAF custom response settings with custom response settings in the protected AWS resource. The response specification for any individual web request comes either completely from AWS WAF or completely from the protected resource.

For web requests that AWS WAF blocks, the following shows the order of precedence.

1. **AWS WAF custom response** – If the AWS WAF Block action has a custom response enabled, the protected resource sends the configured custom response back to the client. This applies whether the custom response that's define in AWS WAF specifies just the HTTP code, just a custom page, or both. Any response settings that you might have defined in the protected resource itself have no effect.

2. **Custom response defined in the protected resource** – Otherwise, if the protected resource has custom response settings specified, the protected resource uses those settings to respond to the client.

3. **AWS WAF default Block response** – Otherwise, the protected resource responds to the client with the AWS WAF default Block response 403 (Forbidden).

For web requests that AWS WAF allows, your configuration of the protected resource determines the response that it sends back to the client. You can't configure response settings in AWS WAF for allowed requests. The only customization that you can configure in AWS WAF for allowed requests is the insertion of custom headers into the original request, before forwarding the request to the protected resource. This option is described in the preceding section, Custom request header insertions for non-blocking actions (p. 127).

**Custom response bodies**

You define the body of a custom response within the context of the web ACL or rule group where you want to use it. After you've defined a custom response body, you can use it by reference anywhere else in the web ACL or rule group where you created it. In the individual Block action settings, you reference the custom body that you want to use and you define the status code and header of the custom response.

When you create a custom response in the console, you can choose from response bodies that you've already defined or you can create a new body. Outside of the console, you define your custom response bodies at the web ACL or rule group level, and then reference them from the action settings within the web ACL or rule group. This is shown in the example JSON in the following section.

**Custom response example**

The following example lists the JSON for a rule group with custom response settings. The custom response body is defined for the entire rule group, then referenced by key in the rule action.

```json
{
    "ARN": "test_rulegroup_arn",
    "Capacity": 1,
    
```
"CustomResponseBodies": {
    "CustomResponseBodyKey1": {
        "Content": "This is a plain text response body.",
        "ContentType": "TEXT_PLAIN"
    }
},

"Description": "This is a test rule group.",
"Id": "test_rulegroup_id",
"Name": "TestRuleGroup",

"Rules": [
    {
        "Action": {
            "Block": {
                "CustomResponse": {
                    "CustomResponseBodyKey": "CustomResponseBodyKey1",
                    "ResponseCode": 404,
                    "ResponseHeaders": [
                        {
                            "Name": "BlockActionHeader1Name",
                            "Value": "BlockActionHeader1Value"
                        }
                    ]
                }
            }
        },
        "Name": "GeoMatchRule",
        "Priority": 1,
        "Statement": {
            "GeoMatchStatement": {
                "CountryCodes": [
                    "US"
                ]
            }
        },
        "VisibilityConfig": {
            "CloudWatchMetricsEnabled": true,
            "MetricName": "TestRuleGroupReferenceMetric",
            "SampledRequestsEnabled": true
        }
    }
],

"VisibilityConfig": {
    "CloudWatchMetricsEnabled": true,
    "MetricName": "TestRuleGroupMetric",
    "SampledRequestsEnabled": true
}

---

**Supported status codes for custom response**

For detailed information about HTTP status codes, see [Status Codes](#) by the Internet Engineering Task Force (IETF) and [List of HTTP status codes](#) on Wikipedia.

The following are the HTTP status codes that AWS WAF supports for custom responses.

- **2xx Successful**
  - 200 – OK
  - 201 – Created
  - 202 – Accepted
  - 204 – No Content
Labels on web requests

A label is metadata added to a web request by a matching rule. You can use labels to communicate rule match results to rules that are evaluated later in the same web ACL.

- Any rule that isn't a rule group reference statement can add labels to matching web requests. When a web request matches a rule, AWS WAF adds the rule's labels to the request. For the geographical match rule, AWS WAF adds the rule's labels to any request that the rule inspects, match or no match.
- AWS WAF adds labels to a request at the end of the rule's inspection of the request. So when a single rule contains multiple statements, for example within a logical AND or OR statement, any labels that the contained statements assign are available on the web request only after all contained statements have been evaluated.
- Once added, labels remain available on the request as long as AWS WAF is evaluating the request against the web ACL.
• You can match against a label in your rule's request inspection criteria using the label match statement. For statement details, see Label match rule statement (p. 97).

Common use cases for AWS WAF labels include the following:

• **Evaluating a web request against multiple rule statements before taking action on the request** – After a match is found with a rule in a web ACL, AWS WAF continues evaluating the request against the web ACL if the rule action is Count. You can use labels to evaluate and collect information from multiple rules before you decide to allow or block the request. To do this, change the actions for your existing rules to Count and configure them to add labels to matching requests. Then, add one or more new rules to run after your other rules, and configure them to evaluate the labels and manage the requests according to the label match combinations.

• **Managing web requests by geographical region** – You can use the geographic match rule alone to manage web requests by the country of origin. To fine-tune the location down to the region level, you use the geo match rule with a Count action followed by a label match rule. For information about the geo match rule, see Geographic match rule statement (p. 91).

• **Reusing logic across multiple rules** – If you need to reuse the same logic across multiple rules, you can use labels to single-source the logic and just test for the results. When you have multiple complex rules that use a common subset of nested rule statements, duplicating the common rule set across your complex rules can be time consuming and error prone. With labels, you can create a new rule with the common rule subset that counts matching requests and adds a label to them. You add the new rule to your web ACL so that it runs before your other rules. Then, in your original rules, you replace the shared rule subset with a single rule that checks for the label.

For example, say you have multiple rules that you want to only apply to your login paths. Rather than have each rule specify the same logic to match potential login paths, you can implement a single new rule that contains that logic. Have the new rule add a label to matching requests to indicate that the request is on a login path. In your web ACL, give this new rule a lower numeric priority setting than your original rules so that it runs first. Then, in your original rules, replace the shared logic with a check for the presence of the label. For information about priority settings, see Processing order of rules and rule groups in a web ACL (p. 14).

• **Creating exceptions to rules in rule groups** – This option is particularly useful for managed rule groups, which you can't view or alter. Many managed rule group rules add labels to matching web requests, to indicate the rules that matched and possibly to provide additional information about the match. When you use a rule group that adds labels to requests, you can override the rule group rules to count matches, and then run a rule after the rule group that handles the web request based on the rule group labels. All AWS Managed Rules add labels to matching web requests. For details, see the rule descriptions at AWS Managed Rules rule groups list (p. 35).

AWS Managed Rules rule groups add labels to the web requests that they evaluate. Most of these labels are added by the rules in the rule groups. Some labels are added by AWS processes that are used by managed rules. For example, the account takeover prevention and Bot Control managed rule groups use AWS WAF token management to add labels to requests that indicate the status of their tokens. For information about managed rule groups and the labels that they add, see AWS Managed Rules rule groups list (p. 35).

**How labeling works**

When a rule matches a web request, if the rule has labels defined, AWS WAF adds the labels to the request. Rules that are evaluated after the matching rule in the same web ACL have access to the labels that the rule has added, and can match against them.

• Any rule that's included in a single web ACL can access labels that have been added by any rule that has already run in the same web ACL. This includes rules that are defined directly inside the web ACL
and those inside rule groups that are used in the web ACL. Labels don't persist with the web request after the web ACL evaluation ends.

- In order for other rules to match against a label that your rule adds, your rule action must not terminate the evaluation of the web request by the web ACL. The rule action must be set to Count, CAPTCHA, or Challenge. When the web ACL evaluation doesn't terminate, subsequent rules in the web ACL can run their label matching criteria against the request. For more information about rule actions, see AWS WAF rule action (p. 84).

- Labels emit Amazon CloudWatch metrics for the first 100 labels on any single request. For information, see Monitoring with Amazon CloudWatch (p. 541).

- AWS WAF records labels in the logs for the first 100 labels on a request. You can use labels, along with the rule action, to filter the logs that AWS WAF records. For information, see Logging web ACL traffic (p. 192).

- Your web ACL evaluation can apply more than 100 labels to a web request and match against more than 100 labels, but AWS WAF only records the first 100 in logs and metrics.

## Label syntax and naming requirements

A label is a string made up of a prefix, optional namespaces, and a name. The components of a label are delimited with a colon. Labels have the following requirements and characteristics:

- Labels are case-sensitive.
- Each label namespace or label name can have up to 128 characters.
- You can specify up to five namespaces in a label.
- Components of a label are separated by colon (:).
- You can't use the following reserved strings in the namespaces or name that you specify for a label: awswaf, aws, waf, rulegroup, webacl, regexpatternset, ipset, and managed.

### Label syntax

A fully qualified label has a prefix, optional namespaces, and label name. The prefix identifies the rule group or web ACL context of the rule that added the label. Namespaces might be used to add more context for the label. The label name provides the lowest level of detail for a label. It often indicates the specific rule that added the label to the request.

The label prefix varies depending on its origin.

- **Your labels** – The following shows the full label syntax for labels that you create in your web ACL and rule group rules. The entity types are rulegroup and webacl.

    `awswaf:<entity owner account id>:<entity type>:<entity name>:<custom namespace>:...:<label name>`

- **Label namespace prefix:** `awswaf:<entity owner account id>:<entity type>:<entity name>`:

- **Custom namespace additions:** `<custom namespace>:...`

When you define a label for a rule in a rule group or web ACL, you control the custom namespace strings and the label name. The rest is generated for you by AWS WAF. AWS WAF automatically prefixes all labels with `awswaf` and the account and web ACL or rule group entity settings.

- **Managed rule group labels** – The following shows the full label syntax for labels that are created by rules in managed rule groups.
Syntax and naming requirements

`awswaf:managed:<vendor>:<rule group name>:<custom namespace>:...:<label name>`

- **Label namespace prefix:** `awswaf:managed:<vendor>:<rule group name>:`
- **Custom namespace additions:** `<custom namespace>:...:`

All AWS Managed Rules rule groups add labels. For information about managed rule groups, see Managed rule groups (p. 26).

- **Labels from other AWS processes** – These processes are used by AWS Managed Rules rule groups, so you see them added to web requests that you evaluate using managed rule groups. The following shows the full label syntax for labels that are created by processes that are called by managed rule groups.

`awswaf:managed:<process>:<custom namespace>:...:<label name>`

- **Label namespace prefix:** `awswaf:managed:<process>:`
- **Custom namespace additions:** `<custom namespace>:...:`

Labels of this type are listed for the managed rule groups that call the AWS process. For information about managed rule groups, see Managed rule groups (p. 26).

**Label examples for your rules**

The following example labels are defined by rules in a rule group named `testRules` that belongs to the account, 111122223333.

- `awswaf:111122223333:rulegroup:testRules:testNS1:testNS2:LabelNameA`
- `awswaf:111122223333:rulegroup:testRules:testNS1:LabelNameQ`
- `awswaf:111122223333:rulegroup:testRules:LabelNameZ`

The following listing shows an example label specification in JSON. These label names include custom namespace strings before the ending label name.

```
Rule: {
  Name: "label_rule",
  Statement: {...}
  RuleLabels: [{
    Name: "header:encoding:utf8",
    Name: "header:user_agent:firefox"
  },
  Action: { Count: {} }
}
```

**Note**

You can access this type of listing in the console through the rule JSON editor.

If you run the preceding rule in the same rule group and account as the preceding label examples, the resulting, fully qualified labels would be the following:

Adding a label to matching web requests

When you define a label for a rule, AWS WAF adds the label to requests that match the rule. You define a label in a rule by specifying the custom namespace strings and name to append to the label namespace prefix. AWS WAF derives the prefix from the context in which you define the rule. For information about this, see the label syntax information under Label syntax and naming requirements (p. 133).

Except for the following, you can add labels to any rule and AWS WAF will add your labels to any web request that matches the rule match statement:

- For rate-based rules, labels are only added to web requests for a particular IP address while that IP address is blocked by AWS WAF due to rate limiting. For information about rate-based rules, see Rate-based rule statement (p. 100).
- You can’t use labels in statements that reference rule groups. If you try to add a label to a rule group rule statement through the API, the operation throws a validation exception. For information about these statement types, see Managed rule group statement (p. 97) and Rule group statement (p. 104).

WCUs – 1 WCU for every 5 labels that you define in your web ACL or rule group rules.

Where to find this

- Rule builder on the console – Under the rule’s Action settings, under Label.
- API data type – Rule RuleLabels

Matching against a label

You can use a label match statement to evaluate web request labels. You can match against Label, which requires the label name, or against Namespace, which requires a namespace specification. For either label or namespace, you can optionally include preceding namespaces and the prefix in your specification. For general information about this statement type, see Label match rule statement (p. 97).

A label’s prefix defines the context of the rule group or web ACL where the label’s rule is defined. In a rule’s label match statement, if your label or namespace match string doesn’t specify the prefix, AWS WAF uses the prefix for the label match rule.

- Labels for rules that are defined directly inside a web ACL have a prefix that specifies the web ACL context.
• Labels for rules that are inside a rule group have a prefix that specifies the rule group context. This could be your own rule group or a rule group that's managed for you.

For information about this, see label syntax under Label syntax and naming requirements (p. 133).

Note
Some managed rule groups add labels. You can retrieve these through the API by calling DescribeManagedRuleGroup. The labels are listed in the AvailableLabels property in the response.

If you want to match against a rule that's in a different context than the context of your rule, you must provide the prefix in your match string. For example, if you want to match against labels that are added by rules in a managed rule group, you could add a rule in your web ACL with a label match statement whose match string specifies the rule group's prefix followed by your additional match criteria.

In the match string for the label match statement, you specify either a label or a namespace:

• **Label** – The label specification for a match consists of the ending part of the label. You can include any number of the contiguous namespaces that immediately precede the label name followed by the name. You can also provide the fully qualified label by starting the specification with the prefix.

Example specifications:
- `testNS1:testNS2:LabelNameA`
- `awswaf:managed:aws:managed-rule-set:testNS1:testNS2:LabelNameA`

• **Namespace** – The namespace specification for a match consists of any contiguous subset of the label specification excluding the name. You can include the prefix and you can include one or more namespace strings.

Example specifications:
- `testNS1:testNS2:
- `awswaf:managed:aws:managed-rule-set:testNS1:

## Label match examples

This section provides examples of match specifications, for the label match rule statement.

Note
These JSON listings were created in the console by adding a rule to a web ACL with the label match specifications and then editing the rule and switching to the Rule JSON editor. You can also get the JSON for a rule group or web ACL through the APIs or the command line interface.

Topics
- Match against a local label (p. 136)
- Match against a label from another context (p. 137)
- Match against a managed rule group label (p. 137)
- Match against a local namespace (p. 138)
- Match against a managed rule group namespace (p. 138)

## Match against a local label

The following JSON listing shows a label match statement for a label that's been added to the web request locally, in the same context as this rule.

```json
Rule: {
}
```
Name: "match_rule",
Statement: {
    LabelMatchStatement: {
        Scope: "LABEL",
        Key: "header:encoding:utf8"
    },
},
RuleLabels: [
    ...generate_more_labels...
],
Action: { Block: {} }

If you use this match statement in account 111122223333, in a rule that you define for web ACL testWebACL, it would match the following labels.

It wouldn't match the following label, because the label string isn't an exact match.

It wouldn't match the following label, because the context isn't the same, so the prefix doesn't match. This is true even if you added the rule group productionRules to the web ACL testWebACL, where the rule is defined.

**Match against a label from another context**

The following JSON listing shows a label match rule that matches against a label from a rule inside a user-created rule group. The prefix is required in the specification for all rules running in the web ACL that aren't part of the named rule group. This example label specification matches only the exact label.

Rule: {
    Name: "match_rule",
    Statement: {
        LabelMatchStatement: {
            Scope: "LABEL",
        },
    },
    RuleLabels: [
        ...generate_more_labels...
    ],
    Action: { Block: {} }
}

**Match against a managed rule group label**

This is a special case of matching against a label that's from another context than that of the match rule. The following JSON listing shows a label match statement for a managed rule group label. This matches only the exact label that's specified in the label match statement's key setting.

Rule: {

Label match examples

```json
Name: "match_rule",
Statement: {
    LabelMatchStatement: {
        Scope: "LABEL",
        Key: "awswaf:managed:aws:managed-rule-set:header:encoding:utf8"
    },
},
RuleLabels: [
    ...generate_more_labels...
],
Action: { Block: {} }
}
```

**Match against a local namespace**

The following JSON listing shows a label match statement for a local namespace.

```json
Rule: {
    Name: "match_rule",
    Statement: {
        LabelMatchStatement: {
            Scope: "NAMESPACE",
            Key: "header:encoding:"
        },
    },
    Labels: [
        ...generate_more_labels...
    ],
    Action: { Block: {} }
}
```

Similar to the local Label match, if you use this statement in account 111122223333, in a rule that you define for web ACL testWebACL, it would match the following label.

It wouldn't match the following label, because the account isn't the same, so the prefix doesn't match.

`awswaf:444455556666:webacl:testWebACL:header:encoding:utf8`

The prefix also doesn't match any labels applied by managed rule groups, like the following.

**Match against a managed rule group namespace**

The following JSON listing shows a label match statement for a managed rule group namespace. For a rule group that you own, you'd also need to provide the prefix in order to match for a namespace that's outside of the rule's context.

```json
Rule: {
    Name: "match_rule",
    Statement: {
        LabelMatchStatement: {
            Scope: "NAMESPACE",
            Key: "awswaf:managed:aws:managed-rule-set:header:"
        }
    }
}
```
This specification matches against the following example labels.

```json
```

It doesn't match the following label.

```json
```

## AWS WAF intelligent threat mitigation

This section covers the managed intelligent threat mitigation features provided by AWS WAF. These are advanced, specialized protections that you can implement in your web ACLs and applications.

**Note**
The features described here incur additional costs, beyond the basic costs of using AWS WAF. For more information, see [AWS WAF Pricing](#).

This guidance is intended for users who know generally how to create and manage AWS WAF web ACLs, rules, and rule groups. Those topics are covered in prior sections of this guide.

### High-level steps for using AWS WAF intelligent threat mitigation

1. **Choose the types of protections that you want to implement** – For a detailed comparison of the options, see [Comparison of the options for intelligent threat mitigation](#) in the following section.

   - **Challenge and CAPTCHA rule actions** – Validate client sessions and end users and acquire AWS WAF tokens for clients to use in their web requests. You can implement these anywhere that you specify a rule action, in your rules and as overrides in rule groups that you use. These actions use AWS WAF JavaScript interstitials to interrogate the client or end user, and they require client applications that support JavaScript. For more information, see [CAPTCHA and Challenge actions in AWS WAF](#).

   - **AWS WAF Fraud Control account takeover prevention (ATP)** – Detects and manages malicious takeover attempts on your application’s login page. The core functionality is provided by the ATP managed rule group. For more information, see [AWS WAF Fraud Control account takeover prevention (ATP)](#) and [AWS WAF Fraud Control account takeover prevention (ATP) rule group](#).

   - **AWS WAF Bot Control** – Identifies, labels, and manages both friendly and malicious bots. This feature provides management for common bots with signatures that are unique across applications, and also for targeted bots that have signatures specific to an application. The core functionality is provided by the Bot Control managed rule group. For more information, see [AWS WAF Bot Control](#) and [AWS WAF Bot Control rule group](#).

   - **Client application integration SDKs** – Validate client sessions and acquire AWS WAF tokens for clients to use in their web requests. If you use ATP or Bot Control, implement the application integration SDKs in your client application if you can, to take full advantage of all of the rule group features. We only recommend using these rule groups without an SDK integration as a
Comparison of the options for intelligent threat mitigation

This section provides a detailed comparison of the options for implementing intelligent threat mitigation.

Your options for implementing intelligent threat mitigation run from the basic use of rule actions to run challenges and enforce token acquisition, to the advanced features offered by the Bot Control and ATP AWS Managed Rules rule groups.

The following tables provide detailed comparisons of the options for the basic and advanced features.

1. Temporary measure, when a critical resource needs to be quickly secured and there isn’t enough time for the SDK integration. For information about implementing the SDKs, see AWS WAF client application integration (p. 175).

The ATP and Bot Control managed rule groups use tokens for advanced detection. For information about the features that tokens enable in the rule groups, see Benefits of challenge tokens for ATP (p. 167) and Benefits of challenge tokens for Bot Control (p. 152).

2. Control costs in your implementation – The intelligent threat mitigation features incur additional costs. For details about pricing, see AWS WAF Pricing.

Control the costs associated with running the paid rule groups and rule actions by reducing the number of web requests that they inspect. For example, you can position them in your web ACL after rules that block web requests based on other criteria. You can use scope-down statements in your paid rule group statement to reduce the requests that it evaluates. You can also reduce the number of times you present the client with a challenge or CAPTCHA by tuning the relative immunity times to the longest that your security requirements permit.

3. Tune how AWS WAF handles tokens – Tune your token management as needed. For example, you can configure a token domain list for your web ACL, to enable token sharing between protected applications. If you use CAPTCHA, you might tune the immunity time to adjust how frequently your end users can be presented with a CAPTCHA. For more information, see AWS WAF tokens (p. 144).

4. If you protect an Application Load Balancer that's the origin for a CloudFront distribution, provide additional configuration – If you associate your web ACL to an Application Load Balancer and you deploy the Application Load Balancer as the origin for a CloudFront distribution, you might need to provide additional configuration to use the AWS WAF intelligent threat mitigation features. For details, see Configuration required for Application Load Balancers that are CloudFront origins (p. 150).

Before you implement any changes to your web ACL, follow the testing and tuning procedures in this guide to be sure that the changes behave as you expect. This is especially important for these paid features. For general guidance, see Testing and tuning your AWS WAF protections (p. 212). For information specific to the paid managed rule groups, see Testing and deploying AWS WAF Bot Control (p. 154) and Testing and deploying ATP (p. 169).

- AWS WAF tokens (p. 144)
- AWS WAF Bot Control (p. 151)
- AWS WAF Fraud Control account takeover prevention (ATP) (p. 165)
- AWS WAF client application integration (p. 175)
- CAPTCHA and Challenge actions in AWS WAF (p. 186)
Challenges and token acquisition

You can provide challenges and acquire tokens using the AWS WAF application integration SDKs or the rule actions Challenge and CAPTCHA. Broadly speaking, the rule actions are easier to implement, but they incur added costs, intrude more on your customer experience, and require JavaScript. The SDKs require programming in your client applications, but they can provide a better customer experience, they're free to use, and they can be used with JavaScript or in Android or iOS applications. You can only use the application integration SDKs with web ACLs that use one of the paid intelligent threat mitigation managed rule groups, described in the following section.

Comparison of options for challenges and token acquisition

<table>
<thead>

- **Additional cost**
  - Yes, for action settings that you specify in your rules or as rule group rule action overrides. No, for rule action configurations in managed rule groups that you use.
  - Yes, for action settings that you specify in your rules or as rule group rule action overrides. No, for rule action configurations in managed rule groups that you use.
  - No, but requires one of the paid rule groups ATP or Bot Control.
  - No, but requires one of the paid rule groups ATP or Bot Control.

For details about costs associated with these options, see the intelligent threat mitigation information at [AWS WAF Pricing](#).

It can be simpler to run challenges and provide basic token enforcement by just adding a rule with a Challenge or CAPTCHA action. You might be required to use the rule actions if you don’t have access to the application code or if you don’t want to use either the Bot Control or ATP managed rule group.

If you can implement the SDKs however, you can save costs and also reduce latency in your web ACL evaluation of client web requests, compared to using the Challenge action:

- You can write your SDK implementation to run the challenge at any point in your application. You can acquire the token in the background, prior to any customer action that would send a web request to your protected resource. This way, the token is available to send with your client’s first request.
- If instead you acquire tokens by implementing a rule with the Challenge action, the rule and action require additional web request evaluation and processing when the client first sends a request and anytime the token expires. The Challenge action blocks the request that doesn’t have a valid, unexpired token, and sends the challenge interstitial back to the client. After the client successfully responds to the challenge, the interstitial resends the original web request with the valid token, which is then evaluated a second time by the web ACL.

**Managed rule groups**

The AWS Managed Rules rule groups that provide intelligent threat mitigation include management of basic bots, detection and mitigation of advanced, malicious bots, and detection and mitigation...
Comparison of account takeover attempts. These rule groups, combined with the application integration SDKs described in the prior section, provide the most advanced protections and secure coupling with your client applications.

## Comparison of the managed rules group options

</tr>
</tbody>
</table>
Token characteristics

Each token has the following characteristics:

- The token is stored in a cookie named `aws-waf-token`.
- The token is encrypted.
- The token fingerprints the client session with a sticky granular identifier that contains the following information:
  - The timestamp of the client's latest successful response to a silent challenge.
  - The timestamp of the end user's latest successful response to a CAPTCHA. This is only present if you use CAPTCHA in your protections.
- Additional information about the client and client behavior that can help separate your legitimate clients from unwanted traffic. The information includes various client identifiers and client-side signals that can be used to detect automated activities. The information gathered is non-unique and can't be mapped to an individual human being.
For security reasons, AWS doesn't provide a complete description of the contents of AWS WAF tokens or detailed information about the token encryption process.

**Timestamp expiration: token immunity times**

AWS WAF uses challenge and CAPTCHA immunity times to control how frequently a single client session can be presented with a challenge or CAPTCHA. After an end user successfully responds to a CAPTCHA, the CAPTCHA immunity time determines how long the end user remains immune from being presented with another CAPTCHA. Similarly, the challenge immunity time determines how long a client session remains immune from being challenged again after successfully responding to a challenge.

AWS WAF records a successful response to a challenge or CAPTCHA by updating the corresponding timestamp inside the token. When AWS WAF inspects the token for challenge or CAPTCHA, it subtracts the timestamp from the current time. If the result is greater than the configured immunity time, the timestamp is expired.

You can configure the challenge and CAPTCHA immunity times in the web ACL and also in any rule that uses the CAPTCHA or Challenge rule action.

- The default web ACL setting for both immunity times is 300 seconds.
- You can specify the immunity time for any rule that uses the CAPTCHA or Challenge action. If you don't specify the immunity time for the rule, it inherits the setting from the web ACL.
- For a rule inside a rule group that uses the CAPTCHA or Challenge action, if you don't specify the immunity time for the rule, it will inherit the setting from each web ACL where you use the rule group.
- The application integration SDKs use the web ACL's challenge immunity time.

The minimum value for the challenge immunity time is 300 seconds. The minimum value for the CAPTCHA immunity time is 60 seconds. The maximum value for both immunity times is 259,200 seconds, or three days.

You can use the web ACL and rule level immunity time settings to tune the CAPTCHA action, Challenge, or SDK challenge management behavior. For example, you might configure rules that control access to highly sensitive data with low immunity times, and then set higher immunity times in your web ACL for your other rules and the SDKs to inherit.

In particular for CAPTCHA, solving a puzzle can degrade your customer's website experience, so tuning the CAPTCHA immunity time can help you mitigate the impact on customer experience while still providing the protections that you want.

For additional information about tuning the immunity times for your use of the rule actions Challenge and CAPTCHA, see Best practices for using the CAPTCHA and Challenge actions (p. 191).

**Setting the immunity times**

You can set the immunity times in your web ACL and in your rules that use the Challenge and CAPTCHA rule actions.

For general information about managing a web ACL and its rules, see Working with web ACLs (p. 18).

**Where to set the immunity time for a web ACL**

- **Console** – When you edit the web ACL, in the Rules tab, edit and change the settings in the Web ACL CAPTCHA configuration and Web ACL Challenge configuration panes. In the console, you can configure the web ACL CAPTCHA and challenge immunity times only after you've created the web ACL.
- **Outside of the console** – The web ACL data type has CAPTCHA and challenge configuration parameters, which you can configure and provide to your create and update operations on the web ACL.
Where to set the immunity time for a rule

- **Console** – When you create or edit a rule and specify the CAPTCHA or Challenge action, you can modify the rule's immunity time setting.
- **Outside of the console** – The rule data type has CAPTCHA and challenge configuration parameters, which you can configure when you define the rule.

Token usage

AWS WAF uses tokens to record and verify the following types of client session validation:

- **CAPTCHA** – CAPTCHA puzzles help distinguish bots from human users. A CAPTCHA is run only by the CAPTCHA rule action. Upon successful completion of the puzzle, the CAPTCHA script updates the token's CAPTCHA timestamp. For more information, see CAPTCHA and Challenge actions in AWS WAF (p. 186).
- **Challenge** – Challenges run silently to help distinguish regular client sessions from bot sessions and to make it more costly for bots to operate. When the challenge completes successfully, the challenge script automatically procures a new token from AWS WAF if needed, and then updates the token's challenge timestamp.

AWS WAF runs challenges in the following situations:

- **Challenge rule action** – For more information, see CAPTCHA and Challenge actions in AWS WAF (p. 186).
- **Application integration SDKs** – The application integration SDKs run inside your client application sessions and help ensure that login attempts are only allowed after the client has successfully responded to a challenge. For more information, see AWS WAF client application integration (p. 175).
- **CAPTCHA** – When a CAPTCHA interstitial runs, if the client doesn't have a token yet, the script automatically runs a challenge first, to verify the client session and to initialize the token.

Additionally, tokens are required by many of the rules in the ATP and Bot Control AWS Managed Rules rule groups. These rule groups invoke AWS WAF token management to apply token labeling to the requests that the rule groups use in their inspections.

- **AWS WAF Fraud Control account takeover prevention (ATP)** – The ATP rules that prevent high volume and long lasting sessions require web requests that have a valid token with an unexpired challenge timestamp. For more information, see AWS WAF Fraud Control account takeover prevention (ATP) rule group (p. 60).
- **AWS WAF Bot Control** – The targeted rules in this rule group place a limit on the number of web requests that a client can send without a valid token, and they use token session tracking for session-level monitoring and management. As needed, the rules apply the Challenge and CAPTCHA rule actions to enforce token acquisition and valid client behavior. For more information, see AWS WAF Bot Control rule group (p. 53).

Token domains and domain lists

When AWS WAF creates a token for a client, it configures it with a token domain. When AWS WAF inspects a token in a web request, it rejects the token as invalid if its domain doesn't match any of the domains that are considered valid for the web ACL.

By default, AWS WAF only accepts tokens whose domain setting exactly matches the host domain of the resource that's associated with the web ACL. This is the value of the Host header in the web request. In a browser, you can find this domain in the JavaScript window.location.hostname property and in the address that your user sees in their address bar.
You can specify token domains for AWS WAF to use when setting the domain and when evaluating a token in a web ACL. The domains that you specify can't be public suffixes such as usa.gov.

**The web ACL token domain list**

You can configure a web ACL to share tokens across multiple protected resources by providing a token domain list with the additional domains that you want AWS WAF to accept. With a token domain list, AWS WAF still accepts the resource's host domain. Additionally, it accepts all domains in the token domain list, including their prefixed subdomains.

For example, a domain specification example.com in your token domain list matches example.com (from http://example.com/), api.example.com (from http://api.example.com/), and www.example.com (from http://www.example.com/). It doesn't match example.api.com (from http://example.api.com/), or apiexample.com (from http://apiexample.com/).

You can configure the token domain list in your web ACL when you create or edit it. For general information about managing a web ACL, see Working with web ACLs (p. 18).

**Controlling the domain setting in the token**

AWS WAF creates tokens at the request of the challenge scripts, which are run by the application integration SDKs and the Challenge rule action.

The domain that AWS WAF sets in a token is determined by the type of challenge script that's requesting it and additional token domain configuration that you provide. AWS WAF sets the domain in the token to the shortest, most general setting that it can find in the configuration.

- **JavaScript SDK** – You can configure the JavaScript SDK with a token domain specification, which can include one or more domains. The domains that you configure must be domains that AWS WAF will accept, based on the protected host domain and the web ACL's token domain list.

  AWS WAF sets the token domain to one that matches the host domain and is the shortest, from among the host domain and the domains in the list. For example, if the host domain is api.example.com and the token domain list has example.com, AWS WAF uses example.com in the token, because it matches the host domain and is shorter. If you don't provide a token domain list in the JavaScript SDK configuration, AWS WAF sets the domain to the host domain of the protected resource.

  For more information, see Providing domains for use in the tokens (p. 177).

- **Mobile SDK** – You must configure the mobile SDK with a token domain for AWS WAF to use in the token. The domain that you configure must be a domain that AWS WAF will accept, based on the protected host domain and the web ACL's token domain list. AWS WAF doesn't consider the host domain in the token domain setting for the mobile SDK.

  For more information, see the WAFConfiguration domainName setting at The AWS WAF mobile SDK specification (p. 180).

- **Challenge action** – If you specify a token domain list in the web ACL, AWS WAF sets the token domain to one that matches the host domain and is the shortest, from among the host domain and the domains in the list. For example, if the host domain is api.example.com and the token domain list has example.com, AWS WAF uses example.com in the token, because it matches the host domain and is shorter. If you don't provide a token domain list in the web ACL, AWS WAF sets the domain to the host domain of the protected resource.

**Token labeling by the Bot Control and ATP managed rule groups**

When you use the ATP and Bot Control AWS Managed Rules rule groups, the rule groups use AWS WAF token management to inspect web request tokens and apply token labeling to the requests.
Note
AWS WAF token management only applies token labels when you use the Bot Control or ATP managed rule group.

AWS WAF applies one of the following labels when it inspects a web request's token and challenge timestamp. AWS WAF doesn't add labeling about the status of the CAPTCHA timestamp.

- **awswaf:managed:token:accepted** – The request token is present and has an unexpired challenge timestamp.
- **awswaf:managed:token:rejected** – The request token is present but is either corrupt or has an expired challenge timestamp.
- **awswaf:managed:token:absent** – The request doesn't have a token.

You can add your own rules after either of these managed rule groups in your web ACL, to match against the token labels. For information about label matching in your rules, see Matching against a label (p. 135).

For information about the managed rule groups and the labels that their rules add to web requests, see AWS WAF Bot Control rule group (p. 53) and AWS WAF Fraud Control account takeover prevention (ATP) rule group (p. 60).

**Blocking requests that don't have a valid token**

When you use the AWS Managed Rules rule groups AWSManagedRulesATPRuleSet and AWSManagedRulesBotControlRuleSet, the rule groups invoke the AWS WAF token management to evaluate the status of the AWS token in web requests and to label them accordingly.

Note
Token labeling is only applied to web requests that you evaluate using one of these two managed rule groups.

AWS WAF applies one of the following labels when it inspects a web request's token and challenge timestamp. AWS WAF doesn't add labeling about the status of the CAPTCHA timestamp.

- **awswaf:managed:token:accepted** – The request token is present and has an unexpired challenge timestamp.
- **awswaf:managed:token:rejected** – The request token is present but is either corrupt or has an expired challenge timestamp.
- **awswaf:managed:token:absent** – The request doesn't have a token.

The AWSManagedRulesATPRuleSet blocks requests with the awswaf:managed:token:rejected label. The AWSManagedRulesBotControlRuleSet challenges clients after they send 5 requests without an accepted token. For details about the rule groups, see AWS WAF Fraud Control account takeover prevention (ATP) rule group (p. 60) and AWS WAF Bot Control rule group (p. 53).

The Bot Control rule group doesn't block a request with a rejected token, and neither rule group blocks an individual request that's missing its token. If the request isn't blocked by some other rule in the rule group, it can exit the rule group evaluation and continue to be evaluated by the web ACL.

To block all requests that are missing their token or whose token is rejected, add a rule to run immediately after the managed rule group to capture and block requests that the rule group doesn't handle for you.

The following is an example JSON listing for a web ACL that uses the ATP managed rule group. The web ACL has an added rule to capture the awswaf:managed:token:absent label and handle it. The rule
narrowst its evaluation to web requests going to the login endpoint, to match the scope of the ATP rule
group. The added rule is listed in bold.

Configuration required for Application Load Balancers that are CloudFront origins

Read this section if you associate your web ACL to an Application Load Balancer and you deploy the Application Load Balancer as the origin for a CloudFront distribution.

With this architecture, you need to provide the following additional configuration in order for the token information to be handled correctly.

- Configure CloudFront to forward the aws-waf-token cookie to the Application Load Balancer. By default, CloudFront removes cookies from the web request before forwarding it to the origin. To keep the token cookie with the web request, configure CloudFront cache behavior to include either just
the token cookie or all cookies. For information about how to do this, see Caching content based on cookies in the Amazon CloudFront Developer Guide.

- Configure AWS WAF so that it recognizes the domain of the CloudFront distribution as a valid token domain. By default, CloudFront sets the Host header to the Application Load Balancer origin, and AWS WAF uses that as the domain of the protected resource. The client browser, however, sees the CloudFront distribution as the host domain, and tokens that are generated for the client use the CloudFront domain as the token domain. Without any additional configuration, when AWS WAF checks the protected resource domain against the token domain, it will get a mismatch. To fix this, add the CloudFront distribution domain name to the token domain list in your web ACL configuration. For information about how to do this, see Token domains and domain lists (p. 146).

### AWS WAF Bot Control

The Bot Control managed rule group provides a basic, common protection level that adds labels to self-identifying bots, verifies generally desirable bots, and detects high confidence bot signatures. This gives you the ability to monitor and control common categories of bot traffic. Bot Control also provides a targeted protection level that adds detection for advanced bots that don’t self identify. Targeted protections use advanced detection techniques such as browser interrogation, fingerprinting, and behavior heuristics to identify bad bot traffic and then applies mitigation controls such as rate limiting and CAPTCHA and Challenge rule actions. For additional details, see AWS WAF Bot Control rule group (p. 53).

**Note**

You are charged additional fees when you use this managed rule group. For more information, see AWS WAF Pricing.

With Bot Control, you can easily monitor, block, or rate limit bots such as scrapers, scanners, crawlers, status monitors, and search engines. If you use the targeted inspection level of the rule group, you can also challenge bots that don’t self identify, making it harder and more expensive for malicious bots to operate against your website. You can protect your applications using the Bot Control managed rule group alone, or in combination with other AWS Managed Rules rule groups and your own custom AWS WAF rules.

Bot Control includes a console dashboard that shows how much of your current traffic is coming from bots, based on request sampling. With the Bot Control managed rule group added to your web ACL, you can take action against bot traffic and receive detailed, real-time information about common bot traffic coming to your applications.

When AWS WAF evaluates a web request against the Bot Control managed rule group, the rule group adds labels to requests that it detects as bot related, for example the category of bot and the bot name. You can match against these labels in your own AWS WAF rules to customize handling. The labels that are generated by the Bot Control managed rule group are included in Amazon CloudWatch metrics and your web ACL logs.

You can also use AWS Firewall Manager AWS WAF policies to deploy the Bot Control managed rule group across your applications in multiple accounts that are part of your organization in AWS Organizations.

### Bot Control components

The main components of a Bot Control implementation are the following:

- **AWSManagedRulesBotControlRuleSet** – The Bot Control managed rule group whose rules detect and handle various categories of bots. For information about the rule group's rules, see AWS WAF Bot Control rule group (p. 53). You include this rule group in your web ACL using a managed rule group reference statement, and indicate the inspection level that you want to use. This rule group add labels to web requests that it detects as bot traffic.
Note
You are charged additional fees when you use this managed rule group. For more information, see AWS WAF Pricing.

- **Bot Control dashboard** – The bot monitoring dashboard for your web ACL, available through the web ACL Bot Control tab. Use this dashboard to monitor your traffic and understand how much of it comes from various types of bots. This can be a starting point for customizing your bot management, as described in this topic. You can also use it to verify your changes and monitor activity for various bots and bot categories.

- **JavaScript and mobile application integration SDKs** – You should implement the AWS WAF JavaScript and mobile SDKs if you use the targeted protection level of the Bot Control rule group. The targeted rules use information provided by the SDKs in the client tokens for enhanced detection against malicious bots. For more information about the SDKs, see AWS WAF client application integration (p. 175).

- **Logging and metrics** – You can monitor your bot traffic and understand how the Bot Control managed rule group evaluates and handles your traffic by studying the logs and Amazon CloudWatch metrics for your web ACL. The labels that Bot Control adds to your web requests are included in the logs and in Amazon CloudWatch metrics. For information about configuring and using logging and metrics, see Logging web ACL traffic (p. 192) and Monitoring with Amazon CloudWatch (p. 541).

Depending on your needs and the traffic that you see, you might want to customize your Bot Control implementation. The following are some of the most commonly used options.

- **Scope-down statements** – You can exclude some traffic from the web requests that the Bot Control managed rule group evaluates by adding a scope-down statement inside the Bot Control managed rule group reference statement. A scope-down statement can be any nestable rule statement. When a request doesn't match the scope-down statement, AWS WAF evaluates it as not matching the rule group reference statement without evaluating it against the rule group. For more information about scope-down statements, see Scope-down statements (p. 117).

Pricing for the Bot Control managed rule group goes up with the number of web requests that AWS WAF evaluates with it. You can help reduce these costs by using a scope-down statement to limit the requests that the rule group evaluates. For example, you might want to allow your homepage to load for everyone, including bots, and then apply the rule group rules to requests that are going to your application APIs or that contain a particular type of content.

- **Labels and label matching rules** – You can customize how the Bot Control rule group handles some of the bot traffic that it identifies using the AWS WAF label match rule statement. The Bot Control rule group adds labels to your web requests. You can add label matching rules after the Bot Control rule group that match on Bot Control labels and apply the handling that you need. For more information about labeling and using label match statements, see Label match rule statement (p. 97) and Labels on web requests (p. 131).

- **Custom requests and responses** – You can add custom headers to requests that you allow and you can send custom responses for requests that you block by pairing label matching with the AWS WAF custom request and response features. For more information about customizing requests and responses, see Customized web requests and responses in AWS WAF (p. 126).

**Benefits of challenge tokens for Bot Control**

The targeted protection rules of the Bot Control managed rule group only work for web requests that include tokens. Tokens are acquired for the client by the silent challenge script that's run by the application integration SDKs and by the Challenge or CAPTCHA rule actions. Without the tokens, you can use the Bot Control common level protections only. For a comparison of the protection levels offered by the rule group, see AWS WAF Bot Control rule group (p. 53).

When you implement the application integration SDKs in your clients or use the Challenge action on web requests that the rule group will evaluate, you expand the capabilities of the rule group and of your overall client application security.
Tokens provide client information with each web request. This additional information enables the Bot Control rule group to separate legitimate client sessions from ill-behaved client sessions, even when both originate from a single IP address. The rule group uses information in the tokens to aggregate client session request behavior for the fine-tuned detection and mitigation that the targeted protections level provide. For more information about AWS WAF tokens, see AWS WAF tokens (p. 144). For information about the SDKs, see AWS WAF client application integration (p. 175). For information about the Challenge rule action, see CAPTCHA and Challenge actions in AWS WAF (p. 186).

Adding the AWS WAF Bot Control managed rule group to your web ACL

The Bot Control managed rule group AWSManagedRulesBotControlRuleSet requires additional configuration to identify the protection level that you want to implement.

This guidance is intended for users who know generally how to create and manage AWS WAF web ACLs, rules, and rule groups. Those topics are covered in prior sections of this guide.

To use the AWSManagedRulesBotControlRuleSet rule group in your web ACL

1. Add the AWS managed rule group, AWSManagedRulesBotControlRuleSet to your web ACL. For the full rule group description, see the section called “Bot Control rule group” (p. 53).

   Note
   You are charged additional fees when you use this managed rule group. For more information, see AWS WAF Pricing.

   When you add the rule group, edit it to open the configuratation page for the rule group.

2. On the rule group's configuration page, in the Inspection level pane, select the inspection level that you want to use.

   - **Common** – Detects a variety of self-identifying bots, such as web scraping frameworks, search engines, and automated browsers. Bot Control protections at this level identify common bots using traditional bot detection techniques, such as static request data analysis. The rules label traffic from these bots and block the ones that they cannot verify.

   - **Targeted** – Includes the common-level protections and adds detection for advanced bots that do not self identify. Targeted protections use advanced detection techniques such as browser interrogation, fingerprinting, and behavior heuristics to identify bad bot traffic. The protections target these bots using a combination of rate limiting and CAPTCHA and background browser challenges. The rules that provide targeted protection have names that begin with TGT_.

   For more information about this choice, see AWS WAF Bot Control rule group (p. 53).

3. Add a scope-down statement for the rule group, to contain the costs of using it. A scope-down statement narrows the set of requests that the rule group inspects. For example use cases, start with AWS WAF Bot Control example: Use Bot Control only for the login page (p. 162) and AWS WAF Bot Control example: Use Bot Control only for dynamic content (p. 163).

4. Provide any additional configuration that you need for the rule group.

5. Save your changes to the web ACL.

6. If you use the targeted protection level of the rule group, also implement the application integration SDKs to acquire challenge tokens for the web requests that the rule group inspects. If you can't implement the SDKs, then provide the token by adding a rule before the rule group that matches all web requests that the rule group will inspect and that has a Challenge rule action. The Challenge rule incurs additional expense that the application integration SDKs do not. For a full comparison of these two options, see Comparison of the options for intelligent threat mitigation (p. 140).

   To understand the benefits of tokens for Bot Control, see Benefits of challenge tokens for Bot Control (p. 152).
To implement the integration SDKs, follow the guidance at AWS WAF client application integration (p. 175).

Before you deploy your Bot Control implementation for production traffic, test and tune it in a staging or testing environment until you are comfortable with the potential impact to your traffic. Then test and tune the rules in count mode with your production traffic before enabling them. See the sections that follow for guidance.

False positives with AWS WAF Bot Control

We have carefully selected the rules in the AWS WAF Bot Control managed rule group to minimize false positives. We test the rules against global traffic and monitor their impact on test web ACLs. However, it's still possible to get false positives due to changes in traffic patterns. Additionally, some use cases are known to cause false positives and will require customization specific to your web traffic.

Situations where you might encounter false positives include the following:

- Mobile apps typically have non-browser user agents, which the SignalNonBrowserUserAgent rule blocks by default. If you expect traffic from mobile apps, or any other legitimate traffic with non-browser user agents, you'll need to add an exception to allow it.
- You might rely on some specific bot traffic for things like uptime monitoring, integration testing, or marketing tools. If Bot Control identifies and blocks the bot traffic that you want to allow, you need to alter the handling by adding your own rules. While this isn't a false positive scenario for all customers, if it is for you, you will need to handle it the same as for a false positive.
- The Bot Control managed rule group verifies bots using the IP addresses from AWS WAF. If you use Bot Control and you have verified bots that route through a proxy or load balancer, you might need to explicitly allow them using a custom rule. For information about how to create a custom rule of this type, see Forwarded IP address (p. 117).
- A Bot Control rule with a low global false positive rate might heavily impact specific devices or applications. For example, in testing and validation, we might not have observed requests from applications with low traffic volumes or from less common browsers or devices.
- A Bot Control rule that has a historically low false positive rate might have increased false positives for valid traffic. This might be due to new traffic patterns or request attributes that emerge with valid traffic, causing it to match the rule where it didn't before. These changes might be due to situations like the following:
  - Traffic details that are altered as traffic flows through network appliances, such as load balancers or content distribution networks (CDN).
  - Emerging changes in traffic data, for example new browsers or new versions for existing browsers.

For information about how to handle false positives that you might get from the AWS WAF Bot Control managed rule group, see the guidance in the section that follows, Testing and deploying AWS WAF Bot Control (p. 154).

Testing and deploying AWS WAF Bot Control

This section provides general guidance for configuring and testing an AWS WAF Bot Control implementation for your site. The specific steps that you choose to follow will depend on your needs, resources, and the web requests that you receive.

This information is in addition to the general information about testing and tuning provided at Testing and tuning your AWS WAF protections (p. 212).

Note

AWS Managed Rules are designed to protect you from common web threats. When used in accordance with the documentation, AWS Managed Rules rule groups add another layer of
security for your applications. However, AWS Managed Rules rule groups aren't intended as a replacement for your security responsibilities, which are determined by the AWS resources that you select. Refer to the Shared Responsibility Model to ensure that your resources in AWS are properly protected.

**Production traffic risk**

Before you deploy your Bot Control implementation for production traffic, test and tune it in a staging or testing environment until you are comfortable with the potential impact to your traffic. Then test and tune the rules in count mode with your production traffic before enabling them.

This guidance is intended for users who know generally how to create and manage AWS WAF web ACLs, rules, and rule groups. Those topics are covered in prior sections of this guide.

**To configure and test a Bot Control implementation**

Perform these steps first in a test environment, then in production.

1. **Add the Bot Control managed rule group**
   
   **Note**
   
   You are charged additional fees when you use this managed rule group. For more information, see AWS WAF Pricing.

   Add the managed AWS rule group AWSManagedRulesBotControlRuleSet to a new or existing web ACL and configure it so that it doesn't alter current web ACL behavior.

   • When you add the managed rule group, edit it and do the following:
     
     • In the Inspection level pane, select the inspection level that you want to use.
       
       • **Common** – Detects a variety of self-identifying bots, such as web scraping frameworks, search engines, and automated browsers. Bot Control protections at this level identify common bots using traditional bot detection techniques, such as static request data analysis. The rules label traffic from these bots and block the ones that they cannot verify.
       
       • **Targeted** – Includes the common-level protections and adds detection for advanced bots that do not self identify. Targeted protections use advanced detection techniques such as browser interrogation, fingerprinting, and behavior heuristics to identify bad bot traffic. The protections target these bots using a combination of rate limiting and CAPTCHA and background browser challenges. The rules that provide targeted protection have names that begin with TGT_.
     
     For more information about this choice, see AWS WAF Bot Control rule group (p. 53).
     
   • In the Rules pane, open the Override all rule actions dropdown and choose Count. With this configuration, AWS WAF evaluates requests against all of the rules in the rule group and only counts the matches that result, while still adding labels to requests. For more information, see Overriding rule actions in a rule group (p. 22).

     With this override, you can monitor the potential impact of the Bot Control rules on your traffic, to determine whether you want to add exceptions for things like internal use cases or desired bots.

   • Position the rule group so that it's evaluated last in the web ACL, with a priority setting that's numerically higher than any other rules or rule groups that you're already using. For more information, see Processing order of rules and rule groups in a web ACL (p. 14).

   This way, your current handling of traffic isn't disrupted. For example, if you have rules that detect malicious traffic such as SQL injection or cross-site scripting, they'll continue to detect and log those requests. Alternately, if you have rules that allow known non-malicious traffic, they can continue to allow that traffic, without having it blocked by the Bot Control managed rule group. You might decide to adjust the processing order during your testing and tuning activities, but this is a good way to start.
2. **Enable sampling, logging, and metrics for the web ACL**

As needed, configure logging for the web ACL, and enable sampling and Amazon CloudWatch metrics. You can use metrics and logging to monitor the interaction of your web traffic with the Bot Control managed rule group.

- For information about configuring and using logging, see [Logging web ACL traffic](p. 192).
- For information about Amazon CloudWatch metrics, see [Monitoring with Amazon CloudWatch](p. 541).
- For information about web request sampling, see [Viewing a sample of web requests](p. 219).

3. **Associate the web ACL with a resource**

If the web ACL isn't already associated with a resource, associate it. For information, see [Associating or disassociating a web ACL with an AWS resource](p. 23).

4. **Monitor traffic and Bot Control rule matches**

Make sure that traffic is flowing and that the Bot Control managed rule group rules are adding labels to matching web requests. You can see the labels in the logs and see bot and label metrics in the Amazon CloudWatch metrics. In the logs, the rules that you've overridden to count in the rule group show up in the `ruleGroupList` with `action` set to `count`, and with `overriddenAction` indicating the configured rule action that you overrode.

**Note**

The Bot Control managed rule group verifies bots using the IP addresses from AWS WAF. If you use Bot Control and you have verified bots that route through a proxy or load balancer, you might need to explicitly allow them using a custom rule. For information about how to create a custom rule, see [Forwarded IP address](p. 117). For information about how you can use the rule to customize Bot Control web request handling, see the next step.

Carefully review the web request handling for any false positives that you might need to mitigate with custom handling. For examples of false positives, see [False positives with AWS WAF Bot Control](p. 154).

5. **Customize Bot Control web request handling**

As needed, add your own rules that explicitly allow or block requests, to change how Bot Control rules would otherwise handle them.

How you do this depends on your use case, but the following are common solutions:

- Explicitly allow requests with a rule that you add before the Bot Control managed rule group. With this, the allowed requests never reach the rule group for evaluation. This can help contain the cost of using the Bot Control managed rule group.

- Exclude requests from Bot Control evaluation by adding a scope-down statement inside the Bot Control managed rule group statement. This functions the same as the preceding option. It can help contain the cost of using the Bot Control managed rule group because the requests that don't match the scope-down statement never reach rule group evaluation. For information about scope-down statements, see [Scope-down statements](p. 117).

For examples, see the following:

- [Exclude IP range from bot management](p. 164)
- [Allow traffic from a bot that you control](p. 164)
- Use Bot Control labels in request handling to allow or block requests. Add a label match rule after the Bot Control managed rule group to filter out labeled requests that you want to allow from those that you want to block.
After testing, keep the related Bot Control rules in count mode, and maintain the request handling decisions in your custom rule. For information about label match statements, see Label match rule statement (p. 97).

For examples of this type of customization, see the following:
- Create an exception for a blocked user agent (p. 161)
- Allow a specific blocked bot (p. 159)
- Block verified bots (p. 158)

For additional examples, see AWS WAF Bot Control examples (p. 157).

6. As needed, enable the Bot Control managed rule group settings

Depending on your situation, you might have decided that you want to leave some Bot Control rules in count mode or with a different action override. For the rules that you want to have run as they are configured inside the rule group, enable the regular rule configuration. To do this, edit the rule group statement in your web ACL and make your changes in the Rules pane.

AWS WAF Bot Control examples

This section shows example configurations that satisfy a variety of common use cases for AWS WAF Bot Control implementations.

Each example provides a description of the use case and then shows the solution in JSON listings for the custom configured rules.

Note
The JSON listings shown in these examples were created in the console by configuring the rule and then editing it using the Rule JSON editor. You can also retrieve the JSON for the rules in an entire rule group or web ACL using get commands through the APIs or the command line interface.

AWS WAF Bot Control example: Simple configuration

The following JSON listing shows an example web ACL with an AWS WAF Bot Control managed rule group. Note the visibility configuration, which causes AWS WAF to store request samples and metrics for monitoring purposes.

```json
{
    "Name": "Bot-Beta-WebACL",
    "Id": "...",
```
AWS WAF Bot Control doesn't block bots that are known by AWS to be common and verifiable bots. When Bot Control identifies a web request as coming from a verified bot, it adds a label that names the bot and a label that indicates that it's a verified bot. Bot Control doesn't add any other labels, such as signals labels, in order to prevent known good bots from being blocked. You might have other AWS WAF rules that block verified bots. If you want to ensure that verified bots are allowed, add a custom rule to allow them based on the Bot Control labels. Your new rule must run after the Bot Control managed rule group, so that the labels are available to match against.

The following rule explicitly allows verified bots.

```json
[  
    "Name": "match_rule",  
    "Statement": {  
        "LabelMatchStatement": {  
            "Scope": "LABEL",  
            "Key": "awswaf:managed:aws:bot-control:bot:verified"  
        },  
        "RuleLabels": [],  
        "Action": {  
            "Allow": {}  
        }  
    }  
]
```

### AWS WAF Bot Control example: Block verified bots

In order to block verified bots, you must add a rule to block them that runs after the AWS WAF Bot Control managed rule group. To do this, identify the bot names that you want to block and use a label
match statement to identify and block them. If you want to just block all verified bots, you can omit the
match against the bot:name: label.

The following rule blocks only the bingbot verified bot. This rule must run after the Bot Control
managed rule group.

```json
{
  "Name": "match_rule",
  "Statement": {
    "AndStatement": {
      "Statements": [
        { "LabelMatchStatement": {
          "Scope": "LABEL",
          "Key": "awswaf:managed:aws:bot-control:bot:name:bingbot"
        } },
        { "LabelMatchStatement": {
          "Scope": "LABEL",
          "Key": "awswaf:managed:aws:bot-control:bot:verified"
        } }
      ]
    },
    "RuleLabels": [],
    "Action": {
      "Block": {}
    }
  }
}
```

The following rule blocks all verified bots.

```json
{
  "Name": "match_rule",
  "Statement": {
    "LabelMatchStatement": {
      "Scope": "LABEL",
      "Key": "awswaf:managed:aws:bot-control:bot:verified"
    }
  },
  "RuleLabels": [],
  "Action": {
    "Block": {}
  }
}
```

**AWS WAF Bot Control example: Allow a specific blocked bot**

It's possible for a bot to be blocked by more than one of the Bot Control rules. Run through the following
procedure for each blocking rule.

If a AWS WAF Bot Control rule is blocking a bot that you do not want to block, do the following:

1. Identify the Bot Control rule that's blocking the bot by checking the logs. The blocking rule will be
specified in the logs in the fields whose names start with terminatingRule. For information about
the web ACL logs, see Logging web ACL traffic (p. 192). Note the label that the rule is adds to the
requests.

2. In your web ACL, override the action of the blocking rule to count. To do this in the console, edit the
rule group rule in the web ACL and choose a rule action override of Count for the rule. This ensures
that the bot is not blocked by the rule, but the rule will still apply its label to matching requests.
3. Add a label matching rule to your web ACL, after the Bot Control managed rule group. Configure the rule to match against the overridden rule's label and to block all matching requests except for the bot that you don’t want to block.

Your web ACL is now configured so that the bot you want to allow is no longer blocked by the blocking rule that you identified through the logs.

Check traffic and your logs again, to be sure that the bot is being allowed through. If not, run through the above procedure again.

For example, suppose you want to block all monitoring bots except for pingdom. In this case, you override the CategoryMonitoring rule to count and then write a rule to block all monitoring bots except for those with the bot name label pingdom.

The following rule uses the Bot Control managed rule group but overrides the rule action for CategoryMonitoring to count. The category monitoring rule applies its labels as usual to matching requests, but only counts them instead of performing its usual action of block.

```json
{
  "Name": "AWS-AWSBotControl-Example",
  "Priority": 5,
  "Statement": {
    "ManagedRuleGroupStatement": {
      "VendorName": "AWS",
      "Name": "AWSManagedRulesBotControlRuleSet",
      "RuleActionOverrides": [
        {
          "ActionToUse": {
            "Count": {}
          },
          "Name": "CategoryMonitoring"
        }
      ],
      "ExcludedRules": []
    },
    "VisibilityConfig": {
      "SampledRequestsEnabled": true,
      "CloudWatchMetricsEnabled": true,
      "MetricName": "AWS-AWSBotControl-Example"
    }
  }
}
```

The following rule matches against the category monitoring label that the preceding CategoryMonitoring rule adds to matching web requests. Among the category monitoring requests, this rule blocks all but those that have a label for the bot name pingdom.

The following rule must run after the preceding Bot Control managed rule group in the web ACL processing order.

```json
{
  "Name": "match_rule",
  "Priority": 0,
  "Statement": {
    "AndStatement": {
      "Statements": [
        {
          "LabelMatchStatement": {
            "Scope": "LABEL",
            "Key": "awswaf:managed:aws:bot-control:bot:category:monitoring"
          }
        }
      ]
    }
  }
}
```
AWS WAF Bot Control example: Create an exception for a blocked user agent

If traffic from some non-browser user agents is being erroneously blocked, you can create an exception by setting the offending AWS WAF Bot Control rule SignalNonBrowserUserAgent to Count and then combining the rule's labeling with your exception criteria.

**Note**
Mobile apps typically have non-browser user agents, which the SignalNonBrowserUserAgent rule blocks by default.

The following rule uses the Bot Control managed rule group but overrides the rule action for SignalNonBrowserUserAgent to Count. The signal rule applies its labels as usual to matching requests, but only counts them instead of performing its usual action of block.

```json
{
    "Name": "AWS-AWSBotControl-Example",
    "Priority": 5,
    "Statement": {
        "ManagedRuleGroupStatement": {
            "VendorName": "AWS",
            "Name": "AWSManagedRulesBotControlRuleSet",
            "RuleActionOverrides": [
                {
                    "ActionToUse": {
                        "Count": {}
                    },
                    "Name": "SignalNonBrowserUserAgent"
                }
            ],
            "ExcludedRules": []
        },
        "VisibilityConfig": {
            "SampledRequestsEnabled": true,
            "CloudWatchMetricsEnabled": true,
            "MetricName": "match_rule"
        }
    }
}
```
The following rule matches against the signal label that the Bot Control
SignalNonBrowserUserAgent rule adds to its matching web requests. Among the signal requests, this
rule blocks all but those that have the user agent that we want to allow.

The following rule must run after the preceding Bot Control managed rule group in the web ACL
processing order.

```
{
    "Name": "match_rule",
    "Statement": {
        "AndStatement": {
            "Statements": [
                {
                    "LabelMatchStatement": {
                        "Scope": "LABEL",
                        "Key": "awswaf:managed:aws:bot-control:signal:non_browser_user_agent"
                    }
                },
                {
                    "NotStatement": {
                        "Statement": {
                            "ByteMatchStatement": {
                                "FieldToMatch": {
                                    "SingleHeader": {
                                        "Name": "user-agent"
                                    }
                                },
                                "PositionalConstraint": "EXACTLY",
                                "SearchString": "PostmanRuntime/7.29.2",
                                "TextTransformations": [
                                    {
                                        "Priority": 0,
                                        "Type": "NONE"
                                    }
                                ]
                            }
                        },
                        "VisibilityConfig": {
                            "SampledRequestsEnabled": true,
                            "CloudWatchMetricsEnabled": true,
                            "MetricName": "match_rule"
                        }
                    }
                }
            ]
        },
        "RuleLabels": [],
        "Action": {
            "Block": {}.
        }
    }
}
```

**AWS WAF Bot Control example: Use Bot Control only for the login page**

The following example uses a scope-down statement to apply AWS WAF Bot Control only for traffic
that's coming to a website's login page, which is identified by the URI path `login`. The URI path to your
login page might be different from the example, depending on your application and environment.

```
{
    "Name": "AWS-AWSBotControl-Example",
    "Priority": 5,
    "Statement": {
```

162
AWS WAF Bot Control example: Use Bot Control only for dynamic content

This example uses a scope-down statement to apply AWS WAF Bot Control only to dynamic content.

The scope-down statement excludes static content by negating the match results for a regex pattern set:

- The regex pattern set is configured to match extensions of static content. For example, the regex pattern set specification might be (\?.*\.(jpe?g|gif|png|svg|ico|css|js|woff2?)$). For information about regex pattern sets and statements, see Regex pattern set match rule statement (p. 103).
- In the scope-down statement, we exclude the matching static content by nesting the regex pattern set statement inside a NOT statement. For information about the NOT statement, see NOT rule statement (p. 98).

```json
{
    "Name": "AWS-AWSBotControl-Example",
    "Priority": 5,
    "Statement": {
        "ManagedRuleGroupStatement": {
            "VendorName": "AWS",
            "Name": "AWSManagedRulesBotControlRuleSet",
            "RuleActionOverrides": [],
            "ExcludedRules": []
        },
        "VisibilityConfig": {
            "SampledRequestsEnabled": true,
            "CloudWatchMetricsEnabled": true,
            "MetricName": "AWS-AWSBotControl-Example"
        },
        "ScopeDownStatement": {
            "NotStatement": {
                "RegexPatternSetReferenceStatement": {
                    "Name": "AWS-AWSBotControl-Example",
                    "Priority": 0,
                    "Type": "NONE",
                    "PositionalConstraint": "CONTAINS"
                }
            }
        }
    }
}
```
AWS WAFBot Control example: Exclude IP range from bot management

If you want to exclude a subset of web traffic from AWS WAF Bot Control management, and you can identify that subset using a rule statement, then exclude it by adding a scope-down statement to your Bot Control managed rule group statement.

The following rule performs normal Bot Control bot management on all web traffic except for web requests coming from a specific IP address range.

```json
{
    "Name": "AWS-AWSBotControl-Example",
    "Priority": 5,
    "Statement": {
        "ManagedRuleGroupStatement": {
            "VendorName": "AWS",
            "Name": "AWSManagedRulesBotControlRuleSet",
            "RuleActionOverrides": [],
            "ExcludedRules": []
        },
        "VisibilityConfig": {
            "SampledRequestsEnabled": true,
            "CloudWatchMetricsEnabled": true,
            "MetricName": "AWS-AWSBotControl-Example"
        },
        "ScopeDownStatement": {
            "NotStatement": {
                "Statement": {
                    "IPSetReferenceStatement": {
                        "ARN": "arn:aws:wafv2:us-east-1:123456789:regional/ipset/friendlyips/00000000-0000-0000-0000-000000000000"
                    }
                }
            }
        }
    }
}
```

AWS WAF Bot Control example: Allow traffic from a bot that you control

You can configure some site monitoring bots and custom bots to send custom headers. If you want to allow traffic from these types of bots, you can configure them to add a shared secret in a header. You then can exclude messages that have the header by adding a scope-down statement to the AWS WAF Bot Control managed rule group statement.

The following example rule excludes traffic with a secret header from Bot Control inspection.

```json
{
    "Name": "AWS-AWSBotControl-Example",
    "Priority": 5,
    "Statement": {
        "ManagedRuleGroupStatement": {
            "VendorName": "AWS",
            "Name": "AWSManagedRulesBotControlRuleSet",
            "RuleActionOverrides": [],
            "ExcludedRules": []
        },
        "VisibilityConfig": {
            "SampledRequestsEnabled": true,
            "CloudWatchMetricsEnabled": true,
            "MetricName": "AWS-AWSBotControl-Example"
        },
        "ScopeDownStatement": {
            "NotStatement": {
                "Statement": {
                    "IPSetReferenceStatement": {
                        "ARN": "arn:aws:wafv2:us-east-1:123456789:regional/ipset/friendlyips/00000000-0000-0000-0000-000000000000"
                    }
                }
            }
        }
    }
}
```
Account takeover is an online illegal activity in which an attacker gains unauthorized access to a person’s account. The attacker might do this in a number of ways, such as using stolen credentials or guessing the victim’s password through a series of attempts. When the attacker gains access, they might steal money, information, or services from the victim. The attacker might pose as the victim to gain access to other accounts that the victim owns, or to gain access to the accounts of other people or organizations. Additionally, they might attempt to change the user’s password in order to block the victim from their own accounts.

You can monitor and control account takeover attempts by implementing the AWS WAF Fraud Control account takeover prevention (ATP) feature. AWS WAF offers this feature in the AWS Managed Rules rule group AWSManagedRulesATPRuleSet and companion application integration SDKs.

**Note**
You are charged additional fees when you use this managed rule group. For more information, see AWS WAF Pricing.

ATP gives you visibility and control over anomalous login attempts and login attempts that use stolen credentials, to prevent account takeovers that might lead to fraudulent activity. ATP checks user name...
and password combinations against its stolen credential database, which is updated regularly as new leaked credentials are found on the dark web.

Note
This feature is not available for Amazon Cognito user pools.

ATP components

The primary components of AWS WAF Fraud Control account takeover prevention (ATP) are the following:

- **AWSManagedRulesATPRuleSet** – The rules in this AWS Managed Rules rule group detect, label, and handle various types of account takeover activity. The rule group inspects HTTP POST web requests sent to the login endpoint that you specify. For a list of the rule group’s rules, see [AWS WAF Fraud Control account takeover prevention (ATP) rule group](#). You include this rule group in your web ACL using a managed rule group reference statement. For information about using this rule group, see [Adding the ATP managed rule group to your web ACL](#).

Note
You are charged additional fees when you use this managed rule group. For more information, see [AWS WAF Pricing](#).

- **Details about your application's login page** – You must provide information about your login page when you add the AWSManagedRulesATPRuleSet rule group to your web ACL. This lets the rule group narrow the scope of the requests it inspects and properly validate credentials usage in web requests. For more information, see [Adding the ATP managed rule group to your web ACL](#).

- **JavaScript and mobile application integration SDKs** – Implement the AWS WAF JavaScript and mobile SDKs with your ATP implementation to enable the full set of capabilities that the rule group offers. Many of the ATP rules use the information provided by the SDKs for session level client verification and behavior aggregation, required to separate legitimate client traffic from bot traffic. For more information about the SDKs, see [AWS WAF client application integration](#).

You can combine your ATP implementation with the following to help you monitor, tune, and customize your protections.

- **Logging and metrics** – You can monitor your traffic, and understand how the ATP managed rule group affects it, by configuring and enabling logs and Amazon CloudWatch metrics for your web ACL. The labels that AWSManagedRulesATPRuleSet adds to your web requests are included in the logs and in Amazon CloudWatch metrics. For information about logging and metrics, see [Logging web ACL traffic](#) and [Monitoring with Amazon CloudWatch](#).

Depending on your needs and the traffic that you see, you might want to customize your AWSManagedRulesATPRuleSet implementation. For example, you might want to exclude some traffic from ATP evaluation, or you might want to alter how it handles some of the account takeover attempts that it identifies, using AWS WAF features like scope-down statements or label matching rules.

- **Labels and label matching rules** – For any of the rules in AWSManagedRulesATPRuleSet, you can switch the blocking behavior to count, and then match against the labels that are added by the rules. Use this approach to customize how you handle web requests that are identified by the ATP managed rule group. For more information about labeling and using label match statements, see [Label match rule statement](#) and [Labels on web requests](#).

- **Custom requests and responses** – You can add custom headers to the requests that you allow and you can send custom responses for requests that you block. To do this, you pair your label matching with the AWS WAF custom request and response features. For more information about customizing requests and responses, see [Customized web requests and responses in AWS WAF](#).
Benefits of challenge tokens for ATP

The ATP managed rule group requires the tokens that the silent challenge script generates, to enable the full set of protections that the rule group offers. The challenge script is run by the application integration SDKs and by the Challenge or CAPTCHA rule actions. The script must be run before the ATP rule group in order for the rule group to benefit from the tokens that the script acquires.

Capabilities of the ATP rule group that don't require a token

At a high level, when web requests don't have a token, the ATP managed rule group is capable of blocking the following types of traffic:

- Single IP addresses that make a lot of login requests.
- Login attempts with password traversal, using the same username but changing passwords.

Capabilities of the ATP rule group that require a token

When you implement the application integration SDKs in your clients or use the Challenge rule action, the web requests that your clients send will include a token. The information provided in the token expands the capabilities of the rule group and of your overall client application security.

The token provides client information with each web request that enables the ATP rule group to separate legitimate client sessions from ill-behaved client sessions, even when both originate from a single IP address. The rule group uses information in the tokens to aggregate client session request behavior for fine-tuned detection and mitigation.

When the token is available in web requests, the ATP rule group can detect and block the following additional categories of clients at the session level:

- Client sessions that fail the silent challenge that the SDKs manage.
- Client sessions that traverse usernames or passwords. This is also known as credential stuffing.
- Client sessions that repeatedly use stolen credentials to log in.
- Client sessions that spend a long time trying to log in.
- Clients sessions that make a lot of login requests. The ATP rule group provides better client isolation than the AWS WAF rate-based rule, which blocks all clients for an IP address. The rule group also uses a lower threshold.

For more information about the rule group capabilities see AWS WAF Fraud Control account takeover prevention (ATP) rule group (p. 60).

For information about AWS WAF tokens, see AWS WAF tokens (p. 144). For information about the SDKs, see AWS WAF client application integration (p. 175). For information about the rule actions, see CAPTCHA and Challenge actions in AWS WAF (p. 186).

Adding the ATP managed rule group to your web ACL

The ATP managed rule group AWSManagedRulesATPRuleSet requires additional configuration for recognizing and handling account takeover activities in your web traffic. This configuration information is specific to your web request handling.

This guidance is intended for users who know generally how to create and manage AWS WAF web ACLs, rules, and rule groups. Those topics are covered in prior sections of this guide.

To use the AWSManagedRulesATPRuleSet rule group in your web ACL

1. Add the AWS managed rule group, AWSManagedRulesATPRuleSet to your web ACL, and edit the rule group settings when you add it.
Note
You are charged additional fees when you use this managed rule group. For more information, see AWS WAF Pricing.

Note
For basic information about how to add a managed rule group to your web ACL, see Adding a managed rule group to a web ACL through the console (p. 30).

2. The ATP managed rule group requires information about your application’s login page that it uses to monitor, label, and handle login attempts to your application. You provide this configuration in addition to any of the standard managed rule group configuration settings that you might want to apply.

In the Rule group configuration pane, provide the following information about your application’s login page.

- For Login path, provide the path of the login endpoint for your application. For example, for the URL https://example.com/web/login, you would provide the path /web/login.

  The rule group inspects only HTTP POST requests to your specified login endpoint.

- For Payload type, select either JSON or form encoded.

- For Username field and Password field, enter the field names within the request body where the username and password are provided.

Your specification of these field names depends on the payload type that you’ve selected:

- For JSON payloads, specify the field names in JSON pointer syntax. For information about the JSON Pointer syntax, see the Internet Engineering Task Force (IETF) documentation JavaScript Object Notation (JSON) Pointer.

  For example, for the following example JSON payload, the username field specification is /login/username and the password field specification is /login/password.

  ```json
  {
    "login": {
      "username": "THE_USERNAME",
      "password": "THE_PASSWORD"
    }
  }
  ```

- For form encoded payloads, use the HTML form names.

  For example, for an HTML form with input elements named username1 and password1, the username field specification is username1 and the password field specification is password1.

3. Provide any additional configuration that you want for the rule group.

You can further limit the scope of requests that the rule group inspects by adding a scope-down statement to the managed rule group statement. For example, you can inspect only requests with a specific query argument or cookie. The rule group will inspect only HTTP POST requests that match the criteria in your scope-down statement. For information about scope-down statements, see Scope-down statements (p. 117).

4. Save your changes to the web ACL.

5. Implement the application integration SDKs to acquire challenge tokens for the web requests that the rule group inspects. If you can’t implement the SDKs, then provide the token by adding a rule before the rule group that matches all web requests that the rule group will inspect and that has a Challenge rule action. The Challenge rule incurs additional expense that the application integration SDKs do not. For a full comparison of these two options, see Comparison of the options for intelligent threat mitigation (p. 140).
To understand the benefits of this, see Benefits of challenge tokens for ATP (p. 167).

To implement the integration SDKs, follow the guidance at AWS WAF client application integration (p. 175).

Before you deploy your ATP implementation for production traffic, test and tune it in a staging or testing environment until you are comfortable with the potential impact to your traffic. Then test and tune the rules in count mode with your production traffic before enabling them. See the section that follows for guidance.

Testing and deploying ATP

This section provides general guidance for configuring and testing an AWS WAF Fraud Control account takeover prevention (ATP) implementation for your site. The specific steps that you choose to follow will depend on your needs, resources, and web requests that you receive.

This information is in addition to the general information about testing and tuning provided at Testing and tuning your AWS WAF protections (p. 212).

Note
AWS Managed Rules are designed to protect you from common web threats. When used in accordance with the documentation, AWS Managed Rules rule groups add another layer of security for your applications. However, AWS Managed Rules rule groups aren't intended as a replacement for your security responsibilities, which are determined by the AWS resources that you select. Refer to the Shared Responsibility Model to ensure that your resources in AWS are properly protected.

Production traffic risk
Before you deploy your ATP implementation for production traffic, test and tune it in a staging or testing environment until you are comfortable with the potential impact to your traffic. Then test and tune the rules in count mode with your production traffic before enabling them.

AWS WAF provides test credentials that you can use to verify your ATP configuration. In the following procedure, you'll configure a test web ACL to use the ATP managed rule group, configure a rule to capture the label added by the rule group, and then run a login attempt using these test credentials. You'll verify that your web ACL has properly managed the attempt by checking the Amazon CloudWatch metrics for the login attempt.

This guidance is intended for users who know generally how to create and manage AWS WAF web ACLs, rules, and rule groups. Those topics are covered in prior sections of this guide.

To configure and test an AWS WAF Fraud Control account takeover prevention (ATP) implementation

Perform these steps first in a test environment, then in production.

1. Add the AWS WAF Fraud Control account takeover prevention (ATP) managed rule group

   Note
   You are charged additional fees when you use this managed rule group. For more information, see AWS WAF Pricing.

   Add the AWS Managed Rules rule group AWSManagedRulesATPRuleSet to a new or existing web ACL and configure it so that it doesn't alter the current web ACL behavior. For details about the rules and labels for this rule group, see AWS WAF Fraud Control account takeover prevention (ATP) rule group (p. 60).

   • When you add the managed rule group, edit it and do the following:
1. In the Rule group configuration pane, provide the details of your application's login page. The ATP rule group uses this information to monitor sign-in activities. For more information, see Adding the ATP managed rule group to your web ACL (p. 167).

2. In the Rules pane, open the Override all rule actions dropdown and choose Count. With this configuration, AWS WAF evaluates requests against all of the rules in the rule group and only counts the matches that result, while still adding labels to requests. For more information, see Overriding rule actions in a rule group (p. 22).

   With this override, you can monitor the potential impact of the ATP managed rules to determine whether you want to add exceptions, such as exceptions for internal use cases.

3. Position the rule group so that it's evaluated after your existing rules in the web ACL, with a priority setting that's numerically higher than any rules or rule groups that you're already using. For more information, see Processing order of rules and rule groups in a web ACL (p. 14).

   This way, your current handling of traffic isn't disrupted. For example, if you have rules that detect malicious traffic such as SQL injection or cross-site scripting, they'll continue to detect and log that. Alternately, if you have rules that allow known non-malicious traffic, they can continue to allow that traffic, without having it blocked by the ATP managed rule group. You might decide to adjust the processing order during your testing and tuning activities.

2. **Add a rule to match against the ATP rule group's label for compromised credentials**

   Immediately after the ATP rule group, add a label match rule as follows:

   - Set the rule action to Count.
   - Make sure this rule has a higher numeric priority setting than the ATP rule group so that this rule runs after the ATP rules. In the console, it should be listed last. For more information, see Processing order of rules and rule groups in a web ACL (p. 14).

   You'll look for the name of this rule in your Amazon CloudWatch metrics, when you test your configuration.

3. **Enable sampling, logging, and metrics for the web ACL**

   As needed, configure logging for the web ACL, and enable sampling and Amazon CloudWatch metrics. You can use these visibility tools to monitor the interaction of the ATP managed rule group with your traffic.

   - For information about configuring and using logging, see Logging web ACL traffic (p. 192).
   - For information about Amazon CloudWatch metrics, see Monitoring with Amazon CloudWatch (p. 541).
   - For information about web request sampling, see Viewing a sample of web requests (p. 219).

4. **Associate the web ACL with a resource**

   If the web ACL isn't already associated with a test resource, associate it. For information, see Associating or disassociating a web ACL with an AWS resource (p. 23).

5. **Monitor traffic and ATP rule matches**

   Make sure that your normal traffic is flowing and that the ATP managed rule group rules are adding labels to matching web requests. You can see the labels in the logs and see the label match rule metrics in Amazon CloudWatch metrics.

   In the logs, the rules that you've overridden to count in the rule group show up under the ruleGroupList with a count action and an overriddenAction set to the rule's configured action setting. For older web ACL configurations, if you've set the rules to count by excluding them, they show up under the rule group list as excludedRules.
6. **Test the rule group's credential checking capabilities**

   Perform a login attempt with test compromised credentials and check that the rule group matches against them as expected. Do the following:

   a. Log in to your protected resource's login page using the following AWS WAF test credential pair:
      
      - User: WAF_TEST_CREDENTIAL@wafexample.com
      - Password: WAF_TEST_CREDENTIAL_PASSWORD

      These test credentials are categorized as compromised credentials, and the ATP managed rule group will add the `awswaf:managed:aws:atp:signal:credential_compromised` label to the login request.

   b. Check for the following results from your test:
      
      - In your Amazon CloudWatch metrics, look for `CountedRequest` metrics for your rule that matches against the compromised credentials label. For information about Amazon CloudWatch metrics, see [Monitoring with Amazon CloudWatch](p. 541).
      - In your web ACL logs, look for the `awswaf:managed:aws:atp:signal:credential_compromised` label in the `labels` field on the log entry for your test login web request. For information about logging, see [Logging web ACL traffic](p. 192).

   After you've verified that the rule group captures compromised credentials as expected, you can take steps to configure its implementation as you need for your protected resource.

7. **Customize ATP web request handling**

   As needed, add your own rules that explicitly allow or block requests, to change how ATP rules would otherwise handle them.

   For example, you can use ATP labels to allow or block requests or to customize request handling. You can add a label match rule after the ATP managed rule group to filter labeled requests for the handling that you want to apply. After testing, keep the related ATP rules in count mode, and maintain the request handling decisions in your custom rule. For an example, see [ATP example: Custom handling for missing and compromised credentials](p. 173).

8. **Remove your test rule and enable the ATP managed rule group settings**

   Depending on your situation, you might have decided that you want to leave some ATP rules in count mode. For the rules that you want to run the way that they're configured inside the rule group, enable the regular rule configuration. To do this, disable count mode in the web ACL rule group configuration for the rules. When you're finished testing, you can also remove your test label match rule.

9. **Monitor and tune**

   To be sure that web requests are being handled as you want, closely monitor your traffic after you enable the ATP functionality that you intend to use. Adjust the behavior as needed with the rules count override on the rule group and with your own rules.

   After you finish testing your ATP rule group implementation, we recommend that you integrate the AWS WAF ATP JavaScript SDK into your browser login page, for enhanced detection capabilities. AWS WAF also provides mobile SDKs to integrate iOS and Android devices. For more information about the integration SDKs, see [AWS WAF client application integration](p. 175).
AWS WAF Fraud Control account takeover prevention (ATP) examples

This section shows example configurations that satisfy common use cases for the AWS WAF Fraud Control account takeover prevention (ATP) implementations.

Each example provides a description of the use case and then shows the solution in JSON listings for the custom configured rules.

Note
You can retrieve JSON listings like the ones shown in these examples through the console web ACL JSON download or rule JSON editor, or through the getWebACL operation in the APIs and the command line interface.

Topics
• ATP example: Simple configuration (p. 172)
• ATP example: Custom handling for missing and compromised credentials (p. 173)

ATP example: Simple configuration

The following JSON listing shows an example web ACL with an AWS WAF Fraud Control account takeover prevention (ATP) managed rule group. Note the additional sign-in page configuration, which gives the rule group the information it needs to monitor and manage your login requests. This JSON includes the web ACL's automatically generated settings, like the label namespace and the web ACL's application integration URL.

```
{
    "WebACL": {
        "LabelNamespace": "awswaf:111122223333:webacl:ATPModuleACL:",
        "Capacity": 50,
        "Description": "This is a test web ACL for ATP.",
        "Rules": [
            {
                "Priority": 1,
                "OverrideAction": {
                    "None": {}
                },
                "VisibilityConfig": {
                    "SampledRequestsEnabled": true,
                    "CloudWatchMetricsEnabled": true,
                    "MetricName": "AccountTakeOverValidationRule"
                },
                "Name": "DetectCompromisedUserCredentials",
                "Statement": {
                    "ManagedRuleGroupStatement": {
                        "VendorName": "AWS",
                        "Name": "AWSManagedRulesATPRuleSet",
                        "ManagedRuleGroupConfigs": [
                            {
                                "UsernameField": {
                                    "Identifier": "/form/username"
                                }
                            },
                            {
                                "PasswordField": {
                                    "Identifier": "/form/password"
                                }
                            },
                            {
                                "PayloadType": "JSON"
                            }
                        ]
                    }
                }
            }
        ]
    }
}
```
ATP example: Custom handling for missing and compromised credentials

By default, the credentials checks that are performed by the rule group 
AWSManagedRulesATPRuleSet handle web requests as follows:

- **Missing credentials** – Label and block request.
- **Compromised credentials** – Label request but don't block or count it.

For details about the rule group and rule behavior, see AWS WAF Fraud Control account takeover prevention (ATP) rule group (p. 60).

You can add custom handling for web requests that have missing or compromised credentials by doing the following:

- **Override the MissingCredential rule to Count** – This rule action override causes the rule to only count and label matching requests.
- **Add a label match rule with custom handling** – Configure this rule to match against both of the ATP labels and to perform your custom handling. For example, you might redirect the customer to your sign-up page.

The following rule shows the ATP managed rule group from the prior example, with the MissingCredential rule action overridden to count. This causes the rule to apply its label to matching requests, and then only count the requests, instead of blocking them.

```
"Rules": [
  {
    "Priority": 1,
    "OverrideAction": {
      "None": {}
    },
    "VisibilityConfig": {
      "SampledRequestsEnabled": true,
      "CloudWatchMetricsEnabled": true,
      "MetricName": "ATPValidationAcl"
    },
    "DefaultAction": {
      "Allow": {}
    },
    "ManagedByFirewallManager": false,
    "Id": "32q10987-65rs-4tuv-3210-98765wxyz432",
    "ARN": "arn:aws:wafv2:us-east-1:111122223333:regional/webacl/ATPModuleACL/32q10987-65rs-4tuv-3210-98765wxyz432",
    "Name": "ATPModuleACL"
  }
]```

173
With this configuration, when this rule group evaluates any web request that has missing or compromised credentials, it will label the request, but not block it.

The following rule has a higher numeric priority than the preceding rule group, so it's evaluated after the rule group evaluation. The rule is configured to match either of the credentials labels and to send a custom response for matching requests.

```json
"Name": "redirectToSignup",
"Priority": 10,
"Statement": {
  "OrStatement": {
    "Statements": [
      {
        "LabelMatchStatement": {
          "Scope": "LABEL",
          "Key": "awswaf:managed:aws:atp:simple:missing_credential"
        }
      },
      {
        "LabelMatchStatement": {
          "Scope": "LABEL",
          "Key": "awswaf:managed:aws:atp:simple:credential_compromised"
        }
      }
    ]
  }
}
```
AWS WAF client application integration

Use the AWS WAF application integration SDKs to couple client-side protections with your AWS server-side web ACL protections, adding verifications that the client applications that send web requests to your protected resource are the intended ones. The application SDKs verify the client application with silent challenges and provide AWS token acquisition and management, similar to the functionality provided by the AWS WAF Challenge rule action.

The integration SDKs manage token authorization for your client application sessions and help ensure that login attempts to your protected resource are only allowed after the client has acquired a valid token. Additionally, the SDKs gather information about the client to help determine whether it's being operated by a bot or by a human being.

The application integration SDKs work with web ACLs that use one or both of the rule groups AWSManagedRulesBotControlRuleSet and AWSManagedRulesATPRuleSet. The SDKs enable the full functionality of these advanced managed rule groups.

- AWS WAF Fraud Control account takeover prevention (ATP) managed rule group AWSManagedRulesATPRuleSet.
  
  Account takeover is an online illegal activity in which an attacker gains unauthorized access to a person's account. The ATP managed rule group provides rules to block, label, and manage requests that might be part of malicious account takeover attempts. The SDKs enable fine-tuned client verification and behavior aggregation that the ATP rules use to separate valid client traffic from malicious traffic.
  
  For more information, see AWS WAF Fraud Control account takeover prevention (ATP) rule group (p. 60) and AWS WAF Fraud Control account takeover prevention (ATP) (p. 165).

- AWS WAF Bot Control managed rule group AWSManagedRulesBotControlRuleSet.
  
  Bots run from self-identifying and useful ones, such as most search engines and crawlers, to malicious bots that operate against your website and don’t self-identify. The Bot Control managed rule group provides rules to monitor, label, and manage the bot activity in your web traffic. When you use the targeted protection level of this rule group, the targeted rules use the client session information that the SDKs provide to better detect malicious bots.
  
  For more information, see AWS WAF Bot Control rule group (p. 53) and AWS WAF Bot Control (p. 151).

To add one of these managed rule groups to your web ACL, see the procedures Adding the AWS WAF Bot Control managed rule group to your web ACL (p. 153) and Adding the ATP managed rule group to your web ACL (p. 167).
The managed rule groups currently don't block requests that are missing tokens. In order to block requests that are missing tokens, after you implement your application integration SDK, follow the guidance at "Blocking requests that don't have a valid token" (p. 148).

The JavaScript SDK is generally available, and you can use it for your browsers and other devices that execute JavaScript. For Android and iOS mobile apps, AWS WAF also offers custom SDKs. For access to the mobile SDKs, contact sales at Contact AWS.

To access the application integration SDKs through the console

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. Choose Application integration in the navigation pane.
3. In the Application integration SDKs page, you can see the following:
   - The web ACLs that are enabled for managed application integration. Each web ACL that uses an AWS Managed Rules rule group with managed integration support is listed. When you implement an SDK, you use the integration URL for the web ACL that you want to integrate with.
   - The SDKs that you have access to. The JavaScript SDK is always available. For access to the mobile SDKs, contact sales at Contact AWS.

To implement an SDK, follow the guidance for the SDK type. After you've implemented your SDK, to block requests that are missing tokens, follow the guidance at "Blocking requests that don't have a valid token" (p. 148).

Topics
- AWS WAF JavaScript SDK (p. 176)
- AWS WAF mobile SDK (p. 179)

AWS WAF JavaScript SDK

You can use the AWS WAF JavaScript SDK to implement AWS WAF application integrations in your browsers and other devices that execute JavaScript. The JavaScript SDK lets you manage token authorization, and to include the tokens in the requests that you send to your protected resources. By using the SDK, you ensure that the remote procedure calls by your client contain a valid token. Additionally, when this integration is in place on your application's pages, you can implement mitigating rules in your web ACL, such as blocking requests that don't contain a valid token.

The following listing shows basic components of a typical implementation of the JavaScript SDK in a web application page.

```html
<head>
    <script type="text/javascript" src="Web ACL integration URL/challenge.js" defer></script>
</head>
<script>
    const login_response = await AwsWafIntegration.fetch(login_url, {
        method: 'POST',
        headers: {
            'Content-Type': 'application/json'
        },
        body: login_body
    });
</script>
```
Installing the AWS WAF JavaScript SDK

Implement the JavaScript SDK first in a test environment, then in production.

To begin using the JavaScript SDK

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Application integration. This takes you to the Application integration SDKs page.
3. In the Application integration SDKs page, in the pane Web ACLs that are enabled for application integration, locate the web ACL that you're integrating with. Copy and save the web ACL integration URL for use in your implementation. You can also obtain this URL through the API call GetWebACL.
4. In your application page code, in the <head> section, insert the following <script> tag, and populate it with your web ACL’s integration URL. This inclusion causes your client application to automatically retrieve a token in the background on page load.

    <script type="text/javascript" src="Web ACL integration URL/challenge.js" defer></script>

This <script> listing is configured with the defer attribute, but you can change the setting to async if you want a different behavior for your page.

5. Complete coding your integration to ensure that token retrieval completes before the client's login request is sent. If you are already using the fetch API to make your call, you can substitute the AWS WAF integration fetch wrapper. If you don't use the fetch API, you can use the AWS WAF integration getToken operation instead.

    For coding guidance, see the following sections.

Providing domains for use in the tokens

You can provide a domain configuration for the tokens that AWS WAF creates for the SDK. To do this, configure the global variable window.awsWafCookieDomainList with one or more token domains.

Example settings:

    window.awsWafCookieDomainList = ['.aws.amazon.com']

    window.awsWafCookieDomainList = ['.aws.amazon.com', 'abc.aws.amazon.com']

Public suffixes aren't allowed. For example, you can't use usa.gov or co.uk as token domains.

The domains that you specify must be ones that AWS WAF will accept, based on the protected host domain and the token domain list that's configured for the web ACL. For more information, see Token domains and domain lists (p. 146).

When AWS WAF creates a token, it uses the most appropriate, shortest domain from the combination of domains from the window.awsWafCookieDomainList configuration and the host domain of the resource that's associated with the web ACL.

For the AWSManagedRulesATPRuleSet managed rule group, this will usually be a single domain that matches the domain in the login path that you provided to the rule group configuration.
How to use the fetch wrapper

You can use the fetch wrapper by changing your normal fetch calls to the fetch API under the AwsWafIntegration namespace. The AWS WAF wrapper supports all of the same options as the standard JavaScript fetch API call. This approach is generally the simplest way to integrate your application.

Before the wrapper implementation

The following example listing shows standard code before implementing the AwsWafIntegration fetch wrapper.

```javascript
const login_response = await fetch(login_url, {
  method: 'POST',
  headers: {
    'Content-Type': 'application/json'
  },
  body: login_body
});
```

After the wrapper implementation

The following listing shows the same code with the AwsWafIntegration fetch wrapper implementation.

```javascript
const login_response = await AwsWafIntegration.fetch(login_url, {
  method: 'POST',
  headers: {
    'Content-Type': 'application/json'
  },
  body: login_body
});
```

How to use getToken

AWS WAF requires your login requests to include the cookie named aws-waf-token with the value of your current token.

The getToken operation is an asynchronous SDK call that retrieves the AWS WAF token and stores it in a cookie on the current page with name aws-waf-token, and the value set to the token value. You can use this token cookie as needed in your page.

When you call getToken, it does the following:

- If an unexpired token is already available, the call returns it immediately.
- Otherwise, the call retrieves a new token from the token provider, waiting for up to 2 seconds for the token acquisition workflow to complete before timing out. If the operation times out, it throws an error, which your calling code must handle.

The getToken operation has an accompanying hasToken operation, which indicates whether the aws-waf-token cookie currently holds an unexpired token.

Basic getToken implementation

The following example listing shows standard code for implementing the getToken operation.

```javascript
const login_response = await AwsWafIntegration.getToken()
.catch(e => {
```
// Implement error handling logic for your use case

// The getToken call returns the token, and doesn't typically require special handling
.then(token => {
  return loginToMyPage()
})

async function loginToMyPage() {
  // Your existing login code
}

Submit form only after token is available from getToken

The following listing shows how to register an event listener to intercept form submissions until a valid
token is available for use.

AWS WAF mobile SDK

You can use the AWS WAF mobile SDKs to implement AWS WAF application integrations for Android
and iOS mobile applications. With the mobile SDK, you can manage token authorization, and include
the tokens in the requests that you send to your protected resources. By using the SDK, you ensure that
these remote procedure calls by your client contain a valid token. Additionally, when this integration is in
place on your application's pages, you can implement mitigating rules in your web ACL, such as blocking
requests that don't contain a valid token.

For access to the mobile SDKs, contact sales at Contact AWS.

The basic approach for using the SDK is to create a token provider using a configuration object, then
to use the token provider to retrieve tokens from AWS WAF. By default, the token provider includes the
retrieved tokens in your web requests to your protected resource.

The following is a partial listing of an SDK implementation, which shows the main components. For more
detailed examples, see Writing your code for the AWS WAF mobile SDK (p. 184).
iOS

```swift
let url: URL = URL(string: "Web ACL integration URL")!
let configuration = WAFConfiguration(applicationIntegrationUrl: url, domainName: "Domain name")
let tokenProvider = WAFTokenProvider(configuration)
let token = tokenProvider.getToken()
```

Android

```java
URL applicationIntegrationURL = new URL("Web ACL integration URL");
String domainName = "Domain name";
WAFConfiguration configuration = 
    WAFConfiguration.builder().applicationIntegrationURL(applicationIntegrationURL).domainName(domainName).build();
WAFTokenProvider tokenProvider = new WAFTokenProvider(Application context, configuration);
WAFToken token = tokenProvider.getToken();
```

Installing the AWS WAF mobile SDK

Implement the mobile SDK first in a test environment, then in production.

**To install the AWS WAF mobile SDK**

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Application integration. This takes you to the Application integration SDKs page.
3. In the Application integration SDKs page, do the following:
   a. In the pane Web ACLs that are enabled for application integration, locate the web ACL that you're integrating with. Copy and save the web ACL integration URL for use in your implementation. You can also obtain this URL through the API call GetWebACL.
   b. Choose the mobile device type and version, then choose Download. You can choose any version you like, but we recommend using the latest version. AWS WAF downloads the zip file for your device to your standard download location.
4. In your app development environment, unzip the file to a work location of your choice. In the top-level directory of the zip file, locate and open the README. Follow the instructions in the README file to install the AWS WAF mobile SDK for use in your mobile app code.
5. Program your app according to the guidance in the following sections.

The AWS WAF mobile SDK specification

This section lists the SDK objects, operations, and configuration settings for the AWS WAF mobile SDK. For detailed information about how the token provider and operations work for the various combinations of configuration settings, see How the AWS WAF mobile SDK works (p. 183).

**WAFToken**

Holds an AWS WAF token.

```swift
getValue()
```

Retrieves the String representation of the WAFToken.

**WAFTokenProvider**

Manages tokens in your mobile app. Implement this using a WAFConfiguration object.
getToken()

If background refresh is enabled, this returns the cached token. If background refresh is disabled, this makes a synchronous, blocking call to AWS WAF to retrieve a new token.

onTokenReady(WAFTokenResultCallback)

Instructs the token provider to refresh the token and invoke the provided callback when an active token is ready. The token provider will invoke your callback in a background thread when the token is cached and ready. Call this when your app first loads and also when it comes back to an active state. For more information about returning to an active state, see the section called “Retrieving a token following app inactivity” (p. 184).

For Android or iOS apps, you can set WAFTokenResultCallback to the operation that you want the token provider to invoke when a requested token is ready. Your implementation of WAFTokenResultCallback must take the parameters WAFToken, SdkError. For iOS apps, you can alternately create an inline function.

WAFConfiguration

Holds the configuration for the implementation of the WAFTokenProvider. When you implement this, you provide your web ACL's integration URL, the domain name to use in the token, and any non-default settings that you want the token provider to use.

The following list specifies the configuration settings that you can manage in the WAFConfiguration object.

applicationIntegrationUrl

The application integration URL. Get this from the AWS WAF console or through the getWebACL API call.

Required: Yes

Type: App-specific URL. For iOS, see iOS URL. For Android, see java.net URL.

backgroundRefreshEnabled

Indicates whether you want the token provider to refresh the token in the background. If you set this, the token provider refreshes your tokens in the background according to the configuration settings that govern automatic token refresh activities.

Required: No

Type: Boolean

Default value: TRUE

domainName

The domain to use in the token, which is used in token acquisition and cookie storage. For example, example.com or aws.amazon.com. This is usually the host domain of your resource that's associated with the web ACL, where you'll be sending web requests. For the AWSManagedRulesATPRuleSet managed rule group, this will usually be a single domain that matches the domain in the login path that you provided to the rule group configuration.

Public suffixes aren't allowed. For example, you can't use usa.gov or co.uk as the token domain.

The domain must be one that AWS WAF will accept, based on the protected host domain and the web ACL's token domain list. For more information, see Token domains and domain lists (p. 146).

Required: Yes
**maxErrorTokenRefreshDelayMsec**

The maximum time in milliseconds to wait before repeating a token refresh after a failed attempt. This value is used after token retrieval has failed and been retried `maxRetryCount` times.

Required: No
Type: Integer
Default value: 5000 (5 seconds)
Minimum value allowed: 1 (1 millisecond)
Maximum value allowed: 30000 (30 seconds)

**maxRetryCount**

The maximum number of retries to perform with exponential backoff when a token is requested.

Required: No
Type: Integer
Default value: If background refresh is enabled, 5. Otherwise, 3.
Minimum value allowed: 0
Maximum value allowed: 10

**setTokenCookie**

Indicates whether you want the SDK's cookie manager to add a token cookie in your requests. By default, this adds a token cookie to all requests. The cookie manager adds a token cookie to any request whose path is under the path specified in `tokenCookiePath`.

Required: No
Type: Boolean
Default value: TRUE

**tokenCookiePath**

Used when `setTokenCookie` is TRUE. Indicates the top-level path where you want the SDK's cookie manager to add a token cookie. The manager adds a token cookie to all requests that you send to this path and to all child paths.

For example, if you set this to `/web/login`, then the manager includes the token cookie for everything sent to `/web/login` and any of its child paths, like `/web/login/help`. It doesn't include the token for requests sent to other paths, like ``, `/web`, or `/web/order`.

Required: No
Type: String
Default value: `/`

**tokenRefreshDelaySec**

Used for background refresh. The maximum amount of time in seconds between background token refreshes.

Required: No
Type: Integer

Default value: 300 (5 minutes)

Minimum value allowed: 300 (5 minutes)

Maximum value allowed: 600 (10 minutes)

How the AWS WAF mobile SDK works

The mobile SDKs provide you with a configurable token provider that you can use for token retrieval and use. The token provider verifies that the requests that you allow are from legitimate customers. When you send requests to the AWS resources that you protect with AWS WAF, you include the token in a cookie, to validate the request. You can handle the token cookie manually or have the token provider do it for you.

This section covers the interactions between the classes, properties, and methods that are included in the mobile SDK. For the SDK specification, see The AWS WAF mobile SDK specification (p. 180).

Token retrieval and caching

When you create the token provider instance in your mobile app, you configure how you want it to manage tokens and token retrieval. Your main choice is how to maintain valid, unexpired tokens for use in your app's web requests:

- **Background refresh enabled** – This is the default. The token provider automatically refreshes the token in the background and caches it. With background refresh enabled, when you call getToken(), the operation retrieves the cached token.

  The token provider performs the token refresh at configurable intervals, so that an unexpired token is always available in the cache while the application is active. Background refresh is paused while your application is in an inactive state. For information about this, see Retrieving a token following app inactivity (p. 184).

- **Background refresh disabled** – You can disable background token refresh, and then retrieve tokens only on demand. Tokens retrieved on demand aren't cached, and you can retrieve more than one if you want. Each token is independent of any others that you retrieve, and each has its own timestamp that's used to calculate expiration.

  You have the following choices for token retrieval when background refresh is disabled:

  - **getToken()** – When you call getToken() with background refresh disabled, the call synchronously retrieves a new token from AWS WAF. This is a potentially blocking call that may affect app responsiveness if you invoke it on the main thread.

  - **onTokenReady(WAFTokenResultCallback)** – This call asynchronously retrieves a new token and then invokes the provided result callback in a background thread when a token is ready.

How the token provider retries failed token retrievals

The token provider automatically retries token retrieval when retrieval fails. Retries are initially performed using exponential backoff with a starting retry wait time of 100 ms. For information about exponential retries, see Error retries and exponential backoff in AWS.

When the number of retries reaches the configured maxRetryCount, the token provider either stops trying or switches to trying every maxErrorTokenRefreshDelayMsec milliseconds, depending on the type of token retrieval:

- **onTokenReady()** – The token provider switches to waiting maxErrorTokenRefreshDelayMsec milliseconds between attempts, and continues trying to retrieve the token.
• **Background refresh** – The token provider switches to waiting `maxErrorTokenRefreshDelayMsec` milliseconds between attempts, and continues trying to retrieve the token.

• **On-demand getToken() calls, when background refresh is disabled** – The token provider stops trying to retrieve a token and returns the previous token value, or a null value if there is no previous token.

**Retrieving a token following app inactivity**

Background refresh is only performed while your app is considered active for your app type:

- **iOS** – Background refresh is performed when the app is in the foreground.
- **Android** – Background refresh is performed when the app isn't closed, whether it's in the foreground or background.

If your app remains in any state that doesn't support background refresh for longer than your configured `tokenRefreshDelaySec` seconds, the token provider pauses background refresh. For example, for an iOS app, if `tokenRefreshDelaySec` is 300 and the app closes or goes into the background for more than 300 seconds, the token provider stops refreshing the token. When the app returns to an active state, the token provider automatically restarts background refresh.

When your app comes back to an active state, call `onTokenReady()` so you can be notified when the token provider has retrieved and cached a new token. Don't just call `getToken()`, because the cache may not yet contain a current, valid token.

**Writing your code for the AWS WAF mobile SDK**

This section provides code examples for using the mobile SDK.

**Initializing the token provider and getting tokens**

You initiate your token provider instance using a configuration object. Then you can retrieve tokens using the available operations. The following shows the basic components of the required code.

**iOS**

```swift
let url: URL = URL(string: "Web ACL integration URL")!
let configuration = WAFConfiguration(applicationIntegrationUrl: url, domainName: "Domain name")
let tokenProvider = WAFTokenProvider(configuration)

//onTokenReady can be add as an observer for
UIApplication.willEnterForegroundNotification
self.tokenProvider.onTokenReady() { token, error in
  if let token = token {
    //token available
  }
  if let error = error {
    //error occurred after exhausting all retries
  }
}

//getToken()
let token = tokenProvider.getToken()
```

**Android**

```java
String applicationIntegrationURL = "Web ACL integration URL";
```
Or

URL applicationIntegrationURL = new URL("Web ACL integration URL");

String domainName = "Domain name";

WAFConfiguration configuration =
    WAFConfiguration.builder().applicationIntegrationURL(applicationIntegrationURL).domainName(domainName).build();

WAFTokenProvider tokenProvider = new WAFTokenProvider(Application context, configuration);

// implement a token result callback
WAFTokenResultCallback callback = (wafToken, error) -> {
    if (wafToken != null) {
        // token available
    } else {
        // error occurred in token refresh
    }
};

// Add this callback to application creation or activity creation where token will be used
tokenProvider.onTokenReady(callback);

// Once you have token in token result callback
// if background refresh is enabled you can call getToken() from same tokenprovider object
// if background refresh is disabled you can directly call getToken() (blocking call)
// for new token
WAFToken token = tokenProvider.getToken();

### Allowing the SDK to provide the token cookie in your HTTP requests

If `setTokenCookie` is TRUE, the token provider includes the token cookie for you in your web requests to all locations under the path that's specified in `tokenCookiePath`. By default, `setTokenCookie` is TRUE and `tokenCookiePath` is `/.

You can narrow the scope of the requests that include a token cookie by specifying the token cookie path, for example, `/web/login`. If you do this, check that your AWS WAF rules don't inspect for tokens in the requests that you send to other paths. When you use the `AWSManagedRulesATPRuleSet` rule group, you configure the login path, and the rule group checks for tokens in requests that are sent to that path. For more information, see Adding the ATP managed rule group to your web ACL (p. 167).

**iOS**

When `setTokenCookie` is TRUE, the token provider stores the AWS WAF token in a `HTTPCookieStorage.shared` and automatically includes the cookie in requests to the domain that you specified in `WAFConfiguration`.

```java
let request = URLRequest(url: URL(string: domainEndpointUrl)!) // The token cookie is set automatically as cookie header
let task = URLSession.shared.dataTask(with: request) { data, urlResponse, error in
    // Do something with the data...
}
```

**Android**

When `setTokenCookie` is TRUE, the token provider stores the AWS WAF token in a `CookieHandler` instance that's shared application wide. The token provider automatically includes the cookie in requests to the domain that you specified in `WAFConfiguration`.

```java
URL url = new URL("Domain name");`
Captcha and Challenge actions

// The token cookie is set automatically as cookie header
HttpsURLConnection connection = (HttpsURLConnection) url.openConnection();
connection.getResponseCode();

If you already have the CookieHandler default instance initialized, the token provider will use it to manage cookies. If not, the token provider will initialize a new CookieManager instance with the AWS WAF token and CookiePolicy.ACCEPTORIGINAL_SERVER and then set this new instance as the default instance in CookieHandler.

The following code shows how the SDK initializes the cookie manager and cookie handler when they aren't available in your app.

```java
CookieManager cookieManager = (CookieManager) CookieHandler.getDefault();
if (cookieManager == null) {
    // Cookie manager is initialized with CookiePolicy.ACCEPTORIGINAL_SERVER
    cookieManager = new CookieManager();
    CookieHandler.setDefault(cookieManager);
}
```

Manually providing the token cookie in your HTTP requests

If you set setTokenCookie to FALSE, then you need to provide the token cookie manually, as a Cookie HTTP request header, in your requests to your protected endpoint. The following code shows how to do this.

iOS

```objective-c
var request = URLRequest(url: wafProtectedEndpoint)
request.setValue("aws-waf-token=token from token provider", forHTTPHeaderField:
    "Cookie")
request.httpShouldHandleCookies = true
NSURLSession.shared.dataTask(with: request) { data, response, error in }
```

Android

```java
URL url = new URL("Domain name");
HttpsURLConnection connection = (HttpsURLConnection) url.openConnection();
String wafTokenCookie = "aws-waf-token=token from token provider";
connection.setRequestProperty("Cookie", wafTokenCookie);
connection.getInputStream();
```

CAPTCHA and Challenge actions in AWS WAF

You can configure your AWS WAF rules to run a CAPTCHA or Challenge action against web requests that match your rule's inspection criteria.

- CAPTCHA requires the end user to solve a CAPTCHA puzzle to prove that a human being is sending the request.
- Challenge runs a silent challenge that requires the client session to verify that it's a browser, and not a bot. The verification runs in the background without involving the end user. This is a good option for verifying clients that you suspect of being invalid without negatively impacting the end user experience with a CAPTCHA puzzle.

The Challenge rule action is similar to the challenges in the application integration SDKs, described at AWS WAF client application integration (p. 175).
Note
You are charged additional fees when you use the CAPTCHA or Challenge rule action in one of your rules or as a rule action override in a rule group. For more information, see AWS WAF Pricing.

After the user or client responds successfully, the script running the CAPTCHA or challenge automatically resubmits the original web request with the updated token.

For a description of rule action settings, see AWS WAF rule action (p. 84).

Topics
- What is a CAPTCHA puzzle? (p. 187)
- How the CAPTCHA and Challenge actions work (p. 188)
- Best practices for using the CAPTCHA and Challenge actions (p. 191)

What is a CAPTCHA puzzle?

AWS WAF provides standard CAPTCHA functionality that challenges users to confirm that they are human beings. CAPTCHA stands for Completely Automated Public Turing test to tell Computers and Humans Apart. CAPTCHA puzzles are designed to verify that a human is sending requests and to prevent activity like web scraping, credential stuffing, and spam.

Each CAPTCHA puzzles includes a standard set of controls for the end user to request a new puzzle, switch between audio and visual puzzles, access additional instructions, and submit a puzzle solution. All puzzles include support for screen readers, keyboard controls, and contrasting colors.

The written instructions for CAPTCHA puzzles are provided in multiple languages, with the language choice available through a dropdown menu. The audio portion of the audio puzzles is provided in English only.

A typical visual puzzle requires interaction to complete a specific part of an image, as shown in the following screenshot.

![Solve the puzzle](image-url)
AWS WAF CAPTCHA puzzles are designed to be intuitive across multiple geographic regions. The default puzzles rely on visual elements and various forms of computer interaction. AWS WAF CAPTCHA includes alternative audio-based puzzles for users with visual impairment. The puzzles meet the requirements of the Web Content Accessibility Guidelines (WCAG). For information, see Web Content Accessibility Guidelines (WCAG) Overview at the World Wide Web Consortium (W3C) website.

The audio puzzle option provides background noise overlaid with instructions in English about text that the user should type into a text box. The following screenshot shows the display for the audio puzzle choice.

**Solve the puzzle**

**Click play to listen to instructions**

Keyboard audio toggle: alt + space

**Enter your response**

Capture by listening to the recording and typing your answer into the text box.

Submit

CAPTCHA puzzles are intended to be fairly easy and quick for humans to complete successfully and hard for computers to either complete successfully or to randomly complete with any meaningful rate of success. CAPTCHA is commonly used when a block action would stop too many legitimate requests, but letting all traffic through would result in unacceptably high levels of unwanted requests, such as from bots.

CAPTCHA can’t weed out all unwanted requests. A lot of CAPTCHA puzzles have been solved using machine learning and artificial intelligence. In an effort to circumvent CAPTCHA, some organizations supplement automated techniques with human intervention. In spite of this, CAPTCHA continues to be a useful tool to prevent less sophisticated bot traffic and to increase the resources required for large-scale operations.

AWS WAF randomly generates its CAPTCHA puzzles and rotates through them to ensure that users are presented with unique challenges. AWS WAF regularly adds new types and styles of puzzles to remain effective against automation techniques. In addition to the puzzles, the AWS WAF CAPTCHA script gathers data about the client to ensure that the task is being completed by a human and to prevent replay attacks.

**How the CAPTCHA and Challenge actions work**

AWS WAF CAPTCHA and Challenge are standard rule actions, so they're relatively easy to implement. To use either of them, you create the inspection criteria for your rule that identifies the requests that you
want to inspect, and then specify one of the two rule actions. For general information about rule action options, see AWS WAF rule action (p. 84).

Topics
- CAPTCHA and Challenge action behavior (p. 189)
- CAPTCHA and Challenge actions in the logs and metrics (p. 190)

CAPTCHA and Challenge action behavior

When a web request matches the inspection criteria of a rule with CAPTCHA or Challenge action, AWS WAF determines how to handle the request according to the state of its token and immunity time configuration. AWS WAF also considers whether the request can handle the CAPTCHA puzzle or challenge script interstitials. The scripts are designed to be handled as HTML content, and they can only be handled properly by a client that's expecting HTML content.

Note
You are charged additional fees when you use the CAPTCHA or Challenge rule action in one of your rules or as a rule action override in a rule group. For more information, see AWS WAF Pricing.

How the action handles the web request

AWS WAF applies the CAPTCHA or Challenge action to a web request as follows:

- **Valid token** – AWS WAF handles this similar to a Count action. AWS WAF applies any labels and request customizations that you've configured for the rule action, and then continues evaluating the request using the remaining rules in the web ACL.
- **Missing, invalid, or expired token** – AWS WAF discontinues the web ACL evaluation of the request and blocks it from going to its intended destination.

AWS WAF generates a response that it sends back to the client, according to the rule action type:

- **Challenge** – AWS WAF includes the following in the response:
  - The header x-amzn-waf-action with a value of challenge.
  - The HTTP status code 202 Request Accepted.
  - If the request contains an Accept header with a value of text/html, the response includes a JavaScript page interstitial with a challenge script.
- **CAPTCHA** – AWS WAF includes the following in the response:
  - The header x-amzn-waf-action with a value of captcha.
  - The HTTP status code 405 Method Not Allowed.
  - If the request contains an Accept header with a value of text/html, the response includes a JavaScript page interstitial with a CAPTCHA script.

What the interstitial does

When a challenge interstitial runs, after the client responds successfully, if it doesn't already have a token, the interstitial initializes one for it. Then it updates the token with the challenge solve timestamp.

When a CAPTCHA interstitial runs, if the client doesn't have a token yet, the CAPTCHA interstitial invokes the challenge script first to challenge the browser and initialize the token. Then the interstitial runs its CAPTCHA puzzle. When the end user successfully completes the puzzle, the interstitial updates the token with the CAPTCHA solve timestamp.

In either case, after the client responds successfully and the script updates the token, the script resubmits the original web request using the updated token.
You can configure how AWS WAF handles token domains and token timestamp expiration. For information see AWS WAF tokens (p. 144).

**CAPTCHA and Challenge actions in the logs and metrics**

The CAPTCHA and Challenge actions can be non-terminating, like Count, or terminating, like Block. The outcome depends on whether the request has a valid token with an unexpired timestamp for the action type.

- **Valid token** – When the action finds a valid token and doesn't block the request, AWS WAF captures metrics and logs as follows:
  - Increments the metrics for either CaptchaRequests and RequestsWithValidCaptchaToken or ChallengeRequests and RequestsWithValidChallengeToken.
  - Logs the match as a nonTerminatingMatchingRules entry with action of CAPTCHA or Challenge. The following listing shows the section of a log for this type of match with the CAPTCHA action.

```
"nonTerminatingMatchingRules": [
  {
    "ruleId": "captcha-rule",
    "action": "CAPTCHA",
    "ruleMatchDetails": [],
    "captchaResponse": {
      "responseCode": 0,
      "solveTimestamp": 1632420429
    }
  }
]
```

- **Missing, invalid, or expired token** – When the action blocks the request due to a missing or invalid token, AWS WAF captures metrics and logs as follows:
  - Increments the metric for CaptchaRequests or ChallengeRequests.
  - Logs the match as a CaptchaResponse entry with HTTP 405 status code or as a ChallengeResponse entry with HTTP 202 status code. The log indicates whether the request was missing the token or had an expired timestamp. The log also indicates whether AWS WAF sent a CAPTCHA interstitial page to the client or a silent challenge to the client browser. The following listing shows the sections of a log for this type of match with the CAPTCHA action.

```
"terminatingRuleId": "captcha-rule",
"terminatingRuleType": "REGULAR",
"action": "CAPTCHA",
"terminatingRuleMatchDetails": [],
...```

```
"responseCodeSent": 405,
...
"captchaResponse": {
  "responseCode": 405,
  "solveTimestamp": 0,
  "FailureReason": "TOKEN_MISSING"
}
```

For information about the AWS WAF logs, see Logging web ACL traffic (p. 192).

For information about AWS WAF metrics, see AWS WAF metrics and dimensions (p. 542).

For information about rule action options, see AWS WAF rule action (p. 84).
Best practices for using the CAPTCHA and Challenge actions

Follow the guidance in this section to plan and implement AWS WAF CAPTCHA or challenge.

Plan your CAPTCHA and challenge implementation

Determine where to place CAPTCHA puzzles or silent challenges based on your website usage, the sensitivity of the data that you want to protect, and the type of requests. Select the requests where you’ll apply CAPTCHA so that you present the puzzles as needed, but avoid presenting them where they wouldn’t be useful and might degrade the user experience. Use the Challenge action to run silent challenges that have less impact on the end user, but still help verify that the request is coming from a JavaScript enabled browser.

Identify requests that you don’t want to have impacted by CAPTCHA, for example, requests for CSS or images. Avoid using CAPTCHA unnecessarily. For example, if you plan to have a CAPTCHA check at login, and the user is always taken directly from the login to another screen, requiring a CAPTCHA check at the second screen would probably not be needed and might degrade your end user experience.

Use the Challenge action only on GET text/html requests. Do not use it for POST or other request types, because browser behavior for other requests can vary and might not be able to handle the interstitial challenge properly.

It's possible for a client to accept HTML but still not be able to handle the CAPTCHA or challenge interstitial. For example, a widget on a webpage with a small iFrame might accept HTML but not be able to display a CAPTCHA or process it. Avoid placing the rule actions for these types of requests, the same as for requests that don't accept HTML.

How to protect your sensitive non-HTML data with CAPTCHA and Challenge

You can use CAPTCHA and Challenge protections for sensitive non-HTML data, like APIs, with the following approach.

1. Identify requests that take HTML responses and that are run in close proximity to the requests for your sensitive, non-HTML data.
2. Write CAPTCHA or Challenge rules that match against the requests for HTML and that match against the requests for your sensitive data.
3. Tune your CAPTCHA and Challenge immunity time settings so that, for normal user interactions, the tokens that clients obtain from the HTML requests are available and unexpired in their requests for your sensitive data.

When a request for your sensitive data matches a CAPTCHA or Challenge rule, it won’t be blocked if the client still has a valid token from the prior puzzle or challenge. If the token isn’t available or the timestamp is expired, the request to access your sensitive data will fail. For more information about how the rule actions work, see CAPTCHA and Challenge action behavior (p. 189).

Use CAPTCHA and Challenge to tune your existing rules

Review your existing rules, to see if you want to alter or add to them. The following are some common scenarios to consider.

- If you have a rate-based rule that blocks traffic, but you keep the rate limit relatively high to avoid blocking legitimate users, consider adding a second rate-based rule, before the blocking rule, that has a lower limit and CAPTCHA or Challenge action. The blocking rule will still block any IP from sending requests at too high a rate, and the new rule will block most automated traffic at an even lower rate. For information about rate-based rules, see Rate-based rule statement (p. 100).
- If you have a managed rule group that blocks requests, you can switch the behavior for some or all of the rules from Block to CAPTCHA or Challenge. To do this, in the managed rule group configuration,
Logging web ACL traffic

You can enable logging to get detailed information about traffic that is analyzed by your web ACL. Logged information includes the time that AWS WAF received a web request from your AWS resource, detailed information about the request, and details about the rules that the request matched. You can send your logs to an Amazon CloudWatch Logs log group, an Amazon Simple Storage Service (Amazon S3) bucket, or an Amazon Kinesis Data Firehose.

Pricing for logging web ACL traffic information

You are charged for logging web ACL traffic information according to the costs associated with each log destination type. These charges are in addition to the charges for using AWS WAF. Your costs can vary depending on factors such as the destination type that you choose and the amount of data that you log.

The following provides links to the pricing information for each logging destination type:

- **CloudWatch Logs** – The charges are for vended log delivery. See [Amazon CloudWatch Logs Pricing](https://aws.amazon.com/cloudwatch/pricing/). Under **Paid Tier**, choose the **Logs** tab, and then under **Vended Logs**, see the information for **Delivery to CloudWatch Logs**.
- **Amazon S3 buckets** – The Amazon S3 charges are the combined charges for CloudWatch Logs vended log delivery to the Amazon S3 buckets and for using Amazon S3.
  - For Amazon S3, see [Amazon S3 Pricing](https://aws.amazon.com/s3/pricing/).
  - For CloudWatch Logs vended log delivery to the Amazon S3, see [Amazon CloudWatch Logs Pricing](https://aws.amazon.com/cloudwatch/pricing/). Under **Paid Tier**, choose the **Logs** tab, and then under **Vended Logs**, see the information for **Delivery to S3**.
- **Kinesis Data Firehose** – See [Amazon Kinesis Data Firehose Pricing](https://aws.amazon.com/kinesis/pricing/).

For information about AWS WAF pricing, see [AWS WAF Pricing](https://aws.amazon.com/waf/pricing/).

AWS WAF logging destinations

This section describes the logging destinations that you can choose from for your AWS WAF logs. Each section provides guidance for configuring logging for the destination type and information about any...
behavior that's specific to the destination type. After you've configured your logging destination, you can provide its specifications to your web ACL logging configuration to start logging to it.

**Topics**
- Amazon CloudWatch Logs (p. 193)
- Amazon Simple Storage Service (p. 194)
- Amazon Kinesis Data Firehose (p. 199)

**Amazon CloudWatch Logs**

This topic provides information for sending your web ACL traffic logs to a CloudWatch Logs log group.

**Note**
You are charged for logging in addition to the charges for using AWS WAF. For information, see Pricing for logging web ACL traffic information (p. 192).

To send logs to Amazon CloudWatch Logs, you create a CloudWatch Logs log group. When you enable logging in AWS WAF, you provide the log group ARN. After you enable logging for your web ACL, AWS WAF delivers logs to the CloudWatch Logs log group in log streams.

When you use CloudWatch Logs, you can explore the logs for your web ACL in the AWS WAF console. In your web ACL page, select the tab **Logging insights**. This option is in addition to the logging insights that are provided for CloudWatch Logs through the CloudWatch console.

Configure the log group for AWS WAF web ACL logs in the same Region as the web ACL and using the same account as you use to manage the web ACL. For information about configuring a CloudWatch Logs log group, see Working with Log Groups and Log Streams.

**Quotas for log groups**

The following default maximum quotas apply to the space and throughput allowances for CloudWatch Logs log groups. If your logging requirements are too high for these settings, you'll see throttling metrics for PutLogEvent for your account. If you see indications of throttling, you can request limit increases from both AWS WAF and CloudWatch Logs through the Service Quotas console at Service Quotas.

- **Number of log streams per web ACL** – 35. You can request an increase for this from AWS WAF.
- **Throughput per log stream** – 5 MB per second. This setting is fixed.
- **Throughput for all log streams for an account** – 1,500 MB per second. You can request an increase for this from CloudWatch Logs.

**Log group naming**

Your log group names must start with `aws-waf-logs-` and can end with any suffix you like, for example, `aws-waf-logs-testLogGroup2`.

The resulting ARN format is as follows:

```
```

The log streams have the following naming format:

```
Region_web-acl-name_log-stream-number
```
The log stream number is a positive integer that's less than or equal to the AWS WAF quota for the number of log streams per web ACL, as described earlier. The quota is 35 by default.

The following shows an example log stream for web ACL TestWebACL in Region us-east-1.

| us-east-1_TestWebACL_19 |

Permissions to publish logs to CloudWatch Logs

Configuring web ACL traffic logging for a CloudWatch Logs log group requires the permissions settings described in this section. The permissions are set for you when you use one of the AWS WAF full access managed policies, AWSWAFConsoleFullAccess or AWSWAFFullAccess. If you want to manage finer-grained access to your logging and AWS WAF resources, you can set the permissions yourself. For information about managing permissions, see Access management for AWS resources in the IAM User Guide. For information about the AWS WAF managed policies, see AWS managed policies for AWS WAF (p. 233).

These permissions allow you to change the web ACL logging configuration, to configure log delivery for CloudWatch Logs, and to retrieve information about your log group. These permissions must be attached to the user that you use to manage AWS WAF.

      "Action": [
        "logs:CreateLogDelivery",
        "logs:DeleteLogDelivery",
        "logs:PutResourcePolicy",
        "logs:DescribeResourcePolicies",
        "logs:DescribeLogGroups"
      ],
      "Resource": [
        "*"
      ],
      "Effect":"Allow"
    }
  ]
}
```

When actions are permitted on all AWS resources, it's indicated in the policy with a "Resource" setting of "*". This means that the actions are permitted on all AWS resources that each action supports. For example, the action wafv2:PutLoggingConfiguration is supported only for wafv2 logging configuration resources.

Amazon Simple Storage Service

This topic provides information for sending your web ACL traffic logs to an Amazon S3 bucket.
Note
You are charged for logging in addition to the charges for using AWS WAF. For information, see Pricing for logging web ACL traffic information (p. 192).

To send your web ACL traffic logs to Amazon S3, you need to set up an Amazon S3 bucket for the logs. When you enable logging in AWS WAF, you provide the bucket ARN. For information about creating your logging bucket, see Create a Bucket in the Amazon Simple Storage Service User Guide.

Note
AWS WAF supports encryption with Amazon S3 buckets for key type Amazon S3 key (SSE-S3) and for AWS Key Management Service (SSE-KMS) AWS KMS keys. AWS WAF doesn't support encryption for AWS Key Management Service keys that are managed by AWS.

Your web ACLs publish their log files to the Amazon S3 bucket at 5-minute intervals. Each log file contains log records for the traffic recorded in the previous 5 minutes.

The maximum file size for a log file is 75 MB. If the log file reaches the file size limit within the 5-minute period, the log stops adding records to it, publishes it to the Amazon S3 bucket, and then creates a new log file.

A single log file contains interleaved entries with multiple records. To see all the log files for a web ACL, look for entries aggregated by the web ACL name, Region, and your account ID.

Naming requirements and syntax
Your bucket names for AWS WAF logging must start with aws-waf-logs- and can end with any suffix you want. For example, aws-waf-logs-DOC-EXAMPLE-BUCKET-SUFFIX.

The bucket locations use the following syntax:
s3://aws-waf-logs-DOC-EXAMPLE-BUCKET-SUFFIX/

The format of the bucket Amazon Resource Name (ARN) is as follows:
arn:aws:s3:::aws-waf-logs-DOC-EXAMPLE-BUCKET-SUFFIX

Inside your buckets, your AWS WAF logs are written under a folder structure that's determined by your account ID, the Region, the web ACL name, and the date and time.

AWSLogs/account-id/WAFLogs/Region/web-acl-name/YYYY/MM/dd/HH/mm

Inside the folders, the log file names follow a similar format:
account-id_waflogs_Region_web-acl-name_timestamp_hash.log.gz

The time specifications used in the folder structure and in the log file name adhere to the timestamp format specification YYYYMMddTHHmmZ.

The following shows an example log file in an Amazon S3 bucket for a bucket named DOC-EXAMPLE-BUCKET. The AWS account is 11111111111. The web ACL is TEST-WEBAACL and the Region is us-east-1.

s3://DOC-EXAMPLE-BUCKET/AWSLogs/11111111111/WAFLogs/us-east-1/TEST-WEBAACL/2021/10/28/19/50/11111111111_waflogs-us-east-1_TEST-WEBAACL_20211028T1950Z_e0ca43b5.log.gz
Note
Your bucket names for AWS WAF logging must start with `aws-waf-logs-` and can end with any suffix you want.

Permissions to publish logs to Amazon S3

Configuring web ACL traffic logging for an Amazon S3 bucket requires the following permissions settings. These permissions are set for you when you use one of the AWS WAF full access managed policies, `AWSWAFConsoleFullAccess` or `AWSWAFFullAccess`. If you want to manage finer-grained access to your logging and AWS WAF resources, you can set these permissions yourself. For information about managing permissions, see Access management for AWS resources in the IAM User Guide. For information about the AWS WAF managed policies, see AWS managed policies for AWS WAF (p. 233).

The following permissions allow you to change the web ACL logging configuration and to configure log delivery to your Amazon S3 bucket. These permissions must be attached to the user that you use to manage AWS WAF.

Note
When you set the permissions listed below, you might see errors in your AWS CloudTrail logs that indicate access denied, but the permissions are correct for AWS WAF logging.

```json
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Action": [
            "wafv2:PutLoggingConfiguration",
            "wafv2:DeleteLoggingConfiguration"
         ],
         "Resource": [
            "*"
         ],
         "Effect": "Allow",
         "Sid": "LoggingConfigurationAPI"
      },
      {
         "Sid": "WebACLLogDelivery",
         "Action": [
            "logs:CreateLogDelivery",
            "logs:DeleteLogDelivery"
         ],
         "Resource": "*",
         "Effect": "Allow"
      },
      {
         "Sid": "WebACLLoggingS3",
         "Action": [
            "s3:PutBucketPolicy",
            "s3:GetBucketPolicy"
         ],
         "Resource": [
            "arn:aws:s3:::aws-waf-logs-example-bucket"
         ],
         "Effect": "Allow"
      }
   ]
}
```
When actions are permitted on all AWS resources, it's indicated in the policy with a "Resource" setting of "*". This means that the actions are permitted on all AWS resources that each action supports. For example, the action wafv2:PutLoggingConfiguration is supported only for wafv2 logging configuration resources.

By default, Amazon S3 buckets and the objects that they contain are private. Only the bucket owner can access the bucket and the objects stored in it. The bucket owner, however, can grant access to other resources and users by writing an access policy.

If the user creating the log owns the bucket, the service automatically attaches the following policy to the bucket to give the log permission to publish logs to it:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AWSLogDeliveryWrite",
      "Effect": "Allow",
      "Principal": {
        "Service": "delivery.logs.amazonaws.com"
      },
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::aws-waf-logs-example-bucket/AWSLogs/account-id/**",
      "Condition": {
        "StringEquals": {
          "s3:x-amz-acl": "bucket-owner-full-control",
          "aws:SourceAccount": ["account-id"]
        },
        "ArnLike": {
          "aws:SourceArn": ["arn:aws:logs:region:account-id:**"]
        }
      }
    },
    {
      "Sid": "AWSLogDeliveryAclCheck",
      "Effect": "Allow",
      "Principal": {
        "Service": "delivery.logs.amazonaws.com"
      },
      "Action": "s3:GetBucketAcl",
      "Resource": "arn:aws:s3:::aws-waf-logs-example-bucket",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": ["account-id"]
        },
        "ArnLike": {
          "aws:SourceArn": ["arn:aws:logs:region:account-id:**"]
        }
      }
    }
  ]
}
```

**Note**
Your bucket names for AWS WAF logging must start with `aws-waf-logs-` and can end with any suffix you want.

If the user creating the log doesn't own the bucket, or doesn't have the GetBucketPolicy and PutBucketPolicy permissions for the bucket, the log creation fails. In this case, the bucket owner
must manually add the preceding policy to the bucket and specify the log creator's AWS account ID. For more information, see How Do I Add an S3 Bucket Policy? in the Amazon Simple Storage Service User Guide. If the bucket receives logs from multiple accounts, add a Resource element entry to the AWSLogDeliveryWrite policy statement for each account.

For example, the following bucket policy allows AWS account 111122223333 to publish logs to a bucket named aws-waf-logs-doc-example:

```json
{
    "Version": "2012-10-17",
    "Id": "AWSLogDeliveryWrite20150319",
    "Statement": [
        {
            "Sid": "AWSLogDeliveryWrite",
            "Effect": "Allow",
            "Principal": {
                "Service": "delivery.logs.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::aws-waf-logs-example-bucket/AWSLogs/111122223333/*",
            "Condition": {
                "StringEquals": {
                    "s3:x-amz-acl": "bucket-owner-full-control",
                    "aws:SourceAccount": ["111122223333"]
                },
                "ArnLike": {
                    "aws:SourceArn": ["arn:aws:logs:us-east-1:111122223333:*"]
                }
            }
        },
        {
            "Sid": "AWSLogDeliveryAclCheck",
            "Effect": "Allow",
            "Principal": {
                "Service": "delivery.logs.amazonaws.com"
            },
            "Action": "s3:GetBucketAcl",
            "Resource": "arn:aws:s3:::aws-waf-logs-example-bucket",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": ["111122223333"]
                },
                "ArnLike": {
                    "aws:SourceArn": ["arn:aws:logs:us-east-1:111122223333:*"]
                }
            }
        }
    ]
}
```

**Amazon S3 log file access**

In addition to the required bucket policies, Amazon S3 uses access control lists (ACLs) to manage access to the log files created by an AWS WAF log. By default, the bucket owner has FULL_CONTROL permissions on each log file. The log delivery owner, if different from the bucket owner, has no permissions. The log delivery account has READ and WRITE permissions. For more information, see Access Control List (ACL) Overview in the Amazon Simple Storage Service User Guide.

The log files are compressed. If you open the files using the Amazon S3 console, Amazon S3 decompresses the log records and displays them. If you download the log files, you must decompress them to view the records.
Amazon Kinesis Data Firehose

This section provides information for sending your web ACL traffic logs to an Amazon Kinesis Data Firehose.

**Note**
You are charged for logging in addition to the charges for using AWS WAF. For information, see Pricing for logging web ACL traffic information (p. 192).

To send logs to Amazon Kinesis Data Firehose, you send logs from your web ACL to an Amazon Kinesis Data Firehose with a configured storage destination. After you enable logging, AWS WAF delivers logs to your storage destination through the HTTPS endpoint of Kinesis Data Firehose.

For information about how to create an Amazon Kinesis Data Firehose and review your stored logs, see What Is Amazon Kinesis Data Firehose? To understand the permissions required for your Kinesis Data Firehose configuration, see Controlling Access with Amazon Kinesis Data Firehose.

You must have the following permissions to successfully enable logging with an Amazon Kinesis Data Firehose

- iam:CreateServiceLinkedRole
- firehose:ListDeliveryStreams
- wafv2:PutLoggingConfiguration

For information about service-linked roles and the iam:CreateServiceLinkedRole permission, see Using service-linked roles for AWS WAF (p. 239).

For more information about creating your delivery stream, see Creating an Amazon Kinesis Data Firehose Delivery Stream.

Configure an Amazon Kinesis Data Firehose delivery stream for your web ACL as follows.

- Create it using the same account as you use to manage the web ACL.
- Create it in the same Region as the web ACL. If you are capturing logs for Amazon CloudFront, create the firehose in US East (N. Virginia) Region, us-east-1.
- Give the data firehose a name that starts with the prefix aws-waf-logs-. For example, aws-waf-logs-us-east-2-analytcs.
- Configure it for direct put, which allows applications to access the delivery stream directly. In the Amazon Kinesis Data Firehose console, for the delivery stream Source setting, choose Direct PUT or other sources. Through the API, set the delivery stream property DeliveryStreamType to DirectPut.

**Note**
Do not use a Kinesis stream as your source.

One AWS WAF log is equivalent to one Kinesis Data Firehose record. If you typically receive 10,000 requests per second and you enable full logs, you should have a 10,000 records per second setting in Kinesis Data Firehose. If you don't configure Kinesis Data Firehose correctly, AWS WAF won't record all logs. For more information, see Amazon Kinesis Data Firehose Quotas.

Managing logging for a web ACL

You can enable and disable logging for a web ACL at any time.

**Note**
You are charged for logging in addition to the charges for using AWS WAF. For information, see Pricing for logging web ACL traffic information (p. 192).
In the logging configuration for your web ACL, you can customize what AWS WAF sends to the logs.

- **Field redaction** – You can redact some fields from the log records. Redacted fields appear as XXX in the logs. For example, if you redact the URI field, the URI field in the logs will be XXX. For a list of the log fields, see Log Fields (p. 200).

- **Log filtering** – You can add filtering to specify which web requests are kept in the logs and which are dropped. You filter on the settings that AWS WAF applies during the web request evaluation. You can filter on the following settings:
  - **Rule action** – For information about rule action settings, see AWS WAF rule action (p. 84).
  - **Fully qualified label** – Fully qualified labels have a prefix, optional namespaces, and label name. The prefix identifies the rule group or web ACL context of the rule that added the label. For information about labels, see Labels on web requests (p. 131).

### To enable logging for a web ACL

This procedure requires a configured logging destination. For information about your destination choices and the requirements for each, see AWS WAF logging destinations (p. 192).

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Web ACLs.
3. Choose the name of the web ACL that you want to enable logging for. The console takes you to the web ACL's description, where you can edit it.
4. On the Logging tab, choose Enable logging.
5. Choose the logging destination type, and then choose the logging destination that you configured. You must choose a logging destination whose name begins with aws-waf-logs-.
6. (Optional) If you don't want certain fields and their values included in the logs, redact those fields. Choose the field to redact, and then choose Add. Repeat as necessary to redact additional fields. The redacted fields appear as XXX in the logs. For example, if you redact the URI field, the URI field in the logs will be XXX.
7. (Optional) If you don't want to send all requests to the logs, add your filtering criteria and behavior. Under Filter logs, for each filter that you want to apply, choose Add filter, then choose your filtering criteria and specify whether you want to keep or drop requests that match the criteria. When you finish adding filters, if needed, modify the Default logging behavior.
8. Choose Enable logging.

**Note**

When you successfully enable logging, AWS WAF will create a service linked role with the necessary permissions to write logs to the logging destination. For more information, see Using service-linked roles for AWS WAF (p. 239).

### To disable logging for a web ACL

1. In the navigation pane, choose Web ACLs.
2. Choose the name of the web ACL that you want to disable logging for. The console takes you to the web ACL's description, where you can edit it.
3. On the Logging tab, choose Disable logging.
4. In the dialog box, choose Disable logging.

### Log Fields

The following list describes the possible log fields.
action

The action that was applied to the request. Allow and Block are terminating rule actions. Count is a non-terminating rule action. CAPTCHA and Challenge are non-terminating if the request includes a valid token and terminating if it doesn’t.

args

The query string.

captchaResponse

The CAPTCHA response to the request, populated when the CAPTCHA action results in the termination of web request inspection. The CAPTCHA action terminates web request inspection when the request either doesn't include a token or the token is invalid or expired. This field includes a response code and a failure reason.

challengeResponse

The challenge response to the request, populated when the Challenge action results in the termination of web request inspection. The Challenge action terminates web request inspection when the request either doesn't include a token or the token is invalid or expired. This field includes a response code and a failure reason.

clientIp

The IP address of the client sending the request.

country

The source country of the request. If AWS WAF is unable to determine the country of origin, it sets this field to -.

excludedRules

Used only for rule group rules. The list of rules in the rule group that you have excluded. The action for these rules is set to Count.

If you override a rule to count using the override rule action option, matches aren't listed here. They're listed as the action pairs action and overriddenAction.

exclusionType

A type that indicates that the excluded rule has the action Count.

ruleId

The ID of the rule within the rule group that is excluded.

formatVersion

The format version for the log.

headers

The list of headers.

httpMethod

The HTTP method in the request.

httpRequest

The metadata about the request.

httpSourceId

The source ID. This field shows the ID of the associated resource.
Log Fields

httpSourceName

The source of the request. Possible values: CF for Amazon CloudFront, APIGW for Amazon API Gateway, ALB for Application Load Balancer, and APPSYNC for AWS AppSync.

httpVersion

The HTTP version.

labels

The labels on the web request. These labels were applied by rules that were used to evaluate the request. AWS WAF logs the first 100 labels.

limitKey

Indicates the IP address source that AWS WAF should use to aggregate requests for rate limiting by a rate-based rule. Possible values are IP, for web request origin, and FORWARDED_IP, for an IP forwarded in a header in the request.

limitValue

The IP address used by a rate-based rule to aggregate requests for rate limiting. If a request contains an IP address that isn't valid, the limitValue is INVALID.

maxRateAllowed

The maximum number of requests, which have an identical value in the field that is specified by limitKey, allowed in a five minute period. If the number of requests exceeds the maxRateAllowed and the other predicates specified in the rule are also met, AWS WAF triggers the action that is specified for this rule.

nonTerminatingMatchingRules

The list of non-terminating rules that match the request.

action

The action that AWS WAF applied to the request. This indicates either count, CAPTCHA, or challenge. The CAPTCHA and Challenge are non-terminating when the web request contains a valid token.

 overriddenAction

Used only for rule group rules that have a rule action override in place in the web ACL. This is the action that the rule group rule is configured for, and not the action that was applied to the request. The action that AWS WAF applied is the action value.

ruleId

The ID of the rule that matched the request and was non-terminating.

ruleMatchDetails

Detailed information about the rule that matched the request. This field is only populated for SQL injection and cross-site scripting (XSS) match rule statements. A matching rule might require a match for more than one inspection criteria, so these match details are provided as an array of match criteria.

oversizeFields

The list of fields in the web request that were inspected by the web ACL and that are over the AWS WAF inspection limit. If a field is oversize but the web ACL doesn't inspect it, it won't be listed here.

This list can contain zero or more of the following values: REQUEST_BODY, REQUEST_JSON_BODY, REQUEST_HEADERS, and REQUEST_COOKIES. For more information about oversize fields, see Inspection of the request body, headers, and cookies (p. 120).
rateBasedRuleId

The ID of the rate-based rule that acted on the request. If this has terminated the request, the ID for rateBasedRuleId is the same as the ID for terminatingRuleId.

rateBasedRuleList

The list of rate-based rules that acted on the request.

rateBasedRuleName

The name of the rate-based rule that acted on the request.

requestHeadersInserted

The list of headers inserted for custom request handling.

requestId

The ID of the request, which is generated by the underlying host service. For Application Load Balancer, this is the trace ID. For all others, this is the request ID.

responseCodeSent

The response code sent with a custom response.

ruleGroupId

The ID of the rule group. If the rule blocked the request, the ID for ruleGroupID is the same as the ID for terminatingRuleId.

ruleGroupList

The list of rule groups that acted on this request, with match information.

terminatingRule

The rule that terminated the request. If this is a non-null value, it contains the following additional fields.

action

The action that AWS WAF applied to the request. This indicates either allow, block, CAPTCHA, or challenge. The CAPTCHA and Challenge actions are terminating when the web request doesn't contain a valid token.

overriddenAction

Used only for rule group rules that have a rule action override in place in the web ACL. This is the action that the rule group rule is configured for, and not the action that was applied to the request. The action that AWS WAF applied is the action value.

ruleId

The ID of the rule that matched the request.

ruleMatchDetails

Detailed information about the rule that matched the request. This field is only populated for SQL injection and cross-site scripting (XSS) match rule statements. A matching rule might require a match for more than one inspection criteria, so these match details are provided as an array of match criteria.

terminatingRuleId

The ID of the rule that terminated the request. If nothing terminates the request, the value is Default_Action.
terminatingRuleMatchDetails

Detailed information about the terminating rule that matched the request. A terminating rule has an action that ends the inspection process against a web request. Possible actions for a terminating rule include Allow, Block, CAPTCHA, and Challenge. During the inspection of a web request, at the first rule that matches the request and that has a terminating action, AWS WAF stops the inspection and applies the action. The web request might contain other threats, in addition to the one that’s reported in the log for the matching terminating rule.

This is only populated for SQL injection and cross-site scripting (XSS) match rule statements. The matching rule might require a match for more than one inspection criteria, so these match details are provided as an array of match criteria.

terminatingRuleType

The type of rule that terminated the request. Possible values: RATE_BASED, REGULAR, GROUP, and MANAGED_RULE_GROUP.

timestamp

The timestamp in milliseconds.

uri

The URI of the request.

webaclId

The GUID of the web ACL.

Log Examples

Example Log output for a rule that triggered on SQLi detection (terminating)

```json
{
    "timestamp": 1576280412771,
    "formatVersion": 1,
    "terminatingRuleId": "STMTest_SQLi_XSS",
    "terminatingRuleType": "REGULAR",
    "action": "BLOCK",
    "terminatingRuleMatchDetails": [
        {
            "conditionType": "SQL_INJECTION",
            "sensitivityLevel": "HIGH",
            "location": "HEADER",
            "matchedData": [
                "10",
                "AND",
                "1"
            ]
        }
    ],
    "httpSourceName": "-",
    "httpSourceId": "-",
    "ruleGroupList": [],

Example Log output for a CAPTCHA rule against a web request with a valid, unexpired CAPTCHA token

The following log listing is for a web request that matched a rule with CAPTCHA action. The web request has a valid and unexpired CAPTCHA token, and is only noted as a CAPTCHA match by AWS WAF, similar to the behavior for the Count action. This CAPTCHA match is noted under nonTerminatingMatchingRules.

```json

Listing IP addresses blocked by rate-based rules

You can access the list of IP addresses that are currently blocked by a rate-based rule by using the CLI, the API, or any of the SDKs. This topic covers access using the CLI and APIs. The console doesn’t provide this functionality at this time.

For the AWS WAF API, the command is `GetRateBasedStatementManagedKeys`.

For the AWS WAF CLI, the command is `get-rate-based-statement-managed-keys`.

The maximum number of IP addresses that can be blocked for a single rate-based rule instance is 10,000. If more than 10,000 addresses exceed the rate limit, AWS WAF blocks those with the highest rates.

The following shows the syntax for retrieving the list of blocked IP addresses for a rate-based rule that's being used in a web ACL on an Amazon CloudFront distribution.

```
aws wafv2 get-rate-based-statement-managed-keys --scope=CLOUDFRONT --region=us-east-1 --web-acl-name=WebACLName --web-acl-id=WebACLId --rule-name=RuleName
```

The following shows the syntax for a regional application, an Amazon API Gateway REST API, an Application Load Balancer, an AWS AppSync GraphQL API, or an Amazon Cognito user pool.

```
aws wafv2 get-rate-based-statement-managed-keys --scope=REGIONAL --region=region --web-acl-name=WebACLName --web-acl-id=WebACLId --rule-name=RuleName
```

AWS WAF monitors web requests and manages keys independently for each unique combination of web ACL, optional rule group, and rate-based rule. For example, if you define a rate-based rule inside a rule group, and then use the rule group in a web ACL, AWS WAF monitors web requests and manages keys for that web ACL, rule group reference statement, and rate-based rule instance. If you use the same rule group in a second web ACL, AWS WAF monitors web requests and manages keys for this second usage completely independent of your first.

For a rate-based rule that you've defined inside a rule group, you need to provide the name of the rule group reference statement in your request, in addition to the web ACL name and the name of the rate-based rule name inside the rule group. The following shows the syntax for a regional application where the rate-based rule is defined inside a rule group, and the rule group is used in a web ACL.

```
aws wafv2 get-rate-based-statement-managed-keys --scope=REGIONAL --region=region --web-acl-name=WebACLName --web-acl-id=WebACLId --rule-group-rule-name=RuleGroupRuleName --rule-name=RuleName
```

Testing and tuning your AWS WAF protections

We recommend that you test and tune any changes to your AWS WAF web ACL before applying them to your website or web application traffic.

**Production traffic risk**

Before you deploy your web ACL implementation for production traffic, test and tune it in a staging or testing environment until you are comfortable with the potential impact to your traffic. Then test and tune the rules in count mode with your production traffic before enabling them.

This section provides guidance for testing and tuning your AWS WAF web ACLs, rules, rule groups, IP sets, and regex pattern sets.

This section also provides general guidance for testing your use of rule groups that are managed by someone else. These include AWS Managed Rules rule groups, AWS Marketplace managed rule groups,
and rule groups that are shared with you by another account. For these rule groups, also follow any
guidance that you get from the rule group provider.

- For the Bot Control AWS Managed Rules rule group, also see Testing and deploying AWS WAF Bot
  Control (p. 154).
- For the account takeover prevention AWS Managed Rules rule group, also see Testing and deploying
  ATP (p. 169).

Temporary inconsistencies during updates

When you create or change a web ACL or other AWS WAF resources, the changes take a small amount of
time to propagate to all areas where the resources are stored. The propagation time can be from a few
seconds to a number of minutes.

The following are examples of the temporary inconsistencies that you might notice during change
propagation:

- After you create a web ACL, if you try to associate it with a resource, you might get an exception
  indicating that the web ACL is unavailable.
- After you add a rule group to a web ACL, the new rule group rules might be in effect in one area where
  the web ACL is used and not in another.
- After you change a rule action setting, you might see the old action in some places and the new action
  in others.
- After you add an IP address to an IP set that is in use in a blocking rule, the new address might be
  blocked in one area while still allowed in another.

Testing and tuning high-level steps

This section provides a checklist of the steps for testing changes to your web ACL, including any rules or
rule groups that it uses.

Note
To follow the guidance in this section, you need to understand how to create and manage AWS
WAF protections like web ACLs, rules, and rule groups. That information is covered in earlier
sections of this guide.

To test and tune your web ACL

Perform these steps first in a test environment, then in production.

1. Prepare for testing

Prepare your monitoring environment, switch your AWS WAF protections to count mode for testing,
and create any resource associations that you need.

See Preparing for testing (p. 214).

2. Monitor and tune in test and production environments

Monitor and adjust your AWS WAF protections first in a test or staging environment, then in
production, until you're satisfied that they can handle traffic as you need them to.

See Monitoring and tuning (p. 215).

3. Enable your protections in production

When you're satisfied with your test protections, switch them to production mode, clean up any
unnecessary testing artifacts, and continue monitoring.
Preparing for testing

This section describes how to get set up to test and tune your AWS WAF protections.

Note
To follow the guidance in this section, you need to understand generally how to create and manage AWS WAF protections like web ACLs, rules, and rule groups. That information is covered in earlier sections of this guide.

To prepare for testing

1. Enable web ACL logging, Amazon CloudWatch metrics, and web request sampling for the web ACL

Use logging, metrics, and sampling to monitor the interaction of the web ACL rules with your web traffic.

• Logging – You can configure AWS WAF to log the web requests that a web ACL evaluates. You can send logs to CloudWatch logs, an Amazon S3 bucket, or an Amazon Kinesis Data Firehose. You can redact fields and apply filtering. For more information, see Logging web ACL traffic (p. 192).

• Amazon CloudWatch metrics – In your web ACL configuration, provide metric specifications for everything that you want to monitor. You can view metrics through the AWS WAF and CloudWatch consoles. For more information, see Monitoring with Amazon CloudWatch (p. 541).

• Web request sampling – You can view a sample of all web requests that your web ACL evaluates. For information about web request sampling, see Viewing a sample of web requests (p. 219).

2. Set your protections to Count mode

In your web ACL configuration, switch anything that you want to test to count mode. This causes the test protections to record matches against web requests without altering how the requests are handled. You'll be able to see the matches in your metrics, logs, and sampled requests, to verify the match criteria and to understand what the effects might be on your web traffic. Rules that add labels to matching requests will add labels regardless of the rule action.

• Rule defined in the web ACL – Edit the rules in the web ACL and set their actions to Count.

• Rule group – In your web ACL configuration, edit the rule statement for the rule group and, in the Rules pane, open the Override all rule actions dropdown and choose Count. If you manage the web ACL in JSON, add the rules to the RuleActionOverrides settings in the rule group reference statement, with ActionToUse set to Count. The following example listing shows overrides for two rules in the AWSManagedRulesAnonymousIpList AWS Managed Rules rule group.

```json
"ManagedRuleGroupStatement": {
 "VendorName": "AWS",
 "Name": "AWSManagedRulesAnonymousIpList",
 "RuleActionOverrides": [
 { "ActionToUse": { "Count": {} }, "Name": "AnonymousIpList" }
 ]
}
```

See Enabling your protections in production (p. 220).

After you've finished implementing your changes, continue monitoring your web traffic and protections in production to make sure that they're working as you want them to. Web traffic patterns can change over time, so you might need to adjust the protections occasionally.
Monitoring and tuning

This section describes how to monitor and tune your AWS WAF protections.

**Note**
To follow the guidance in this section, you need to understand generally how to create and manage AWS WAF protections like web ACLs, rules, and rule groups. That information is covered in earlier sections of this guide.

Monitor web traffic and rule matches to verify the behavior of the web ACL. If you find problems, adjust your rules to correct and then monitor to verify the adjustments.

Repeat the following procedure until the web ACL is managing your web traffic as you need it to.

**To monitor and tune**

1. **Monitor traffic and rule matches**

   Make sure that traffic is flowing and that your test rules are finding matching requests.
Look for the following information for the protections that you're testing:

- **Logs** – In the logs, the test rules that match a web request appear as follows:
  - Rules in the web ACL that have Count action are listed as `nonTerminatingMatchingRules`.
  - Rule groups are identified in the `ruleGroupId` field.
  - Rule group rules that you've set to Count through your web ACL configuration show up under the `ruleGroupList` in one of two ways, depending on how and when you configured the Count override:
    - For rule action override with Count chosen, the match is listed under `nonTerminatingMatchingRules`, the action is Count and the `overriddenAction` is the action that the rule is configured for in the rule group, which is usually Block. Rule action override is the most current, recommended option for overriding rule group rule actions, and it's the only option available through the console wizard.
    - For an excluded rule, the match is listed under `excludedRules`. This is an older option that's been superceded by the override option, and is no longer available through the console. Web ACLs that you configured through the console wizard prior to 2022-10-27 might still use it, and you can also still choose this option through the APIs.
  - Labels that rules have applied to the request are listed in the `Labels` field.

  For more information about logging contents, see Log Fields (p. 200).

- **Metrics** – Metrics for the test rules that match a web request appear as follows:
  - Rules in the web ACL that have Count action are listed as `Count` metrics for the web ACL.
  - For your rule groups, rules that you've set to Count through your web ACL configuration are listed under the rule group metrics.

  **Note**
  AWS WAF doesn't generate metrics for rules that are configured with Count action in the rule group configuration. It only generates metrics for rules that you override to Count through your web ACL configuration of the rule group reference statement.

  - For managed rule groups, rules that you've set to Count through your web ACL configuration are listed under the web ACL metrics. Only the rule group owner can see rule group metrics.

  For more information about metrics, see Viewing metrics for your web ACL (p. 218).

- **Sampled web requests** – Sampled requests provide information for the test rules that match the web request as follows:
  - The sample information identifies matching rules by the metric name for the rule in the web ACL. For rule groups, the metric identifies the rule group reference statement.
  - For rules inside rule groups, the sample lists the matching rule name in `RuleWithinRuleGroup`.

  For more about request samples, see Viewing a sample of web requests (p. 219).

2. **Configure mitigations to address false positives**

   If you determine that a rule is generating false positives, by matching web requests when it shouldn't, the following options can help you tune your web ACL protections to mitigate.

   **Correcting rule inspection criteria**

   For your own rules, you often just need to adjust the settings that you're using to inspect web requests. Examples include changing the specifications in a regex pattern set, adjusting the text transformations that you apply to a request component before inspection, or switching to using a forwarded IP address. See the guidance for the rule type that's causing problems, under AWS WAF rule statements (p. 85).
Correcting more complex problems

For inspection criteria that you don't control and for some complex rules, you might need to make other changes, like adding rules that explicitly allow or block requests or that eliminate requests from evaluation by the problematic rule. Managed rule groups most commonly need this type of mitigation, but other rules can too. Examples include the rate-based rule statement and the SQL injection attack rule statement.

What you do to mitigate false positives depends on your use case. The following are common approaches:

- **Add a mitigating rule** – Add a rule that runs before the new rule and that explicitly allows requests that are causing false positives. For information about rule evaluation order in a web ACL, see Processing order of rules and rule groups in a web ACL (p. 14).

  With this approach, the allowed requests are sent to the protected resource, so they never reach the new rule for evaluation. If the new rule is a paid managed rule group, this approach can also help contain the cost of using the rule group.

- **Add a logical rule with a mitigating rule** – Use logical rule statements to combine the new rule with a rule that excludes the false positives. Logical rule statements are listed under Rule statements list (p. 86).

  For example, say you're adding an SQL injection attack match statement that's generating false positives for a category of requests. Create a rule that matches those requests, and then combine the rules using logical rule statements so that you match only on requests that don't match the false positives criteria and do match the SQL injection attack criteria.

- **Add a scope-down statement** – For rate-based statements and managed rule group reference statements, exclude requests that result in false positives from evaluation by adding a scope-down statement inside the main statement.

  A request that doesn't match the scope-down statement never reaches the rule group or rate-based evaluation. For information about scope-down statements, see Scope-down statements (p. 117). For an example, see Exclude IP range from bot management (p. 164).

- **Add a label match rule** – For rule groups that use labeling, identify the label that the problematic rule is applying to requests. Add a label match rule, positioned to run after the rule group, that matches against the identified label. In the label match rule, you can filter the requests that you want to allow from those that you want to block.

  If you use this approach, when you're finished testing, keep the problematic rule in count mode in the rule group, and keep your custom label match rule in place. For information about label match statements, see Label match rule statement (p. 97). For examples, see Allow a specific blocked bot (p. 159) and ATP example: Custom handling for missing and compromised credentials (p. 173).

- **Change the version of a managed rule group** – For versioned managed rule groups, change the version that you're using. For example, you could switch back to the last static version that you were using successfully.

  This is usually a temporary fix. You might change the version for your production traffic while you continue testing the latest version in your test or staging environment, or while you wait for a more compatible version from the provider. For information about managed rule group versions, see Managed rule groups (p. 26).

When you're satisfied that the new rules are matching requests as you need them to, move to the next stage of your testing and repeat this procedure. Perform the final stage of testing and tuning in your production environment.
Viewing metrics for your web ACL

After you've associated a web ACL with one or more AWS resources, you can view the resulting metrics for the association in an Amazon CloudWatch graph.

For information about CloudWatch metrics, see the Amazon CloudWatch documentation. For a list of the metrics that AWS WAF provides, see AWS WAF metrics and dimensions (p. 542).

For each rule in a web ACL and for all the requests that an associated resource forwards to AWS WAF for a web ACL, CloudWatch lets you do the following:

- View data for the preceding hour or preceding three hours.
- Change the interval between data points.
- Change the calculation that CloudWatch performs on the data, such as maximum, minimum, average, or sum.

**Note**
AWS WAF with CloudFront is a global service and metrics are available only when you choose the US East (N. Virginia) Region in the AWS Management Console. If you choose another region, no AWS WAF metrics will appear in the CloudWatch console.

To view data for the rules in a web ACL

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to the one where your AWS resources are located. For CloudFront, choose the US East (N. Virginia) Region.
3. In the navigation pane, under Metrics, choose All metrics and then search under the Browse tab for AWS::WAFv2.
4. Select the check box for the web ACL that you want to view data for.
5. Change the applicable settings:

   **Statistic**
   - Choose the calculation that CloudWatch performs on the data.

   **Time range**
   - Choose whether you want to view data for the preceding hour or the preceding three hours.

   **Period**
   - Choose the interval between data points in the graph.

   **Rules**
   - Choose the rules for which you want to view data.

Note the following:

- If you recently associated a web ACL with an AWS resource, you might need to wait a few minutes for data to appear in the graph and for the metric for the web ACL to appear in the list of available metrics.
- If you associate more than one resource with a web ACL, the CloudWatch data will include requests for all of them.
- You can hover the cursor over a data point to get more information.
• The graph doesn’t refresh itself automatically. To update the display, choose the refresh 🔁 icon.

For more information about CloudWatch metrics, see Monitoring AWS WAF, AWS Firewall Manager, and AWS Shield Advanced (p. 539).

Viewing a sample of web requests

In the AWS WAF console, if you have request sampling enabled, you can view a sample of the requests that AWS WAF has inspected and either allowed or blocked. For each sampled request, you can view detailed data about the request, such as the originating IP address and the headers included in the request. You can also view the rules that matched the request, and the rule action settings.

The sample of requests contains up to 100 requests that matched the criteria for a rule in the web ACL and another 100 requests for requests that didn’t match any rules and had the web ACL default action applied. The requests in the sample come from all the protected resources that have received requests for your content in the previous three hours.

When a web request matches all the criteria in a rule and the action for that rule is Count, AWS WAF continues inspecting the web request using the subsequent rules in the web ACL. Because of this, a web request could appear multiple times in the list of sampled requests.

To view a sample of the web requests that a protected resource has forwarded to AWS WAF for inspection

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, choose Web ACLs.
3. Choose the name of the web ACL for which you want to view requests. The console takes you to the web ACL’s description, where you can edit it.
4. In the Overview tab, the Sampled requests table displays the following values for each request:

   Metric name
   
   The CloudWatch metric name for the rule in the web ACL that matched the request. If a web request doesn’t match any rule in the web ACL, this value is Default.

   Source IP
   
   Either the IP address that the request originated from or, if the viewer used an HTTP proxy or an Application Load Balancer to send the request, the IP address of the proxy or Application Load Balancer.

   URI
   
   The part of a URL that identifies a resource, for example, /images/daily-ad.jpg.

   Rule inside rule group
   
   If the metric name identifies a rule group reference statement, this identifies the rule inside the rule group that matched the request.

   Action
   
   Indicates whether the action for the corresponding rule is Allow, Block, or Count.

   Time
   
   The time that AWS WAF received the request from the protected resource.
5. To display additional information about the components of the web request, choose the arrow on the left side of the row for that request.

Enabling your protections in production

When you've finished the final stage of testing and tuning in your production environment, enable your protections in production mode.

**Production traffic risk**
Before you deploy your web ACL implementation for production traffic, test and tune it in a test environment until you are comfortable with the potential impact to your traffic. Also test and tune it in count mode with your production traffic before enabling your protections for production traffic.

**Note**
To follow the guidance in this section, you need to understand generally how to create and manage AWS WAF protections like web ACLs, rules, and rule groups. That information is covered in earlier sections of this guide.

Perform these steps first in your test environment, then in production.

Enable your AWS WAF protections in production

1. **Switch to your production protections**

   Update your web ACL and switch your settings for production.

   a. **Remove any test rules that you don't need**

      If you added test rules that you don't need in production, remove them. If you're using any label matching rules to filter the results of managed rule group rules, be sure to leave those in place.

   b. **Switch to production actions**

      Change the action settings for your new rules to their intended production settings.

      - **Rule defined in the web ACL** – Edit the rules in the web ACL and change their actions from Count to their production actions.

      - **Rule group** – In your web ACL configuration of the rule group, switch rules to use their own actions or leave them with the Count action override, according to the results of your testing and tuning activities. If you're using a label matching rule to filter the results of a rule group rule, be sure to leave the override for that rule in place.

      To switch to using a rule's action, in your web ACL configuration, edit the rule statement for the rule group and remove the Count override for the rule. If you manage the web ACL in JSON, in the rule group reference statement, remove the entry for the rule from the RuleActionOverrides list.

      - **Web ACL** – If you changed the web ACL default action for your tests, switch it to its production setting.

      With these settings, your new protections will be managing web traffic as you intend.

When you save your web ACL, the resources that it's associated with will be using your production settings.
2. Monitor and tune

To be sure that web requests are being handled as you want, closely monitor your traffic after you enable the new functionality. You'll be monitoring metrics and logs for your production rule actions, instead of the count actions that you were monitoring for in your tuning work. Keep monitoring and adjust the behavior as needed to adapt to changes in your web traffic.

How AWS WAF works with Amazon CloudFront features

When you create a web ACL, you can specify one or more CloudFront distributions that you want AWS WAF to inspect. AWS WAF starts to inspect and manage web requests for those distributions based on the criteria that you identify in the web ACL. CloudFront provides some features that enhance the AWS WAF functionality. This chapter describes a few ways that you can configure CloudFront to make CloudFront and AWS WAF work better together.

Topics

- Using AWS WAF with CloudFront custom error pages (p. 221)
- Using AWS WAF with CloudFront for applications running on your own HTTP server (p. 222)
- Choosing the HTTP methods that CloudFront responds to (p. 222)

Using AWS WAF with CloudFront custom error pages

By default, when AWS WAF blocks a web request based on the criteria that you specify, it returns HTTP status code 403 (Forbidden) to CloudFront, and CloudFront returns that status code to the viewer. The viewer then displays a brief and sparsely formatted default message similar to the following:

Forbidden: You don't have permission to access /myfile.html on this server.

You can override this behavior in your AWS WAF web ACL rules by defining custom responses. For more information about customizing response behavior using AWS WAF rules, see Custom responses for Block actions (p. 128).

Note

Responses that you customize using AWS WAF rules take precedence over any response specifications that you define in CloudFront custom error pages.

If you'd rather display a custom error message through CloudFront, possibly using the same formatting as the rest of your website, you can configure CloudFront to return to the viewer an object (for example, an HTML file) that contains your custom error message.

Note

CloudFront can't distinguish between an HTTP status code 403 that is returned by your origin and one that is returned by AWS WAF when a request is blocked. This means that you can't return different custom error pages based on the different causes of an HTTP status code 403.

For more information about CloudFront custom error pages, see Generating custom error responses in the Amazon CloudFront Developer Guide.
Using AWS WAF with CloudFront for applications running on your own HTTP server

When you use AWS WAF with CloudFront, you can protect your applications running on any HTTP webserver, whether it's a webserver that's running in Amazon Elastic Compute Cloud (Amazon EC2) or a webserver that you manage privately. You can also configure CloudFront to require HTTPS between CloudFront and your own webserver, as well as between viewers and CloudFront.

Requiring HTTPS between CloudFront and your own webserver

To require HTTPS between CloudFront and your own webserver, you can use the CloudFront custom origin feature and configure the Origin Protocol Policy and the Origin Domain Name settings for specific origins. In your CloudFront configuration, you can specify the DNS name of the server along with the port and the protocol that you want CloudFront to use when fetching objects from your origin. You should also ensure that the SSL/TLS certificate on your custom origin server matches the origin domain name you’ve configured. When you use your own HTTP webserver outside of AWS, you must use a certificate that is signed by a trusted third-party certificate authority (CA), for example, Comodo, DigiCert, or Symantec. For more information about requiring HTTPS for communication between CloudFront and your own webserver, see the topic Requiring HTTPS for Communication Between CloudFront and Your Custom Origin in the Amazon CloudFront Developer Guide.

Requiring HTTPS between a viewer and CloudFront

To require HTTPS between viewers and CloudFront, you can change the Viewer Protocol Policy for one or more cache behaviors in your CloudFront distribution. For more information about using HTTPS between viewers and CloudFront, see the topic Requiring HTTPS for Communication Between Viewers and CloudFront in the Amazon CloudFront Developer Guide. You can also bring your own SSL certificate so viewers can connect to your CloudFront distribution over HTTPS using your own domain name, for example https://www.mysite.com. For more information, see the topic Configuring Alternate Domain Names and HTTPS in the Amazon CloudFront Developer Guide.

Choosing the HTTP methods that CloudFront responds to

When you create an Amazon CloudFront web distribution, you choose the HTTP methods that you want CloudFront to process and forward to your origin. You can choose from the following options:

• GET, HEAD – You can use CloudFront only to get objects from your origin or to get object headers.
• GET, HEAD, OPTIONS – You can use CloudFront only to get objects from your origin, get object headers, or retrieve a list of the options that your origin server supports.
• GET, HEAD, OPTIONS, PUT, POST, PATCH, DELETE – You can use CloudFront to get, add, update, and delete objects, and to get object headers. In addition, you can perform other POST operations such as submitting data from a web form.

You also can use AWS WAF byte match rule statements to allow or block requests based on the HTTP method, as described in String match rule statement (p. 106). If you want to use a combination of methods that CloudFront supports, such as GET and HEAD, then you don't need to configure AWS WAF to block requests that use the other methods. If you want to allow a combination of methods that CloudFront doesn't support, such as GET, HEAD, and POST, you can configure CloudFront to respond to all methods, and then use AWS WAF to block requests that use other methods.

For more information about choosing the methods that CloudFront responds to, see Allowed HTTP Methods in the topic Values that You Specify When You Create or Update a Web Distribution in the Amazon CloudFront Developer Guide.
Security in your use of the AWS WAF service

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to AWS WAF, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using AWS WAF. The following topics show you how to configure AWS WAF to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your AWS WAF resources.

Topics

- Data protection in AWS WAF (p. 223)
- Identity and access management in AWS WAF (p. 224)
- Logging and monitoring in AWS WAF (p. 241)
- Compliance validation for AWS WAF (p. 242)
- Resilience in AWS WAF (p. 243)
- Infrastructure security in AWS WAF (p. 243)

Data protection in AWS WAF

The AWS shared responsibility model applies to data protection in AWS WAF. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
• If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers’ email addresses, into tags or free-form fields such as a Name field. This includes when you work with AWS WAF or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

AWS WAF entities—such as web ACLs, rule groups, and IP sets—are encrypted at rest, except in certain Regions where encryption is not available, including China (Beijing) and China (Ningxia). Unique encryption keys are used for each Region.

Deleting AWS WAF resources

You can delete the resources that you create in AWS WAF. See the guidance for each resource type in following sections.

• Deleting a web ACL (p. 25)
• Deleting a rule group (p. 82)
• Deleting an IP set (p. 123)
• Deleting a regex pattern set (p. 125)

Identity and access management in AWS WAF

Access to AWS WAF requires credentials. Those credentials must have permissions to access AWS resources, such as an AWS WAF resource or an Amazon S3 bucket. The following sections provide details on how you can use AWS Identity and Access Management (IAM) and AWS WAF to help secure access to your resources.

• Authentication (p. 224)
• Access control (p. 225)

Authentication

You can access AWS as any of the following types of identities:

• AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don’t use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the AWS Account Management Reference Guide.

• IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating
IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can’t sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

- IAM role

An IAM role is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user in that it is an AWS identity with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. IAM roles with temporary credentials are useful in the following situations:

  - Federated user access – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.

  - AWS service access – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

  - Applications running on Amazon EC2 – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

Access control

You can have valid credentials to authenticate your requests, but unless you have permissions you can't create or access AWS WAF resources. For example, you must have permissions to create an AWS WAF web ACL or rule group.

The following sections describe how to manage permissions for AWS WAF. We recommend that you read the overview first.

- Overview of managing access permissions to your AWS WAF resources (p. 226)
- Using identity-based policies (IAM policies) for AWS WAF (p. 230)
- AWS WAF API permissions: Actions, resources, and conditions reference (p. 236)
AWS Identity and Access Management

AWS WAF integrates with AWS Identity and Access Management (IAM), a service that lets your organization do the following:

• Create users and groups under your organization’s AWS account
• Share your AWS account resources with users in the account
• Assign unique security credentials to each user
• Control user access to services and resources

For example, you can use IAM with AWS WAF to control which users in your AWS account can create a new web ACL.

For general information about IAM, see the following documentation:

• AWS Identity and Access Management (IAM)
• IAM Getting Started Guide
• IAM User Guide

Overview of managing access permissions to your AWS WAF resources

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles). Some services also support attaching permissions policies to resources.

Note
An account administrator (or administrator user) is a user with administrator privileges. For more information, see IAM Best Practices in the IAM User Guide.

When granting permissions, you decide who is getting the permissions, the resources they get permissions for, and the specific operations that you want to allow on those resources.

Topics

• AWS WAF resources and operations (p. 226)
• Understanding resource ownership (p. 227)
• Managing access to resources (p. 228)
• Specifying policy elements: Actions, effects, resources, and principals (p. 229)
• Specifying conditions in a policy (p. 229)

AWS WAF resources and operations

In AWS WAF, the resources are web ACLs, rule groups, IP sets, and regex pattern sets. To allow or deny access to a subset of AWS WAF resources, include the ARN of the resource in the resource element of your policy. The ARNs for AWS WAF resources have the following format:

```
```

The following table lists the format for each resource.
<table>
<thead>
<tr>
<th>Name in AWS WAF Console</th>
<th>Name in AWS WAF SDK/CLI</th>
<th>ARN Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ACL</td>
<td>WebACL</td>
<td>arn:aws:wafv2:region:account:scope/webacl/name/ID</td>
</tr>
<tr>
<td>Rule group</td>
<td>RuleGroup</td>
<td>arn:aws:wafv2:region:account:scope/rulegroup/name/ID</td>
</tr>
<tr>
<td>IP set</td>
<td>IPSet</td>
<td>arn:aws:wafv2:region:account:scope/ipset/name/ID</td>
</tr>
<tr>
<td>Regex pattern set</td>
<td>RegexPatternSet</td>
<td>arn:aws:wafv2:region:account:scope/regexpatternset/name/ID</td>
</tr>
</tbody>
</table>

To specify an AWS WAF resource ARN, replace the variables in the ARN formats with valid values as follows:

- **region**: The AWS Region you're using. For Amazon CloudFront, set this to **us-east-1**. For regional resources, set this to the Region you're interested in.
- **account**: The ID of your AWS account.
- **scope**: The scope of the resource, which can be either **global**, for use with an Amazon CloudFront distribution, or **regional**, for use with an Amazon API Gateway REST API, an Application Load Balancer, an AWS AppSync GraphQL API, or an Amazon Cognito user pool.
- **name**: The name that you gave the AWS WAF resource, or a wildcard (*) to indicate all resources of the specified type that are associated with the specified AWS account. If you use the wildcard for the name, you must also use it for the ID.
- **ID**: The ID of the AWS WAF resource, or a wildcard (*) to indicate all resources of the specified type that are associated with the specified AWS account. If you use the wildcard for the ID, you must also use it for the name.

For example, the following ARN specifies all web ACLs with regional scope for the account 111122223333 in Region **us-east-1**:

```
arwn:aws:wafv2:us-east-1:111122223333:regional/webacl/*/*
```

For more information, see Resources in the IAM User Guide.

AWS WAF provides a set of operations to work with AWS WAF resources. For a list of available operations, see Actions.

**Understanding resource ownership**

A **resource owner** is the AWS account that creates the resource. That is, the resource owner is the AWS account of the principal entity (the root account, an IAM user, or an IAM role) that authenticates the request that creates the resource. The following examples illustrate how this works:

- If you use the root account credentials of your AWS account to create an AWS WAF resource, your AWS account is the owner of the resource.
- If you create an IAM user in your AWS account and grant permissions to create an AWS WAF resource to that user, the user can create an AWS WAF resource. However, your AWS account, to which the user belongs, owns the AWS WAF resource.
If you create an IAM role in your AWS account with permissions to create an AWS WAF resource, anyone who can assume the role can create an AWS WAF resource. Your AWS account, to which the role belongs, owns the AWS WAF resource.

Managing access to resources

A permissions policy describes who has access to what. The following sections explain the available options for creating permissions policies.

Note

These sections discuss using IAM in the context of AWS WAF. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the IAM User Guide. For information about IAM policy syntax and descriptions, see AWS Identity and Access Management Policy Reference in the IAM User Guide.

Policies that are attached to an IAM identity are known as identity-based policies, and policies that are attached to a resource are known as resource-based policies. AWS WAF supports only identity-based policies.

Topics

- Identity-based policies (IAM policies) (p. 228)
- Resource-based policies (p. 229)

Identity-based policies (IAM policies)

You can attach policies to IAM identities. For example, you can do the following:

- **Attach a permissions policy to a user or a group in your account** – An account administrator can use a permissions policy that is associated with a particular user to grant permissions for that user to create an AWS WAF resource.

- **Attach a permissions policy to a role (grant cross-account permissions)** – You can attach an identity-based permissions policy to an IAM role to grant cross-account permissions. For example, the administrator in Account A can create a role to grant cross-account permissions to another AWS account (for example, Account B) or an AWS service as follows:
  1. Account A administrator creates an IAM role and attaches a permissions policy to the role that grants permissions on resources in Account A.
  2. Account A administrator attaches a trust policy to the role identifying Account B as the principal who can assume the role.
  3. Account B administrator can then delegate permissions to assume the role to any users in Account B. Doing this allows users in Account B to create or access resources in Account A. The principal in the trust policy also can be an AWS service principal if you want to grant an AWS service permissions to assume the role.

For more information about using IAM to delegate permissions, see Access Management in the IAM User Guide.

The following is an example policy that grants permissions for the wafv2:ListWebACLs action on all resources. In the current implementation, AWS WAF doesn't support identifying specific resources using the resource ARNs (also referred to as resource-level permissions) for some of the API actions, so you must specify a wildcard character (*) :

```json
{
  "Version": "2019-07-29",
  "Statement": [
  
}
"Sid": "ListWebACLs",
"Effect": "Allow",
"Action": [
  "wafv2:ListWebACLs"
],
"Resource": "*"
}
}

For more information about using identity-based policies with AWS WAF, see Using identity-based policies (IAM policies) for AWS WAF (p. 230). For more information about users, groups, roles, and permissions, see Identities (Users, Groups, and Roles) in the IAM User Guide.

Resource-based policies

Other services, such as Amazon S3, also support resource-based permissions policies. For example, you can attach a policy to an S3 bucket to manage access permissions to that bucket. AWS WAF doesn’t support resource-based policies.

Specifying policy elements: Actions, effects, resources, and principals

For each AWS WAF resource (see AWS WAF resources and operations (p. 226)), the service defines a set of API operations (see AWS WAF API permissions: Actions, resources, and conditions reference (p. 236)). To grant permissions for these API operations, AWS WAF defines a set of actions that you can specify in a policy. Note that performing an API operation can require permissions for more than one action. When granting permissions for specific actions, you also identify the resource on which the actions are allowed or denied.

The following are the most basic policy elements:

- **Resource** – In a policy, you use an Amazon Resource Name (ARN) to identify the resource to which the policy applies. For more information, see AWS WAF resources and operations (p. 226).
- **Action** – You use action keywords to identify resource operations that you want to allow or deny. For example, the wafv2:CreateRuleGroup permission allows the user permissions to perform the AWS WAF CreateRuleGroup operation.
- **Effect** – You specify the effect when the user requests the specific action. This can be either allow or deny. If you don’t explicitly grant access to a resource, access is implicitly denied. You also can explicitly deny access to a resource, which you might do to make sure that a user cannot access it, even if a different policy grants access.
- **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. AWS WAF doesn’t support resource-based policies.

To learn more about IAM policy syntax and descriptions, see AWS Identity and Access Management Policy Reference in the IAM User Guide.

For a table that shows all the AWS WAF API actions and the resources that they apply to, see AWS WAF API permissions: Actions, resources, and conditions reference (p. 236).

Specifying conditions in a policy

When you grant permissions, you can use the IAM policy language to specify the conditions when a policy should take effect. For example, you might want a policy to be applied only after a specific date. For more information about specifying conditions in a policy language, see Condition in the IAM User Guide.

To express conditions, you use predefined condition keys. There are no condition keys specific to AWS WAF. However, there are general AWS condition keys that you can use as appropriate. For a complete list of AWS keys, see Available Keys for Conditions in the IAM User Guide.
Using identity-based policies (IAM policies) for AWS WAF

This section provides examples of identity-based policies that demonstrate how an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on AWS WAF resources.

Important
We recommend that you first review the introductory topics that explain the basic concepts and options available for you to manage access to your AWS WAF resources. For more information, see Overview of managing access permissions to your AWS WAF resources (p. 226).

For a table that shows all the AWS WAF API actions and the resources that they apply to, see AWS WAF API permissions: Actions, resources, and conditions reference (p. 236).

Topics

- Permissions required to use the AWS WAF console (p. 230)
- AWS managed (predefined) policies for AWS WAF (p. 230)
- Customer managed policy examples (p. 231)

Permissions required to use the AWS WAF console

The AWS WAF console provides an integrated environment for you to create and manage AWS WAF resources. The console provides many features and workflows that often require permissions to create an AWS WAF resource in addition to the API-specific permissions that are documented in the AWS WAF API permissions: Actions, resources, and conditions reference (p. 236). For more information about these additional console permissions, see Customer managed policy examples (p. 231).

AWS managed (predefined) policies for AWS WAF

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. Managed policies grant necessary permissions for common use cases so you can avoid having to investigate what permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

The following AWS managed policies, which you can attach to users in your account, are specific to AWS WAF:

- AWSSWAFReadOnlyAccess – Grants read-only access to AWS WAF resources.
- AWSSWAFFullAccess – Grants full access to AWS WAF resources.
- AWSSWAFConsoleReadOnlyAccess – Grants read-only access to the AWS WAF console, which includes resources for AWS WAF and integrated services, such as Amazon CloudFront, Amazon API Gateway, Application Load Balancer, AWS AppSync, and Amazon Cognito.
- AWSSWAFConsoleFullAccess – Grants full access to the AWS WAF console, which includes resources for AWS WAF and integrated services, such as Amazon CloudFront, Amazon API Gateway, Application Load Balancer, AWS AppSync, and Amazon Cognito.
- WAFV2LoggingServiceRolePolicy – Grants access write logs to AWS WAF logging destinations.

Note
You can review these permissions policies by signing in to the IAM console and searching for specific policies there.

You also can create your own custom IAM policies to allow permissions for AWS WAF API operations and resources. You can attach these custom policies to the IAM users or groups that require those permissions or to custom execution roles (IAM roles) that you create for your AWS WAF resources.
Customer managed policy examples

The examples in this section provide a group of sample policies that you can attach to a user. If you are new to creating policies, we recommend that you first create an IAM user in your account and attach the policies to the user, in the sequence outlined in the steps in this section.

You can use the console to verify the effects of each policy as you attach the policy to the user. Initially, the user doesn't have permissions, and the user won't be able to do anything on the console. As you attach policies to the user, you can verify that the user can perform various operations on the console.

We recommend that you use two browser windows: one to create the user and grant permissions, and the other to sign in to the AWS Management Console using the user's credentials and verify permissions as you grant them to the user.

For examples that show how to create an IAM role that you can use as an execution role for your AWS WAF resource, see Creating IAM Roles in the IAM User Guide.

Example topics

- Example 1: Give users read-only access to AWS WAF, CloudFront, and CloudWatch (p. 231)
- Example 2: Give users full access to AWS WAF, CloudFront, and CloudWatch (p. 232)
- Example 3: Granting access to a specified AWS account (p. 232)
- Example 4: Granting access to a specified Web ACL (p. 233)

Create an IAM user

First, you need to create an IAM user, add the user to an IAM group with administrative permissions, and then grant administrative permissions to the IAM user that you created. You then can access AWS using a special URL and the user's credentials.

For instructions, see Creating Your First IAM User and Administrators Group in the IAM User Guide.

Example 1: Give users read-only access to AWS WAF, CloudFront, and CloudWatch

The following policy grants users read-only access to AWS WAF resources, to Amazon CloudFront web distributions, and to Amazon CloudWatch metrics. It's useful for users who need permission to view the settings in AWS WAF conditions, rules, and web ACLs to see which distribution is associated with a web ACL, and to monitor metrics and a sample of requests in CloudWatch. These users can't create, update, or delete AWS WAF resources.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "wafv2:Get*",
                "wafv2:List*",
                "cloudfront:GetDistribution",
                "cloudfront:GetDistributionConfig",
                "cloudfront:ListDistributions",
                "cloudfront:ListDistributionsByWebACLId",
                "cloudwatch:ListMetrics",
                "cloudwatch:GetMetricStatistics",
                "ec2:DescribeRegions"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

231
Example 2: Give users full access to AWS WAF, CloudFront, and CloudWatch

The following policy lets users perform any AWS WAF operation, perform any operation on CloudFront web distributions, and monitor metrics and a sample of requests in CloudWatch. It's useful for users who are AWS WAF administrators.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "wafv2:*",
        "cloudfront:CreateDistribution",
        "cloudfront:GetDistribution",
        "cloudfront:GetDistributionConfig",
        "cloudfront:UpdateDistribution",
        "cloudfront:ListDistributions",
        "cloudfront:ListDistributionsByWebACLId",
        "cloudfront:DeleteDistribution",
        "cloudwatch:ListMetrics",
        "cloudwatch:GetMetricStatistics",
        "ec2:DescribeRegions"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

We strongly recommend that you configure multi-factor authentication (MFA) for users who have administrative permissions. For more information, see Using Multi-Factor Authentication (MFA) Devices with AWS in the IAM User Guide.

Example 3: Granting access to a specified AWS account

This policy grants the following permissions to the account 444455556666:

- Full access to all AWS WAF operations and resources.
- Read and update access to all CloudFront distributions, which allows you to associate web ACLs and CloudFront distributions.
- Read access to all CloudWatch metrics and metric statistics, so that you can view CloudWatch data and a sample of requests in the AWS WAF console.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["wafv2:*"]
    },
    {
      "Effect": "Allow",
      "Action": ["cloudfront:GetDistribution", "cloudfront:GetDistributionConfig", "cloudfront:ListDistributions"]
    }
  ]
}
```
Example 4: Granting access to a specified Web ACL

This policy grants the following permissions to the webacl ID 112233d7c-86b2-458b-af83-51c51example in the account 444455556666:

- Full access to AWS WAF Get, Update, and Delete operations and resources

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "wafv2:*"
         ],
         "Resource": [
            "arn:aws:wafv2:us-east-1:444455556666:regional/webacl/test123/112233d7c-86b2-458b-af83-51c51example"
         ]
      }
   ]
}
```

AWS managed policies for AWS WAF

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can’t change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won’t break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ViewOnlyAccess AWS managed policy provides read-only access to many AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.
## AWS WAF updates to AWS managed policies

View details about updates to AWS managed policies for AWS WAF since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the AWS WAF document history page at [Document history](p. 566).

AWS WAF API permissions: Actions, resources, and conditions reference

When you set up Access control (p. 225) and writing permissions policies that you can attach to an IAM identity (identity-based policies), use the information in this section as a guide. For each AWS WAF API operation, you need to know the actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

Note
To specify an action, use the wafv2: prefix followed by the API operation name (for example, wafv2:CreateIPSet).

You can use general AWS condition keys in your AWS WAF policies to express conditions. For a complete list of AWS keys, see Available Keys for Conditions in the IAM User Guide.

Global and regional settings

In the resource settings in this section, use the following scope and region settings:

- For CloudFront distributions, set scope to global and set region to us-east-1.
- For an Amazon API Gateway REST API, an Application Load Balancer, an AWS AppSync GraphQL API, or an Amazon Cognito user pool, set scope to regional and set the region to the region you're interested in.

AWS WAF API permissions for references to resources

For all resource permissions settings, if a resource references any other resource by Amazon resource name (ARN), you must have permissions to access the referenced resources, in addition to the permission required to access the first resource. For example, to work with a web ACL that references an IP set, regex pattern set, or rule group, you need to have access to the IP set, regex pattern set, or rule group resource in addition to having access to the web ACL resource.

AWS WAF standard API permissions

The basic CRUD and list operations on AWS resources follow a standard pattern for permissions granting. The pattern applies to web ACLs, rule groups, IP sets, and regex pattern sets.

To grant permissions for Web ACLs

Apply the permissions for the web ACL and for any resource the web ACL references:

- Use the CRUD and list operations permissions guidance in this section for WebACL and webacl.
- For any rule groups that the web ACL references, use the guidance in this section with RuleGroup and rulegroup.
- For any managed rule groups that the web ACL references, provide the permissions for DescribeManagedRuleGroup, listed under AWS WAF non-standard API and required permissions for actions (p. 237).
- For any IP sets that the web ACL references, use the guidance in this section with IPSet and ipset.
- For any regex pattern sets that the web ACL references, use the guidance in this section with RegexPatternSet and regexpatternset.

To grant permissions for rule groups

Apply the permissions for the rule group and for any resource the rule group references:
• Use the CRUD and list operations permissions guidance in this section with RuleGroup and rulegroup.
• For any IP sets that the rule group references, use the guidance in this section with IPSet and ipset.
• For any regex pattern sets that the rule group references, use the guidance in this section with RegexPatternSet and regexpatternset.

To grant permissions for IP sets

For IP sets, use the CRUD and list operations permissions guidance in this section with IPSet and ipset.

To grant permissions for regex pattern sets

For regex pattern sets, use the CRUD and list operations permissions guidance in this section with RegexPatternSet and regexpatternset.

AWS WAF CRUD and List permissions

The patterns for CRUD and list apply to web ACLs, rule groups, IP sets, and regex pattern sets. This section shows the pattern for web ACL operations. For other resource types, substitute in the strings for those, according to the guidance preceding this section.

CRUD operations for web ACL

• AWS WAF API Operations – CreateWebACL, GetWebACL, UpdateWebACL, and DeleteWebACL
• API Actions – wafv2:CreateWebACL, wafv2:GetWebACL, wafv2:UpdateWebACL, wafv2:DeleteWebACL
• Resources – arn:aws:wafv2:region:account-id:scope/webacl/entity-name/entity-ID

List operations for web ACL

• AWS WAF API Operation – ListWebACLs
• API Actions – wafv2:ListWebACLs
• Resources – arn:aws:wafv2:region:account-id:scope/webacl/*

If you want to list all resources in your account, call the list operation once for global, and once for each regional application region.

AWS WAF non-standard API permissions

The following operations don't follow the standard CRUD and list pattern and require specific resource permissions settings.

For each operation, we list the required policy actions and their associated policy resources.

AssociateWebACL

• API Actions – wafv2:AssociateWebACL, elasticloadbalancing:SetWebACL, apigateway:SetWebACL, appsync:SetWebACL, cognito-idp:AssociateWebACL
• Resources – arn:aws:wafv2:region:account-id:scope/webacl/entity-name/entity-ID
   arn:aws:elasticloadbalancing:region:account-id:loadbalancer/app/ApplicationLoadBalancerName/ApplicationLoadBalancerID
CheckCapacity

**API Action** – wafv2:CheckCapacity

**Resource** – This requires permissions on all ARNs that are referenced in the contained rules. It doesn't require any other permissions.

DescribeManagedRuleGroup

**API Action** – wafv2:DescribeManagedRuleGroup

DisassociateWebACL

**Resources** –

arn:aws:wafv2:region:account-id:scope/webacl/entity-name/entity-ID

arn:aws:elasticloadbalancing:region:account-id:loadbalancer/app/ApplicationLoadBalancerName/ApplicationLoadBalancerID

arn:aws:apigateway:region::/restapis/api-ID/stages/stage-name

arn:aws:appsync:region:account-id:apis/GraphQLApiId

arn:aws:cognito-idp:region:account-id:userpool/USER_POOL_ID

GetRateBasedStatementManagedKeys

**API Action** – wafv2:GetRateBasedStatementManagedKeys

GetSampledRequests

**API Action** – wafv2:GetSampledRequests

**Resource** – The resource permissions depend on the parameters that you specify in the API call. You must have access to the web ACL that corresponds to the request for samples. For example:

arn:aws:wafv2:region:account-id:scope/webacl/entity-name/entity-ID

GetWebACLForResource

**API Action** – wafv2:GetWebACLForResource, cognito-idp:GetWebACLForResource

**Resource** – The resource permissions depend on the resource that you specify in the API call. You must have access to the web ACL that corresponds to the request.

**Resources** –

arn:aws:wafv2:region:account-id:scope/webacl/entity-name/entity-ID

arn:aws:wafv2:region:account-id:scope/webacl/entity-name/entity-ID

arn:aws:elasticloadbalancing:region:account-id:loadbalancer/app/ApplicationLoadBalancerName/ApplicationLoadBalancerID
Using service-linked roles for AWS WAF

AWS WAF uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to AWS WAF. Service-linked roles are predefined by AWS WAF and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up AWS WAF easier because you don't have to manually add the necessary permissions. AWS WAF defines the permissions of its service-linked roles, and unless defined otherwise, only AWS WAF can assume its roles. The defined permissions include the trust policy and the permissions policy. That permissions policy can’t be attached to any other IAM entity.

You can delete a service-linked role only after first deleting the role's related resources. This protects your AWS WAF resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for AWS WAF

AWS WAF uses the service-linked role AWSServiceRoleForWAFV2Logging.

AWS WAF uses this service-linked role to write logs to Amazon Kinesis Data Firehose. This role is used only if you enable logging in AWS WAF. For more information, see Logging web ACL traffic (p. 192).

The AWSServiceRoleForWAFV2Logging service-linked role trusts the service to assume the role wafv2.amazonaws.com.
The permissions policies of the role allows AWS WAF to complete the following actions on the specified resources:

- **Action:** firehose:PutRecord and firehose:PutRecordBatch on Amazon Kinesis Data Firehose data stream resources with a name that starts with "aws-waf-logs-." For example, aws-waf-logs-us-east-2-analytics.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

**Creating a service-linked role for AWS WAF**

You don't need to manually create a service-linked role. When you enable AWS WAF logging on the AWS Management Console, or you make a PutLoggingConfiguration request in the AWS WAF CLI or the AWS WAF API, AWS WAF creates the service-linked role for you.

You must have the iam:CreateServiceLinkedRole permission to enable logging.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable AWS WAF logging, AWS WAF creates the service-linked role for you again.

**Editing a service-linked role for AWS WAF**

AWS WAF doesn't allow you to edit the AWSServiceRoleForWAFV2Logging service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

**Deleting a service-linked role for AWS WAF**

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

**Note**

If the AWS WAF service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

**To delete AWS WAF resources used by the AWSServiceRoleForWAFV2Logging**

1. On the AWS WAF console, remove logging from every web ACL. For more information, see Logging web ACL traffic (p. 192).
2. Using the API or CLI, submit a DeleteLoggingConfiguration request for each web ACL that has logging enabled. For more information, see AWS WAF API Reference.

**To manually delete the service-linked role using IAM**

Use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForWAFV2Logging service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

**Supported Regions for AWS WAF service-linked roles**

AWS WAF supports using service-linked roles in all of the regions where the service is available. For more information, see AWS WAF endpoints and quotas.
Logging and monitoring in AWS WAF

Monitoring is an important part of maintaining the reliability, availability, and performance of AWS WAF and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your AWS WAF resources and responding to potential events:

**Amazon CloudWatch alarms**

Using CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, CloudWatch sends a notification to an Amazon SNS topic or AWS Auto Scaling policy. For more information, see Monitoring with Amazon CloudWatch (p. 541).

**AWS CloudTrail logs**

CloudTrail provides a record of actions taken by a user, role, or an AWS service in AWS WAF. Using the information collected by CloudTrail, you can determine the request that was made to AWS WAF, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging API calls with AWS CloudTrail (p. 548).

**AWS WAF web ACL traffic logging**

AWS WAF offers logging for the traffic that your web ACLs analyze. The logs include information such as the time that AWS WAF received the request from your protected AWS resource, detailed information about the request, and the action setting for the rule that the request matched. For more information, see Logging web ACL traffic (p. 192).
Compliance validation for AWS WAF

Third-party auditors assess the security and compliance of AWS WAF as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS WAF is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. If your use of AWS WAF is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA Security and Compliance Whitepaper** – This technical paper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
- **AWS Well-Architected Framework** – The AWS Well-Architected Framework helps you build secure cloud applications.
Resilience in AWS WAF

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Infrastructure security in AWS WAF

As a managed service, AWS WAF is protected by the AWS global network security procedures that are described in Amazon Web Services: Overview of Security Processes.

You use AWS published API calls to access AWS WAF through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

AWS WAF quotas

Note
This is the latest version of AWS WAF. For AWS WAF Classic, see AWS WAF Classic (p. 252).

AWS WAF is subject to the following quotas (formerly referred to as limits). These quotas are the same for all Regions in which AWS WAF is available. Each Region is subject to these quotas individually. The quotas are not cumulative across Regions.

AWS WAF has default quotas on the maximum number of entities you can have per account. You can request an increase in these quotas.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default quota per account per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of web ACLs</td>
<td>100</td>
</tr>
<tr>
<td>Maximum number of rule groups</td>
<td>100</td>
</tr>
<tr>
<td>Maximum web ACL capacity units (WCUs) per web ACL</td>
<td>1,500</td>
</tr>
<tr>
<td>Maximum WCUs per rule group</td>
<td>1,500</td>
</tr>
<tr>
<td>Maximum number of IP sets</td>

</tr>
<tr>
<td>Maximum number of requests per second per web ACL</td>
<td>25,000</td>
</tr>
<tr>
<td>Maximum number of custom request headers per web ACL or rule group</td>
<td>100</td>
</tr>
<tr>
<td>Maximum number of custom response headers per web ACL or rule group</td>
<td>100</td>
</tr>
</tbody>
</table>
### AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide

#### AWS WAF quotas

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default quota per account per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of custom response bodies per web ACL or rule group</td>
<td>50</td>
</tr>
<tr>
<td>Maximum number of Amazon CloudWatch Logs log streams per web ACL, for logging web ACL traffic to an CloudWatch Logs log group</td>
<td>35</td>
</tr>
</tbody>
</table>

The maximum requests per second (RPS) allowed for AWS WAF on CloudFront is set by CloudFront and described in the [CloudFront Developer Guide](https://docs.aws.amazon.com/cur/v2021-12-30/development-guide/)

AWS WAF has fixed quotas on the following entity settings per account per Region. These quotas can't be changed.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Quota per account per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of references per rule group to IP sets and regex pattern sets</td>
<td>50</td>
</tr>
<tr>
<td>Maximum number of references per web ACL to IP sets, regex pattern sets, and rule groups</td>
<td>50</td>
</tr>
<tr>
<td>Maximum number of IP addresses in CIDR notation per IP set</td>
<td>10,000</td>
</tr>
<tr>
<td>Maximum number of rate-based rules per web ACL</td>
<td>10</td>
</tr>
<tr>
<td>Maximum number of rate-based rules per rule group</td>
<td>4</td>
</tr>
<tr>
<td>Maximum number of unique IP addresses that can be blocked per rate-based rule</td>
<td>10,000</td>
</tr>
<tr>
<td>Maximum number of characters in a string match statement</td>
<td>200</td>
</tr>
<tr>
<td>Maximum number of characters in each regex pattern</td>
<td>200</td>
</tr>
<tr>
<td>Maximum number of unique regex patterns per regex set</td>
<td>10</td>
</tr>
<tr>
<td>Maximum number of regex sets</td>
<td>10</td>
</tr>
<tr>
<td>Maximum size of a web request body that can be inspected</td>
<td>8 KB</td>
</tr>
<tr>
<td>Minimum request rate that can be defined for a rate-based rule</td>
<td>100</td>
</tr>
<tr>
<td>Maximum number of text transformations per rule statement</td>
<td>3</td>
</tr>
<tr>
<td>Maximum size of the custom response body content for a single custom response definition</td>
<td>4 KB</td>
</tr>
<tr>
<td>Maximum number of custom headers for a single custom response definition</td>
<td>10</td>
</tr>
<tr>
<td>Maximum number of custom headers for a single custom request definition</td>
<td>10</td>
</tr>
<tr>
<td>Maximum combined size of all response body content for a single rule group or a single web ACL</td>
<td>50 KB</td>
</tr>
</tbody>
</table>

AWS WAF has the following fixed quotas on calls per account per Region. These quotas apply to the total calls to the service through any available means, including the console, CLI, AWS CloudFormation, the REST API, and the SDKs. These quotas can't be changed.
AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide
Migrating your AWS WAF Classic resources to AWS WAF

### Migrating your AWS WAF Classic resources to AWS WAF

This section provides guidance for migrating your rules and web ACLs from AWS WAF Classic to AWS WAF. AWS WAF was released in November 2019. If you created resources like rules and web ACLs using AWS WAF Classic, you either need to work with them using AWS WAF Classic or migrate them to this latest version.

Before you start your migration work, familiarize yourself with AWS WAF by reading through AWS WAF (p. 6).

**Topics**
- Why migrate to AWS WAF? (p. 245)
- How the migration works (p. 246)
- Migration caveats and limitations (p. 247)
- Migrating a web ACL from AWS WAF Classic to AWS WAF (p. 247)

### Why migrate to AWS WAF?

The latest version of AWS WAF provides many improvements over the prior version, while maintaining most of the concepts and terminology that you’re accustomed to.

The following list describes the major changes in the latest AWS WAF. Before you continue with your migration, please take some time to review this list and to familiarize yourself with the rest of the AWS WAF guide.

- **AWS Managed Rules for AWS WAF** – The rule groups now available through AWS Managed Rules provide protection against common web threats. Most of these rule groups are included free of charge with AWS WAF. For more information, see [AWS Managed Rules rule groups list](p. 35) and the blog post [Announcing AWS Managed Rules for AWS WAF](p. 35).
How the migration works

The automated migration carries over most of your AWS WAF Classic web ACL configuration, leaving a few things that you need to handle manually.

The following lists the high-level steps for migrating a web ACL.

1. The automated migration reads everything related to your existing web ACL, without modifying or deleting anything in AWS WAF Classic. It creates a representation of the web ACL and its related resources, compatible with AWS WAF. It generates an AWS CloudFormation template for the new web ACL and stores it in an Amazon S3 bucket.

AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide
How the migration works

- **New AWS WAF API** – The new API allows you to configure all of your AWS WAF resources using a single set of APIs. To distinguish between regional and global applications, the new API includes a scope setting. For more information about the API, see the AWS WAFV2 Actions and AWS WAFV2 Data Types.

  In the APIs, SDKs, CLIs, and AWS CloudFormation, AWS WAF Classic retains its naming schemes and this latest version of AWS WAF is referred to with an added V2 or v2, depending on the context.

- **Simplified service quotas (limits)** – AWS WAF now allows more rules per web ACL and allows you to express longer regex patterns. For more information, see AWS WAF quotas (p. 243).

- **Web ACL limits are now based on computing needs** – Web ACL limits are now based on Web ACL capacity units (WCU). AWS WAF calculates the WCU for a rule according to the operating capacity that's required to run the rule. The WCU of a web ACL is the sum of the WCU of all rules and rule groups in the web ACL.

  For general information about WCU, see How AWS WAF works (p. 6). For information about each rule's WCU usage, see Rule statements (p. 86).

- **Document-based rule writing** – You can now write and express rules, rule groups, and web ACLs in JSON format. You no longer need to use individual API calls to create different conditions and then associate the conditions to a rule. This greatly simplifies how you write and maintain your code. You can access a JSON format of your web ACLs through the console when you're viewing the web ACL, by choosing Download web ACL as JSON. When you are creating your own rule, you can access its JSON representation by choosing Rule JSON editor.

- **Rule nesting and full logical operation support** – You can write complex combined rules by using logical rule statements and by using nesting. You can create statements such as `[A AND NOT(B OR C)]`. For more information, see Rule statements list (p. 86).

- **Variable CIDR range support for IP set** – IP set specifications now have more flexibility in the IP ranges. For IPv4, AWS WAF supports /1 to /32. For IPv6, AWS WAF supports /1 to /128. For more information about IP sets, see IP set match rule statement (p. 96).

- **Chainable text transformations** – AWS WAF can perform multiple text transformations against web request content before inspecting it. For more information, see Text transformations (p. 114).

- **Improved console experience** – The new AWS WAF console features visual rule builder and a more user intuitive console design.

- **Expanded options for Firewall Manager AWS WAF policies** – In the Firewall Manager management of AWS WAF web ACLs, you can now create a set of rule groups that AWS WAF processes first and a set of rule groups that AWS WAF processes last. After you apply the AWS WAF policy, local account owners can add their own rule groups that AWS WAF processes in between these two sets. For more information about Firewall Manager AWS WAF policies, see AWS WAF policies (p. 404).

- **AWS CloudFormation support for all rule statement types** – AWS WAF in AWS CloudFormation supports all rule statement types that the AWS WAF console and API support. Additionally, you can easily convert the rules that you write in JSON format to YAML format.
2. You deploy the template into AWS CloudFormation, in order to recreate the web ACL and related resources in AWS WAF.
3. You review the web ACL, and manually complete the migration, making sure that your new web ACL takes full advantage of the capabilities of the latest AWS WAF.
4. You manually switch your protected resources over to the new web ACL.

Migration caveats and limitations

The migration doesn’t carry over all of your settings, exactly as you have them in AWS WAF Classic. A few things, like managed rules, don’t map exactly between the two versions. Other settings, like the web ACL’s associations with protected AWS resources, are disabled initially in the new version so you can add them when you’re ready.

The following list describes the caveats of the migration and describes any steps you might want to take in response. Use this overview to plan your migration. The detailed migration steps, later on, walk you through the recommended mitigation steps.

- **Single account** – You can only migrate AWS WAF Classic resources for any account to AWS WAF resources for the same account.
- **Managed rules** – The migration doesn’t bring over any managed rules from AWS Marketplace sellers. Some AWS Marketplace sellers have equivalent managed rules for AWS WAF that you can subscribe to again. Before you do this, review the AWS Managed Rules that are provided with the latest version of AWS WAF. Most of these are free of charge for AWS WAF users. For information about managed rules, see Managed rule groups (p. 26).
- **Web ACL associations** – The migration doesn’t bring over any associations between the web ACL and protected resources. This is by design, to avoid affecting your production workload. After you verify that everything is migrated correctly, associate the new web ACL with your resources.
- **Logging** – Logging for the migrated web ACL is disabled by default. This is by design. Enable logging when you are ready to switch over from AWS WAF Classic to AWS WAF.
- **AWS Firewall Manager rule groups** – The migration doesn’t handle rule groups that are managed by Firewall Manager. You can migrate a web ACL that’s managed by Firewall Manager, but the migration doesn’t bring over the rule group. Instead of using the migration tool for these web ACLs, recreate the policy for the new AWS WAF in Firewall Manager.

  **Note**
  The rule groups that Firewall Manager managed for AWS WAF Classic were Firewall Manager rule groups. With the new version of AWS WAF, the rule groups are AWS WAF rule groups. Functionally, they are the same.

- **AWS WAF Security Automations** – Don’t try to migrate any AWS WAF Security Automations. The migration doesn’t convert Lambda functions, which might be in use by the automations. When a new AWS WAF Security Automations solution is available that’s compatible with the latest AWS WAF, redeploy that solution.

Migrating a web ACL from AWS WAF Classic to AWS WAF

To migrate a web ACL and switch over to it, perform the automated migration, then complete a series of manual steps.

**Topics**
- Migrating a web ACL: automated migration (p. 248)
- Migrating a web ACL: manual follow-up (p. 249)
Migrating a web ACL: automated migration

To automatically migrate a web ACL configuration from AWS WAF Classic to AWS WAF

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.

2. Choose **Switch to AWS WAF Classic** and review your configuration settings for the web ACL. Make note of the settings, considering the caveats and limitations described in the preceding section, **Migration caveats and limitations** (p. 247).

3. In the informational dialogue at the top, locate the sentence that starts with **Migrate web ACLs** and choose the link to the **migration wizard**. This launches the migration wizard.

   If you don't see the informational dialogue, you might have closed it since you launched the AWS WAF Classic console. In the navigation bar, choose **Switch to new AWS WAF** then choose **Switch to AWS WAF Classic**, and the informational dialogue should reappear.

4. Select the web ACL that you want to migrate.

5. For **Migration configuration**, provide an Amazon S3 bucket to use for the template. You need an Amazon S3 bucket that's configured properly for the migration API, to store the AWS CloudFormation template that it generates.

   - If the bucket is encrypted, the encryption must use Amazon S3 (SSE-S3) keys. The migration doesn't support encryption with AWS Key Management Service (SSE-KMS) keys.
   - The bucket name must start with `aws-waf-migration-`. For example, `aws-waf-migration-my-web-acl`.
   - The bucket must be in the Region where you are deploying the template. For example, for a web ACL in `us-west-2`, you must use an Amazon S3 bucket in `us-west-2` and you must deploy the template stack to `us-west-2`.

6. For **S3 bucket policy**, we recommend choosing **Auto apply the bucket policy required for migration**. Alternatively, if you want to manage the bucket on your own, you must manually apply the following bucket policy:

   - For global Amazon CloudFront applications (**waf**):

     ```json
     {
       "Version": "2012-10-17",
       "Statement": [
         {
           "Effect": "Allow",
           "Principal": {
             "Service": "apiv2migration.waf.amazonaws.com"
           },
           "Action": "s3:PutObject",
           "Resource": "arn:aws:s3::<BUCKET_NAME>/AWSWAF/<CUSTOMER_ACCOUNT_ID>/*"
         }
       ]
     }
     ```

   - For regional Amazon API Gateway or Application Load Balancer applications (**waf-regional**):

     ```json
     {
       "Version": "2012-10-17",
       "Statement": [
         {
           "Effect": "Allow",
           "Principal": {
             "Service": "apiv2migration.waf.amazonaws.com"
           },
           "Action": "s3:PutObject",
           "Resource": "arn:aws:s3::<BUCKET_NAME>/AWSWAF/<CUSTOMER_ACCOUNT_ID>/*"
         }
       ]
     }
     ```
For **Choose how to handle rules that cannot be migrated**, choose either to exclude rules that can't be migrated, or to stop the migration. For information about rules that can't be migrated, see Migration caveats and limitations (p. 247).

Choose Next.

For **Create AWS CloudFormation template**, verify your settings, then choose Start creating AWS CloudFormation template to begin the migration process. This can take a few minutes, depending on the complexity of your web ACL.

In **Create and run AWS CloudFormation stack to complete migration**, you can choose to go to the AWS CloudFormation console to create a stack from the template, to create the new web ACL and its resources. To do this, choose Create AWS CloudFormation stack.

After the automatic migration process completes, you're ready to proceed to the manual follow-up steps. See Migrating a web ACL: manual follow-up (p. 249).

**Migrating a web ACL: manual follow-up**

After the automated migration is complete, review the newly created web ACL and fill in the components that the migration doesn't bring over for you. The following procedure covers the aspects of web ACL management that the migration doesn't handle. For the list, see Migration caveats and limitations (p. 247).

**To finish the basic migration - manual steps**

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
2. The console should automatically use the latest version of AWS WAF. To verify this, in the navigation pane, check that you can see the option Switch to AWS WAF Classic. If you see Switch to new AWS WAF, choose that to switch to the latest version.
3. In the navigation pane, choose Web ACLs.
4. In the Web ACLs page, locate your new web ACL in the list for the Region where you created it. Choose the web ACL's name to bring up the settings for the web ACL.
5. Review all of the settings for the new web ACL against your prior AWS WAF Classic web ACL. By default, logging and protected resource associations are disabled. You enable those when you're ready to switch over.
6. If your AWS WAF Classic web ACL had a rate-based rule with a condition, the condition wasn't brought over in the migration. You can add conditions to the rule in the new web ACL.
   a. In your web ACL settings page, choose the Rules tab.
   b. Locate your rate-based rule in the list, select it, and choose Edit.
   c. For Criteria to count request towards rate limit, select Only consider requests that match the criteria in a rule statement, then provide your additional criteria. You can add the criteria using any rule statement that can be nested, including logical statements. For information about your choices, see Rule statements list (p. 86).
7. If your AWS WAF Classic web ACL had a managed rule group, the rule group inclusion wasn’t brought over in the migration. You can add managed rule groups to the new web ACL. Review the information about managed rule groups, including the list of AWS Managed Rules that are available with the new version of AWS WAF, at Managed rule groups (p. 26). To add a managed rule group, do the following:

   a. In your web ACL settings page, choose the web ACL Rules tab.
   b. Choose Add rules, then choose Add managed rule groups.
   c. Expand the listing for the vendor of your choice and select the rule groups that you want to add. For AWS Marketplace sellers, you might need to subscribe to the rule groups. For more information about using managed rule groups in your web ACL, see Managed rule groups (p. 26) and Web ACL rule and rule group evaluation (p. 13).

After you finish the basic migration process, we recommend that you review your needs and consider additional options, to be sure that the new configuration is as efficient as possible and that it's using the latest available security options. See Migrating a web ACL: additional considerations (p. 250).

### Migrating a web ACL: additional considerations

Review your new web ACL and consider the options available to you in the new AWS WAF to be sure that the configuration is as efficient as possible and that it's using the latest available security options.

### Additional AWS Managed Rules

Consider implementing additional AWS Managed Rules in your web ACL to increase the security posture for your application. These are included with AWS WAF at no additional cost. AWS Managed Rules feature the following types of rule groups:

- Baseline rule groups provide general protection against a variety of common threats, such as stopping known bad inputs from making it into your application and preventing admin page access.
- Use-case specific rule groups provide incremental protection for many diverse use cases and environments.
- IP reputation lists provide threat intelligence based on the client’s source IP.

For more information, see AWS Managed Rules for AWS WAF (p. 34).

### Rule optimization and cleanup

Revisit your old rules and consider optimizing them by rewriting them or removing outdated ones. For example, if in the past, you deployed an AWS CloudFormation template from the technical paper for OWASP Top 10 Web Application Vulnerabilities, Prepare for the OWASP Top 10 Web Application Vulnerabilities Using AWS WAF and Our New White Paper, you should consider replacing that with AWS Managed Rules. While the concept found within the document is still applicable and may assist you in writing your own rules, the rules created by the template have been largely superseded by AWS Managed Rules.

### Amazon CloudWatch metrics and alarms

Revisit your Amazon CloudWatch metrics and set up alarms as needed. The migration doesn't carry over CloudWatch alarms and it’s possible that your metric names aren't what you want.

### Review with your application team

Work with your application team and check your security posture. Find out what fields are parsed frequently by the application and add rules to sanitize the input accordingly. Check for any edge cases and add rules to catch these cases if the application's business logic fails to process them.
Plan the switchover

Plan the timing of the switch with your application team. The switch from the old web ACL association to the new one can take a small amount of time to propagate to all areas where your resources are stored. The propagation time can be from a few seconds to a number of minutes. During this time, some requests will be processed by the old web ACL and others will be processed by the new web ACL. Your resources will be protected throughout the switch, but you might notice inconsistencies in request handling while the switch is underway.

When you are ready to switch over, follow the procedure at Migrating a web ACL: switchover (p. 251).

Migrating a web ACL: switchover

After you've verified your new web ACL settings, you can start to use it in place of your AWS WAF Classic web ACL.

To begin using your new AWS WAF web ACL

1. Associate the AWS WAF web ACL with the resources that you want to protect, following the guidance at Associating or disassociating a web ACL with an AWS resource (p. 23). This automatically disassociates the resources from the old web ACL.

   The switch can take from a few seconds to a number of minutes to propagate. During this time, some requests might be processed by the old web ACL and others by the new web ACL. Your resources will be protected throughout the switch, but you might notice inconsistencies in request handling until it's complete.

2. Configure logging for the new web ACL, following the guidance at Logging web ACL traffic (p. 192).

3. (Optional) If your AWS WAF Classic web ACL is no longer associated with any resources, consider removing it entirely from AWS WAF Classic. For information, see Deleting a Web ACL (p. 311).
**AWS WAF Classic**

*Note*
This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see [Migrating your AWS WAF Classic resources to AWS WAF](#).

For the latest version of AWS WAF, see [AWS WAF](#).

AWS WAF Classic is a web application firewall that lets you monitor the HTTP and HTTPS requests that are forwarded to an Amazon API Gateway API, Amazon CloudFront or an Application Load Balancer. AWS WAF Classic also lets you control access to your content. Based on conditions that you specify, such as the IP addresses that requests originate from or the values of query strings, API Gateway, CloudFront or an Application Load Balancer responds to requests either with the requested content or with an HTTP 403 status code (Forbidden). You also can configure CloudFront to return a custom error page when a request is blocked.

---

**Setting up AWS WAF Classic**

*Note*
This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see [Migrating your AWS WAF Classic resources to AWS WAF](#).

For the latest version of AWS WAF, see [AWS WAF](#).

This topic describes preliminary steps, such as creating an AWS account, to prepare you to use AWS WAF Classic. You are not charged to set up this account and other preliminary items. You are charged only for AWS services that you use.
Note
If you are a new user, don't follow these setup steps for AWS WAF Classic. Instead, follow the steps for the latest version of AWS WAF, at Setting up (p. 3).

After you complete these steps, see Getting started with AWS WAF Classic (p. 258) to continue getting started with AWS WAF Classic.

Note
AWS Shield Standard is included with AWS WAF Classic and does not require additional setup. For more information, see How AWS Shield works (p. 461).

Before you use AWS WAF Classic or AWS Shield Advanced for the first time, complete the following tasks:

- Step 1: Sign up for an AWS account (p. 253)
- Step 2: Create an IAM user (p. 253)
- Step 3: Download tools (p. 255)

Step 1: Sign up for an AWS account

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all services in AWS, including AWS WAF Classic. You are charged only for the services that you use.

If you have an AWS account already, skip to the next task. If you don't have an AWS account, use the following procedure to create one.

To sign up for AWS

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

   When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

   Note your AWS account number, because you'll need it for the next task.

Step 2: Create an IAM user

To use the AWS WAF Classic console, you must sign in to confirm that you have permission to perform AWS WAF Classic operations. You can use the root credentials for your AWS account, but we don't recommend it. For greater security and control of your account, we recommend that you use AWS Identity and Access Management (IAM) to do the following:

- Create an IAM user account for yourself or your business.
- Either add the IAM user account to an IAM group that has administrative permissions, or grant administrative permissions directly to the IAM user account.
- Verify that the account has full access to AWS WAF Classic and related services, for general use and for console access. For information, see AWS managed (predefined) policies for AWS WAF Classic (p. 337).
You then can sign in to the AWS WAF Classic console (and other service consoles) by using a special URL and the credentials for the IAM user. You also can add other users to the IAM user account, and control their level of access to AWS services and to your resources.

**Note**
For information about creating access keys to access AWS WAF Classic by using the AWS Command Line Interface (AWS CLI), Tools for Windows PowerShell, the AWS SDKs, or the AWS WAF Classic API, see Managing Access Keys for IAM Users.

If you signed up for AWS but have not created an IAM user for yourself, you can create one using the IAM console. If you aren't familiar with using the console, see Working with the AWS Management Console for an overview.

To create an administrator user, choose one of the following options.

<table>
<thead>
<tr>
<th>Choose one way to manage your administrator</th>
<th>To</th>
<th>By</th>
<th>You can also</th>
</tr>
</thead>
<tbody>
<tr>
<td>In IAM Identity Center (Recommended)</td>
<td>Use short-term credentials to access AWS.</td>
<td>Following the instructions in Getting started in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.</td>
<td>Configure programmatic access by Configuring the AWS CLI to use AWS IAM Identity Center (successor to AWS Single Sign-On) in the AWS Command Line Interface User Guide.</td>
</tr>
<tr>
<td>In IAM (Not recommended)</td>
<td>Use long-term credentials to access AWS.</td>
<td>Following the instructions in Creating your first IAM admin user and user group in the IAM User Guide.</td>
<td>Configure programmatic access by Managing access keys for IAM users in the IAM User Guide.</td>
</tr>
</tbody>
</table>

To sign in as this new IAM user, first sign out of the AWS Management Console. Then use the following URL, where `your_aws_account_id` is your AWS account number without the hyphens. For example, if your AWS account number is `1234-5678-9012`, your AWS account ID is `123456789012`:

```
https://your_aws_account_id.signin.aws.amazon.com/console/
```

Enter the IAM user name and password that you just created. When you're signed in, the navigation bar displays "`your_user_name @ your_aws_account_id`".

If you don't want the URL for your sign-in page to contain your AWS account ID, you can create an account alias. From the IAM dashboard, choose Customize and enter an alias, such as your company name. To sign in after you create an account alias, use the following URL:

```
https://your_account_alias.signin.aws.amazon.com/console/
```

To verify the sign-in link for IAM users for your account, open the IAM console and check under the IAM users sign-in link on the dashboard.
After you complete these steps, you can stop here and go to Getting started with AWS WAF Classic (p. 258) to continue getting started with AWS WAF Classic using the console. If you want to access AWS WAF Classic programmatically using the AWS WAF Classic API, continue on to the next step, Step 3: Download tools (p. 255).

Step 3: Download tools

The AWS Management Console includes a console for AWS WAF Classic, but if you want to access AWS WAF Classic programmatically, the following documentation and tools will help you:

- If you want to call the AWS WAF Classic API without having to handle low-level details like assembling raw HTTP requests, you can use an AWS SDK. The AWS SDKs provide functions and data types that encapsulate the functionality of AWS WAF Classic and other AWS services. To download an AWS SDK, see the applicable page, which also includes prerequisites and installation instructions:
  - Java
  - JavaScript
  - .NET
  - Node.js
  - PHP
  - Python
  - Ruby

For a complete list of AWS SDKs, see Tools for Amazon Web Services.

- If you’re using a programming language for which AWS doesn’t provide an SDK, the AWS WAF API Reference documents the operations that AWS WAF Classic supports.

- The AWS Command Line Interface (AWS CLI) supports AWS WAF Classic. The AWS CLI lets you control multiple AWS services from the command line and automate them through scripts. For more information, see AWS Command Line Interface.

- AWS Tools for Windows PowerShell supports AWS WAF Classic. For more information, see AWS Tools for PowerShell Cmdlet Reference.

How AWS WAF Classic works

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

You use AWS WAF Classic to control how API Gateway, Amazon CloudFront or an Application Load Balancer responds to web requests. You start by creating conditions, rules, and web access control lists (web ACLs). You define your conditions, combine your conditions into rules, and combine the rules into a web ACL.

Note
You can also use AWS WAF Classic to protect your applications that are hosted in Amazon Elastic Container Service (Amazon ECS) containers. Amazon ECS is a highly scalable, fast container management service that makes it easy to run, stop, and manage Docker containers on a cluster. To use this option, you configure Amazon ECS to use an AWS WAF Classic enabled Application Load Balancer to route and protect HTTP/HTTPS (layer 7) traffic across the tasks in your service. For more information, see the topic Service Load Balancing in the Amazon Elastic Container Service Developer Guide.
Conditions

Conditions define the basic characteristics that you want AWS WAF Classic to watch for in web requests:

- Scripts that are likely to be malicious. Attackers embed scripts that can exploit vulnerabilities in web applications. This is known as cross-site scripting.
- IP addresses or address ranges that requests originate from.
- Country or geographical location that requests originate from.
- Length of specified parts of the request, such as the query string.
- SQL code that is likely to be malicious. Attackers try to extract data from your database by embedding malicious SQL code in a web request. This is known as SQL injection.
- Strings that appear in the request, for example, values that appear in the User-Agent header or text strings that appear in the query string. You can also use regular expressions (regex) to specify these strings.

Some conditions take multiple values. For example, you can specify up to 10,000 IP addresses or IP address ranges in an IP condition.

Rules

You combine conditions into rules to precisely target the requests that you want to allow, block, or count. AWS WAF Classic provides two types of rules:

Regular rule

Regular rules use only conditions to target specific requests. For example, based on recent requests that you’ve seen from an attacker, you might create a rule that includes the following conditions:

- The requests come from 192.0.2.44.
- They contain the value BadBot in the User-Agent header.
- They appear to include SQL-like code in the query string.

When a rule includes multiple conditions, as in this example, AWS WAF Classic looks for requests that match all conditions—that is, it ANDs the conditions together.

Add at least one condition to a regular rule. A regular rule without conditions can’t match any requests, so the rule’s action (allow, count, or block) is never triggered.

Rate-based rule

Rate-based rules are like regular rules with an added rate limit. A rate-based rule counts the requests that arrive from IP addresses that satisfy the rule’s conditions. If the requests from an IP address exceed the rate limit in a five-minute period, the rule can trigger an action. It can take a minute or two for the action to trigger.

Conditions are optional for rate-based rules. If you don’t add any conditions in a rate-based rule, the rate limit applies to all IP addresses. If you combine conditions with the rate limit, the rate limit applies to IP addresses that match the conditions.

For example, based on recent requests that you’ve seen from an attacker, you might create a rate-based rule that includes the following conditions:

- The requests come from 192.0.2.44.
- They contain the value BadBot in the User-Agent header.

In this rate-based rule, you also define a rate limit. In this example, let’s say that you create a rate limit of 1,000. Requests that meet both of the preceding conditions and exceed 1,000...
requests per five minutes trigger the rule’s action (block or count), which is defined in the web ACL.

Requests that don’t meet both conditions aren’t counted towards the rate limit and aren’t affected by this rule.

As a second example, suppose that you want to limit requests to a particular page on your website. To do this, you could add the following string match condition to a rate-based rule:

- The **Part of the request to filter on** is **URI**.
- The **Match Type** is **Starts with**.
- A **Value to match** is **login**.

Further, you specify a **RateLimit** of 1,000.

By adding this rate-based rule to a web ACL, you could limit requests to your login page without affecting the rest of your site.

**Web ACLs**

After you combine your conditions into rules, you combine the rules into a web ACL. This is where you define an action for each rule—allow, block, or count—and a default action:

**An action for each rule**

When a web request matches all the conditions in a rule, AWS WAF Classic can either block the request or allow the request to be forwarded to the API Gateway API, CloudFront distribution or an Application Load Balancer. You specify the action that you want AWS WAF Classic to perform for each rule.

AWS WAF Classic compares a request with the rules in a web ACL in the order in which you listed the rules. AWS WAF Classic then takes the action that is associated with the first rule that the request matches. For example, if a web request matches one rule that allows requests and another rule that blocks requests, AWS WAF Classic will either allow or block the request depending on which rule is listed first.

If you want to test a new rule before you start using it, you also can configure AWS WAF Classic to count the requests that meet all the conditions in the rule. As with rules that allow or block requests, a rule that counts requests is affected by its position in the list of rules in the web ACL. For example, if a web request matches a rule that allows requests and another rule that counts requests, and if the rule that allows requests is listed first, the request isn’t counted.

**A default action**

The default action determines whether AWS WAF Classic allows or blocks a request that doesn’t match all the conditions in any of the rules in the web ACL. For example, suppose you create a web ACL and add only the rule that you defined before:

- The requests come from 192.0.2.44.
- They contain the value BadBot in the **User-Agent** header.
- They appear to include malicious SQL code in the query string.

If a request doesn’t meet all three conditions in the rule and if the default action is **ALLOW**, AWS WAF Classic forwards the request to API Gateway, CloudFront or an Application Load Balancer, and the service responds with the requested object.

If you add two or more rules to a web ACL, AWS WAF Classic performs the default action only if a request doesn’t satisfy all the conditions in any of the rules. For example, suppose you add a second rule that contains one condition:

- Requests that contain the value BIGBadBot in the **User-Agent** header.
AWS WAF Classic performs the default action only when a request doesn't meet all three conditions in the first rule and doesn't meet the one condition in the second rule.

On some occasions, AWS WAF might encounter an internal error that delays the response to Amazon API Gateway, Amazon CloudFront or an Application Load Balancer about whether to allow or block a request. On those occasions CloudFront will typically allow the request or serve the content. API Gateway and an Application Load Balancer typically will deny the request and not serve the content.

**AWS WAF Classic pricing**

*Note*

This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see [Migrating your AWS WAF Classic resources to AWS WAF](#p. 245).

*For the latest version of AWS WAF, see AWS WAF (p. 6).*

With AWS WAF Classic, you pay only for the web ACLs and rules that you create, and for the number of HTTP requests that AWS WAF Classic inspects. For more information, see [AWS WAF Classic Pricing](#).

**Getting started with AWS WAF Classic**

*Note*

This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see [Migrating your AWS WAF Classic resources to AWS WAF](#p. 245).

*For the latest version of AWS WAF, see AWS WAF (p. 6).*

This tutorial shows how to use AWS WAF Classic to perform the following tasks:

- Set up AWS WAF Classic.
- Create a web access control list (web ACL) using the AWS WAF Classic console, and specify the conditions that you want to use to filter web requests. For example, you can specify the IP addresses that the requests originate from and values in the request that are used only by attackers.
- Add the conditions to a rule. Rules let you target the web requests that you want to block or allow. A web request must match all the conditions in a rule before AWS WAF Classic blocks or allows requests based on the conditions that you specify.
- Add the rules to your web ACL. This is where you specify whether you want to block web requests or allow them based on the conditions that you add to each rule.
- Specify a default action, either block or allow. This is the action that AWS WAF Classic takes when a web request doesn't match any of your rules.
- Choose the Amazon CloudFront distribution that you want AWS WAF Classic to inspect web requests for. This tutorial covers the steps only for CloudFront, but the process for an Application Load Balancer and Amazon API Gateway APIs essentially is the same. AWS WAF Classic for CloudFront is available for all AWS Regions. AWS WAF Classic for use with API Gateway or an Application Load Balancer is available in the Regions listed at [AWS service endpoints](#).

*Note*

AWS typically bills you less than US $0.25 per day for the resources that you create during this tutorial. When you're finished with the tutorial, we recommend that you delete the resources to prevent incurring unnecessary charges.
Step 1: Set up AWS WAF Classic

If you already signed up for an AWS account and created an IAM user as described in Setting up AWS WAF Classic (p. 252), go to Step 2: Create a Web ACL (p. 259).

If not, go to Setting up AWS WAF Classic (p. 252) and perform at least the first two steps. (You can skip downloading tools for now because this Getting Started topic focuses on using the AWS WAF Classic console.)

Step 2: Create a Web ACL

The AWS WAF Classic console guides you through the process of configuring AWS WAF Classic to block or allow web requests based on conditions that you specify, such as the IP addresses that the requests originate from or values in the requests. In this step, you create a web ACL.

To create a web ACL

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see Switch to AWS WAF Classic in the navigation pane, select it.

2. If this is your first time using AWS WAF Classic, choose Go to AWS WAF Classic, and then choose Configure web ACL.

   If you've used AWS WAF Classic before, choose Web ACLs in the navigation pane, and then choose Create web ACL.

3. On the Name web ACL page, for Web ACL name, enter a name.

   Note
   You can't change the name after you create the web ACL.

4. For CloudWatch metric name, enter a name. The name can contain only alphanumeric characters (A-Z, a-z, 0-9). It can't contain white space.

   Note
   You can't change the name after you create the web ACL.

5. For Region, choose a Region. If you will associate this web ACL with a CloudFront distribution, choose Global (CloudFront).
6. For AWS resource to associate, choose the resource that you want to associate with your web ACL, and then choose Next.

Step 3: Create an IP match condition

An IP match condition specifies the IP addresses or IP address ranges that requests originate from. In this step, you create an IP match condition. In a later step, you specify whether you want to allow requests or block requests that originate from the specified IP addresses.

Note
For more information about IP match conditions, see Working with IP match conditions (p. 274).

To create an IP match condition

1. On the Create conditions page, for IP match conditions, choose Create condition.
2. In the Create IP match condition dialog box, for Name, enter a name. The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: `-!"#`'`*},./ .
3. For Address, enter 192.0.2.0/24. This IP address range, specified in CIDR notation, includes the IP addresses from 192.0.2.0 to 192.0.2.255. (The 192.0.2.0/24 IP address range is reserved for examples, so no web requests will originate from these IP addresses.)

AWS WAF Classic supports IPv4 address ranges: /8 and any range between /16 through /32. AWS WAF Classic supports IPv6 address ranges: /24, /32, /48, /56, /64, and /128. (To specify a single IP address, such as 192.0.2.44, enter 192.0.2.44/32.) Other ranges aren't supported.

4. Choose Create.

Step 4: Create a geo match condition

A geo match condition specifies the country or countries that requests originate from. In this step, you create a geo match condition. In a later step, you specify whether you want to allow requests or block requests that originate from the specified countries.

Note
For more information about geo match conditions, see Working with geographic match conditions (p. 277).

To create a geo match condition

1. On the Create conditions page, for Geo match conditions, choose Create condition.
2. In the Create geo match condition dialog box, for Name, enter a name. The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: `-!"#`'`*},./ .
3. Choose a Location type and a country. Currently, Location type can only be Country.
4. Choose Add location.
5. Choose Create.

Step 5: Create a string match condition

A string match condition identifies the strings that you want AWS WAF Classic to search for in a request, such as a specified value in a header or in a query string. Usually, a string consists of printable ASCII characters, but you can specify any character from hexadecimal 0x00 to 0xFF (decimal 0 to 255). In this
Step 5: Create a string match condition

In a later step, you specify whether you want to allow or block requests that contain the specified strings.

**Note**
For more information about string match conditions, see Working with string match conditions (p. 288).

To create a string match condition

1. On the Create conditions page, for String and regex match conditions, choose Create condition.
2. In the Create string match condition dialog box, enter the following values:

   - **Name**: Enter a name. The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _-!"`#+*},./.
   - **Type**: Choose String match.
   - **Part of the request to filter on**: Choose the part of the web request that you want AWS WAF Classic to inspect for a specified string.

   **Note**
   If you choose Body for the value of Part of the request to filter on, AWS WAF Classic inspects only the first 8192 bytes (8 KB) because CloudFront forwards only the first 8192 bytes for inspection. To allow or block requests for which the body is longer than 8192 bytes, you can create a size constraint condition. (AWS WAF Classic gets the length of the body from the request headers.) For more information, see Working with size constraint conditions (p. 279).

   - **Header (Required if "Part of the request to filter on" is "Header")**: Because you chose Header for Part of the request to filter on, you must specify which header you want AWS WAF Classic to inspect. Enter User-Agent. (This value is not case sensitive.)
   - **Match type**: Choose where the specified string must appear in the User-Agent header, for example, at the beginning, at the end, or anywhere in the string.

   **Note**
   In an effort to bypass AWS WAF Classic, attackers use unusual formatting in web requests, for example, by adding white space or by URL-encoding some or all of the request. Transformations convert the web request to a more standard format by removing white space, by URL-decoding the request, or by performing other operations that eliminate much of the unusual formatting that attackers commonly use.

   You can only specify a single type of text transformation.

   - **Transformation**: For this example, choose None.
   - **Value is base64 encoded**: When the value that you enter in Value to match is already base64-encoded, select this check box.
Step 5A: Create a regex condition (optional)

A regular expression condition is a type of string match condition and similar in that it identifies the strings that you want AWS WAF Classic to search for in a request, such as a specified value in a header or in a query string. The primary difference is that you use a regular expression (regex) to specify the string pattern that you want AWS WAF Classic to search for. In this step, you create a regex match condition. In a later step, you specify whether you want to allow or block requests that contain the specified strings.

**Note**
For more information about regex match conditions, see Working with regex match conditions (p. 293).

To create a regex match condition

1. On the Create conditions page, for String match and regex conditions, choose Create condition.
2. In the Create string match condition dialog box, enter the following values:

   **Name**
   Enter a name. The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _-!"#$`+*},./ .

   **Type**
   Choose Regex match.

   **Part of the request to filter on**
   Choose the part of the web request that you want AWS WAF Classic to inspect for a specified string.

   For this example, choose Body.

   **Note**
   If you choose Body for the value of Part of the request to filter on, AWS WAF Classic inspects only the first 8192 bytes (8 KB) because CloudFront forwards only the first
8192 bytes for inspection. To allow or block requests for which the body is longer than 8192 bytes, you can create a size constraint condition. (AWS WAF Classic gets the length of the body from the request headers.) For more information, see Working with size constraint conditions (p. 279).

**Transformation**

In an effort to bypass AWS WAF Classic, attackers use unusual formatting in web requests, for example, by adding white space or by URL-encoding some or all of the request. Transformations convert the web request to a more standard format by removing white space, by URL-decoding the request, or by performing other operations that eliminate much of the unusual formatting that attackers commonly use.

You can only specify a single type of text transformation.

For this example, choose **None**.

**Regex patterns to match to request**

Choose **Create regex pattern set**.

**New pattern set name**

Enter a name and then specify the regex pattern that you want AWS WAF Classic to search for.

Next, enter the regular expression \[a@]mAB\[a@]dRequest. AWS WAF Classic will inspect the User-Agent header in web requests for the values:

- IamABadRequest
- IamAB@dRequest
- I@mABadRequest
- I@mAB@dRequest

3. Choose **Create pattern set and add filter**.
4. Choose **Create**.

### Step 6: Create a SQL injection match condition

A SQL injection match condition identifies the part of web requests, such as a header or a query string, that you want AWS WAF Classic to inspect for malicious SQL code. Attackers use SQL queries to extract data from your database. In this step, you create a SQL injection match condition. In a later step, you specify whether you want to allow requests or block requests that appear to contain malicious SQL code.

**Note**

For more information about string match conditions, see Working with SQL injection match conditions (p. 284).

**To create a SQL injection match condition**

1. On the **Create conditions** page, for **SQL injection match conditions**, choose **Create condition**.
2. In the **Create SQL injection match condition** dialog box, enter the following values:
   
   **Name**
   
   Enter a name.

   **Part of the request to filter on**
   
   Choose the part of web requests that you want AWS WAF Classic to inspect for malicious SQL code.

   For this example, choose **Query string**.
Step 7: (Optional) create additional conditions

AWS WAF Classic includes other conditions, including the following:

- **Size constraint conditions** – Identifies the part of web requests, such as a header or a query string, that you want AWS WAF Classic to check for length. For more information, see Working with size constraint conditions (p. 279).

- **Cross-site scripting match conditions** – Identifies the part of web requests, such as a header or a query string, that you want AWS WAF to inspect for malicious scripts. For more information, see Working with cross-site scripting match conditions (p. 270).

You can optionally create these conditions now, or you can skip to Step 8: Create a rule and add conditions (p. 264).

Step 8: Create a rule and add conditions

You create a rule to specify the conditions that you want AWS WAF Classic to search for in web requests. If you add more than one condition to a rule, a web request must match all the conditions in the rule for AWS WAF Classic to allow or block requests based on that rule.

**Note**
For more information about rules, see Working with rules (p. 299).

To create a rule and add conditions

1. On the Create rules page, choose Create rule.
2. In the Create rule dialog box, enter the following values:

**Name**

Enter a name.

**CloudWatch metric name**

Enter a name for the CloudWatch metric that AWS WAF Classic will create and will associate with the rule. The name can contain only alphanumeric characters (A-Z, a-z, 0-9). It can't contain white space.
Step 8: Create a rule and add conditions

**Rule type**

Choose either **Regular rule** or **Rate-based rule**. Rate-based rules are identical to regular rules but also take into account how many requests arrive from the identified IP address in any five-minute period. For more information about the rule types, see *How AWS WAF Classic works* (p. 255). For this example, choose **Regular rule**.

**Rate limit**

For a rate-based rule, enter the maximum number of requests to allow in any five-minute period from an IP address that matches the rule’s conditions.

3. For the first condition that you want to add to the rule, specify the following settings:

   - Choose whether you want AWS WAF Classic to allow or block requests based on whether a web request does or does not match the settings in the condition.

   For this example, choose **does**.

   - Choose the type of condition that you want to add to the rule: an IP match set condition, a string match set condition, or a SQL injection match set condition.

   For this example, choose **originate from IP addresses in**.

   - Choose the condition that you want to add to the rule.

   For this example, choose the IP match condition that you created in previous tasks.

4. Choose **Add condition**.

5. Add the geo match condition that you created earlier. Specify the following values:

   - **When a request does**
   - **originate from a geographic location in**
   - Choose your geo match condition.

6. Choose **Add another condition**.

7. Add the string match condition that you created earlier. Specify the following values:

   - **When a request does**
   - **match at least one of the filters in the string match condition**
   - Choose your string match condition.

8. Choose **Add condition**.

9. Add the SQL injection match condition that you created earlier. Specify the following values:

   - **When a request does**
   - **match at least one of the filters in the SQL injection match condition**
   - Choose your SQL injection match condition.

10. Choose **Add condition**.

11. Add the size constraint condition that you created earlier. Specify the following values:

   - **When a request does**
   - **match at least one of the filters in the size constraint condition**
   - Choose your size constraint condition.

12. If you created any other conditions, such as a regex condition, add those in a similar manner.

13. Choose **Create**.

14. For the **Default action**, choose **Allow all requests that don’t match any rules**.

15. Choose **Review and create**.
Step 9: Add the rule to a Web ACL

When you add the rule to a web ACL, you specify the following settings:

- The action that you want AWS WAF Classic to take on web requests that match all the conditions in the rule: allow, block, or count the requests.
- The default action for the web ACL. This is the action that you want AWS WAF Classic to take on web requests that do not match all the conditions in the rule: allow or block the requests.

AWS WAF Classic starts blocking CloudFront web requests that match all the following conditions (and any others you might have added):

- The value of the User-Agent header is BadBot
- (If you created and added the regex condition) The value of the Body is any of the four strings that matches the pattern I[a@]mAB[a@]dRequest
- The requests originate from IP addresses in the range 192.0.2.0-192.0.2.255
- The requests originate from the country that you selected in your geo match condition
- The requests appear to include malicious SQL code in the query string

AWS WAF Classic allows CloudFront to respond to any requests that don't meet all three of these conditions.

Step 10: Clean up your resources

You've now successfully completed the tutorial. To prevent your account from accruing additional AWS WAF Classic charges, you should clean up the AWS WAF Classic objects that you created. Alternatively, you can change the configuration to match the web requests that you really want to allow, block, and count.

Note
AWS typically bills you less than US $0.25 per day for the resources that you create during this tutorial. When you're finished, we recommend that you delete the resources to prevent incurring unnecessary charges.

To delete the objects that AWS WAF Classic charges for

1. Disassociate your web ACL from your CloudFront distribution:
   a. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   b. Choose the name of the web ACL that you want to delete. This opens a page with the web ACL's details in the right pane.
   c. In the right pane, on the Rules tab, go to the AWS resources using this web ACL section. For the CloudFront distribution that you associated the web ACL with, choose the x in the Type column.
2. Remove the conditions from your rule:
   a. In the navigation pane, choose Rules.
   b. Choose the rule that you created during the tutorial.
   c. Choose Edit rule.
   d. Choose the x at the right of each condition heading.
e. Choose **Update**.

3. Remove the rule from your web ACL, and delete the web ACL:
   
a. In the navigation pane, choose **Web ACLs**.
   
b. Choose the name of the web ACL that you created during the tutorial. This opens a page with the web ACL’s details in the right pane.
   
c. On the **Rules** tab, choose **Edit web ACL**.
   
d. Choose the x at the right of the rule heading.
   
e. Choose **Actions**, and then choose **Delete web ACL**.

4. Delete your rule:
   
a. In the navigation pane, choose **Rules**.
   
b. Choose the rule that you created during the tutorial.
   
c. Choose **Delete**.
   
d. In the **Delete** dialog box, choose **Delete** again to confirm.

AWS WAF Classic doesn’t charge for conditions, but if you want to complete the cleanup, perform the following procedure to remove filters from conditions and delete the conditions.

### To delete filters and conditions

1. Delete the IP address range in your IP match condition, and delete the IP match condition:
   
a. In the navigation pane of the AWS WAF Classic console, choose **IP addresses**.
   
b. Choose the IP match condition that you created during the tutorial.
   
c. Select the check box for the IP address range that you added.
   
d. Choose **Delete IP address or range**.
   
e. In the **IP match conditions** pane, choose **Delete**.
   
f. In the **Delete** dialog box, choose **Delete** again to confirm.

2. Delete the filter in your SQL injection match condition, and delete the SQL injection match condition:
   
a. In the navigation pane, choose **SQL injection**.
   
b. Choose the SQL injection match condition that you created during the tutorial.
   
c. Select the check box for the filter that you added.
   
d. Choose **Delete filter**.
   
e. In the **SQL injection match conditions** pane, choose **Delete**.
   
f. In the **Delete** dialog box, choose **Delete** again to confirm.

3. Delete the filter in your string match condition, and delete the string match condition:
   
a. In the navigation pane, choose **String and regex matching**.
   
b. Choose the string match condition that you created during the tutorial.
   
c. Select the check box for the filter that you added.
   
d. Choose **Delete filter**.
   
e. In the **String match conditions** pane, choose **Delete**.
   
f. In the **Delete** dialog box, choose **Delete** again to confirm.

4. If you created one, delete the filter in your regex match condition, and delete the regex match condition:
   
a. In the navigation pane, choose **String and regex matching**.
Creating and configuring a Web Access Control List (Web ACL)

**Note**
This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of **AWS WAF**, see AWS WAF (p. 6).

A web access control list (web ACL) gives you fine-grained control over the web requests that your Amazon API Gateway API, Amazon CloudFront distribution or Application Load Balancer responds to. You can allow or block the following types of requests:

- Originates from an IP address or a range of IP addresses
- Originates from a specific country or countries
- Contain a specified string or match a regular expression (regex) pattern in a particular part of requests
- Exceed a specified length
- Appear to contain malicious SQL code (known as SQL injection)
- Appear to contain malicious scripts (known as cross-site scripting)

You can also test for any combination of these conditions, or block or count web requests that not only meet the specified conditions, but also exceed a specified number of requests in any 5-minute period.

To choose the requests that you want to allow to have access to your content or that you want to block, perform the following tasks:

1. Choose the default action, allow or block, for web requests that don't match any of the conditions that you specify. For more information, see Deciding on the default action for a Web ACL (p. 306).
2. Specify the conditions under which you want to allow or block requests:
   - To allow or block requests based on whether the requests appear to contain malicious scripts, create cross-site scripting match conditions. For more information, see Working with cross-site scripting match conditions (p. 270).
   - To allow or block requests based on the IP addresses that they originate from, create IP match conditions. For more information, see Working with IP match conditions (p. 274).
• To allow or block requests based on the country that they originate from, create geo match conditions. For more information, see Working with geographic match conditions (p. 277).
• To allow or block requests based on whether the requests exceed a specified length, create size constraint conditions. For more information, see Working with size constraint conditions (p. 279).
• To allow or block requests based on whether the requests appear to contain malicious SQL code, create SQL injection match conditions. For more information, see Working with SQL injection match conditions (p. 284).
• To allow or block requests based on strings that appear in the requests, create string match conditions. For more information, see Working with string match conditions (p. 288).
• To allow or block requests based on a regex pattern that appear in the requests, create regex match conditions. For more information, see Working with regex match conditions (p. 293).

3. Add the conditions to one or more rules. If you add more than one condition to the same rule, web requests must match all the conditions for AWS WAF Classic to allow or block requests based on the rule. For more information, see Working with rules (p. 299). Optionally, you can use a rate-based rule instead of a regular rule to limit the number of requests from any IP address that meets the conditions.

4. Add the rules to a web ACL. For each rule, specify whether you want AWS WAF Classic to allow or block requests based on the conditions that you added to the rule. If you add more than one rule to a web ACL, AWS WAF Classic evaluates the rules in the order that they’re listed in the web ACL. For more information, see Working with web ACLs (p. 306).

When you add a new rule or update existing rules, it can take up to one minute for those changes to appear and be active across your web ACLs and resources.

Topics
• Working with conditions (p. 269)
• Working with rules (p. 299)
• Working with web ACLs (p. 306)

Working with conditions

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

Conditions specify when you want to allow or block requests.

• To allow or block requests based on whether the requests appear to contain malicious scripts, create cross-site scripting match conditions. For more information, see Working with cross-site scripting match conditions (p. 270).
• To allow or block requests based on the IP addresses that they originate from, create IP match conditions. For more information, see Working with IP match conditions (p. 274).
• To allow or block requests based on the country that they originate from, create geo match conditions. For more information, see Working with geographic match conditions (p. 277).
• To allow or block requests based on whether the requests exceed a specified length, create size constraint conditions. For more information, see Working with size constraint conditions (p. 279).
• To allow or block requests based on whether the requests appear to contain malicious SQL code, create SQL injection match conditions. For more information, see Working with SQL injection match conditions (p. 284).
• To allow or block requests based on strings that appear in the requests, create string match conditions. For more information, see Working with string match conditions (p. 288).

• To allow or block requests based on a regex pattern that appear in the requests, create regex match conditions. For more information, see Working with regex match conditions (p. 293).

• Working with SQL injection match conditions (p. 284)
• Working with string match conditions (p. 288)
• Working with regex match conditions (p. 293)

Working with cross-site scripting match conditions

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

Attackers sometimes insert scripts into web requests in an effort to exploit vulnerabilities in web applications. You can create one or more cross-site scripting match conditions to identify the parts of web requests, such as the URI or the query string, that you want AWS WAF Classic to inspect for possible malicious scripts. Later in the process, when you create a web ACL, you specify whether to allow or block requests that appear to contain malicious scripts.

Topics

• Creating cross-site scripting match conditions (p. 270)
• Values that you specify when you create or edit cross-site scripting match conditions (p. 271)
• Adding and deleting filters in a cross-site scripting match condition (p. 273)
• Deleting cross-site scripting match conditions (p. 274)

Creating cross-site scripting match conditions

When you create cross-site scripting match conditions, you specify filters. The filters indicate the part of web requests that you want AWS WAF Classic to inspect for malicious scripts, such as the URI or the query string. You can add more than one filter to a cross-site scripting match condition, or you can create a separate condition for each filter. Here’s how each configuration affects AWS WAF Classic behavior:

• More than one filter per cross-site scripting match condition (recommended) – When you add a cross-site scripting match condition that contains multiple filters to a rule and add the rule to a web ACL, a web request must match only one of the filters in the cross-site scripting match condition for AWS WAF Classic to allow or block the request based on that condition.

For example, suppose you create one cross-site scripting match condition, and the condition contains two filters. One filter instructs AWS WAF Classic to inspect the URI for malicious scripts, and the other instructs AWS WAF Classic to inspect the query string. AWS WAF Classic allows or blocks requests if they appear to contain malicious scripts either in the URI or in the query string.
• **One filter per cross-site scripting match condition** – When you add the separate cross-site scripting match conditions to a rule and add the rule to a web ACL, web requests must match all the conditions for AWS WAF Classic to allow or block requests based on the conditions.

Suppose you create two conditions, and each condition contains one of the two filters in the preceding example. When you add both conditions to the same rule and add the rule to a web ACL, AWS WAF Classic allows or blocks requests only when both the URI and the query string appear to contain malicious scripts.

**Note**
When you add a cross-site scripting match condition to a rule, you also can configure AWS WAF Classic to allow or block web requests that *do not* appear to contain malicious scripts.

**To create a cross-site scripting match condition**

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.

   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.

2. In the navigation pane, choose **Cross-site scripting**.

3. Choose **Create condition**.

4. Specify the applicable filter settings. For more information, see **Values that you specify when you create or edit cross-site scripting match conditions** (p. 271).

5. Choose **Add another filter**.

6. If you want to add another filter, repeat steps 4 and 5.

7. When you're done adding filters, choose **Create**.

**Values that you specify when you create or edit cross-site scripting match conditions**

When you create or update a cross-site scripting match condition, you specify the following values:

**Name**

The name of the cross-site scripting match condition.

The name can contain only the characters A-Z, a-z, 0-9, and the special characters: _-!"#$`+*},./ . You can't change the name of a condition after you create it.

**Part of the request to filter on**

Choose the part of each web request that you want AWS WAF Classic to inspect for malicious scripts:

**Header**

A specified request header, for example, the User-Agent or Referer header. If you choose **Header**, specify the name of the header in the **Header** field.

**HTTP method**

The HTTP method, which indicates the type of operation that the request is asking the origin to perform. CloudFront supports the following methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, and PUT.

**Query string**

The part of a URL that appears after a ? character, if any.
Note
For cross-site scripting match conditions, we recommend that you choose **All query parameters (values only)** instead of **Query string** for **Part of the request to filter on**.

**URI**

The URI path of the request, which identifies the resource, for example, /images/daily-ad.jpg. This doesn't include the query string or fragment components of the URI. For information, see Uniform Resource Identifier (URI): Generic Syntax.

Unless a **Transformation** is specified, a URI is not normalized and is inspected just as AWS receives it from the client as part of the request. A **Transformation** will reformat the URI as specified.

**Body**

The part of a request that contains any additional data that you want to send to your web server as the HTTP request body, such as data from a form.

Note
If you choose **Body** for the value of **Part of the request to filter on**, AWS WAF Classic inspects only the first 8192 bytes (8 KB). To allow or block requests for which the body is longer than 8192 bytes, you can create a size constraint condition. (AWS WAF Classic gets the length of the body from the request headers.) For more information, see Working with size constraint conditions (p. 279).

**Single query parameter (value only)**

Any parameter that you have defined as part of the query string. For example, if the URL is "www.xyz.com?UserName=abc&SalesRegion=seattle" you can add a filter to either the **UserName** or **SalesRegion** parameter.

If you choose **Single query parameter (value only)**, you will also specify a **Query parameter name**. This is the parameter in the query string that you will inspect, such as **UserName** or **SalesRegion**. The maximum length for **Query parameter name** is 30 characters. **Query parameter name** is not case sensitive. For example, it you specify **UserName** as the **Query parameter name**, this will match all variations of **UserName**, such as **username** and **USERName**.

**All query parameters (values only)**

Similar to **Single query parameter (value only)**, but rather than inspecting the values of a single parameter, AWS WAF Classic inspects all parameter values within the query string for possible malicious scripts. For example, if the URL is "www.xyz.com?UserName=abc&SalesRegion=seattle," and you choose **All query parameters (values only)**, AWS WAF Classic will trigger a match if either the value of **UserName** or **SalesRegion** contain possible malicious scripts.

**Header**

If you chose **Header** for **Part of the request to filter on**, choose a header from the list of common headers, or enter the name of a header that you want AWS WAF Classic to inspect for malicious scripts.

**Transformation**

A transformation reformats a web request before AWS WAF Classic inspects the request. This eliminates some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF Classic.

You can only specify a single type of text transformation.

Transformations can perform the following operations:
None

AWS WAF Classic doesn’t perform any text transformations on the web request before inspecting it for the string in **Value to match**.

**Convert to lowercase**

AWS WAF Classic converts uppercase letters (A-Z) to lowercase (a-z).

**HTML decode**

AWS WAF Classic replaces HTML-encoded characters with unencoded characters:
- Replaces `"` with `&`
- Replaces `&nbsp;` with a non-breaking space
- Replaces `\lt;` with `<`
- Replaces `\gt;` with `>`
- Replaces characters that are represented in hexadecimal format, `&#xhhhh;`, with the corresponding characters
- Replaces characters that are represented in decimal format, `&#nnnn;`, with the corresponding characters

**Normalize white space**

AWS WAF Classic replaces the following characters with a space character (decimal 32):
- `\f`, formfeed, decimal 12
- `\t`, tab, decimal 9
- `\n`, newline, decimal 10
- `\r`, carriage return, decimal 13
- `\v`, vertical tab, decimal 11
- non-breaking space, decimal 160

In addition, this option replaces multiple spaces with one space.

**Simplify command line**

For requests that contain operating system command line commands, use this option to perform the following transformations:
- Delete the following characters: `\ " ' ^`
- Delete spaces before the following characters: `/ (`
- Replace the following characters with a space: `, ;`
- Replace multiple spaces with one space
- Convert uppercase letters (A-Z) to lowercase (a-z)

**URL decode**

Decode a URL-encoded request.

---

**Adding and deleting filters in a cross-site scripting match condition**

You can add or delete filters in a cross-site scripting match condition. To change a filter, add a new one and delete the old one.

**To add or delete filters in a cross-site scripting match condition**

   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **Cross-site scripting**.
3. Choose the condition that you want to add or delete filters in.
4. To add filters, perform the following steps:
   a. Choose **Add filter**.
   b. Specify the applicable filter settings. For more information, see [Values that you specify when you create or edit cross-site scripting match conditions](p. 271).
   c. Choose **Add**.
5. To delete filters, perform the following steps:
   a. Select the filter that you want to delete.
   b. Choose **Delete filter**.

**Deleting cross-site scripting match conditions**

If you want to delete a cross-site scripting match condition, you must first delete all filters in the condition and remove the condition from all the rules that are using it, as described in the following procedure.

**To delete a cross-site scripting match condition**

   - If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **Cross-site scripting**.
3. In the **Cross-site scripting match conditions** pane, choose the cross-site scripting match condition that you want to delete.
4. In the right pane, choose the **Associated rules** tab.
   - If the list of rules using this cross-site scripting match condition is empty, go to step 6. If the list contains any rules, make note of the rules, and continue with step 5.
5. To remove the cross-site scripting match condition from the rules that are using it, perform the following steps:
   a. In the navigation pane, choose **Rules**.
   b. Choose the name of a rule that is using the cross-site scripting match condition that you want to delete.
   c. In the right pane, select the cross-site scripting match condition that you want to remove from the rule, and choose **Remove selected condition**.
   d. Repeat steps b and c for all the remaining rules that are using the cross-site scripting match condition that you want to delete.
   e. In the navigation pane, choose **Cross-site scripting**.
   f. In the **Cross-site scripting match conditions** pane, choose the cross-site scripting match condition that you want to delete.
6. Choose **Delete** to delete the selected condition.

**Working with IP match conditions**

**Note**

This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not
If you want to allow or block web requests based on the IP addresses that the requests originate from, create one or more IP match conditions. An IP match condition lists up to 10,000 IP addresses or IP address ranges that your requests originate from. Later in the process, when you create a web ACL, you specify whether to allow or block requests from those IP addresses.

**Topics**
- Creating an IP Match Condition (p. 275)
- Editing IP match conditions (p. 276)
- Deleting IP match conditions (p. 276)

### Creating an IP Match Condition

If you want to allow some web requests and block others based on the IP addresses that the requests originate from, create an IP match condition for the IP addresses that you want to allow and another IP match condition for the IP addresses that you want to block.

**Note**
When you add an IP match condition to a rule, you also can configure AWS WAF Classic to allow or block web requests that *do not* originate from the IP addresses that you specify in the condition.

**To create an IP match condition**

   - If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **IP addresses**.
3. Choose **Create condition**.
4. Enter a name in the **Name** field.
   - The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _-!"'#*+,./. You can’t change the name of a condition after you create it.
5. Select the correct IP version and specify an IP address or range of IP addresses by using CIDR notation. Here are some examples:
   - To specify the IPv4 address 192.0.2.44, type **192.0.2.44/32**.
   - To specify the IPv6 address 0:0:0:0:0:ffff:c000:22c, type **0:0:0:0:0:ffff:c000:22c/128**.
   - To specify the range of IPv4 addresses from 192.0.2.0 to 192.0.2.255, type **192.0.2.0/24**.
   - To specify the range of IPv6 addresses from 2620:0:2d0:200:0:0:0:0 to 2620:0:2d0:200:0:0:0:0 to 2620:0:2d0:200::ffff:ffff:ffff:ffff, enter **2620:0:2d0:200::/64**.

   AWS WAF Classic supports IPv4 address ranges: /8 and any range between /16 through /32. AWS WAF Classic supports IPv6 address ranges: /24, /32, /48, /56, /64, and /128. For more information about CIDR notation, see the Wikipedia entry [Classless Inter-Domain Routing](https://en.wikipedia.org/wiki/Classless_inter-domain_routing).
6. Choose **Add another IP address or range**.
7. If you want to add another IP address or range, repeat steps 5 and 6.
8. When you’re finished adding values, choose **Create IP match condition**.
Editing IP match conditions

You can add an IP address range to an IP match condition or delete a range. To change a range, add a new one and delete the old one.

To edit an IP match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.

   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose IP addresses.
3. In the IP match conditions pane, choose the IP match condition that you want to edit.
4. To add an IP address range:
   a. In the right pane, choose Add IP address or range.
   b. Select the correct IP version and enter an IP address range by using CIDR notation. Here are some examples:
      - To specify the IPv4 address 192.0.2.44, enter 192.0.2.44/32.
      - To specify the IPv6 address 0:0:0:0:ffff:c000:22c, enter 0:0:0:0:ffff:c000:22c/128.
      - To specify the range of IPv4 addresses from 192.0.2.0 to 192.0.2.255, enter 192.0.2.0/24.
      - To specify the range of IPv6 addresses from 2620:0:2d0:200:: to 2620:0:2d0:200::, enter 2620:0:2d0:200::/64.

   AWS WAF Classic supports IPv4 address ranges: /8 and any range between /16 through /32. AWS WAF Classic supports IPv6 address ranges: /24, /32, /48, /56, /64, and /128. For more information about CIDR notation, see the Wikipedia entry Classless Inter-Domain Routing.
   c. To add more IP addresses, choose Add another IP address and enter the value.
   d. Choose Add.
5. To delete an IP address or range:
   a. In the right pane, select the values that you want to delete.
   b. Choose Delete IP address or range.

Deleting IP match conditions

If you want to delete an IP match condition, you must first delete all IP addresses and ranges in the condition and remove the condition from all the rules that are using it, as described in the following procedure.

To delete an IP match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.

   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose IP addresses.
3. In the IP match conditions pane, choose the IP match condition that you want to delete.
4. In the right pane, choose the Rules tab.

   If the list of rules using this IP match condition is empty, go to step 6. If the list contains any rules, make note of the rules, and continue with step 5.
5. To remove the IP match condition from the rules that are using it, perform the following steps:
   a. In the navigation pane, choose Rules.
   b. Choose the name of a rule that is using the IP match condition that you want to delete.
   c. In the right pane, select the IP match condition that you want to remove from the rule, and choose Remove selected condition.
   d. Repeat steps b and c for all the remaining rules that are using the IP match condition that you want to delete.
   e. In the navigation pane, choose IP match conditions.
   f. In the IP match conditions pane, choose the IP match condition that you want to delete.
6. Choose Delete to delete the selected condition.

Working with geographic match conditions

   **Note**
   This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
   For the latest version of AWS WAF, see AWS WAF (p. 6).

If you want to allow or block web requests based on the country that the requests originate from, create one or more geo match conditions. A geo match condition lists countries that your requests originate from. Later in the process, when you create a web ACL, you specify whether to allow or block requests from those countries.

You can use geo match conditions with other AWS WAF Classic conditions or rules to build sophisticated filtering. For example, if you want to block certain countries, but still allow specific IP addresses from that country, you could create a rule containing a geo match condition and an IP match condition. Configure the rule to block requests that originate from that country and do not match the approved IP addresses. As another example, if you want to prioritize resources for users in a particular country, you could include a geo match condition in two different rate-based rules. Set a higher rate limit for users in the preferred country and set a lower rate limit for all other users.

   **Note**
   If you are using the CloudFront geo restriction feature to block a country from accessing your content, any request from that country is blocked and is not forwarded to AWS WAF Classic. So if you want to allow or block requests based on geography plus other AWS WAF Classic conditions, you should not use the CloudFront geo restriction feature. Instead, you should use an AWS WAF Classic geo match condition.

**Topics**
- Creating a geo match condition (p. 277)
- Editing geo match conditions (p. 278)
- Deleting geo match conditions (p. 278)

**Creating a geo match condition**

If you want to allow some web requests and block others based on the countries that the requests originate from, create a geo match condition for the countries that you want to allow and another geo match condition for the countries that you want to block.

   **Note**
   When you add a geo match condition to a rule, you also can configure AWS WAF Classic to allow or block web requests that do not originate from the country that you specify in the condition.
To create a geo match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.

    If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **Geo match**.
3. Choose **Create condition**.
4. Enter a name in the **Name** field.

    The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _-!*#`+*},./ . You can't change the name of a condition after you create it.
5. Choose a **Region**.
6. Choose a **Location type** and a country. **Location type** can currently only be **Country**.
7. Choose **Add location**.
8. Choose **Create**.

Editing geo match conditions

You can add countries to or delete countries from your geo match condition.

To edit a geo match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.

    If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **Geo match**.
3. In the **Geo match conditions** pane, choose the geo match condition that you want to edit.
4. To add a country:
   a. In the right pane, choose **Add filter**.
   b. Choose a **Location type** and a country. **Location type** can currently only be **Country**.
   c. Choose **Add**.
5. To delete a country:
   a. In the right pane, select the values that you want to delete.
   b. Choose **Delete filter**.

Deleting geo match conditions

If you want to delete a geo match condition, you must first remove all countries in the condition and remove the condition from all the rules that are using it, as described in the following procedure.

To delete a geo match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.

    If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. Remove the geo match condition from the rules that are using it:
   a. In the navigation pane, choose **Rules**.
b. Choose the name of a rule that is using the geo match condition that you want to delete.
c. In the right pane, choose Edit rule.
d. Choose the X next to the condition you want to delete.
e. Choose Update.
f. Repeat for all the remaining rules that are using the geo match condition that you want to delete.

3. Remove the filters from the condition you want to delete:
   a. In the navigation pane, choose Geo match.
   b. Choose the name of the geo match condition that you want to delete.
   c. In the right pane, choose the check box next to Filter in order to select all of the filters.
   d. Choose the Delete filter.

4. In the navigation pane, choose Geo match.
5. In the Geo match conditions pane, choose the geo match condition that you want to delete.
6. Choose Delete to delete the selected condition.

Working with size constraint conditions

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

If you want to allow or block web requests based on the length of specified parts of requests, create one or more size constraint conditions. A size constraint condition identifies the part of web requests that you want AWS WAF Classic to look at, the number of bytes that you want AWS WAF Classic to look for, and an operator, such as greater than (>) or less than (<). For example, you can use a size constraint condition to look for query strings that are longer than 100 bytes. Later in the process, when you create a web ACL, you specify whether to allow or block requests based on those settings.

Note that if you configure AWS WAF Classic to inspect the request body, for example, by searching the body for a specified string, AWS WAF Classic inspects only the first 8192 bytes (8 KB). If the request body for your web requests will never exceed 8192 bytes, you can create a size constraint condition and block requests that have a request body greater than 8192 bytes.

Topics
- Creating size constraint conditions (p. 279)
- Values that you specify when you create or edit size constraint conditions (p. 280)
- Adding and deleting filters in a size constraint condition (p. 283)
- Deleting size constraint conditions (p. 283)

Creating size constraint conditions

When you create size constraint conditions, you specify filters that identify the part of web requests for which you want AWS WAF Classic to evaluate the length. You can add more than one filter to a size constraint condition, or you can create a separate condition for each filter. Here’s how each configuration affects AWS WAF Classic behavior:

- One filter per size constraint condition – When you add the separate size constraint conditions to a rule and add the rule to a web ACL, web requests must match all the conditions for AWS WAF Classic to allow or block requests based on the conditions.
For example, suppose you create two conditions. One matches web requests for which query strings are greater than 100 bytes. The other matches web requests for which the request body is greater than 1024 bytes. When you add both conditions to the same rule and add the rule to a web ACL, AWS WAF Classic allows or blocks requests only when both conditions are true.

- **More than one filter per size constraint condition** – When you add a size constraint condition that contains multiple filters to a rule and add the rule to a web ACL, a web request needs only to match one of the filters in the size constraint condition for AWS WAF Classic to allow or block the request based on that condition.

Suppose you create one condition instead of two, and the one condition contains the same two filters as in the preceding example. AWS WAF Classic allows or blocks requests if either the query string is greater than 100 bytes or the request body is greater than 1024 bytes.

**Note**
When you add a size constraint condition to a rule, you also can configure AWS WAF Classic to allow or block web requests that do not match the values in the condition.

**To create a size constraint condition**

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **Size constraints**.
3. Choose **Create condition**.
4. Specify the applicable filter settings. For more information, see **Values that you specify when you create or edit size constraint conditions** (p. 280).
5. Choose **Add another filter**.
6. If you want to add another filter, repeat steps 4 and 5.
7. When you’re finished adding filters, choose **Create size constraint condition**.

**Values that you specify when you create or edit size constraint conditions**

When you create or update a size constraint condition, you specify the following values:

**Name**

Enter a name for the size constraint condition.

The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _-!"#$`+*},./. You can’t change the name of a condition after you create it.

**Part of the request to filter on**

Choose the part of each web request for which you want AWS WAF Classic to evaluate the length:

**Header**

A specified request header, for example, the User-Agent or Referer header. If you choose **Header**, specify the name of the header in the **Header** field.

**HTTP method**

The HTTP method, which indicates the type of operation that the request is asking the origin to perform. CloudFront supports the following methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, and PUT.
Query string

The part of a URL that appears after a ? character, if any.

URI

The URI path of the request, which identifies the resource, for example, /images/daily-ad.jpg. This doesn't include the query string or fragment components of the URI. For information, see Uniform Resource Identifier (URI): Generic Syntax.

Unless a Transformation is specified, a URI is not normalized and is inspected just as AWS receives it from the client as part of the request. A Transformation will reformat the URI as specified.

Body

The part of a request that contains any additional data that you want to send to your web server as the HTTP request body, such as data from a form.

Single query parameter (value only)

Any parameter that you have defined as part of the query string. For example, if the URL is "www.xyz.com?UserName=abc&SalesRegion=seattle" you can add a filter to either the UserName or SalesRegion parameter.

If you choose Single query parameter (value only), you will also specify a Query parameter name. This is the parameter in the query string that you will inspect, such as UserName. The maximum length for Query parameter name is 30 characters. Query parameter name is not case sensitive. For example, it you specify UserName as the Query parameter name, this will match all variations of UserName, such as username and USERName.

All query parameters (values only)

Similar to Single query parameter (value only), but rather than inspecting the value of a single parameter, AWS WAF Classic inspects the values of all parameters within the query string for the size constraint. For example, if the URL is "www.xyz.com?UserName=abc&SalesRegion=seattle," and you choose All query parameters (values only), AWS WAF Classic will trigger a match the value of if either UserName or SalesRegion exceed the specified size.

Header (Only When "Part of the request to filter on" is "Header")

If you chose Header for Part of the request to filter on, choose a header from the list of common headers, or type the name of a header for which you want AWS WAF Classic to evaluate the length.

Comparison operator

Choose how you want AWS WAF Classic to evaluate the length of the query string in web requests with respect to the value that you specify for Size.

For example, if you choose Is greater than for Comparison operator and type 100 for Size, AWS WAF Classic evaluates web requests for a query string that is longer than 100 bytes.

Size

Enter the length, in bytes, that you want AWS WAF Classic to watch for in query strings.

Note

If you choose URI for the value of Part of the request to filter on, the / in the URI counts as one character. For example, the URI path /logo.jpg is nine characters long.

Transformation

A transformation reformats a web request before AWS WAF Classic evaluates the length of the specified part of the request. This eliminates some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF Classic.
Note
If you choose Body for Part of the request to filter on, you can't configure AWS WAF Classic to perform a transformation because only the first 8192 bytes are forwarded for inspection. However, you can still filter your traffic based on the size of the HTTP request body and specify a transformation of None. (AWS WAF Classic gets the length of the body from the request headers.)

You can only specify a single type of text transformation.

Transformations can perform the following operations:

None

AWS WAF Classic doesn't perform any text transformations on the web request before checking the length.

Convert to lowercase

AWS WAF Classic converts uppercase letters (A-Z) to lowercase (a-z).

HTML decode

AWS WAF Classic replaces HTML-encoded characters with unencoded characters:
- Replaces &quot; with &
- Replaces &nbsp; with a non-breaking space
- Replaces &lt; with <
- Replaces &gt; with >
- Replaces characters that are represented in hexadecimal format, &#xhhhh;, with the corresponding characters
- Replaces characters that are represented in decimal format, &#nnnn;, with the corresponding characters

Normalize white space

AWS WAF Classic replaces the following characters with a space character (decimal 32):
- \f, formfeed, decimal 12
- \t, tab, decimal 9
- \n, newline, decimal 10
- \r, carriage return, decimal 13
- \v, vertical tab, decimal 11
- non-breaking space, decimal 160

In addition, this option replaces multiple spaces with one space.

Simplify command line

For requests that contain operating system command line commands, use this option to perform the following transformations:
- Delete the following characters: \ " ^
- Delete spaces before the following characters: / ( 
- Replace the following characters with a space: . , 
- Replace multiple spaces with one space
- Convert uppercase letters (A-Z) to lowercase (a-z)

URL decode

Decode a URL-encoded request.
Adding and deleting filters in a size constraint condition

You can add or delete filters in a size constraint condition. To change a filter, add a new one and delete the old one.

To add or delete filters in a size constraint condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose Size constraint.
3. Choose the condition that you want to add or delete filters in.
4. To add filters, perform the following steps:
   a. Choose Add filter.
   b. Specify the applicable filter settings. For more information, see Values that you specify when you create or edit size constraint conditions (p. 280).
   c. Choose Add.
5. To delete filters, perform the following steps:
   a. Select the filter that you want to delete.
   b. Choose Delete filter.

Deleting size constraint conditions

If you want to delete a size constraint condition, you need to first delete all filters in the condition and remove the condition from all the rules that are using it, as described in the following procedure.

To delete a size constraint condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose Size constraints.
3. In the Size constraint conditions pane, choose the size constraint condition that you want to delete.
4. In the right pane, choose the Associated rules tab.
   If the list of rules using this size constraint condition is empty, go to step 6. If the list contains any rules, make note of the rules, and continue with step 5.
5. To remove the size constraint condition from the rules that are using it, perform the following steps:
   a. In the navigation pane, choose Rules.
   b. Choose the name of a rule that is using the size constraint condition that you want to delete.
   c. In the right pane, select the size constraint condition that you want to remove from the rule, and then choose Remove selected condition.
   d. Repeat steps b and c for all the remaining rules that are using the size constraint condition that you want to delete.
   e. In the navigation pane, choose Size constraint.
   f. In the Size constraint conditions pane, choose the size constraint condition that you want to delete.
6. Choose Delete to delete the selected condition.
Working with SQL injection match conditions

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

Attackers sometimes insert malicious SQL code into web requests in an effort to extract data from your database. To allow or block web requests that appear to contain malicious SQL code, create one or more SQL injection match conditions. A SQL injection match condition identifies the part of web requests, such as the URI path or the query string, that you want AWS WAF Classic to inspect. Later in the process, when you create a web ACL, you specify whether to allow or block requests that appear to contain malicious SQL code.

Topics
- Creating SQL injection match conditions (p. 284)
- Values that you specify when you create or edit SQL injection match conditions (p. 285)
- Adding and deleting filters in a SQL injection match condition (p. 287)
- Deleting SQL injection match conditions (p. 287)

Creating SQL injection match conditions

When you create SQL injection match conditions, you specify filters, which indicate the part of web requests that you want AWS WAF Classic to inspect for malicious SQL code, such as the URI or the query string. You can add more than one filter to a SQL injection match condition, or you can create a separate condition for each filter. Here's how each configuration affects AWS WAF Classic behavior:

- More than one filter per SQL injection match condition (recommended) – When you add a SQL injection match condition containing multiple filters to a rule and add the rule to a web ACL, a web request needs only to match one of the filters in the SQL injection match condition for AWS WAF Classic to allow or block the request based on that condition.

For example, suppose you create one SQL injection match condition, and the condition contains two filters. One filter instructs AWS WAF Classic to inspect the URI for malicious SQL code, and the other instructs AWS WAF Classic to inspect the query string. AWS WAF Classic allows or blocks requests if they appear to contain malicious SQL code either in the URI or in the query string.

- One filter per SQL injection match condition – When you add the separate SQL injection match conditions to a rule and add the rule to a web ACL, web requests must match all the conditions for AWS WAF Classic to allow or block requests based on the conditions.

Suppose you create two conditions, and each condition contains one of the two filters in the preceding example. When you add both conditions to the same rule and add the rule to a web ACL, AWS WAF Classic allows or blocks requests only when both the URI and the query string appear to contain malicious SQL code.

Note
When you add a SQL injection match condition to a rule, you also can configure AWS WAF Classic to allow or block web requests that do not appear to contain malicious SQL code.

To create a SQL injection match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
If you see **Switch to AWS WAF Classic** in the navigation pane, select it.

2. In the navigation pane, choose **SQL injection**.

3. Choose **Create condition**.

4. Specify the applicable filter settings. For more information, see Values that you specify when you create or edit SQL injection match conditions (p. 285).

5. Choose **Add another filter**.

6. If you want to add another filter, repeat steps 4 and 5.

7. When you're finished adding filters, choose **Create**.

### Values that you specify when you create or edit SQL injection match conditions

When you create or update a SQL injection match condition, you specify the following values:

**Name**

The name of the SQL injection match condition.

The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _-!^`+*},./. You can't change the name of a condition after you create it.

**Part of the request to filter on**

Choose the part of each web request that you want AWS WAF Classic to inspect for malicious SQL code:

**Header**

A specified request header, for example, the User-Agent or Referer header. If you choose **Header**, specify the name of the header in the **Header** field.

**HTTP method**

The HTTP method, which indicates the type of operation that the request is asking the origin to perform. CloudFront supports the following methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, and PUT.

**Query string**

The part of a URL that appears after a ? character, if any.

**Note**

For SQL injection match conditions, we recommend that you choose **All query parameters (values only)** instead of **Query string** for **Part of the request to filter on**.

**URI**

The URI path of the request, which identifies the resource, for example, /images/daily-ad.jpg. This doesn't include the query string or fragment components of the URI. For information, see Uniform Resource Identifier (URI): Generic Syntax.

Unless a Transformation is specified, a URI is not normalized and is inspected just as AWS receives it from the client as part of the request. A Transformation will reformat the URI as specified.

**Body**

The part of a request that contains any additional data that you want to send to your web server as the HTTP request body, such as data from a form.

**Note**

If you choose **Body** for the value of **Part of the request to filter on**, AWS WAF Classic inspects only the first 8192 bytes (8 KB). To allow or block requests for which the body
is longer than 8192 bytes, you can create a size constraint condition. (AWS WAF Classic gets the length of the body from the request headers.) For more information, see Working with size constraint conditions (p. 279).

**Single query parameter (value only)**

Any parameter that you have defined as part of the query string. For example, if the URL is "www.xyz.com?UserName=abc&SalesRegion=seattle" you can add a filter to either the `UserName` or `SalesRegion` parameter.

If you choose **Single query parameter (value only)** you will also specify a **Query parameter name**. This is the parameter in the query string that you will inspect, such as `UserName` or `SalesRegion`. The maximum length for **Query parameter name** is 30 characters. **Query parameter name** is not case sensitive. For example, if you specify `UserName` as the **Query parameter name**, this will match all variations of `UserName`, such as `username` and `UsERName`.

**All query parameters (values only)**

Similar to **Single query parameter (value only)**, but rather than inspecting the value of a single parameter, AWS WAF Classic inspects the value of all parameters within the query string for possible malicious SQL code. For example, if the URL is "www.xyz.com?UserName=abc&SalesRegion=seattle," and you choose **All query parameters (values only)**, AWS WAF Classic will trigger a match if the value of either `UserName` or `SalesRegion` contain possible malicious SQL code.

**Header**

If you chose **Header** for **Part of the request to filter on**, choose a header from the list of common headers, or enter the name of a header that you want AWS WAF Classic to inspect for malicious SQL code.

**Transformation**

A transformation reformats a web request before AWS WAF Classic inspects the request. This eliminates some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF Classic.

You can only specify a single type of text transformation.

Transformations can perform the following operations:

**None**

AWS WAF Classic doesn't perform any text transformations on the web request before inspecting it for the string in **Value to match**.

**Convert to lowercase**

AWS WAF Classic converts uppercase letters (A-Z) to lowercase (a-z).

**HTML decode**

AWS WAF Classic replaces HTML-encoded characters with unencoded characters:

- Replaces `&quot;` with `"`
- Replaces `&nbsp;` with a non-breaking space
- Replaces `&lt;` with `<`
- Replaces `&gt;` with `>`
- Replaces characters that are represented in hexadecimal format, `&#xhhhh;`, with the corresponding characters
- Replaces characters that are represented in decimal format, `&#nnnn;`, with the corresponding characters
Normalize white space

AWS WAF Classic replaces the following characters with a space character (decimal 32):
- \f, formfeed, decimal 12
- \t, tab, decimal 9
- \n, newline, decimal 10
- \r, carriage return, decimal 13
- \v, vertical tab, decimal 11
- non-breaking space, decimal 160

In addition, this option replaces multiple spaces with one space.

Simplify command line

For requests that contain operating system command line commands, use this option to perform the following transformations:
- Delete the following characters: \ " ' ^
- Delete spaces before the following characters: / ( 
- Replace the following characters with a space: , ;
- Replace multiple spaces with one space
- Convert uppercase letters (A-Z) to lowercase (a-z)

URL decode

Decode a URL-encoded request.

Adding and deleting filters in a SQL injection match condition

You can add or delete filters in a SQL injection match condition. To change a filter, add a new one and delete the old one.

To add or delete filters in a SQL injection match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose SQL injection.
3. Choose the condition that you want to add or delete filters in.
4. To add filters, perform the following steps:
   a. Choose Add filter.
   b. Specify the applicable filter settings. For more information, see Values that you specify when you create or edit SQL injection match conditions (p. 285).
   c. Choose Add.
5. To delete filters, perform the following steps:
   a. Select the filter that you want to delete.
   b. Choose Delete filter.

Deleting SQL injection match conditions

If you want to delete a SQL injection match condition, you need to first delete all filters in the condition and remove the condition from all the rules that are using it, as described in the following procedure.
To delete a SQL injection match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.

2. In the navigation pane, choose **SQL injection**.

3. In the **SQL injection match conditions** pane, choose the SQL injection match condition that you want to delete.

4. In the right pane, choose the **Associated rules** tab.
   
   If the list of rules using this SQL injection match condition is empty, go to step 6. If the list contains any rules, make note of the rules, and continue with step 5.

5. To remove the SQL injection match condition from the rules that are using it, perform the following steps:
   
   a. In the navigation pane, choose **Rules**.
   
   b. Choose the name of a rule that is using the SQL injection match condition that you want to delete.
   
   c. In the right pane, select the SQL injection match condition that you want to remove from the rule, and choose **Remove selected condition**.
   
   d. Repeat steps b and c for all of the remaining rules that are using the SQL injection match condition that you want to delete.
   
   e. In the navigation pane, choose **SQL injection**.
   
   f. In the **SQL injection match conditions** pane, choose the SQL injection match condition that you want to delete.

6. Choose **Delete** to delete the selected condition.

Working with string match conditions

**Note**

This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see **Migrating your AWS WAF Classic resources to AWS WAF** (p. 245).

**For the latest version of AWS WAF**, see **AWS WAF** (p. 6).

If you want to allow or block web requests based on strings that appear in the requests, create one or more string match conditions. A string match condition identifies the string that you want to search for and the part of web requests, such as a specified header or the query string, that you want AWS WAF Classic to inspect for the string. Later in the process, when you create a web ACL, you specify whether to allow or block requests that contain the string.

**Topics**

- Creating a string match condition (p. 288)
- Values that you specify when you create or edit string match conditions (p. 289)
- Adding and deleting filters in a string match condition (p. 292)
- Deleting string match conditions (p. 293)

Creating a string match condition

When you create string match conditions, you specify filters that identify the string that you want to search for and the part of web requests that you want AWS WAF Classic to inspect for that string, such
as the URI or the query string. You can add more than one filter to a string match condition, or you can create a separate string match condition for each filter. Here’s how each configuration affects AWS WAF Classic behavior:

- **One filter per string match condition** – When you add the separate string match conditions to a rule and add the rule to a web ACL, web requests must match all the conditions for AWS WAF Classic to allow or block requests based on the conditions.

  For example, suppose you create two conditions. One matches web requests that contain the value BadBot in the User-Agent header. The other matches web requests that contain the value BadParameter in query strings. When you add both conditions to the same rule and add the rule to a web ACL, AWS WAF Classic allows or blocks requests only when they contain both values.

- **More than one filter per string match condition** – When you add a string match condition that contains multiple filters to a rule and add the rule to a web ACL, a web request needs only to match one of the filters in the string match condition for AWS WAF Classic to allow or block the request based on the one condition.

  Suppose you create one condition instead of two, and the one condition contains the same two filters as in the preceding example. AWS WAF Classic allows or blocks requests if they contain *either* BadBot in the User-Agent header or BadParameter in the query string.

  **Note**
  When you add a string match condition to a rule, you also can configure AWS WAF Classic to allow or block web requests that do not match the values in the condition.

**To create a string match condition**

   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.

2. In the navigation pane, choose **String and regex matching**.

3. Choose **Create condition**.

4. Specify the applicable filter settings. For more information, see **Values that you specify when you create or edit string match conditions** (p. 289).

5. Choose **Add filter**.

6. If you want to add another filter, repeat steps 4 and 5.

7. When you’re finished adding filters, choose **Create**.

**Values that you specify when you create or edit string match conditions**

When you create or update a string match condition, you specify the following values:

**Name**

Enter a name for the string match condition. The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _ `-!"#` `*` `,` `/`. You can’t change the name of a condition after you create it.

**Type**

Choose **String match**.

**Part of the request to filter on**

Choose the part of each web request that you want AWS WAF Classic to inspect for the string that you specify in **Value to match**:
Header

A specified request header, for example, the `User-Agent` or `Referer` header. If you choose `Header`, specify the name of the header in the `Header` field.

HTTP method

The HTTP method, which indicates the type of operation that the request is asking the origin to perform. CloudFront supports the following methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, and PUT.

Query string

The part of a URL that appears after a `?` character, if any.

URI

The URI path of the request, which identifies the resource, for example, `/images/daily-ad.jpg`. This doesn't include the query string or fragment components of the URI. For information, see Uniform Resource Identifier (URI): Generic Syntax.

Unless a Transformation is specified, a URI is not normalized and is inspected just as AWS receives it from the client as part of the request. A Transformation will reformat the URI as specified.

Body

The part of a request that contains any additional data that you want to send to your web server as the HTTP request body, such as data from a form.

Note

If you choose `Body` for the value of Part of the request to filter on, AWS WAF Classic inspects only the first 8192 bytes (8 KB). To allow or block requests for which the body is longer than 8192 bytes, you can create a size constraint condition. (AWS WAF Classic gets the length of the body from the request headers.) For more information, see Working with size constraint conditions (p. 279).

Single query parameter (value only)

Any parameter that you have defined as part of the query string. For example, if the URL is `www.xyz.com?UserName=abc&SalesRegion=seattle` you can add a filter to either the `UserName` or `SalesRegion` parameter.

If duplicate parameters appear in the query string, the values are evaluated as an “OR.” That is, either value will trigger a match. For example, in the URL `www.xyz.com?SalesRegion=boston&SalesRegion=seattle`, either “boston” or “seattle” in Value to match will trigger a match.

If you choose Single query parameter (value only) you will also specify a Query parameter name. This is the parameter in the query string that you will inspect, such as `UserName` or `SalesRegion`. The maximum length for Query parameter name is 30 characters. Query parameter name is not case sensitive. For example, if you specify `UserName` as the Query parameter name, this will match all variations of `UserName`, such as `username` and `USERName`.

All query parameters (values only)

Similar to Single query parameter (value only), but rather than inspecting the value of a single parameter, AWS WAF Classic inspects the value of all parameters within the query string for the Value to match. For example, if the URL is `www.xyz.com?UserName=abc&SalesRegion=seattle`, and you choose All query parameters (values only), AWS WAF Classic will trigger a match if the value of either `UserName` or `SalesRegion` is specified as the Value to match.
Header (Only When "Part of the request to filter on" is "Header")

If you chose Header from the Part of the request to filter on list, choose a header from the list of common headers, or enter the name of a header that you want AWS WAF Classic to inspect.

Match type

Within the part of the request that you want AWS WAF Classic to inspect, choose where the string in Value to match must appear to match this filter:

Contains

The string appears anywhere in the specified part of the request.

Contains word

The specified part of the web request must include Value to match, and Value to match must contain only alphanumeric characters or underscore (A-Z, a-z, 0-9, or _). In addition, Value to match must be a word, which means one of the following:

• Value to match exactly matches the value of the specified part of the web request, such as the value of a header.
• Value to match is at the beginning of the specified part of the web request and is followed by a character other than an alphanumeric character or underscore (_), for example, BadBot ;.
• Value to match is at the end of the specified part of the web request and is preceded by a character other than an alphanumeric character or underscore (_), for example, ;BadBot.
• Value to match is in the middle of the specified part of the web request and is preceded and followed by characters other than alphanumeric characters or underscore (_), for example, -BadBot;.

Exactly matches

The string and the value of the specified part of the request are identical.

Starts with

The string appears at the beginning of the specified part of the request.

Ends with

The string appears at the end of the specified part of the request.

Transformation

A transformation reformats a web request before AWS WAF Classic inspects the request. This eliminates some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF Classic.

You can only specify a single type of text transformation.

Transformations can perform the following operations:

None

AWS WAF Classic doesn't perform any text transformations on the web request before inspecting it for the string in Value to match.

Convert to lowercase

AWS WAF Classic converts uppercase letters (A-Z) to lowercase (a-z).

HTML decode

AWS WAF Classic replaces HTML-encoded characters with unencoded characters:

• Replaces &quot; with &
Working with conditions

- Replaces &nbsp; with a non-breaking space
- Replaces &lt; with <
- Replaces &gt; with >
- Replaces characters that are represented in hexadecimal format, &#xhhhh;, with the corresponding characters
- Replaces characters that are represented in decimal format, &#nnnn;, with the corresponding characters

Normalize white space

AWS WAF Classic replaces the following characters with a space character (decimal 32):
- \f, formfeed, decimal 12
- \t, tab, decimal 9
- \n, newline, decimal 10
- \r, carriage return, decimal 13
- \v, vertical tab, decimal 11
- non-breaking space, decimal 160

In addition, this option replaces multiple spaces with one space.

Simplify command line

When you're concerned that attackers are injecting an operating system command line command and using unusual formatting to disguise some or all of the command, use this option to perform the following transformations:
- Delete the following characters: ", " ^
- Delete spaces before the following characters: / ( 
- Replace the following characters with a space: , ;
- Replace multiple spaces with one space
- Convert uppercase letters (A-Z) to lowercase (a-z)

URL decode

Decode a URL-encoded request.

Value is base64 encoded

If the value in Value to match is base64-encoded, select this check box. Use base64-encoding to specify non-printable characters, such as tabs and linefeeds, that attackers include in their requests.

Value to match

Specify the value that you want AWS WAF Classic to search for in web requests. The maximum length is 50 bytes. If you're base64-encoding the value, the 50-byte maximum length applies to the value before you encode it.

Adding and deleting filters in a string match condition

You can add filters to a string match condition or delete filters. To change a filter, add a new one and delete the old one.

To add or delete filters in a string match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
If you see **Switch to AWS WAF Classic** in the navigation pane, select it.

2. In the navigation pane, choose **String and regex matching**.
3. Choose the condition that you want to add or delete filters in.
4. To add filters, perform the following steps:
   a. Choose **Add filter**.
   b. Specify the applicable filter settings. For more information, see Values that you specify when you create or edit string match conditions (p. 289).
   c. Choose **Add**.
5. To delete filters, perform the following steps:
   a. Select the filter that you want to delete.
   b. Choose **Delete Filter**.

### Deleting string match conditions

If you want to delete a string match condition, you need to first delete all filters in the condition and remove the condition from all the rules that are using it, as described in the following procedure.

**To delete a string match condition**

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. Remove the string match condition from the rules that are using it:
   a. In the navigation pane, choose **Rules**.
   b. Choose the name of a rule that is using the string match condition that you want to delete.
   c. In the right pane, choose **Edit rule**.
   d. Choose the X next to the condition you want to delete.
   e. Choose **Update**.
   f. Repeat for all the remaining rules that are using the string match condition that you want to delete.
3. Remove the filters from the condition you want to delete:
   a. In the navigation pane, choose **String and regex matching**.
   b. Choose the name of the string match condition that you want to delete.
   c. In the right pane, choose the check box next to **Filter** in order to select all of the filters.
   d. Choose the **Delete filter**.
4. In the navigation pane, choose **String and regex matching**.
5. In the **String and regex match conditions** pane, choose the string match condition that you want to delete.
6. Choose **Delete** to delete the selected condition.

### Working with regex match conditions

**Note**

This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not
migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

If you want to allow or block web requests based on strings that match a regular expression (regex) pattern that appears in the requests, create one or more regex match conditions. A regex match condition is a type of string match condition that identifies the pattern that you want to search for and the part of web requests, such as a specified header or the query string, that you want AWS WAF Classic to inspect for the pattern. Later in the process, when you create a web ACL, you specify whether to allow or block requests that contain the pattern.

Topics

- Creating a regex match condition (p. 294)
- Values that you specify when you create or edit RegEx match conditions (p. 295)
- Editing a regex match condition (p. 297)

Creating a regex match condition

When you create regex match conditions, you specify pattern sets that identify the string (using a regular expression) that you want to search for. You then add those pattern sets to filters that specify the part of web requests that you want AWS WAF Classic to inspect for that pattern set, such as the URI or the query string.

You can add multiple regular expressions to a single pattern set. If you do so, those expressions are combined with an OR. That is, a web request will match the pattern set if the appropriate part of the request matches any of the expressions listed.

When you add a regex match condition to a rule, you also can configure AWS WAF Classic to allow or block web requests that do not match the values in the condition.

AWS WAF Classic supports most standard Perl Compatible Regular Expressions (PCRE). However, the following are not supported:

- Backreferences and capturing subexpressions
- Arbitrary zero-width assertions
- Subroutine references and recursive patterns
- Conditional patterns
- Backtracking control verbs
- The \C single-byte directive
- The \R newline match directive
- The \K start of match reset directive
- Callouts and embedded code
- Atomic grouping and possessive quantifiers

To create a regex match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose String and regex matching.
3. Choose Create condition.
4. Specify the applicable filter settings. For more information, see Values that you specify when you create or edit RegEx match conditions (p. 295).

5. Choose Create pattern set and add filter (if you created a new pattern set) or Add filter if you used an existing pattern set.

6. Choose Create.

Values that you specify when you create or edit RegEx match conditions

When you create or update a regex match condition, you specify the following values:

Name

Enter a name for the regex match condition. The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _-!"#$`+*},./. You can't change the name of a condition after you create it.

Type

Choose Regex match.

Part of the request to filter on

Choose the part of each web request that you want AWS WAF Classic to inspect for the pattern that you specify in Value to match:

Header

A specified request header, for example, the User-Agent or Referer header. If you choose Header, specify the name of the header in the Header field.

HTTP method

The HTTP method, which indicates the type of operation that the request is asking the origin to perform. CloudFront supports the following methods: DELETE, GET, HEAD, OPTIONS, PATCH, POST, and PUT.

Query string

The part of a URL that appears after a ? character, if any.

URI

The URI path of the request, which identifies the resource, for example, /images/daily-ad.jpg. This doesn't include the query string or fragment components of the URI. For information, see Uniform Resource Identifier (URI): Generic Syntax.

Unless a Transformation is specified, a URI is not normalized and is inspected just as AWS receives it from the client as part of the request. A Transformation will reformat the URI as specified.

Body

The part of a request that contains any additional data that you want to send to your web server as the HTTP request body, such as data from a form.

Note

If you choose Body for the value of Part of the request to filter on, AWS WAF Classic inspects only the first 8192 bytes (8 KB). To allow or block requests for which the body is longer than 8192 bytes, you can create a size constraint condition. (AWS WAF Classic gets the length of the body from the request headers.) For more information, see Working with size constraint conditions (p. 279).
Single query parameter (value only)

Any parameter that you have defined as part of the query string. For example, if the URL is "www.xyz.com?UserName=abc&SalesRegion=seattle" you can add a filter to either the UserName or SalesRegion parameter.

If duplicate parameters appear in the query string, the values are evaluated as an "OR." That is, either value will trigger a match. For example, in the URL "www.xyz.com?SalesRegion=boston&SalesRegion=seattle", a pattern that matches either "boston" or "seattle" in Value to match will trigger a match.

If you choose Single query parameter (value only) you will also specify a Query parameter name. This is the parameter in the query string that you will inspect, such as UserName or SalesRegion. The maximum length for Query parameter name is 30 characters. Query parameter name is not case sensitive. For example, if you specify UserName as the Query parameter name, this will match all variations of UserName, such as username and USERName.

All query parameters (values only)

Similar to Single query parameter (value only), but rather than inspecting the value of a single parameter, AWS WAF Classic inspects the value of all parameters within the query string for the pattern specified in the Value to match. For example, in the URL "www.xyz.com?UserName=abc&SalesRegion=seattle", a pattern in Value to match that matches either the value in UserName or SalesRegion will trigger a match.

Header (Only When "Part of the request to filter on" is "Header")

If you chose Header from the Part of the request to filter on list, choose a header from the list of common headers, or enter the name of a header that you want AWS WAF Classic to inspect.

Transformation

A transformation reformats a web request before AWS WAF Classic inspects the request. This eliminates some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF Classic.

You can only specify a single type of text transformation.

Transformations can perform the following operations:

None

AWS WAF Classic doesn't perform any text transformations on the web request before inspecting it for the string in Value to match.

Convert to lowercase

AWS WAF Classic converts uppercase letters (A-Z) to lowercase (a-z).

HTML decode

AWS WAF Classic replaces HTML-encoded characters with unencoded characters:
- Replaces &quot; with 
- Replaces &nbsp; with a non-breaking space
- Replaces &lt; with <
- Replaces &gt; with >
- Replaces characters that are represented in hexadecimal format, &#xhhhh;, with the corresponding characters
- Replaces characters that are represented in decimal format, &#nnnn;, with the corresponding characters
Normalize white space

AWS WAF Classic replaces the following characters with a space character (decimal 32):
- \f, formfeed, decimal 12
- \t, tab, decimal 9
- \n, newline, decimal 10
- \r, carriage return, decimal 13
- \v, vertical tab, decimal 11
- non-breaking space, decimal 160

In addition, this option replaces multiple spaces with one space.

Simplify command line

When you’re concerned that attackers are injecting an operating system command line command and using unusual formatting to disguise some or all of the command, use this option to perform the following transformations:
- Delete the following characters: \ " ' ^
- Delete spaces before the following characters: / ( 
- Replace the following characters with a space: , ;
- Replace multiple spaces with one space
- Convert uppercase letters (A-Z) to lowercase (a-z)

URL decode

Decode a URL-encoded request.

Regex pattern to match to request

You can choose an existing pattern set, or create a new one. If you create a new one specify the following:

New pattern set name

Enter a name and then specify the regex pattern that you want AWS WAF Classic to search for.

If you add multiple regular expressions to a pattern set, those expressions are combined with an OR. That is, a web request will match the pattern set if the appropriate part of the request matches any of the expressions listed.

The maximum length of Value to match is 70 characters.

Editing a regex match condition

You can make the following changes to an existing regex match condition:
- Delete a pattern from an existing pattern set
- Add a pattern to an existing pattern set
- Delete a filter to an existing regex match condition
- Add a filter to an existing regex match condition (You can have only one filter in a regex match condition. Therefore, in order to add a filter, you must delete the existing filter first.)
- Delete an existing regex match condition

Note

You cannot add or delete a pattern set from an existing filter. You must either edit the pattern set, or delete the filter and create a new filter with a new pattern set.
To delete a pattern from an existing pattern set

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **String and regex matching**.
3. Choose **View regex pattern sets**.
4. Choose the name of the pattern set you want to edit.
5. Choose **Edit**.
6. Choose the X next to the pattern you want to delete.
7. Choose **Save**.

To add a pattern to an existing pattern set

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **String and regex matching**.
3. Choose **View regex pattern sets**.
4. Choose the name of the pattern set to edit.
5. Choose **Edit**.
6. Enter a new regex pattern.
7. Choose the + next to the new pattern.
8. Choose **Save**.

To delete a filter from an existing regex match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **String and regex matching**.
3. Choose the name of the condition with the filter you want to delete.
4. Choose the box next to the filter you want to delete.
5. Choose **Delete filter**.

To delete a regex match condition

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. Delete the filter from the regex condition. See To delete a filter from an existing regex match condition (p. 298) for instructions to do this.
3. Remove the regex match condition from the rules that are using it:
   
   a. In the navigation pane, choose **Rules**.
   b. Choose the name of a rule that is using the regex match condition that you want to delete.
   c. In the right pane, choose **Edit rule**.
d. Choose the X next to the condition you want to delete.
e. Choose Update.
f. Repeat for all the remaining rules that are using the regex match condition that you want to delete.

4. In the navigation pane, choose String and regex matching.
5. Select the button next to the condition you want to delete.
6. Choose Delete.

To add or change a filter to an existing regex match condition

You can have only one filter in a regex match condition. If you want to add or change the filter, you must first delete the existing filter.

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. Delete the filter from the regex condition you want to change. See To delete a filter from an existing regex match condition (p. 298) for instructions to do this.
3. In the navigation pane, choose String and regex matching.
4. Choose the name of the condition you want to change.
5. Choose Add filter.
6. Enter the appropriate values for the new filter and choose Add.

Working with rules

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

Rules let you precisely target the web requests that you want AWS WAF Classic to allow or block by specifying the exact conditions that you want AWS WAF Classic to watch for. For example, AWS WAF Classic can watch for the IP addresses that requests originate from, the strings that the requests contain and where the strings appear, and whether the requests appear to contain malicious SQL code.

Topics
- Creating a rule and adding conditions (p. 299)
- Adding and removing conditions in a rule (p. 301)
- Deleting a rule (p. 302)
- AWS Marketplace rule groups (p. 303)

Creating a rule and adding conditions

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

If you add more than one condition to a rule, a web request must match all the conditions for AWS WAF Classic to allow or block requests based on that rule.

**To create a rule and add conditions**

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter the following values:

   **Name**
   
   Enter a name.

   **CloudWatch metric name**
   
   Enter a name for the CloudWatch metric that AWS WAF Classic will create and will associate with the rule. The name can contain only alphanumeric characters (A-Z, a-z, 0-9), with maximum length 128 and minimum length one. It can't contain white space or metric names reserved for AWS WAF Classic, including "All" and "Default_Action.

   **Rule type**
   
   Choose either **Regular rule** or **Rate–based rule**. Rate–based rules are identical to regular rules, but also take into account how many requests arrive from an IP address in a five-minute period. For more information about these rule types, see How AWS WAF Classic works (p. 255).

   **Rate limit**
   
   For a rate-based rule, enter the maximum number of requests to allow in any five-minute period from an IP address that matches the rule's conditions. The rate limit must be at least 100.

   You can specify a rate limit alone, or a rate limit and conditions. If you specify only a rate limit, AWS WAF places the limit on all IP addresses. If you specify a rate limit and conditions, AWS WAF places the limit on IP addresses that match the conditions.

   When an IP address reaches the rate limit threshold, AWS WAF applies the assigned action (block or count) as quickly as possible, usually within 30 seconds. Once the action is in place, if five minutes pass with no requests from the IP address, AWS WAF resets the counter to zero.
5. To add a condition to the rule, specify the following values:

   **When a request does/does not**
   
   If you want AWS WAF Classic to allow or block requests based on the filters in a condition, choose **does**. For example, if an IP match condition includes the IP address range 192.0.2.0/24 and you want AWS WAF Classic to allow or block requests that come from those IP addresses, choose **does**.

   If you want AWS WAF Classic to allow or block requests based on the inverse of the filters in a condition, choose **does not**. For example, if an IP match condition includes the IP address range 192.0.2.0/24 and you want AWS WAF Classic to allow or block requests that do not come from those IP addresses, choose **does not**.

   **match/originate from**
   
   Choose the type of condition that you want to add to the rule:
• Cross-site scripting match conditions – choose **match at least one of the filters in the cross-site scripting match condition**
• IP match conditions – choose **originate from an IP address in**
• Geo match conditions – choose **originate from a geographic location in**
• Size constraint conditions – choose **match at least one of the filters in the size constraint condition**
• SQL injection match conditions – choose **match at least one of the filters in the SQL injection match condition**
• String match conditions – choose **match at least one of the filters in the string match condition**
• Regular expression match conditions – choose **match at least one of the filters in the regex match condition**

**condition name**

Choose the condition that you want to add to the rule. The list displays only conditions of the type that you chose in the preceding step.

6. To add another condition to the rule, choose **Add another condition**, and repeat steps 4 and 5. Note the following:

• If you add more than one condition, a web request must match at least one filter in every condition for AWS WAF to allow or block requests based on that rule.
• If you add two IP match conditions to the same rule, AWS WAF will only allow or block requests that originate from IP addresses that appear in both IP match conditions.

7. When you're finished adding conditions, choose **Create**.

### Adding and removing conditions in a rule

**Note**

This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see [Migrating your AWS WAF Classic resources to AWS WAF](p. 245).

**For the latest version of AWS WAF**, see [AWS WAF](p. 6).

You can change a rule by adding or removing conditions.

#### To add or remove conditions in a rule

   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.

2. In the navigation pane, choose **Rules**.

3. Choose the name of the rule in which you want to add or remove conditions.

4. Choose **Add rule**.

5. To add a condition, choose **Add condition** and specify the following values:

   **When a request does/does not**

   If you want AWS WAF Classic to allow or block requests based on the filters in a condition, for example, web requests that originate from the range of IP addresses 192.0.2.0/24, choose **does**.

   If you want AWS WAF Classic to allow or block requests based on the inverse of the filters in a condition, choose **does not**. For example, if an IP match condition includes the IP address range...
192.0.2.0/24 and you want AWS WAF Classic to allow or block requests that do not come from those IP addresses, choose **does not**. 

**match/originate from**

Choose the type of condition that you want to add to the rule:

- Cross-site scripting match conditions – choose **match at least one of the filters in the cross-site scripting match condition**
- IP match conditions – choose **originate from an IP address in**
- Geo match conditions – choose **originate from a geographic location in**
- Size constraint conditions – choose **match at least one of the filters in the size constraint condition**
- SQL injection match conditions – choose **match at least one of the filters in the SQL injection match condition**
- String match conditions – choose **match at least one of the filters in the string match condition**
- Regular expression match conditions – choose **match at least one of the filters in the regex match condition**

**condition name**

Choose the condition that you want to add to the rule. The list displays only conditions of the type that you chose in the preceding step.

6. To remove a condition, select the X to the right of the condition name
7. Choose **Update**.

### Deleting a rule

**Note**

This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see **Migrating your AWS WAF Classic resources to AWS WAF** (p. 245).

For the latest version of **AWS WAF**, see **AWS WAF** (p. 6).

If you want to delete a rule, you need to first remove the rule from the web ACLs that are using it and remove the conditions that are included in the rule.

**To delete a rule**

   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.
2. To remove the rule from the web ACLs that are using it, perform the following steps for each of the web ACLs:
   a. In the navigation pane, choose **Web ACLs**.
   b. Choose the name of a web ACL that is using the rule that you want to delete.
   c. Choose the **Rules** tab.
   d. Choose **Edit web ACL**.
   e. Choose the X to the right of the rule that you want to delete, and then choose **Update**.
3. In the navigation pane, choose **Rules**.
4. Select the name of the rule you want to delete.
5. Choose **Delete**.
AWS Marketplace rule groups

**Note**
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see [Migrating your AWS WAF Classic resources to AWS WAF](p. 245).

For the latest version of AWS WAF, see [AWS WAF](p. 6).

AWS WAF Classic provides AWS Marketplace rule groups to help you protect your resources. AWS Marketplace rule groups are collections of predefined, ready-to-use rules that are written and updated by AWS and AWS partner companies.

Some AWS Marketplace rule groups are designed to help protect specific types of web applications like WordPress, Joomla, or PHP. Other AWS Marketplace rule groups offer broad protection against known threats or common web application vulnerabilities, such as those listed in the OWASP Top 10.

You can install a single AWS Marketplace rule group from your preferred AWS partner, and you can also add your own customized AWS WAF Classic rules for increased protection. If you are subject to regulatory compliance like PCI or HIPAA, you might be able to use AWS Marketplace rule groups to satisfy web application firewall requirements.

AWS Marketplace rule groups are available with no long-term contracts, and no minimum commitments. When you subscribe to a rule group, you are charged a monthly fee (prorated hourly) and ongoing request fees based on volume. For more information, see [AWS WAF Classic Pricing](p. 6) and the description for each AWS Marketplace rule group on AWS Marketplace.

**Automatic updates**

Keeping up to date on the constantly changing threat landscape can be time consuming and expensive. AWS Marketplace rule groups can save you time when you implement and use AWS WAF Classic. Another benefit is that AWS and our AWS partners automatically update AWS Marketplace rule groups when new vulnerabilities and threats emerge.

Many of our partners are notified of new vulnerabilities before public disclosure. They can update their rule groups and deploy them to you even before a new threat is widely known. Many also have threat research teams to investigate and analyze the most recent threats in order to write the most relevant rules.

**Access to the rules in an AWS Marketplace rule group**

Each AWS Marketplace rule group provides a comprehensive description of the types of attacks and vulnerabilities that it's designed to protect against. To protect the intellectual property of the rule group providers, you can't view the individual rules within a rule group. This restriction also helps to keep malicious users from designing threats that specifically circumvent published rules.

Because you can't view individual rules in an AWS Marketplace rule group, you also can't edit any rules in an AWS Marketplace rule group. However, you can exclude specific rules from a rule group. This is called a "rule group exception." Excluding rules does not remove those rules. Rather, it changes the action for the rules to COUNT. Therefore, requests that match an excluded rule are counted but not blocked. You will receive COUNT metrics for each excluded rule.

Excluding rules can be helpful when troubleshooting rule groups that are blocking traffic unexpectedly (false positives). One troubleshooting technique is to identify the specific rule within the rule group that is blocking the desired traffic and then disable (exclude) that particular rule.

In addition to excluding specific rules, you can refine your protection by enabling or disabling entire rule groups, as well as choosing the rule group action to perform. For more information, see [Using AWS Marketplace rule groups](p. 304).
Quotas

You can enable only one AWS Marketplace rule group. You can also enable one custom rule group that you create using AWS Firewall Manager. These rule groups count towards the 10 rule maximum quota per web ACL. Therefore, you can have one AWS Marketplace rule group, one custom rule group, and up to eight custom rules in a single web ACL.

Pricing

For AWS Marketplace rule group pricing, see AWS WAF Classic Pricing and the description for each AWS Marketplace rule group on AWS Marketplace.

Using AWS Marketplace rule groups

You can subscribe to and unsubscribe from AWS Marketplace rule groups on the AWS WAF Classic console. You can also exclude specific rules from a rule group.

To subscribe to and use an AWS Marketplace rule group

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose Marketplace.
3. In the Available marketplace products section, choose the name of a rule group to view the details and pricing information.
4. If you want to subscribe to the rule group, choose Continue.
   
   Note
   If you don't want to subscribe to this rule group, simply close this page in your browser.
5. Choose Set up your account.
6. Add the rule group to a web ACL, just as you would add an individual rule. For more information, see Creating a Web ACL (p. 307) or Editing a Web ACL (p. 311).
   
   Note
   When adding a rule group to a web ACL, the action that you set for the rule group (either No override or Override to count) is called the rule group override action. For more information, see Rule group override (p. 305).

To unsubscribe from an AWS Marketplace rule group

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. Remove the rule group from all web ACLs. For more information, see Editing a Web ACL (p. 311).
3. In the navigation pane, choose Marketplace.
4. Choose Manage your subscriptions.
5. Choose Cancel subscription next to the name of the rule group that you want to unsubscribe from.
6. Choose Yes, cancel subscription.

To exclude a rule from a rule group (rule group exception)

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
If you see Switch to AWS WAF Classic in the navigation pane, select it.

2. If not already enabled, enable AWS WAF Classic logging. For more information, see Logging Web ACL traffic information (p. 322). Use the AWS WAF Classic logs to identify the IDs of the rules that you want to exclude. These are typically rules that are blocking legitimate requests.

3. In the navigation pane, choose Web ACLs.

4. Choose the name of the web ACL that you want to edit. This opens a page with the web ACL's details in the right pane.

   **Note**
   
   The rule group that you want to edit must be associated with a web ACL before you can exclude a rule from that rule group.

5. On the Rules tab in the right pane, choose Edit web ACL.

6. In the Rule group exceptions section, expand the rule group that you want to edit.

7. Choose the X next to the rule that you want to exclude. You can identify the correct rule ID by using the AWS WAF Classic logs.

8. Choose Update.

   Excluding rules does not remove those rules from the rule group. Rather, it changes the action for the rules to COUNT. Therefore, requests that match an excluded rule are counted but not blocked. You will receive COUNT metrics for each excluded rule.

   **Note**
   
   You can use this same procedure to exclude rules from custom rule groups that you have created in AWS Firewall Manager. However, rather than excluding a rule from a custom rule group using these steps, you can also simply edit a custom rule group using the steps described in Adding and deleting rules from an AWS WAF Classic rule group (p. 316).

**Rule group override**

AWS Marketplace rule groups have two possible actions: No override and Override to count. If you want to test the rule group, set the action to Override to count. This rule group action overrides any block action that is specified by individual rules contained within the group. That is, if the rule group's action is set to Override to count, instead of potentially blocking matching requests based on the action of individual rules within the group, those requests will be counted. Conversely, if you set the rule group's action to No override, actions of the individual rules within the group will be used.

**Troubleshooting AWS Marketplace rule groups**

If you find that an AWS Marketplace rule group is blocking legitimate traffic, perform the following steps.

**To troubleshoot an AWS Marketplace rule group**

1. Exclude the specific rules that are blocking legitimate traffic. You can identify which rules are blocking which requests using the AWS WAF Classic logs. For more information about excluding rules, see To exclude a rule from a rule group (rule group exception) (p. 304).

2. If excluding specific rules does not solve the problem, you can change the action for the AWS Marketplace rule group from No override to Override to count. This allows the web request to pass through, regardless of the individual rule actions within the rule group. This also provides you with Amazon CloudWatch metrics for the rule group.

3. After setting the AWS Marketplace rule group action to Override to count, contact the rule group provider's customer support team to further troubleshoot the issue. For contact information, see the rule group listing on the product listing pages on AWS Marketplace.
Contacting customer support

For problems with AWS WAF Classic or a rule group that is managed by AWS, contact AWS Support. For problems with a rule group that is managed by an AWS partner, contact that partner’s customer support team. To find partner contact information, see the partner’s listing on AWS Marketplace.

Creating and selling AWS Marketplace rule groups

If you want to sell AWS Marketplace rule groups on AWS Marketplace, see How to Sell Your Software on AWS Marketplace.

Working with web ACLs

Note

This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

When you add rules to a web ACL, you specify whether you want AWS WAF Classic to allow or block requests based on the conditions in the rules. If you add more than one rule to a web ACL, AWS WAF Classic evaluates each request against the rules in the order that you list them in the web ACL. When a web request matches all the conditions in a rule, AWS WAF Classic immediately takes the corresponding action—allow or block—and doesn’t evaluate the request against the remaining rules in the web ACL, if any.

If a web request doesn’t match any of the rules in a web ACL, AWS WAF Classic takes the default action that you specified for the web ACL. For more information, see Deciding on the default action for a Web ACL (p. 306).

If you want to test a rule before you start using it to allow or block requests, you can configure AWS WAF Classic to count the web requests that match the conditions in the rule. For more information, see Testing web ACLs (p. 312).

Topics

- Deciding on the default action for a Web ACL (p. 306)
- Creating a Web ACL (p. 307)
- Associating or disassociating a Web ACL with an Amazon API Gateway API, a CloudFront distribution or an Application Load Balancer (p. 310)
- Editing a Web ACL (p. 311)
- Deleting a Web ACL (p. 311)
- Testing web ACLs (p. 312)

Deciding on the default action for a Web ACL

Note

This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

When you create and configure a web ACL, the first and most important decision that you must make is whether the default action should be for AWS WAF Classic to allow web requests or to block
web requests. The default action indicates what you want AWS WAF Classic to do after it inspects a
web request for all the conditions that you specify, and the web request doesn't match any of those
conditions:

- **Allow** – If you want to allow most users to access your website, but you want to block access to
attackers whose requests originate from specified IP addresses, or whose requests appear to contain
malicious SQL code or specified values, choose **Allow** for the default action.

- **Block** – If you want to prevent most would-be users from accessing your website, but you want to
allow access to users whose requests originate from specified IP addresses, or whose requests contain
specified values, choose **Block** for the default action.

Many decisions that you make after you've decided on a default action depend on whether you want
to allow or block most web requests. For example, if you want to **allow** most requests, then the match
conditions that you create generally should specify the web requests that you want to **block**, such as the
following:

- Requests that originate from IP addresses that are making an unreasonable number of requests
- Requests that originate from countries that either you don't do business in or are the frequent source
  of attacks
- Requests that include fake values in the **User-Agent** header
- Requests that appear to include malicious SQL code

**Creating a Web ACL**

*Note*
This is **AWS WAF Classic** documentation. You should only use this version if you created AWS
WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not
migrated them over to the latest version yet. To migrate your resources, see Migrating your **AWS
WAF Classic resources to AWS WAF** (p. 245).
*For the latest version of AWS WAF, see AWS WAF (p. 6).*

**To create a web ACL**

1. Sign in to the AWS Management Console and open the AWS WAF console at [https://
console.aws.amazon.com/wafv2/](https://console.aws.amazon.com/wafv2/).

   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.

2. If this is your first time using AWS WAF Classic, choose **Go to AWS WAF Classic** and then **Configure
Web ACL**. If you've used AWS WAF Classic before, choose **Web ACLs** in the navigation pane, and then
choose **Create web ACL**.

3. For **Web ACL name**, enter a name.

   *Note*
   You can't change the name after you create the web ACL.

4. For **CloudWatch metric name**, change the default name if applicable. The name can contain only
alphanumeric characters (A-Z, a-z, 0-9), with maximum length 128 and minimum length one.
   It can't contain white space or metric names reserved for AWS WAF Classic, including "All" and
   "Default_Action."

   *Note*
   You can't change the name after you create the web ACL.

5. For **Region**, choose a Region.

6. For **AWS resource**, choose the resource that you want to associate with this web ACL, and then
choose **Next**.
7. If you've already created the conditions that you want AWS WAF Classic to use to inspect your web requests, choose Next, and then continue to the next step.

If you haven't already created conditions, do so now. For more information, see the following topics:

- Working with cross-site scripting match conditions (p. 270)
- Working with IP match conditions (p. 274)
- Working with geographic match conditions (p. 277)
- Working with size constraint conditions (p. 279)
- Working with SQL injection match conditions (p. 284)
- Working with string match conditions (p. 288)
- Working with regex match conditions (p. 293)

8. If you've already created the rules or rule groups (or subscribed to an AWS Marketplace rule group) that you want to add to this web ACL, add the rules to the web ACL:

   a. In the Rules list, choose a rule.
   b. Choose Add rule to web ACL.
   c. Repeat steps a and b until you've added all the rules that you want to add to this web ACL.
   d. Go to step 10.

9. If you haven't created rules yet, you can add rules now:

   a. Choose Create rule.
   b. Enter the following values:

   **Name**

   Enter a name.

   **CloudWatch metric name**

   Enter a name for the CloudWatch metric that AWS WAF Classic will create and will associate with the rule. The name can contain only alphanumeric characters (A-Z, a-z, 0-9), with maximum length 128 and minimum length one. It can't contain white space or metric names reserved for AWS WAF Classic, including "All" and "Default_Action."

   **Note**

   You can't change the metric name after you create the rule.

   c. To add a condition to the rule, specify the following values:

   **When a request does/does not**

   If you want AWS WAF Classic to allow or block requests based on the filters in a condition, for example, web requests that originate from the range of IP addresses 192.0.2.0/24, choose does.

   If you want AWS WAF Classic to allow or block requests based on the inverse of the filters in a condition, choose does not. For example, if an IP match condition includes the IP address range 192.0.2.0/24 and you want AWS WAF Classic to allow or block requests that do not come from those IP addresses, choose does not.

   **match/originate from**

   Choose the type of condition that you want to add to the rule:

   - Cross-site scripting match conditions – choose match at least one of the filters in the cross-site scripting match condition
   - IP match conditions – choose originate from an IP address in
   - Geo match conditions – choose originate from a geographic location in
• Size constraint conditions – choose **match at least one of the filters in the size constraint condition**
• SQL injection match conditions – choose **match at least one of the filters in the SQL injection match condition**
• String match conditions – choose **match at least one of the filters in the string match condition**
• Regex match conditions – choose **match at least one of the filters in the regex match condition**

**condition name**

Choose the condition that you want to add to the rule. The list displays only conditions of the type that you chose in the preceding list.

d. To add another condition to the rule, choose **Add another condition**, and then repeat steps b and c. Note the following:

• If you add more than one condition, a web request must match at least one filter in every condition for AWS WAF Classic to allow or block requests based on that rule.
• If you add two IP match conditions to the same rule, AWS WAF Classic will only allow or block requests that originate from IP addresses that appear in both IP match conditions.

e. Repeat step 9 until you've created all the rules that you want to add to this web ACL.

f. Choose **Create**.

g. Continue with step 10.

10. For each rule or rule group in the web ACL, choose the kind of management you want AWS WAF Classic to provide, as follows:

• For each rule, choose whether you want AWS WAF Classic to allow, block, or count web requests based on the conditions in the rule:
  • **Allow** – API Gateway, CloudFront or an Application Load Balancer responds with the requested object. In the case of CloudFront, if the object isn’t in the edge cache, CloudFront forwards the request to the origin.
  • **Block** – API Gateway, CloudFront or an Application Load Balancer responds to the request with an HTTP 403 (Forbidden) status code. CloudFront also can respond with a custom error page. For more information, see Using AWS WAF Classic with CloudFront custom error pages (p. 328).
  • **Count** – AWS WAF Classic increments a counter of requests that match the conditions in the rule, and then continues to inspect the web request based on the remaining rules in the web ACL.

For information about using **Count** to test a web ACL before you start to use it to allow or block web requests, see Counting the web requests that match the rules in a web ACL (p. 312).

• For each rule group, set the override action for the rule group:
  • **No override** – Causes the actions of the individual rules within the rule group to be used.
  • **Override to count** – Overrides any block actions that are specified by individual rules in the group, so that all matching requests are only counted.

For more information, see Rule group override (p. 305).

11. If you want to change the order of the rules in the web ACL, use the arrows in the **Order** column. AWS WAF Classic inspects web requests based on the order in which rules appear in the web ACL.

12. If you want to remove a rule that you added to the web ACL, choose the **x** in the row for the rule.

13. Choose the default action for the web ACL. This is the action that AWS WAF Classic takes when a web request doesn’t match the conditions in any of the rules in this web ACL. For more information, see Deciding on the default action for a Web ACL (p. 306).
15. Review the settings for the web ACL, and choose Confirm and create.

**Associating or disassociating a Web ACL with an Amazon API Gateway API, a CloudFront distribution or an Application Load Balancer**

**Note**
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

To associate or disassociate a web ACL, perform the applicable procedure. Note that you also can associate a web ACL with a CloudFront distribution when you create or update the distribution. For more information, see Using AWS WAF Classic to Control Access to Your Content in the Amazon CloudFront Developer Guide.

The following restrictions apply when associating a web ACL:

- Each API Gateway API, Application Load Balancer and CloudFront distribution can be associated with only one web ACL.
- Web ACLs associated with a CloudFront distribution cannot be associated with an Application Load Balancer or API Gateway API. The web ACL can, however, be associated with other CloudFront distributions.

**To associate a web ACL with an API Gateway API, CloudFront distribution or Application Load Balancer**

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose Web ACLs.
3. Choose the name of the web ACL that you want to associate with an API Gateway API, CloudFront distribution or Application Load Balancer. This opens a page with the web ACL's details in the right pane.
4. On the Rules tab, under AWS resources using this web ACL, choose Add association.
5. When prompted, use the Resource list to choose the API Gateway API, CloudFront distribution or Application Load Balancer that you want to associate this web ACL with. If you choose an Application Load Balancer, you also must specify a Region.
6. Choose Add.
7. To associate this web ACL with an additional API Gateway API, CloudFront distribution or another Application Load Balancer, repeat steps 4 through 6.

**To disassociate a web ACL from an API Gateway API, CloudFront distribution or Application Load Balancer**

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose **Web ACLs**.

3. Choose the name of the web ACL that you want to disassociate from an API Gateway API, CloudFront distribution or Application Load Balancer. This opens a page with the web ACL's details in the right pane.

4. On the **Rules** tab, under **AWS resources using this web ACL**, choose the x for each API Gateway API, CloudFront distribution or Application Load Balancer that you want to disassociate this web ACL from.

### Editing a Web ACL

**Note**

This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see [Migrating your AWS WAF Classic resources to AWS WAF](p. 245).

For the latest version of **AWS WAF**, see [AWS WAF](p. 6).

To add or remove rules from a web ACL or change the default action, perform the following procedure.

**To edit a web ACL**

   
   If you see **Switch to AWS WAF Classic** in the navigation pane, select it.

2. In the navigation pane, choose **Web ACLs**.

3. Choose the name of the web ACL that you want to edit. This opens a page with the web ACL's details in the right pane.

4. On the **Rules** tab in the right pane, choose **Edit web ACL**.

5. To add rules to the web ACL, perform the following steps:

   a. In the **Rules** list, choose the rule that you want to add.

   b. Choose **Add rule to web ACL**.

   c. Repeat steps a and b until you've added all the rules that you want.

6. If you want to change the order of the rules in the web ACL, use the arrows in the **Order** column. AWS WAF Classic inspects web requests based on the order in which rules appear in the web ACL.

7. To remove a rule from the web ACL, choose the x at the right of the row for that rule. This doesn't delete the rule from AWS WAF Classic, it just removes the rule from this web ACL.

8. To change the action for a rule or the default action for the web ACL, choose the preferred option.

   **Note**

   When setting the action for a rule group or an AWS Marketplace rule group (as opposed to a single rule), the action you set for the rule group (either **No override** or **Override to count**) is called the override action. For more information, see [Rule group override](p. 305)

9. Choose **Save changes**.

### Deleting a Web ACL

**Note**

This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see [Migrating your AWS WAF Classic resources to AWS WAF](p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

To delete a web ACL, you must remove the rules that are included in the web ACL and disassociate all CloudFront distributions and Application Load Balancers from the web ACL. Perform the following procedure.

To delete a web ACL

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose Web ACLs.
3. Choose the name of the web ACL that you want to delete. This opens a page with the web ACL's details in the right pane.
4. On the Rules tab in the right pane, choose Edit web ACL.
5. To remove all rules from the web ACL, choose the x at the right of the row for each rule. This doesn't delete the rules from AWS WAF Classic, it just removes the rules from this web ACL.
6. Choose Update.
7. Disassociate the web ACL from all CloudFront distributions and Application Load Balancers. On the Rules tab, under AWS resources using this web ACL, choose the x for each API Gateway API, CloudFront distribution or Application Load Balancer.
8. On the Web ACLs page, confirm that the web ACL that you want to delete is selected, and then choose Delete.

Testing web ACLs

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

To ensure that you don't accidentally configure AWS WAF Classic to block web requests that you want to allow or allow requests that you want to block, we recommend that you test your web ACL thoroughly before you start using it on your website or web application.

Topics
• Counting the web requests that match the rules in a web ACL (p. 312)
• Viewing a sample of the web requests that API Gateway CloudFront or an Application Load Balancer has forwarded to AWS WAF Classic (p. 314)

Counting the web requests that match the rules in a web ACL

When you add rules to a web ACL, you specify whether you want AWS WAF Classic to allow, block, or count the web requests that match all the conditions in that rule. We recommend that you begin with the following configuration:

• Configure all the rules in a web ACL to count web requests
• Set the default action for the web ACL to allow requests

In this configuration, AWS WAF Classic inspects each web request based on the conditions in the first rule. If the web request matches all the conditions in that rule, AWS WAF Classic increments a counter for
that rule. Then AWS WAF Classic inspects the web request based on the conditions in the next rule. If the request matches all the conditions in that rule, AWS WAF Classic increments a counter for the rule. This continues until AWS WAF Classic has inspected the request based on the conditions in all of your rules.

After you've configured all the rules in a web ACL to count requests and associated the web ACL with an Amazon API Gateway API, CloudFront distribution or Application Load Balancer, you can view the resulting counts in an Amazon CloudWatch graph. For each rule in a web ACL and for all the requests that API Gateway, CloudFront or an Application Load Balancer forwards to AWS WAF Classic for a web ACL, CloudWatch lets you:

• View data for the preceding hour or preceding three hours,
• Change the interval between data points
• Change the calculation that CloudWatch performs on the data, such as maximum, minimum, average, or sum

Note
AWS WAF Classic with CloudFront is a global service and metrics are available only when you choose the US East (N. Virginia) Region in the AWS Management Console. If you choose another region, no AWS WAF Classic metrics will appear in the CloudWatch console.

To view data for the rules in a web ACL

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, under Metrics, choose WAF.
3. Select the check box for the web ACL that you want to view data for.
4. Change the applicable settings:

   Statistic
   Choose the calculation that CloudWatch performs on the data.

   Time range
   Choose whether you want to view data for the preceding hour or the preceding three hours.

   Period
   Choose the interval between data points in the graph.

   Rules
   Choose the rules for which you want to view data.

Note the following:

• If you just associated a web ACL with an API Gateway API, CloudFront distribution or Application Load Balancer, you might need to wait a few minutes for data to appear in the graph and for the metric for the web ACL to appear in the list of available metrics.
• If you associate more than one API Gateway API, CloudFront distribution or Application Load Balancer with a web ACL, the CloudWatch data will include all the requests for all the distributions that are associated with the web ACL.
• You can hover the mouse cursor over a data point to get more information.
• The graph doesn't refresh itself automatically. To update the display, choose the refresh (⟳) icon.

5. (Optional) View detailed information about individual requests that API Gateway CloudFront or an Application Load Balancer has forwarded to AWS WAF Classic. For more information, see Viewing
6. If you determine that a rule is intercepting requests that you don't want it to intercept, change the applicable settings. For more information, see Creating and configuring a Web Access Control List (Web ACL) (p. 268).

When you're satisfied that all of your rules are intercepting only the correct requests, change the action for each of your rules to Allow or Block. For more information, see Editing a Web ACL (p. 311).

Viewing a sample of the web requests that API Gateway CloudFront or an Application Load Balancer has forwarded to AWS WAF Classic

In the AWS WAF Classic console, you can view a sample of the requests that API Gateway CloudFront or an Application Load Balancer has forwarded to AWS WAF Classic for inspection. For each sampled request, you can view detailed data about the request, such as the originating IP address and the headers included in the request. You also can view which rule the request matched, and whether the rule is configured to allow or block requests.

The sample of requests contains up to 100 requests that matched all the conditions in each rule and another 100 requests for the default action, which applies to requests that didn't match all the conditions in any rule. The requests in the sample come from all the API Gateway APIs, CloudFront edge locations or Application Load Balancers that have received requests for your content in the previous 15 minutes.

To view a sample of the web requests that API Gateway; CloudFront or an Application Load Balancer has forwarded to AWS WAF Classic

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.

   If you see Switch to AWS WAF Classic in the navigation pane, select it.

2. In the navigation pane, choose the web ACL for which you want to view requests.

3. In the right pane, choose the Requests tab.

The Sampled requests table displays the following values for each request:

Source IP
Either the IP address that the request originated from or, if the viewer used an HTTP proxy or an Application Load Balancer to send the request, the IP address of the proxy or Application Load Balancer.

URI
The URI path of the request, which identifies the resource, for example, /images/daily-ad.jpg. This doesn't include the query string or fragment components of the URI. For information, see Uniform Resource Identifier (URI): Generic Syntax.

Matches rule
Identifies the first rule in the web ACL for which the web request matched all the conditions. If a web request doesn't match all the conditions in any rule in the web ACL, the value of Matches rule is Default.

Note that when a web request matches all the conditions in a rule and the action for that rule is Count, AWS WAF Classic continues inspecting the web request based on subsequent rules in the web ACL. In this case, a web request could appear twice in the list of sampled requests: once for the rule that has an action of Count and again for a subsequent rule or for the default action.
Action
Indicates whether the action for the corresponding rule is Allow, Block, or Count.

Time
The time that AWS WAF Classic received the request from API Gateway, CloudFront or your Application Load Balancer.

4. To display additional information about the request, choose the arrow on the left side of the IP address for that request. AWS WAF Classic displays the following information:

Source IP
The same IP address as the value in the Source IP column in the table.

Country
The two-letter country code of the country that the request originated from. If the viewer used an HTTP proxy or an Application Load Balancer to send the request, this is the two-letter country code of the country that the HTTP proxy or an Application Load Balancer is in.

For a list of two-letter country codes and the corresponding country names, see the Wikipedia entry ISO 3166-1 alpha-2.

Method
The HTTP request method for the request: GET, HEAD, OPTIONS, PUT, POST, PATCH, or DELETE.

URI
The same URI as the value in the URI column in the table.

Request headers
The request headers and header values in the request.

5. To refresh the list of sample requests, choose Get new samples.

Working with AWS WAF Classic rule groups for use with AWS Firewall Manager

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

An AWS WAF Classic rule group is a set of rules that you add to an AWS WAF Classic AWS Firewall Manager policy. You can create your own rule group, or you can purchase a managed rule group from AWS Marketplace.

Important
If you want to add an AWS Marketplace rule group to your Firewall Manager policy, each account in your organization must first subscribe to that rule group. After all accounts have subscribed, you can then add the rule group to a policy. For more information, see AWS Marketplace rule groups (p. 303).

Topics
- Creating an AWS WAF Classic rule group (p. 316)
- Adding and deleting rules from an AWS WAF Classic rule group (p. 316)
Creating an AWS WAF Classic rule group

**Note**
This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245). For the latest version of AWS WAF, see AWS WAF (p. 6).

When you create an AWS WAF Classic rule group to use with AWS Firewall Manager, you specify which rules to add to the group.

To create a rule group (console)

1. Sign in to the AWS Management Console using the AWS Firewall Manager administrator account that you set up in the prerequisites, and then open the Firewall Manager console at [https://console.aws.amazon.com/wafv2/fms](https://console.aws.amazon.com/wafv2/fms).

   **Note**
   For information about setting up a Firewall Manager administrator account, see Step 2: Set the AWS Firewall Manager administrator account (p. 359).

2. In the navigation pane, choose **Switch to AWS WAF Classic**.

3. In the AWS WAF Classic navigation pane, choose **Rule groups**.

4. Choose **Create rule group**.

   **Note**
   You can't add rate-based rules to a rule group.

5. If you have already created the rules that you want to add to the rule group, choose **Use existing rules for this rule group**. If you want to create new rules to add to the rule group, choose **Create rules and conditions for this rule group**.

6. Choose **Next**.

7. If you chose to create rules, follow the steps to create them at Creating a rule and adding conditions (p. 299).

   **Note**
   Use the AWS WAF Classic console to create your rules.

   When you've created all the rules you need, go to the next step.

8. Type a rule group name.

9. To add a rule to the rule group, select a rule then choose **Add rule**. Choose whether to allow, block, or count requests that match the rule's conditions. For more information on the choices, see How AWS WAF Classic works (p. 255).

10. When you are finished adding rules, choose **Create**.

You can test your rule group by adding it to an AWS WAF WebACL and setting the WebACL action to **Override to Count**. This action overrides any action that you choose for the rules contained in the group, and only counts matching requests. For more information, see Creating a Web ACL (p. 307).

Adding and deleting rules from an AWS WAF Classic rule group

**Note**
This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not
AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide
Getting started with AWS Firewall Manager to enable AWS WAF Classic rules

You can add or delete rules in an AWS WAF Classic rule group.

Deleting a rule from the rule group does not delete the rule itself. It only removes the rule from the rule group.

**Getting started with AWS Firewall Manager to enable AWS WAF Classic rules**

**Note**
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

You can use AWS Firewall Manager to enable AWS WAF rules, AWS WAF Classic rules, AWS Shield Advanced protections, and Amazon VPC security groups. The steps for getting set up are slightly different for each:

- To use Firewall Manager to enable rules using the latest version of AWS WAF, don't use this topic. Instead, follow the steps in Getting started with AWS Firewall Manager AWS WAF policies (p. 364).
- To use Firewall Manager to enable AWS Shield Advanced protections, follow the steps in Getting started with AWS Firewall Manager AWS Shield Advanced policies (p. 366).
To use Firewall Manager to enable Amazon VPC security groups, follow the steps in Getting started with AWS Firewall Manager Amazon VPC security group policies (p. 369).

To use Firewall Manager to enable AWS WAF Classic rules, perform the following steps in sequence.

Topics
- Step 1: Complete the prerequisites (p. 318)
- Step 2: Create rules (p. 318)
- Step 3: Create a rule group (p. 318)
- Step 4: Create and apply an AWS Firewall Manager AWS WAF Classic policy (p. 319)

Step 1: Complete the prerequisites

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in AWS Firewall Manager prerequisites (p. 358). Complete all the prerequisites before proceeding to Step 2: Create rules (p. 318).

Step 2: Create rules

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

In this step, you create rules using AWS WAF Classic. If you already have AWS WAF Classic rules that you want to use with AWS Firewall Manager, skip this step and go to Step 3: Create a rule group (p. 318).

Note
Use the AWS WAF Classic console to create your rules.

To create AWS WAF Classic rules (console)

- Create your rules, and then add your conditions to your rules. For more information, see Creating a rule and adding conditions (p. 299).

You are now ready to go to Step 3: Create a rule group (p. 318).

Step 3: Create a rule group

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).
A rule group is a set of rules that defines what actions to take when a particular set of conditions is met. You can use managed rule groups from AWS Marketplace, and you can create your own rule groups. For information about managed rule groups, see AWS Marketplace rule groups (p. 303).

To create your own rule group, perform the following procedure.

**To create a rule group (console)**

1. Sign in to the AWS Management Console using the AWS Firewall Manager administrator account that you set up in the prerequisites, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fms.
2. In the navigation pane, choose Security policies.
3. If you have not met the prerequisites, the console displays instructions about how to fix any issues. Follow the instructions, and then begin this step (create a rule group) again. If you have met the prerequisites, choose Close.
4. Choose Create policy.
   For Policy type, choose AWS WAF Classic.
5. Choose Create an AWS Firewall Manager policy and add a new rule group.
6. Choose an AWS Region, and then choose Next.
7. Because you already created rules, you don't need to create conditions. Choose Next.
8. Because you already created rules, you don't need to create rules. Choose Next.
9. Choose Create rule group.
10. For Name, enter a friendly name.
11. Enter a name for the CloudWatch metric that AWS WAF Classic will create and will associate with the rule group. The name can contain only alphanumeric characters (A-Z, a-z, 0-9) or the following special characters: _-`!#`+*},./. It can't contain white space.
12. Select a rule, and then choose Add rule. A rule has an action setting that allows you to choose whether to allow, block, or count requests that match the rule's conditions. For this tutorial, choose Count. Repeat adding rules until you have added all the rules that you want to the rule group.
13. Choose Create.

You are now ready to go to Step 4: Create and apply an AWS Firewall Manager AWS WAF Classic policy (p. 319).

**Step 4: Create and apply an AWS Firewall Manager AWS WAF Classic policy**

**Note**

This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

After you create the rule group, you create an AWS Firewall Manager AWS WAF policy. A Firewall Manager AWS WAF policy contains the rule group that you want to apply to your resources.

**To create a Firewall Manager AWS WAF policy (console)**

1. After you create the rule group (the last step in the preceding procedure, Step 3: Create a rule group (p. 318)), the console displays the Rule group summary page. Choose Next.
2. For Name, enter a friendly name.
3. For **Policy type**, choose **WAF**.

4. For **Region**, choose an AWS Region. To protect Amazon CloudFront resources, choose **Global**.

   To protect resources in multiple regions (other than CloudFront resources), you must create separate Firewall Manager policies for each Region.

5. Select a rule group to add, and then choose **Add rule group**.

6. A policy has two possible actions: **Action set by rule group** and **Count**. If you want to test the policy and rule group, set the action to **Count**. This action overrides any **block** action specified by the rule group contained in the policy. That is, if the policy's action is set to **Count**, those requests are only counted and not blocked. Conversely, if you set the policy's action to **Action set by rule group**, actions of the rule group in the policy are used. For this tutorial, choose **Count**.

7. Choose **Next**.

8. If you want to include only specific accounts in the policy, or alternatively exclude specific accounts from the policy, select **Select accounts to include/exclude from this policy (optional)**. Choose either **Include only these accounts in this policy** or **Exclude these accounts from this policy**. You can choose only one option. Choose **Add**. Select the account numbers to include or exclude, and then choose **OK**.

   **Note**
   If you don't select this option, Firewall Manager applies a policy to all accounts in your organization in AWS Organizations. If you add a new account to the organization, Firewall Manager automatically applies the policy to that account.

9. Choose the types of resources that you want to protect.

10. If you want to protect only resources with specific tags, or alternatively exclude resources with specific tags, select **Use tags to include/exclude resources**, enter the tags, and then choose either **Include** or **Exclude**. You can choose only one option.

    If you enter more than one tag (separated by commas), and if a resource has any of those tags, it is considered a match.

    For more information about tags, see **Working with Tag Editor**.

11. Choose **Create and apply this policy to existing and new resources**.

    This option creates a web ACL in each applicable account within an organization in AWS Organizations, and associates the web ACL with the specified resources in the accounts. This option also applies the policy to all new resources that match the preceding criteria (resource type and tags). Alternatively, if you choose **Create but do not apply this policy to existing or new resources**, Firewall Manager creates a web ACL in each applicable account within the organization, but doesn't apply the web ACL to any resources. You must apply the policy to resources later.

12. Leave the choice for **Replace existing associated web ACLs** at the default setting.

    When this option is selected, Firewall Manager removed all existing web ACL associations from in-scope resources before it associates the new policy's web ACLs to them.

13. Choose **Next**.

14. Review the new policy. To make any changes, choose **Edit**. When you are satisfied with the policy, choose **Create policy**.

---

**Tutorial: Creating a AWS Firewall Manager policy with hierarchical rules**

**Note**
This is **AWS WAF Classic** documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not
AWS WAF, AWS Firewall Manager, and
AWS Shield Advanced Developer Guide
Step 1: Designate a Firewall Manager administrator account

migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

With AWS Firewall Manager, you can create and apply AWS WAF Classic protection policies that contain hierarchical rules. That is, you can create and enforce certain rules centrally, but delegate the creation and maintenance of account-specific rules to other individuals. You can monitor the centrally applied (common) rules for any accidental removal or mishandling, thereby ensuring that they are applied consistently. The account-specific rules add further protection customized for the needs of individual teams.

Note

In the latest version of AWS WAF, this capability is built in and doesn't require any special handling. If you aren't already using AWS WAF Classic, use the latest version instead. See Creating an AWS Firewall Manager policy for AWS WAF (p. 380).

The following tutorial describes how to create a hierarchical set of protection rules.

Topics

• Step 1: Designate a Firewall Manager administrator account (p. 321)
• Step 2: Create a rule group using the Firewall Manager administrator account (p. 321)
• Step 3: Create a Firewall Manager policy and attach the common rule group (p. 322)
• Step 4: Add account-specific rules (p. 322)
• Conclusion (p. 322)

Step 1: Designate a Firewall Manager administrator account

To use AWS Firewall Manager, you must designate an account in your organization as the Firewall Manager administrator account. This account can be either the management account or a member account in the organization.

You can use the Firewall Manager administrator account to create a set of common rules that you apply to other accounts in the organization. Other accounts in the organization can't change these centrally applied rules.

To designate an account as a Firewall Manager administrator account and complete other prerequisites for using Firewall Manager, see the instructions in AWS Firewall Manager prerequisites (p. 358). If you've already completed the prerequisites, you can skip to step 2 of this tutorial.

In this tutorial, we refer to the administrator account as Firewall-Administrator-Account.

Step 2: Create a rule group using the Firewall Manager administrator account

Next, create a rule group using Firewall-Administrator-Account. This rule group contains the common rules that you will apply to all member accounts governed by the policy that you create in the next step. Only Firewall-Administrator-Account can make changes to these rules and the container rule group.

In this tutorial, we refer to this container rule group as Common-Rule-Group.

To create a rule group, see the instructions in Creating an AWS WAF Classic rule group (p. 316). Remember to sign in to the console using your Firewall Manager administrator account (Firewall-Administrator-Account) when following these instructions.
Step 3: Create a Firewall Manager policy and attach the common rule group

Using Firewall-Administrator-Account, create a Firewall Manager policy. When you create this policy, you must do the following:

- Add Common-Rule-Group to the new policy.
- Include all accounts in the organization that you want Common-Rule-Group applied to.
- Add all resources that you want Common-Rule-Group applied to.

For instructions on creating a policy, see Creating an AWS Firewall Manager policy (p. 380).

This creates a web ACL in each specified account and adds Common-Rule-Group to each of those web ACLs. After you create the policy, this web ACL and the common rules are deployed to all specified accounts.

In this tutorial, we refer to this web ACL as Administrator-Created-ACL. A unique Administrator-Created-ACL now exists in each specified member account of the organization.

Step 4: Add account-specific rules

Each member account in the organization can now add their own account-specific rules to the Administrator-Created-ACL that exists in their account. The common rules already in Administrator-Created-ACL continue to apply, along with the new, account-specific rules. AWS WAF inspects web requests based on the order in which rules appear in the web ACL. This applies to both Administrator-Created-ACL and account-specific rules.

To add rules to Administrator-Created-ACL, see Editing a web ACL (p. 21).

Conclusion

You now have a web ACL that contains common rules administered by the Firewall Manager administrator account as well as account-specific rules maintained by each member account.

The Administrator-Created-ACL in each account references the single Common-Rule-Group. Therefore, future changes by the Firewall Manager administrator account to Common-Rule-Group will immediately take effect in each member account.

Member accounts can't change or remove the common rules in Common-Rule-Group.

Account-specific rules don't affect other accounts.

Logging Web ACL traffic information

Note

This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

You can enable logging to get detailed information about traffic that is analyzed by your web ACL. Information that is contained in the logs include the time that AWS WAF Classic received the request.
from your AWS resource, detailed information about the request, and the action for the rule that each request matched.

To get started, you set up an Amazon Kinesis Data Firehose. As part of that process, you choose a destination for storing your logs. Next, you choose the web ACL that you want to enable logging for. After you enable logging, AWS WAF delivers logs through the firehose to your storage destination.

For information about how to create an Amazon Kinesis Data Firehose and review your stored logs, see What Is Amazon Kinesis Data Firehose? To understand the permissions required for your Kinesis Data Firehose configuration, see Controlling Access with Amazon Kinesis Data Firehose.

You must have the following permissions to successfully enable logging:

- `iam:CreateServiceLinkedRole`
- `firehose:ListDeliveryStreams`
- `waf:PutLoggingConfiguration`

For more information about service-linked roles and the `iam:CreateServiceLinkedRole` permission, see Using service-linked roles for AWS WAF Classic (p. 348).

**To enable logging for a web ACL**

1. Create an Amazon Kinesis Data Firehose using a name starting with the prefix "aws-waf-logs-" For example, `aws-waf-logs-us-east-2-analytics`. Create the data firehose with a PUT source and in the region that you are operating. If you are capturing logs for Amazon CloudFront, create the firehose in US East (N. Virginia). For more information, see Creating an Amazon Kinesis Data Firehose Delivery Stream.

   **Important**

   Do not choose Kinesis stream as your source.

   One AWS WAF Classic log is equivalent to one Kinesis Data Firehose record. If you typically receive 10,000 requests per second and you enable full logs, you should have a 10,000 records per second setting in Kinesis Data Firehose. If you don't configure Kinesis Data Firehose correctly, AWS WAF Classic won't record all logs. For more information, see Amazon Kinesis Data Firehose Quotas.

   If you see Switch to AWS WAF Classic in the navigation pane, select it.

3. In the navigation pane, choose Web ACLs.

4. Choose the name of the web ACL that you want to enable logging for. This opens a page with the web ACL's details in the right pane.

5. On the Logging tab, choose Enable logging.

6. Choose the Kinesis Data Firehose that you created in the first step. You must choose a firehose that begins with "aws-waf-logs-".

7. (Optional) If you don't want certain fields and their values included in the logs, redact those fields. Choose the field to redact, and then choose Add. Repeat as necessary to redact additional fields. The redacted fields appear as XXX in the logs. For example, if you redact the cookie field, the cookie field in the logs will be XXX.

8. Choose Enable logging.

   **Note**

   When you successfully enable logging, AWS WAF Classic will create a service linked role with the necessary permissions to write logs to the Amazon Kinesis Data Firehose. For more information, see Using service-linked roles for AWS WAF Classic (p. 348).
To disable logging for a web ACL

1. In the navigation pane, choose Web ACLs.
2. Choose the name of the web ACL that you want to disable logging for. This opens a page with the web ACL's details in the right pane.
3. On the Logging tab, choose Disable logging.
4. In the dialog box, choose Disable logging.

Example Example log

```
{
  "timestamp":1533689070589,
  "formatVersion":1,
  "webaclId":"385cb038-3a6f-4f2f-ac64-09ab912af590",
  "terminatingRuleId":"Default_Action",
  "terminatingRuleType":"REGULAR",
  "action":"ALLOW",
  "httpSourceName":"CF",
  "httpSourceId":"i-123",
  "ruleGroupList": [
    {
      "ruleGroupId":"41f4eb08-4e1b-2985-92b5-e8abf434fad3",
      "terminatingRule":null,
      "nonTerminatingMatchingRules": [
        {"action": "COUNT",
         "ruleId": "4659b169-2083-4a91-bbd4-08851a9aaf74"},
        {"exclusionType": "EXCLUDED_AS_COUNT",
         "ruleId": "5432a230-0113-5b83-bbb2-89375c5bfa98"}
      ]
    },
    {"rateBasedRuleList": [
      {"rateBasedRuleId":"7c968ef6-32ec-4fee-96cc-51198e412e7f",
       "limitKey": "IP",
       "maxRateAllowed": 100
      },
      {"rateBasedRuleId":"462b169-2083-4a93-bbd4-08851a9aaf30",
       "limitKey": "IP",
       "maxRateAllowed": 100
      }]
    },
    {"nonTerminatingMatchingRules": [
      {"action": "COUNT",
       "ruleId": "4659b181-2011-4a91-bbd4-08851a9aaf52"}
    ]
  }
}
Following is an explanation of each item listed in these logs:

**timestamp**

The timestamp in milliseconds.

**formatVersion**

The format version for the log.

**webaclId**

The GUID of the web ACL.

**terminatingRuleId**

The ID of the rule that terminated the request. If nothing terminates the request, the value is Default_Action.

**terminatingRuleType**

The type of rule that terminated the request. Possible values: RATE_BASED, REGULAR, and GROUP.

**action**

The action. Possible values for a terminating rule: ALLOW and BLOCK. COUNT is not a valid value for a terminating rule.

**terminatingRuleMatchDetails**

Detailed information about the terminating rule that matched the request. A terminating rule has an action that ends the inspection process against a web request. Possible actions for a terminating rule are ALLOW and BLOCK. This is only populated for SQL injection and cross-site scripting (XSS) match rule statements. As with all rule statements that inspect for more than one thing, AWS WAF applies the action on the first match and stops inspecting the web request. A web request with a terminating action could contain other threats, in addition to the one reported in the log.

**httpSourceName**

The source of the request. Possible values: CF (if the source is Amazon CloudFront), APIGW (if the source is Amazon API Gateway), and ALB (if the source is an Application Load Balancer).
httpSourceId

The source ID. This field shows the ID of the associated Amazon CloudFront distribution, the REST API for API Gateway, or the name for an Application Load Balancer.

ruleGroupList

The list of rule groups that acted on this request. In the preceding code example, there is only one.

ruleGroupId

The ID of the rule group. If the rule blocked the request, the ID for ruleGroupId is the same as the ID for terminatingRuleId.

terminatingRule

The rule within the rule group that terminated the request. If this is a non-null value, it also contains a ruleId and action. In this case, the action is always BLOCK.

nonTerminatingMatchingRules

The list of rules in the rule group that match the request. These are always COUNT rules (non-terminating rules that match).

action (nonTerminatingMatchingRules group)

This is always COUNT (non-terminating rules that match).

ruleId (nonTerminatingMatchingRules group)

The ID of the rule within the rule group that matches the request and was non-terminating. That is, COUNT rules.

excludedRules

The list of rules in the rule group that you have excluded. The action for these rules is set to COUNT.

exclusionType (excludedRules group)

A type that indicates that the excluded rule has the action COUNT.

ruleId (excludedRules group)

The ID of the rule within the rule group that is excluded.

rateBasedRuleList

The list of rate-based rules that acted on the request.

rateBasedRuleId

The ID of the rate-based rule that acted on the request. If this has terminated the request, the ID for rateBasedRuleId is the same as the ID for terminatingRuleId.

limitKey

The field that AWS WAF uses to determine if requests are likely arriving from a single source and thus subject to rate monitoring. Possible value: IP.

maxRateAllowed

The maximum number of requests, which have an identical value in the field that is specified by limitKey, allowed in a five-minute period. If the number of requests exceeds the maxRateAllowed and the other predicates specified in the rule are also met, AWS WAF triggers the action that is specified for this rule.

httpRequest

The metadata about the request.

clientIp

The IP address of the client sending the request.
country
The source country of the request. If AWS WAF is unable to determine the country of origin, it sets this field to `-.

headers
The list of headers.

uri
The URI of the request. The preceding code example demonstrates what the value would be if this field had been redacted.

args
The query string.

httpVersion
The HTTP version.

httpMethod
The HTTP method in the request.

requestId
The ID of the request.

Listing IP addresses blocked by rate-based rules

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

AWS WAF Classic provides a list of IP addresses that are blocked by rate-based rules.

To view addresses blocked by rate-based rules

1. Sign in to the AWS Management Console and open the AWS WAF console at https://console.aws.amazon.com/wafv2/.
   - If you see Switch to AWS WAF Classic in the navigation pane, select it.
2. In the navigation pane, choose Rules.
3. In the Name column, choose a rate-based rule.

   The list shows the IP addresses that the rule currently blocks.

How AWS WAF Classic works with Amazon CloudFront features

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
When you create a web ACL, you can specify one or more CloudFront distributions that you want AWS WAF Classic to inspect. AWS WAF Classic starts to allow, block, or count web requests for those distributions based on the conditions that you identify in the web ACL. CloudFront provides some features that enhance the AWS WAF Classic functionality. This chapter describes a few ways that you can configure CloudFront to make CloudFront and AWS WAF Classic work better together.

**Topics**
- Using AWS WAF Classic with CloudFront custom error pages (p. 328)
- Using AWS WAF Classic with CloudFront for applications running on your own HTTP server (p. 328)
- Choosing the HTTP methods that CloudFront responds to (p. 329)

### Using AWS WAF Classic with CloudFront custom error pages

When AWS WAF Classic blocks a web request based on the conditions that you specify, it returns HTTP status code 403 (Forbidden) to CloudFront. Next, CloudFront returns that status code to the viewer. The viewer then displays a brief and sparsely formatted default message similar to this:

Forbidden: You don't have permission to access /myfilename.html on this server.

If you'd rather display a custom error message, possibly using the same formatting as the rest of your website, you can configure CloudFront to return to the viewer an object (for example, an HTML file) that contains your custom error message.

**Note**

CloudFront can't distinguish between an HTTP status code 403 that is returned by your origin and one that is returned by AWS WAF Classic when a request is blocked. This means that you can't return different custom error pages based on the different causes of an HTTP status code 403.

For more information about CloudFront custom error pages, see Customizing Error Responses in the Amazon CloudFront Developer Guide.

### Using AWS WAF Classic with CloudFront for applications running on your own HTTP server

When you use AWS WAF Classic with CloudFront, you can protect your applications running on any HTTP webserver, whether it's a webserver that's running in Amazon Elastic Compute Cloud (Amazon EC2) or a webserver that you manage privately. You can also configure CloudFront to require HTTPS between CloudFront and your own webserver, as well as between viewers and CloudFront.

**Requiring HTTPS Between CloudFront and Your Own Webserver**

To require HTTPS between CloudFront and your own webserver, you can use the CloudFront custom origin feature and configure the Origin Protocol Policy and the Origin Domain Name settings for specific origins. In your CloudFront configuration, you can specify the DNS name of the server along with the port and the protocol that you want CloudFront to use when fetching objects from your origin. You should also ensure that the SSL/TLS certificate on your custom origin server matches the origin domain name you've configured. When you use your own HTTP webserver outside of AWS, you must use a certificate that is signed by a trusted third-party certificate authority (CA), for example, Comodo, DigiCert, or Symantec. For more information about requiring HTTPS for communication between CloudFront and your own webserver, see the topic Requiring HTTPS for Communication Between CloudFront and Your Custom Origin in the Amazon CloudFront Developer Guide.
Choosing the HTTP methods that CloudFront responds to

When you create an Amazon CloudFront web distribution, you choose the HTTP methods that you want CloudFront to process and forward to your origin. You can choose from the following options:

- **GET, HEAD** – You can use CloudFront only to get objects from your origin or to get object headers.
- **GET, HEAD, OPTIONS** – You can use CloudFront only to get objects from your origin, get object headers, or retrieve a list of the options that your origin server supports.
- **GET, HEAD, OPTIONS, PUT, POST, PATCH, DELETE** – You can use CloudFront to get, add, update, and delete objects, and to get object headers. In addition, you can perform other POST operations such as submitting data from a web form.

You also can use AWS WAF Classic string match conditions to allow or block requests based on the HTTP method, as described in *Working with string match conditions* (p. 288). If you want to use a combination of methods that CloudFront supports, such as GET and HEAD, then you don't need to configure AWS WAF Classic to block requests that use the other methods. If you want to allow a combination of methods that CloudFront doesn't support, such as GET, HEAD, and POST, you can configure CloudFront to respond to all methods, and then use AWS WAF Classic to block requests that use other methods.

For more information about choosing the methods that CloudFront responds to, see *Allowed HTTP Methods* in the topic *Values that You Specify When You Create or Update a Web Distribution* in the *Amazon CloudFront Developer Guide*.
Data protection in AWS WAF Classic

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

The AWS shared responsibility model applies to data protection in AWS WAF Classic. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

• Use multi-factor authentication (MFA) with each account.
• Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
• Set up API and user activity logging with AWS CloudTrail.
• Use AWS encryption solutions, along with all default security controls within AWS services.
• Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
• If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form fields such as a Name field. This includes when you work with AWS WAF Classic or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic.
logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

AWS WAF Classic entities—such as web ACLs, rules, and conditions—are encrypted at rest, except in certain Regions where encryption is not available, including China (Beijing) and China (Ningxia). Unique encryption keys are used for each Region.

Deleting AWS WAF Classic resources
You can delete the resources that you create in AWS WAF Classic. See the guidance for each resource type in following sections.

- Deleting a Web ACL (p. 311)
- Adding and deleting rules from an AWS WAF Classic rule group (p. 316)
- Deleting a rule (p. 302)

Identity and access management in AWS WAF Classic

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

Access to AWS WAF Classic requires credentials. Those credentials must have permissions to access AWS resources, such as an AWS WAF Classic resource or an Amazon S3 bucket. The following sections provide details on how you can use AWS Identity and Access Management (IAM) and AWS WAF Classic to help secure access to your resources.

- Authentication (p. 331)
- Access control (p. 332)

Authentication
You can access AWS as any of the following types of identities:

- AWS account root user – When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the AWS Account Management Reference Guide.
- IAM user – An IAM user is an identity within your AWS account that has specific custom permissions (for example, permissions to create a rule in AWS WAF Classic). You can use an IAM user name and password to sign in to secure AWS webpages like the AWS Management Console, AWS Discussion Forums, or the AWS Support Center.

In addition to a user name and password, you can also generate access keys for each user. You can use these keys when you access AWS services programmatically, either through one of the several SDKs or by using the AWS Command Line Interface (CLI). The SDK and CLI tools use the access keys to cryptographically sign your request. If you don't use AWS tools, you must sign the request yourself. AWS WAF Classic supports Signature Version 4, a protocol for authenticating inbound API requests. For
more information about authenticating requests, see Signature Version 4 Signing Process in the AWS General Reference.

- **IAM role** – An IAM role is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user in that it is an AWS identity with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. IAM roles with temporary credentials are useful in the following situations:

  - **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.

  - **AWS service access** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

  - **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

**Access control**

You can have valid credentials to authenticate your requests, but unless you have permissions you can't create or access AWS WAF Classic resources. For example, you must have permissions to create an AWS WAF Classic web ACL or rule.

The following sections describe how to manage permissions for AWS WAF Classic. We recommend that you read the overview first.

- Overview of managing access permissions to your AWS WAF Classic resources (p. 333)
- Using identity-based policies (IAM policies) for AWS WAF Classic (p. 337)
- AWS WAF Classic API permissions: Actions, resources, and conditions reference (p. 340)

**AWS Identity and Access Management**

**Note**

This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not
migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

AWS WAF Classic integrates with AWS Identity and Access Management (IAM), a service that lets your organization do the following:

- Create users and groups under your organization's AWS account
- Share your AWS account resources with users in the account
- Assign unique security credentials to each user
- Control user access to services and resources

For example, you can use IAM with AWS WAF Classic to control which users in your AWS account can create a new web ACL.

For general information about IAM, see the following documentation:

- AWS Identity and Access Management (IAM)
- IAM Getting Started Guide
- IAM User Guide

Overview of managing access permissions to your AWS WAF Classic resources

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles). Some services also support attaching permissions policies to resources.

Note
An account administrator (or administrator user) is a user with administrator privileges. For more information, see IAM Best Practices in the IAM User Guide.

When granting permissions, you decide who is getting the permissions, the resources they get permissions for, and the specific operations that you want to allow on those resources.

Topics

- AWS WAF Classic resources and operations (p. 333)
- Understanding resource ownership (p. 334)
- Managing access to resources (p. 335)
- Specifying policy elements: Actions, effects, resources, and principals (p. 336)
- Specifying conditions in a policy (p. 337)

AWS WAF Classic resources and operations

In AWS WAF Classic, the resources are web ACLs and rules. AWS WAF Classic also supports conditions such as byte match, IP match, and size constraint.
These resources and conditions have unique Amazon Resource Names (ARNs) associated with them, as shown in the following table.

<table>
<thead>
<tr>
<th>Name in AWS WAF Console</th>
<th>Name in AWS WAF SDK/CLI</th>
<th>ARN Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ACL</td>
<td>WebACL</td>
<td>arn:aws:waf::account:webacl/ID</td>
</tr>
<tr>
<td>Rule</td>
<td>Rule</td>
<td>arn:aws:waf::account:rule/ID</td>
</tr>
<tr>
<td>String match condition</td>
<td>ByteMatchSet</td>
<td>arn:aws:waf::account:bytematchset/ID</td>
</tr>
<tr>
<td>SQL injection match condition</td>
<td>SqlInjectionMatchSet</td>
<td>arn:aws:waf::account:sqlinjectionset/ID</td>
</tr>
<tr>
<td>Size constraint condition</td>
<td>SizeConstraintSet</td>
<td>arn:aws:waf::account:sizeconstraintset/ID</td>
</tr>
<tr>
<td>IP match condition</td>
<td>IPSet</td>
<td>arn:aws:waf::account:ipset/ID</td>
</tr>
<tr>
<td>Cross-site scripting match condition</td>
<td>XssMatchSet</td>
<td>arn:aws:waf::account:xssmatchset/ID</td>
</tr>
</tbody>
</table>

To allow or deny access to a subset of AWS WAF Classic resources, include the ARN of the resource in the resource element of your policy. The ARNs for AWS WAF Classic have the following format:

```
arnc waf::account:resource/ID
```

Replace the `account`, `resource`, and `ID` variables with valid values. Valid values can be the following:

- **account**: The ID of your AWS account. You must specify a value.
- **resource**: The type of AWS WAF Classic resource.
- **ID**: The ID of the AWS WAF Classic resource, or a wildcard (*) to indicate all resources of the specified type that are associated with the specified AWS account.

For example, the following ARN specifies all web ACLs for the account 111122223333:

```
arnc waf::111122223333:webacl/`
```

For more information, see Resources in the IAM User Guide.

AWS WAF Classic provides a set of operations to work with AWS WAF Classic resources. For a list of available operations, see Actions.

**Understanding resource ownership**

A *resource owner* is the AWS account that creates the resource. That is, the resource owner is the AWS account of the *principal entity* (the root account, an IAM user, or an IAM role) that authenticates the request that creates the resource. The following examples illustrate how this works:

- If you use the root account credentials of your AWS account to create an AWS WAF Classic resource, your AWS account is the owner of the resource.
• If you create an IAM user in your AWS account and grant permissions to create an AWS WAF Classic resource to that user, the user can create an AWS WAF Classic resource. However, your account, to which the user belongs, owns the AWS WAF Classic resource.

• If you create an IAM role in your AWS account with permissions to create an AWS WAF Classic resource, anyone who can assume the role can create an AWS WAF Classic resource. Your account, to which the role belongs, owns the AWS WAF Classic resource.

Managing access to resources

A permissions policy describes who has access to what. The following sections explain the available options for creating permissions policies.

**Note**

These sections discuss using IAM in the context of AWS WAF Classic. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the IAM User Guide. For information about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

Policies that are attached to an IAM identity are known as identity-based policies, and policies that are attached to a resource are known as resource-based policies. AWS WAF Classic supports only identity-based policies.

**Topics**

- Identity-based policies (IAM policies) (p. 335)
- Resource-based policies (p. 336)

**Identity-based policies (IAM policies)**

You can attach policies to IAM identities. For example, you can do the following:

- **Attach a permissions policy to a user or a group in your account** – An account administrator can use a permissions policy that is associated with a particular user to grant permissions for that user to create an AWS WAF Classic resource.

- **Attach a permissions policy to a role (grant cross-account permissions)** – You can attach an identity-based permissions policy to an IAM role to grant cross-account permissions. For example, the administrator in Account A can create a role to grant cross-account permissions to another AWS account (for example, Account B) or an AWS service as follows:

  1. Account A administrator creates an IAM role and attaches a permissions policy to the role that grants permissions on resources in Account A.

  2. Account A administrator attaches a trust policy to the role identifying Account B as the principal who can assume the role.

  3. Account B administrator can then delegate permissions to assume the role to any users in Account B. Doing this allows users in Account B to create or access resources in Account A. The principal in the trust policy also can be an AWS service principal if you want to grant an AWS service permissions to assume the role.

For more information about using IAM to delegate permissions, see Access Management in the IAM User Guide.

The following is an example policy that grants permissions for the waf:ListRules action on all resources. In the current implementation, AWS WAF Classic doesn't support identifying specific resources using the resource ARNs (also referred to as resource-level permissions) for some of the API actions, so you must specify a wildcard character (*):
For more information about using identity-based policies with AWS WAF Classic, see Using identity-based policies (IAM policies) for AWS WAF Classic (p. 337). For more information about users, groups, roles, and permissions, see Identities (Users, Groups, and Roles) in the IAM User Guide.

Resource-based policies

Other services, such as Amazon S3, also support resource-based permissions policies. For example, you can attach a policy to an S3 bucket to manage access permissions to that bucket. AWS WAF doesn’t support resource-based policies.

Authorization based on AWS WAF Classic tags

You can attach tags to AWS WAF Classic resources or pass tags in a request to AWS WAF Classic. To control access based on tags, you provide tag information in the condition element of a policy. For more information about tagging your resources, see Working with Tag Editor.

Specifying policy elements: Actions, effects, resources, and principals

For each AWS WAF Classic resource (see AWS WAF Classic resources and operations (p. 333)), the service defines a set of API operations (see AWS WAF Classic API permissions: Actions, resources, and conditions reference (p. 340)). To grant permissions for these API operations, AWS WAF Classic defines a set of actions that you can specify in a policy. Note that performing an API operation can require permissions for more than one action. When granting permissions for specific actions, you also identify the resource on which the actions are allowed or denied.

The following are the most basic policy elements:

- **Resource** – In a policy, you use an Amazon Resource Name (ARN) to identify the resource to which the policy applies. For more information, see AWS WAF Classic resources and operations (p. 333).
- **Action** – You use action keywords to identify resource operations that you want to allow or deny. For example, the waf:CreateRule permission allows the user permissions to perform the AWS WAF Classic CreateRule operation.
- **Effect** – You specify the effect when the user requests the specific action. This can be either allow or deny. If you don’t explicitly grant access to allow a resource, access is implicitly denied. You also can explicitly deny access to a resource, which you might do to make sure that a user cannot access it, even if a different policy grants access.
- **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. AWS WAF doesn’t support resource-based policies.

To learn more about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

For a table that shows all the AWS WAF Classic API actions and the resources that they apply to, see AWS WAF Classic API permissions: Actions, resources, and conditions reference (p. 340).
Specifying conditions in a policy

When you grant permissions, you can use the IAM policy language to specify the conditions when a policy should take effect. For example, you might want a policy to be applied only after a specific date. For more information about specifying conditions in a policy language, see Condition in the IAM User Guide.

To express conditions, you use predefined condition keys. There are no condition keys specific to AWS WAF Classic. However, there are general AWS condition keys that you can use as appropriate. For a complete list of AWS keys, see Available Keys for Conditions in the IAM User Guide.

Using identity-based policies (IAM policies) for AWS WAF Classic

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

This section provides examples of identity-based policies that demonstrate how an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on AWS WAF Classic resources.

Important
We recommend that you first review the introductory topics that explain the basic concepts and options available for you to manage access to your AWS WAF Classic resources. For more information, see Overview of managing access permissions to your AWS WAF Classic resources (p. 333).

For a table that shows all the AWS WAF Classic API actions and the resources that they apply to, see AWS WAF Classic API permissions: Actions, resources, and conditions reference (p. 340).

Topics

- Permissions required to use the AWS WAF Classic console (p. 337)
- AWS managed (predefined) policies for AWS WAF Classic (p. 337)
- Customer managed policy examples (p. 338)

Permissions required to use the AWS WAF Classic console

The AWS WAF Classic console provides an integrated environment for you to create and manage AWS WAF Classic resources. The console provides many features and workflows that often require permissions to create an AWS WAF Classic resource in addition to the API-specific permissions that are documented in the AWS WAF Classic API permissions: Actions, resources, and conditions reference (p. 340). For more information about these additional console permissions, see Customer managed policy examples (p. 338).

AWS managed (predefined) policies for AWS WAF Classic

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. Managed policies grant necessary permissions for common use cases so you can avoid having to investigate what permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

The following AWS managed policies, which you can attach to users in your account, are specific to AWS WAF Classic:
AWS WAF, AWS Firewall Manager, and
AWS Shield Advanced Developer Guide
Identity and access management

- AWSWAFReadOnlyAccess – Grants read-only access to AWS WAF Classic resources.
- AWSWAFFullAccess – Grants full access to AWS WAF Classic resources.
- AWSWAFConsoleReadOnlyAccess – Grants read-only access to the AWS WAF Classic console, which includes resources for AWS WAF and integrated services, such as Amazon CloudFront, Amazon API Gateway, Application Load Balancer, and Amazon CloudWatch.
- AWSWAFConsoleFullAccess – Grants full access to the AWS WAF Classic console, which includes resources for AWS WAF and integrated services, such as Amazon CloudFront, Amazon API Gateway, Application Load Balancer, and Amazon CloudWatch.

Note
You can review these permissions policies by signing in to the IAM console and searching for specific policies there.

You also can create your own custom IAM policies to allow permissions for AWS WAF Classic API operations and resources. You can attach these custom policies to the IAM users or groups that require those permissions or to custom execution roles (IAM roles) that you create for your AWS WAF Classic resources.

Customer managed policy examples

The examples in this section provide a group of sample policies that you can attach to a user. If you are new to creating policies, we recommend that you first create an IAM user in your account and attach the policies to the user, in the sequence outlined in the steps in this section.

You can use the console to verify the effects of each policy as you attach the policy to the user. Initially, the user doesn't have permissions, and the user won't be able to do anything on the console. As you attach policies to the user, you can verify that the user can perform various operations on the console.

We recommend that you use two browser windows: one to create the user and grant permissions, and the other to sign in to the AWS Management Console using the user's credentials and verify permissions as you grant them to the user.

For examples that show how to create an IAM role that you can use as an execution role for your AWS WAF Classic resource, see Creating IAM Roles in the IAM User Guide.

Example topics

- Example 1: Give users read-only access to AWS WAF Classic, CloudFront, and CloudWatch (p. 338)
- Example 2: Give users full access to AWS WAF Classic, CloudFront, and CloudWatch (p. 339)
- Example 3: Granting access to a specified AWS account (p. 339)
- Example 4: Granting access to a specified Web ACL (p. 340)

Create an IAM user

First, you need to create an IAM user, add the user to an IAM group with administrative permissions, and then grant administrative permissions to the IAM user that you created. You then can access AWS using a special URL and the user's credentials.

For instructions, see Creating Your First IAM User and Administrators Group in the IAM User Guide.

Example 1: Give users read-only access to AWS WAF Classic, CloudFront, and CloudWatch

The following policy grants users read-only access to AWS WAF Classic resources, to Amazon CloudFront web distributions, and to Amazon CloudWatch metrics. It's useful for users who need permission to view the settings in AWS WAF Classic conditions, rules, and web ACLs to see which distribution is associated with a web ACL, and to monitor metrics and a sample of requests in CloudWatch. These users can't create, update, or delete AWS WAF Classic resources.
Example 2: Give users full access to AWS WAF Classic, CloudFront, and CloudWatch

The following policy lets users perform any AWS WAF Classic operation, perform any operation on CloudFront web distributions, and monitor metrics and a sample of requests in CloudWatch. It's useful for users who are AWS WAF Classic administrators.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "waf:*",
        "cloudfront:*",
        "cloudwatch:*"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

We strongly recommend that you configure multi-factor authentication (MFA) for users who have administrative permissions. For more information, see Using Multi-Factor Authentication (MFA) Devices with AWS in the IAM User Guide.

Example 3: Granting access to a specified AWS account

This policy grants the following permissions to the account 444455556666:

- Full access to all AWS WAF Classic operations and resources.
- Read and update access to all CloudFront distributions, which allows you to associate web ACLs and CloudFront distributions.
- Read access to all CloudWatch metrics and metric statistics, so that you can view CloudWatch data and a sample of requests in the AWS WAF Classic console.
Example 4: Granting access to a specified Web ACL

This policy grants the following permissions to the webacl ID 112233d7c-86b2-458b-af83-51c51example in the account 444455556666:

- Full access to AWS WAF Classic Get, Update, and Delete operations and resources

AWS WAF Classic API permissions: Actions, resources, and conditions reference

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

When you set up Access control (p. 332) and writing permissions policies that you can attach to an IAM identity (identity-based policies), you can use the following table as a reference. The table lists each AWS WAF Classic API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

You can use AWS condition keys in your AWS WAF Classic policies to express conditions. For a complete list of AWS keys, see Available Keys for Conditions in the IAM User Guide.

**Note**

To specify an action, use the waf: prefix followed by the API operation name (for example, waf:CreateIPSet).

**AWS WAF Classic API and required permissions for actions**

CreateByteMatchSet

**Action:** waf:CreateByteMatchSet

**Resource:**

Global (for Amazon CloudFront): arn:aws:waf::account-id:bytematchset/entity-ID

CreateIPSet

**Action:** waf:CreateIPSet

**Resource:**

Global (for Amazon CloudFront): arn:aws:waf::account-id:ipset/entity-ID

CreateRule

**Action:** waf:CreateRule

**Resource:**

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

CreateRateBasedRule

**Action:** waf:CreateRateBasedRule

**Resource:**

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

CreateSizeConstraintSet

**Action:** waf:CreateSizeConstraintSet
Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:sizeconstraintset/entity-ID

CreateSqlInjectionMatchSet

Action: waf:CreateSqlInjectionMatchSet,

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:sqлинjectionmatchset/entity-ID

CreateWebACL

Action: waf:CreateWebACL

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:webacl/entity-ID

CreateXssMatchSet

Action: waf:CreateXssMatchSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:xssmatchset/entity-ID

DeleteByteMatchSet

Action: waf:DeleteByteMatchSet,

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:bytematchset/entity-ID

DeleteIPSet

Action: waf:DeleteIPSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:ipset/entity-ID

DeleteRule

Action: waf:DeleteRule
Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

DeleteRateBasedRule

Action: waf:DeleteRateBasedRule

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

DeleteSizeConstraintSet

Action: waf:DeleteSizeConstraintSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:sizeconstraintset/entity-ID

DeleteSqlInjectionMatchSet

Action: waf:DeleteSqlInjectionMatchSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:sqлинjectionmatchset/entity-ID

DeleteWebACL

Action: waf:DeleteWebACL

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:webacl/entity-ID

DeleteXssMatchSet

Action: waf:DeleteXssMatchSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:xssmatchset/entity-ID

GetByteMatchSet

Action: waf:GetByteMatchSet
Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:bytematchset/entity-ID

GetChangeToken

Action: waf:GetChangeToken

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:changetoken/entity-ID

GetChangeTokenStatus

Action: waf:GetChangeTokenStatus

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:changetoken(token-ID)

GetIPSet

Action: waf:GetIPSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:ipset/entity-ID

GetRule

Action: waf:GetRule

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

GetRateBasedRule

Action: waf:GetRateBasedRule

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

GetRateBasedRuleManagedKeys

Action: waf:GetRateBasedRuleManagedKeys
Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

GetSampledRequests

Action: waf:GetSampledRequests

Resource: Resource depends on the parameters that are specified in the API call. You must have access to the rule or web ACL that corresponds to the request for samples. For example:

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/example1 or arn:aws:waf::account-id:webacl/example2

GetSizeConstraintSet

Action: waf:GetSizeConstraintSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:sizeconstraintset/entity-ID

GetSqlInjectionMatchSet

Action: waf:GetSqlInjectionMatchSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:sqlinjectionmatchset/entity-ID

GetWebACL

Action: waf:GetWebACL

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:webacl/entity-ID

GetXssMatchSet

Action: waf:GetXssMatchSet

Resource:

Global (for Amazon CloudFront): arn:aws:waf::account-id:xssmatchset/entity-ID

ListByteMatchSets

**Action**: waf:ListByteMatchSets

**Resource**:

Global (for Amazon CloudFront): arn:aws:waf::account-id:bytematchset/entity-ID

ListIPSets

**Action**: waf:ListIPSets

**Resource**:

Global (for Amazon CloudFront): arn:aws:waf::account-id:ipset/entity-ID

ListRules

**Action**: waf:ListRules

**Resource**:

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

ListRateBasedRules

**Action**: waf:ListRateBasedRules

**Resource**:

Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

ListSizeConstraintSets

**Action**: waf:ListSizeConstraintSets

**Resource**:

Global (for Amazon CloudFront): arn:aws:waf::account-id:sizeconstraintset/entity-ID

ListSqlInjectionMatchSets

**Action**: waf:ListSqlInjectionMatchSets

**Resource**:

Global (for Amazon CloudFront): arn:aws:waf::account-id:sqlinjectionmatchset/entity-ID

ListWebACLs

**Action:** waf:ListWebACLs

**Resource:**
- Global (for Amazon CloudFront): arn:aws:waf::account-id:webacl/entity-ID

ListXssMatchSets

**Action:** waf:ListXssMatchSets

**Resource:**
- Global (for Amazon CloudFront): arn:aws:waf::account-id:xssmatchset/entity-ID

UpdateByteMatchSet

**Action:** waf:UpdateByteMatchSet

**Resource:**
- Global (for Amazon CloudFront): arn:aws:waf::account-id:bytematchset/entity-ID

UpdateIPSet

**Action:** waf:UpdateIPSet

**Resource:**
- Global (for Amazon CloudFront): arn:aws:waf::account-id:ipset/entity-ID

UpdateRule

**Action:** waf:UpdateRule

**Resource:**
- Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID

UpdateRateBasedRule

**Action:** waf:UpdateRateBasedRule

**Resource:**
- Global (for Amazon CloudFront): arn:aws:waf::account-id:rule/entity-ID
Using service-linked roles for AWS WAF Classic

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

AWS WAF Classic uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to AWS WAF Classic. Service-linked roles are predefined by AWS WAF Classic and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up AWS WAF Classic easier because you don’t have to manually add the necessary permissions. AWS WAF Classic defines the permissions of its service-linked roles, and
unless defined otherwise, only AWS WAF Classic can assume its roles. The defined permissions include the trust policy and the permissions policy. That permissions policy can't be attached to any other IAM entity.

You can delete a service-linked role only after first deleting the role's related resources. This protects your AWS WAF Classic resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for AWS WAF Classic

AWS WAF Classic uses the following service-linked roles:

- AWSServiceRoleForWAFLogging
- AWSServiceRoleForWAFRegionalLogging

AWS WAF Classic uses these service-linked roles to write logs to Amazon Kinesis Data Firehose. These roles are used only if you enable logging in AWS WAF. For more information, see Logging Web ACL traffic information (p. 322).

The AWSServiceRoleForWAFLogging and AWSServiceRoleForWAFRegionalLogging service-linked roles trust the following services (respectively) to assume the role:

- waf.amazonaws.com
- waf-regional.amazonaws.com

The permissions policies of the roles allow AWS WAF Classic to complete the following actions on the specified resources:

- Action: firehose:PutRecord and firehose:PutRecordBatch on Amazon Kinesis Data Firehose data stream resources with a name that starts with "aws-waf-logs-." For example, aws-waf-logs-us-east-2-analytics.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

Creating a service-linked role for AWS WAF Classic

You don't need to manually create a service-linked role. When you enable AWS WAF Classic logging on the AWS Management Console, or you make a PutLoggingConfiguration request in the AWS WAF Classic CLI or the AWS WAF Classic API, AWS WAF Classic creates the service-linked role for you.

You must have the iam:CreateServiceLinkedRole permission to enable logging.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable AWS WAF Classic logging, AWS WAF Classic creates the service-linked role for you again.

Editing a service-linked role for AWS WAF Classic

AWS WAF Classic doesn't allow you to edit the AWSServiceRoleForWAFLogging and AWSServiceRoleForWAFRegionalLogging service-linked roles. After you create a service-linked role,
you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

Deleting a service-linked role for AWS WAF Classic

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

**Note**
If the AWS WAF Classic service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete AWS WAF Classic resources used by the AWSServiceRoleForWAFLogging and AWSServiceRoleForWAFRegionalLogging

1. On the AWS WAF Classic console, remove logging from every web ACL. For more information, see Logging Web ACL traffic information (p. 322).
2. Using the API or CLI, submit a DeleteLoggingConfiguration request for each web ACL that has logging enabled. For more information, see AWS WAF Classic API Reference.

To manually delete the service-linked role using IAM

Use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForWAFLogging and AWSServiceRoleForWAFRegionalLogging service-linked roles. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Supported Regions for AWS WAF Classic service-linked roles

AWS WAF Classic supports using service-linked roles in the following AWS Regions.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region Identity</th>
<th>Support in AWS WAF Classic</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>Yes</td>
</tr>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>Yes</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
<td>Yes</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td>Yes</td>
</tr>
<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1</td>
<td>Yes</td>
</tr>
<tr>
<td>Asia Pacific (Osaka)</td>
<td>ap-northeast-3</td>
<td>Yes</td>
</tr>
<tr>
<td>Asia Pacific (Seoul)</td>
<td>ap-northeast-2</td>
<td>Yes</td>
</tr>
<tr>
<td>Asia Pacific (Singapore)</td>
<td>ap-southeast-1</td>
<td>Yes</td>
</tr>
<tr>

Logging and monitoring in AWS WAF Classic

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

Monitoring is an important part of maintaining the reliability, availability, and performance of AWS WAF Classic and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your AWS WAF Classic resources and responding to potential events:

Amazon CloudWatch Alarms

Using CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, CloudWatch sends a notification to an Amazon SNS topic or AWS Auto Scaling policy. For more information, see Monitoring with Amazon CloudWatch (p. 541).

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in AWS WAF Classic. Using the information collected by CloudTrail, you can determine the request that was made to AWS WAF Classic, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging API calls with AWS CloudTrail (p. 548).
Compliance validation for AWS WAF Classic

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).

For the latest version of AWS WAF, see AWS WAF (p. 6).

Third-party auditors assess the security and compliance of AWS WAF Classic as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS WAF Classic is determined by the sensitivity of your data, your organization’s compliance objectives, and applicable laws and regulations. If your use of AWS WAF Classic is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA Security and Compliance Whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
- **AWS Well-Architected Framework** – The AWS Well-Architected Framework helps you build secure cloud applications.
Resilience in AWS WAF Classic

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Infrastructure security in AWS WAF Classic

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

As a managed service, AWS WAF Classic is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use AWS published API calls to access AWS WAF Classic through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

AWS WAF Classic quotas

Note
This is AWS WAF Classic documentation. You should only use this version if you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated them over to the latest version yet. To migrate your resources, see Migrating your AWS WAF Classic resources to AWS WAF (p. 245).
For the latest version of AWS WAF, see AWS WAF (p. 6).

AWS WAF Classic is subject to the following quotas (formerly referred to as limits).

AWS WAF Classic has default quotas on the number of entities per account per Region. You can request an increase to these.
### AWS WAF Classic quotas

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default quota per account per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ACLs</td>
<td>50</td>
</tr>
<tr>
<td>Rules</td>
<td>100</td>
</tr>
<tr>
<td>Rate-based-rules</td>
<td>5</td>
</tr>
<tr>
<td>Conditions per account per Region</td>
<td>For all conditions except for regex match and geo match, 100 of each condition type. For example, 100 size constraint conditions and 100 IP match conditions. For regex and geo match conditions, see the following table.</td>
</tr>
<tr>
<td>Requests per Second</td>
<td>25,000 per web ACL*</td>
</tr>
</tbody>
</table>

*This quota applies only to AWS WAF Classic on an Application Load Balancer. Requests per Second (RPS) quotas for AWS WAF Classic on CloudFront are the same as the RPS quotas support by CloudFront that is described in the [CloudFront Developer Guide](#).*

The following quotas on AWS WAF Classic entities can't be changed.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Quota per account per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule groups per web ACL</td>
<td>2: 1 customer-created rule group and 1 AWS Marketplace rule group</td>
</tr>
<tr>
<td>Rules per web ACL</td>
<td>10</td>
</tr>
<tr>
<td>Conditions per rule</td>
<td>10</td>
</tr>
<tr>
<td>IP address ranges (in CIDR notation) per IP match condition</td>
<td>10,000</td>
</tr>
</tbody>
</table>

You can update up to 1,000 addresses at a time. The API call `UpdateIPSet` accepts a maximum of 1,000 addresses.
### AWS WAF Classic quotas

<table>
<thead>
<tr>
<th>Resource</th>
<th>Quota per account per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP addresses blocked per rate-based rule</td>
<td>10,000</td>
</tr>
<tr>
<td>Minimum rate-based rule rate limit per 5 minute period</td>
<td>100</td>
</tr>
<tr>
<td>Filters per cross-site scripting match condition</td>
<td>10</td>
</tr>
<tr>
<td>Filters per size constraint condition</td>
<td>10</td>
</tr>
<tr>
<td>Filters per SQL injection match condition</td>
<td>10</td>
</tr>
<tr>
<td>Filters per string match condition</td>
<td>10</td>
</tr>
<tr>
<td>In string match conditions, the number of characters in HTTP header names, when you’ve configured AWS WAF Classic to inspect the headers in web requests for a specified value</td>
<td>40</td>
</tr>
<tr>
<td>In string match conditions, the number of characters in the value that you want AWS WAF Classic to search for</td>
<td>50</td>
</tr>
<tr>
<td>Regex match conditions</td>
<td>10</td>
</tr>
<tr>
<td>In regex match conditions, the number of characters in the pattern that you want AWS WAF Classic to search for</td>
<td>70</td>
</tr>
<tr>
<td>In regex match conditions, the number of patterns per pattern set</td>
<td>10</td>
</tr>
<tr>
<td>In regex match conditions, the number of pattern sets per regex condition</td>
<td>1</td>
</tr>
<tr>
<td>Pattern sets</td>
<td>5</td>
</tr>
<tr>
<td>Geo match conditions</td>
<td>50</td>
</tr>
<tr>
<td>Locations per geo match condition</td>
<td>50</td>
</tr>
</tbody>
</table>

AWS WAF Classic has the following fixed quotas on calls per account per Region. These quotas apply to the total calls to the service through any available means, including the console, CLI, AWS CloudFormation, the REST API, and the SDKs. These quotas can't be changed.

<table>
<thead>
<tr>
<th>Call type</th>
<th>Quota per account per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of calls to AssociateWebACL</td>
<td>1 request every 2 seconds</td>
</tr>
<tr>
<td>Maximum number of calls to DisassociateWebACL</td>
<td>1 request every 2 seconds</td>
</tr>
<tr>
<td>Maximum number of calls to GetWebACLForResource</td>
<td>1 request per second</td>
</tr>
<tr>
<td>Maximum number of calls to ListResourcesForWebACL</td>
<td>1 request per second</td>
</tr>
<tr>
<td>Call type</td>
<td>Quota per account per Region</td>
</tr>
<tr>
<td>--------------------------------------------------------------------------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td>Maximum number of calls to CreateWebACLMigrationStack</td>
<td>1 request per second</td>
</tr>
<tr>
<td>Maximum number of calls to GetChangeToken</td>
<td>10 requests per second</td>
</tr>
<tr>
<td>Maximum number of calls to GetChangeTokenStatus</td>
<td>1 request per second</td>
</tr>
<tr>
<td>Maximum number of calls to any individual List action, if no other quota is defined for it</td>
<td>5 requests per second</td>
</tr>
<tr>
<td>Maximum number of calls to any individual Create, Put, Get, or Update action, if no other quota is defined for it</td>
<td>1 request per second</td>
</tr>
</tbody>
</table>
AWS Firewall Manager

AWS Firewall Manager simplifies your administration and maintenance tasks across multiple accounts and resources for a variety of protections, including AWS WAF, AWS Shield Advanced, Amazon VPC security groups, AWS Network Firewall, and Amazon Route 53 Resolver DNS Firewall. With Firewall Manager, you set up your protections just once and the service automatically applies them across your accounts and resources, even as you add new accounts and resources.

Firewall Manager provides these benefits:

- Helps to protect resources across accounts
- Helps to protect all resources of a particular type, such as all Amazon CloudFront distributions
- Helps to protect all resources with specific tags
- Automatically adds protection to resources that are added to your account
- Allows you to subscribe all member accounts in an AWS Organizations organization to AWS Shield Advanced, and automatically subscribes new in-scope accounts that join the organization
- Allows you to apply security group rules to all member accounts or specific subsets of accounts in an AWS Organizations organization, and automatically applies the rules to new in-scope accounts that join the organization
- Lets you use your own rules, or purchase managed rules from AWS Marketplace

Firewall Manager is particularly useful when you want to protect your entire organization rather than a small number of specific accounts and resources, or if you frequently add new resources that you want to protect. Firewall Manager also provides centralized monitoring of DDoS attacks across your organization.

AWS Firewall Manager pricing

Charges incurred by AWS Firewall Manager are for the underlying services, such as AWS WAF and AWS Config. For more information, see AWS Firewall Manager Pricing.

AWS Firewall Manager prerequisites

This topic shows you how to get ready to administer AWS Firewall Manager. You use one Firewall Manager administrator account to manage all Firewall Manager security policies for your organization in
AWS Organizations. Except where noted, perform the prerequisite steps using the account that you will use as the Firewall Manager administrator.

Before you use Firewall Manager for the first time, perform the following steps in sequence.

Topics

• Step 1: Join and configure AWS Organizations (p. 359)
• Step 2: Set the AWS Firewall Manager administrator account (p. 359)
• Step 3: Enable AWS Config (p. 360)
• Step 4: For third-party policies, subscribe in the AWS Marketplace and configure third-party settings (p. 360)
• Step 5: For Network Firewall and DNS Firewall policies, enable resource sharing (p. 361)
• Step 6: To use AWS Firewall Manager in Regions that are disabled by default (p. 361)

Step 1: Join and configure AWS Organizations

To use Firewall Manager, your account must be a member of the organization in the AWS Organizations service where you want to use your Firewall Manager policies.

Note
For information about Organizations, see AWS Organizations User Guide.

To establish the required AWS Organizations membership and configuration

1. Choose an account to use as the Firewall Manager administrator for the organization in Organizations.
2. If your chosen account isn't already a member of the organization, have it join. Follow the guidance at Inviting an AWS account to join your organization.
3. AWS Organizations has two available feature sets: consolidated billing features and all features. To use Firewall Manager, your organization must be enabled for all features. If your organization is configured only for consolidated billing, follow the guidance at Enabling All Features in Your Organization.

Step 2: Set the AWS Firewall Manager administrator account

This procedure uses the account and organization that you chose and configured in the preceding step.

When you set the Firewall Manager administrator account, Firewall Manager automatically sets it as the AWS Organizations Delegated Administrator for Firewall Manager. This allows Firewall Manager to access information about the organizational units (OUs). You can use OUs to specify the scope of your Firewall Manager policies. For more information about setting policy scope, see the guidance for the individual policy types under Creating an AWS Firewall Manager policy (p. 380). For more information about Organizations and management accounts, see Managing the AWS Accounts in Your Organization.

To set the Firewall Manager administrator account

1. Sign in to the AWS Management Console using an existing AWS Organizations management account. You can sign in using the account's root user (not recommended) or another IAM user or IAM role within the account that has equivalent permissions.
Step 3: Enable AWS Config

To use Firewall Manager, you must enable AWS Config.

**Note**
You incur charges for your AWS Config settings, according to AWS Config pricing. For more information, see Getting Started with AWS Config.

To enable AWS Config for Firewall Manager

1. Enable AWS Config for each of your AWS Organizations member accounts, including the Firewall Manager administrator account. For more information, see Getting Started with AWS Config.

2. Enable AWS Config for each AWS Region that contains the resources that you want to protect. You can enable AWS Config manually, or you can use the AWS CloudFormation template "Enable AWS Config" at AWS CloudFormation StackSets Sample Templates.

If you don't want to enable AWS Config for all resources, then you must enable the following according to the type of Firewall Manager policies that you use:

- **WAF policy** – Enable Config for the resource types CloudFront Distribution, Application Load Balancer (choose ElasticLoadBalancingV2 from the list), API Gateway, WAF WebACL, WAF Regional WebACL, and WAFv2 WebACL. To enable AWS Config to protect a CloudFront distribution, you must be in the US East (N. Virginia) Region. Other Regions don't have CloudFront as an option.

- **Shield policy** – Enable Config for the resource types Shield Protection, ShieldRegional Protection, Application Load Balancer, EC2 EIP, WAF WebACL, WAF Regional WebACL, and WAFv2 WebACL.

- **Security group policy** – Enable Config for the resource types EC2 SecurityGroup, EC2 Instance, and EC2 NetworkInterface.

- **Network Firewall policy** – Enable Config for the resource types NetworkFirewall FirewallPolicy, NetworkFirewall RuleGroup, EC2 VPC, EC2 InternetGateway, EC2 RouteTable, and EC2 Subnet.

- **DNS Firewall policy** – Enable Config for the resource type EC2 VPC.

- **Third-party firewall policy** – Enable Config for the resource types Amazon EC2 VPC, Amazon EC2 InternetGateway, Amazon EC2 RouteTable, Amazon EC2 Subnet, and Amazon EC2 VPCEndpoint.

Step 4: For third-party policies, subscribe in the AWS Marketplace and configure third-party settings

Complete the following prerequisites to get started with Firewall Manager third-party firewall policies.
Step 5: For Network Firewall and DNS Firewall policies, enable resource sharing

Fortigate Cloud Native Firewall (CNF) as a Service policy prerequisites

To use Fortigate CNF for Firewall Manager

1. Subscribe to the Fortigate Cloud Native Firewall (CNF) as a Service service in the AWS Marketplace.
2. First, register a tenant on the Fortigate CNF product portal. Then Add your Firewall Manager administrator account under your tenant on the Fortigate CNF product portal. For more information, see the Fortigate CNF documentation.

Palo Alto Networks Cloud Next Generation Firewall policy prerequisites

To use Palo Alto Networks Cloud NGFW for Firewall Manager

2. Complete the Palo Alto Networks Cloud NGFW deployment steps listed in the Deploy Palo Alto Networks Cloud NGFW for AWS with the AWS Firewall Manager topic in the Palo Alto Networks Cloud Next Generation Firewall for AWS deployment guide.

Step 5: For Network Firewall and DNS Firewall policies, enable resource sharing

To manage Firewall Manager Network Firewall and DNS Firewall policies, you must enable sharing with AWS Organizations in AWS Resource Access Manager. This allows Firewall Manager to deploy protections across your accounts when you create these policy types.

To enable sharing with AWS Organizations in AWS Resource Access Manager

- Follow the guidance at Enable Sharing with AWS Organizations in the AWS Resource Access Manager User Guide.

If you run into problems with resource sharing, see the guidance at Resource sharing for Network Firewall and DNS Firewall policies (p. 424).

Step 6: To use AWS Firewall Manager in Regions that are disabled by default

To use Firewall Manager in a Region that's disabled by default, you must enable the Region for both the management account of your AWS organization and the Firewall Manager administrator account.

For information about Regions that are disabled by default and how to enable them, see Managing AWS Regions in the AWS General Reference.
To enable a disabled Region

- For both the Organizations management account and the Firewall Manager administrator account, follow the guidance at Enabling a Region in the AWS General Reference.

After you follow these steps, you can configure Firewall Manager to begin protecting your resources. For more information, see Getting started with AWS Firewall Manager AWS WAF policies (p. 364).

Managing the AWS Firewall Manager administrator

You use your Firewall Manager administrator account to manage your Firewall Manager policies. When you set the Firewall Manager administrator account, Firewall Manager automatically sets it as the AWS Organizations Delegated Administrator for Firewall Manager. This allows Firewall Manager to access information about the organizational units (OUs) that you use to specify the scope of your Firewall Manager policies. For more information about Organizations and management accounts, see Managing the AWS Accounts in Your Organization.

To begin using Firewall Manager, you set up your Firewall Manager administrator account and perform other required steps. To do this, follow the guidance under AWS Firewall Manager prerequisites (p. 358).

This topic provides information and guidance for managing your existing administrator account.

Required settings for the Firewall Manager administrator

The Firewall Manager administrator account must have the following settings:

- It must be a member of the organization in AWS Organizations where you want to apply your Firewall Manager policies.
- It must be designated as the Firewall Manager administrator by the Organizations management account for the organization.

Changing the AWS Firewall Manager administrator account

To use AWS Firewall Manager, you must log in to the console with a Firewall Manager administrator account. You can designate only one account in an organization as a Firewall Manager administrator account.

To set up an administrator account for the first time, see AWS Firewall Manager prerequisites (p. 358).

After you designate an account as an administrator account, if you later want to designate a different account as the administrator account, perform the following procedure.

**Important**

To designate a different account, you first must revoke administrator privileges from the current administrator account. When you revoke the privileges, all Firewall Manager policies created by that account are deleted. You then must sign into Firewall Manager with the AWS Organizations management account to designate a new administrator account.

**To designate a different account as the AWS Firewall Manager administrator account (console)**

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.
2. In the navigation pane, choose **Settings**.
3. Choose **Revoke administrator account**.

**Important**
When you revoke administrator privileges from the current administrator account, all Firewall Manager policies created by that account are deleted.

4. Sign out of the AWS Management Console.
5. Sign in to the AWS Management Console using your AWS Organizations management account. You can sign in using your root user credentials for the account (not recommended) or you can sign in using an IAM user or IAM role within the account that has equivalent permissions.
7. Choose **Get started**.
8. Type an account ID to associate with Firewall Manager. This account will be the new Firewall Manager administrator account.

**Note**
The account is given permission to create and manage AWS WAF rules and rule groups and AWS WAF Classic rules across all accounts within the organization.

9. Choose **Set administrator**.

---

### Disqualifying changes to the AWS Firewall Manager administrator account

Some changes to the AWS Firewall Manager administrator account can disqualify it from remaining the administrator account.

This section describes the changes that can disqualify the Firewall Manager administrator account, and how AWS and Firewall Manager handle these changes.

#### Account removed from the organization in AWS Organizations

If the AWS Firewall Manager administrator account is removed from the organization in AWS Organizations, it can no longer administer policies for the organization. Firewall Manager takes one of the following actions:

- **Account with no policies** – If the Firewall Manager administrator account has no Firewall Manager policies, Firewall Manager revokes the administrator account.
- **Account with Firewall Manager policies** – If the Firewall Manager administrator account has Firewall Manager policies, Firewall Manager sends an email to inform you of the situation and to provide options that you can take, with the help of your AWS sales account representative.

#### Account closed

If you close the account that you’re using for the AWS Firewall Manager administrator, AWS and Firewall Manager handle the closure as follows:

- AWS revokes the account’s administrator access from Firewall Manager and Firewall Manager deactivates any policies that were managed by the administrator account. The protections that were provided by those policies are stopped across the organization.
- AWS retains the Firewall Manager policy data for the account for 90 days from the effective date of the administrator account closure. During this 90-day period, you can reopen the closed account.
• If you reopen the closed account during the 90-day period, AWS reassigns the account as the Firewall Manager administrator and recovers the Firewall Manager policy data for the account.
• Otherwise, at the end of the 90-day period, AWS permanently deletes all Firewall Manager policy data for the account.

Getting started with AWS Firewall Manager policies

You can use AWS Firewall Manager to enable a number of different types of security policies. The steps for getting set up are slightly different for each.

Topics
• Getting started with AWS Firewall Manager AWS WAF policies (p. 364)
• Getting started with AWS Firewall Manager AWS Shield Advanced policies (p. 366)
• Getting started with AWS Firewall Manager Amazon VPC security group policies (p. 369)
• Getting started with AWS Firewall Manager AWS Network Firewall policies (p. 371)
• Getting started with AWS Firewall Manager DNS Firewall policies (p. 373)
• Getting started with AWS Firewall Manager Palo Alto Networks Cloud Next Generation Firewall policies (p. 374)
• Getting started with AWS Firewall Manager Fortigate CNF policies (p. 377)

Getting started with AWS Firewall Manager AWS WAF policies

To use AWS Firewall Manager to enable AWS WAF rules across your organization, perform the following steps in sequence.

Topics
• Step 1: Complete the prerequisites (p. 364)
• Step 2: Create and apply an AWS WAF policy (p. 364)
• Step 3: Clean Up (p. 366)

Step 1: Complete the prerequisites

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in AWS Firewall Manager prerequisites (p. 358). Complete all of the prerequisites before proceeding to Step 2: Create and apply an AWS WAF policy (p. 364).

Step 2: Create and apply an AWS WAF policy

A Firewall Manager AWS WAF policy contains the rule groups that you want to apply to your resources. Firewall Manager creates a Firewall Manager web ACL in each account where you apply the policy. The individual account managers can add rules and rule groups to the resulting web ACL, in addition to the rule groups that you define here. For information about Firewall Manager AWS WAF policies, see AWS WAF policies (p. 404).
To create a Firewall Manager AWS WAF policy (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.
3. Choose Create policy.
4. For Policy type, choose AWS WAF.
5. For Region, choose an AWS Region. To protect Amazon CloudFront distributions, choose Global.

   To protect resources in multiple Regions (other than CloudFront distributions), you must create separate Firewall Manager policies for each Region.

6. Choose Next.
7. For Policy name, enter a descriptive name. Firewall Manager includes the policy name in the names of the web ACLs that it manages. The web ACL names have FMManagedWebACLV2- followed by the policy name that you enter here, -, and the web ACL creation timestamp, in UTC milliseconds. For example, FMManagedWebACLV2-MyWAFPolicyName-1621880374078.

8. Under Policy rules, for First rule groups, choose Add rule groups. Expand the AWS managed rule groups. For Core rule set, toggle Add to web ACL. For AWS known bad inputs, toggle Add to web ACL. Choose Add rules.

    For Last rule groups, choose Add rule groups. Expand the AWS managed rule groups and for the Amazon IP reputation list, toggle Add to web ACL. Choose Add rules.

Under First rule groups, select Core rule set and choose Move down. AWS WAF evaluates web requests against the AWS known bad inputs rule group before it evaluates against the Core rule set.

   Note
   You can also create your own AWS WAF rule groups if you want, using the AWS WAF console. Any rule groups that you create show up under Your rule groups in the Describe policy : Add rule groups page.

The first and last AWS WAF rule groups that you manage through Firewall Manager have names that begin with PREFMManaged- or POSTFMManaged-, respectively, followed by the Firewall Manager policy name, and the rule group creation timestamp, in UTC milliseconds. For example, PREFMManaged-MyWAFPolicyName-1621880374078.

9. Leave the default action for the web ACL at Allow.
10. Leave the Policy action at the default, to not automatically remediate noncompliant resources. You can change the option later.
11. Choose Next.
12. For Policy scope, you provide the settings for the accounts, resource types, and tagging that identify the resources you want to apply the policy to. For this tutorial, leave the AWS accounts and Resources settings, and choose one or more resource types.
13. Choose Next.
14. For Policy tags, you can add any identifying tags that you want for the Firewall Manager AWS WAF policy. For more information about tags, see Working with Tag Editor. For this tutorial, you can leave this alone.
15. Choose Next.
16. Review the new policy. You can make changes by choosing Edit in the area that you want to change. This returns you to the corresponding step in the creation wizard. When you are satisfied with the policy, choose Create policy.
Step 3: Clean Up

To avoid extraneous charges, delete any unnecessary policies and resources.

To delete a policy (console)

1. On the AWS Firewall Manager policies page, choose the radio button next to the policy name, and then choose Delete.
2. In the Delete confirmation box, select Delete all policy resources, and then choose Delete again.

AWS WAF removes the policy and any associated resources, like web ACLs, that it created in your account. The changes might take a few minutes to propagate to all accounts.

Getting started with AWS Firewall Manager AWS Shield Advanced policies

You can use AWS Firewall Manager to enable AWS Shield Advanced protections across your organization.

Important
Firewall Manager doesn't support Amazon Route 53 or AWS Global Accelerator. If you need to protect these resources with Shield Advanced, you can't use a Firewall Manager policy. Instead, follow the instructions in Adding AWS Shield Advanced protection to AWS resources (p. 502).

To use Firewall Manager to enable Shield Advanced protection, perform the following steps in sequence.

Topics
• Step 1: Complete the prerequisites (p. 366)
• Step 2: Create and apply a Shield Advanced policy (p. 366)
• Step 3: (Optional) authorize the Shield Response Team (SRT) (p. 368)
• Step 4: Configure Amazon SNS notifications and Amazon CloudWatch alarms (p. 368)

Step 1: Complete the prerequisites

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in AWS Firewall Manager prerequisites (p. 358). Complete all the prerequisites before proceeding to Step 2: Create and apply a Shield Advanced policy (p. 366).

Step 2: Create and apply a Shield Advanced policy

After completing the prerequisites, you create an AWS Firewall Manager Shield Advanced policy. A Firewall Manager Shield Advanced policy contains the accounts and resources that you want to protect with Shield Advanced.

Important
Firewall Manager does not support Amazon Route 53 or AWS Global Accelerator. If you need to protect these resources with Shield Advanced, you can't use a Firewall Manager policy. Instead, follow the instructions in Adding AWS Shield Advanced protection to AWS resources (p. 502).

To create a Firewall Manager Shield Advanced policy (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.
Note
For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.
3. Choose Create policy.
4. For Policy type, choose Shield Advanced.

To create a Shield Advanced policy, your Firewall Manager administrator account must be subscribed to Shield Advanced. If you are not subscribed, you are prompted to do so. For information about the cost for subscribing, see AWS Shield Advanced Pricing.

Note
You don't need to manually subscribe each member account to Shield Advanced. Firewall Manager does this for you when it creates the policy.

5. For Region, choose an AWS Region. To protect Amazon CloudFront resources, choose Global.

To protect resources in multiple Regions (other than CloudFront resources), you must create separate Firewall Manager policies for each Region.

6. Choose Next.
7. For Name, enter a descriptive name.
8. (Global Region only) For Global Region policies, you can choose whether you want to manage Shield Advanced automatic application layer DDoS mitigation. For this tutorial, leave this choice at the default setting of Ignore.
9. For Policy action, choose the option that doesn't automatically remediate.
10. Choose Next.
11. AWS accounts this policy applies to allows you to narrow the scope of your policy by specifying accounts to include or exclude. For this tutorial, choose Include all accounts under my organization.
12. Choose the types of resources that you want to protect.

Firewall Manager doesn't support Amazon Route 53 or AWS Global Accelerator. If you need to protect these resources with Shield Advanced, you can't use a Firewall Manager policy. Instead, follow the Shield Advanced guidance at Adding AWS Shield Advanced protection to AWS resources (p. 502).
13. If you want to protect only resources with specific tags, or alternatively exclude resources with specific tags, select Use tags to include/exclude resources, enter the tags separated by commas, and then choose either Include or Exclude. You can choose only one option.

If you enter more than one tag, and if a resource has any of those tags, it is considered a match.

For more information about tags, see Working with Tag Editor.
15. For Policy tags, add any identifying tags that you want for the Firewall Manager policy. For more information about tags, see Working with Tag Editor.
16. Choose Next.
17. Review the new policy. To make any changes, choose Previous. When you are satisfied with the policy, choose Create policy.

Continue to Step 3: (Optional) authorize the Shield Response Team (SRT) (p. 368).
Step 3: (Optional) authorize the Shield Response Team (SRT)

One of the benefits of AWS Shield Advanced is support from the Shield Response Team (SRT). When you experience a potential DDoS attack, you can contact the AWS Support Center. If necessary, the Support Center escalates your issue to the SRT. The SRT helps you analyze the suspicious activity and assists you in mitigating the issue. This mitigation often involves creating or updating AWS WAF rules and web ACLs in your account. The SRT can inspect your AWS WAF configuration and create or update AWS WAF rules and web ACLs for you, but the team needs your authorization to do so. We recommend that as part of setting up AWS Shield Advanced, you proactively provide the SRT with the needed authorization. Providing authorization ahead of time helps prevent mitigation delays in the event of an actual attack.

You authorize and contact the SRT at the account level. That is, the account owner, not the Firewall Manager administrator, must perform the following steps to authorize the SRT to mitigate potential attacks. The Firewall Manager administrator can authorize the SRT only for accounts that they own. Likewise, only the account owner can contact the SRT for support.

**Note**
To use the services of the SRT, you must be subscribed to the Business Support plan or the Enterprise Support plan.

To authorize the SRT to mitigate potential attacks on your behalf, follow the instructions in Shield Response Team (SRT) support (p. 483). You can change SRT access and permissions at any time by using the same steps.

Continue to Step 4: Configure Amazon SNS notifications and Amazon CloudWatch alarms (p. 368).

Step 4: Configure Amazon SNS notifications and Amazon CloudWatch alarms

You can monitor your protected resources for potential DDoS activity using Amazon SNS. To receive notification of possible attacks, create an Amazon SNS topic for each Region.

**To create an Amazon SNS topic in Firewall Manager (console)**

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   **Note**
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, under AWS FMS, choose Settings.
3. Choose Create new topic.
4. Enter a topic name.
5. Enter an email address that the Amazon SNS messages will be sent to, and then choose Add email address.
6. Choose Update SNS configuration.

**Configure Amazon CloudWatch alarms**

Shield Advanced records metrics in CloudWatch that you can monitor. For more information, see AWS Shield Advanced metrics and alarms (p. 545). CloudWatch incurs additional costs. For CloudWatch pricing, see Amazon CloudWatch Pricing.

To create a CloudWatch alarm, follow the instructions in Using Amazon CloudWatch Alarms. By default, Shield Advanced configures CloudWatch to alert you after just one indicator of a potential DDoS event.
If needed, you can use the CloudWatch console to change this setting to alert you only after multiple indicators are detected.

Note
In addition to the alarms, you can also use a CloudWatch dashboard to monitor potential DDoS activity. The dashboard collects and processes raw data from Shield Advanced into readable, near real-time metrics. You can use statistics in Amazon CloudWatch to gain a perspective on how your web application or service is performing. For more information, see What is CloudWatch in the Amazon CloudWatch User Guide. For instructions about creating a CloudWatch dashboard, see Monitoring with Amazon CloudWatch (p. 541). For information about specific Shield Advanced metrics that you can add to your dashboard, see AWS Shield Advanced metrics and alarms (p. 545).

You can continue from this step without configuring Amazon SNS notifications or CloudWatch alarms. However, doing so significantly reduces your visibility of possible DDoS events.

When you've completed your Shield Advanced configuration, familiarize yourself with your options for viewing events at Visibility into DDoS events (p. 508).

**Getting started with AWS Firewall Manager Amazon VPC security group policies**

To use AWS Firewall Manager to enable Amazon VPC security groups across your organization, perform the following steps in sequence.

**Topics**
- Step 1: Complete the prerequisites (p. 369)
- Step 2: Create a Amazon VPC security group to use in your policy (p. 369)
- Step 3: Create and apply a common security group policy (p. 370)

**Step 1: Complete the prerequisites**

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in AWS Firewall Manager prerequisites (p. 358). Complete all the prerequisites before proceeding to Step 2: Create a Amazon VPC security group to use in your policy (p. 369).

**Step 2: Create a Amazon VPC security group to use in your policy**

In this step, you create a security group that you could apply across your organization using Firewall Manager.

Note
For this tutorial, you won't apply your security group policy to the resources in your organization. You'll just create the policy and see what would happen if you applied the policy's security group to your resources. You do this by disabling automatic remediation on the policy.

If you already have a general security group defined, skip this step and go to Step 3: Create and apply a common security group policy (p. 370).

**To create a security group to use in a Firewall Manager common security group policy**

- Create a security group that you could apply to all accounts and resources in your organization, following the guidance under Security Groups for Your VPC in the Amazon VPC User Guide.
For information on the security group rules options, see Security Group Rules Reference.

You are now ready to go to Step 3: Create and apply a common security group policy (p. 370).

**Step 3: Create and apply a common security group policy**

After completing the prerequisites, you create an AWS Firewall Manager common security group policy. A common security group policy provides a centrally controlled security group for your entire AWS organization. It also defines the AWS accounts and resources that the security group applies to. In addition to common security group policies, Firewall Manager supports content audit security group policies, to manage the security group rules in use in your organization, and usage audit security group policies, to manage unused and redundant security groups. For more information, see Security group policies (p. 410).

For this tutorial, you create a common security group policy and set its action to not automatically remediate. This allows you to see what effect the policy would have without making changes to your AWS organization.

**To create a Firewall Manager common security group policy (console)**

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.
   
   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.

3. If you have not met the prerequisites, the console displays instructions about how to fix any issues. Follow the instructions, and then return to this step, to create a common security group policy.

4. Choose Create policy.

5. For Policy type, choose Security group.

6. For Security group policy type, choose Common security groups.

7. For Region, choose an AWS Region.

8. Choose Next.

9. For Policy name, enter a descriptive name.

10. Policy rules allow you to choose how the security groups in this policy are applied and maintained. For this tutorial, leave the options unchecked.

11. Choose Add primary security group, select the security group that you created for this tutorial, and choose Add security group.

12. For Policy action, choose Identify resources that don’t comply with the policy rules, but don’t auto remediate.

13. Choose Next.

14. AWS accounts affected by this policy allows you to narrow the scope of your policy by specifying accounts to include or exclude. For this tutorial, choose Include all accounts under my organization.

15. For Resource type, choose one or more types, according to the resources you have defined for your AWS organization.

16. Resources allows you to narrow the scope of your policy by specifying resource tags for inclusion or exclusion. To use tagging, you need to first tag your resources. For more information about tagging your resources, see Working with Tag Editor. For this tutorial, choose Include all resources that match the selected resource type.

17. Choose Next.
18. Review your policy settings. Check to be sure that **Policy actions** is set to **Identify resources that don't comply with the policy rules, but don't auto remediate**. This allows you to review the changes that your policy would have, without making changes at this time.

19. Choose **Create policy**.

   In the **AWS Firewall Manager policies** pane, your policy should be listed. It will probably indicate **Pending** under the accounts headings and it will indicate that **Automatic remediation** is disabled. The creation of a policy can take several minutes. After the **Pending** status is replaced with account counts, you can choose the policy name to explore the compliance status of the accounts and resources. For information, see **Viewing compliance information for an AWS Firewall Manager policy** (p. 427)

20. When you are finished exploring, if you don't want to keep the policy you created for this tutorial, choose the policy name, choose **Delete**, choose **Clean up resources created by this policy**, and finally choose **Delete**.

For more information about Firewall Manager security group policies, see **Security group policies** (p. 410).

### Getting started with AWS Firewall Manager AWS Network Firewall policies

To use AWS Firewall Manager to enable an AWS Network Firewall firewall across your organization, perform the following steps in sequence. For information about Firewall Manager Network Firewall policies, see **AWS Network Firewall policies** (p. 416).

#### Topics

- Step 1: Complete the general prerequisites (p. 371)
- Step 2: Create a Network Firewall rule group to use in your policy (p. 371)
- Step 3: Create and apply a Network Firewall policy (p. 371)

#### Step 1: Complete the general prerequisites

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in **AWS Firewall Manager prerequisites** (p. 358). Complete all the prerequisites before proceeding to the next step.

#### Step 2: Create a Network Firewall rule group to use in your policy

To follow this tutorial, you should be familiar with AWS Network Firewall and know how to configure its rule groups and firewall policies.

You must have at least one rule group in Network Firewall that will be used in your AWS Firewall Manager policy. If you haven't already created a rule group in Network Firewall, do so now. For information about using Network Firewall, see the **AWS Network Firewall Developer Guide**.

#### Step 3: Create and apply a Network Firewall policy

After completing the prerequisites, you create an AWS Firewall Manager Network Firewall policy. A Network Firewall policy provides a centrally controlled AWS Network Firewall firewall for your entire AWS organization. It also defines the AWS accounts and resources that the firewall applies to.
For more information about how Firewall Manager manages your Network Firewall policies, see AWS Network Firewall policies (p. 416).

To create a Firewall Manager Network Firewall policy (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   **Note**
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.

3. If you haven't met the prerequisites, the console displays instructions about how to fix any issues. Follow the instructions, and then return to this step, to create a Network Firewall policy.

4. Choose Create security policy.

5. For Policy type, choose AWS Network Firewall.

6. For Region, choose an AWS Region.

7. Choose Next.

8. For Policy name, enter a descriptive name.

9. The policy configuration allows you to define the firewall policy. This is the same process as the one you use in the AWS Network Firewall console. You add the rule groups that you want to use in your policy and provide the default stateless actions. For this tutorial, configure this policy as you would a firewall policy in Network Firewall.

   **Note**
   Auto remediation happens automatically for AWS Firewall Manager Network Firewall policies, so you won't see an option to choose not to auto remediate here.

10. Choose Next.

11. For Firewall endpoints, choose Multiple firewall endpoints. This option provides high availability for your firewall. When you create the policy, Firewall Manager creates a firewall subnet in each Availability Zone where you have public subnets to protect.

12. For AWS Network Firewall route configuration, choose Monitor to have Firewall Manager monitor your VPCs for route configuration violations and alert you with remediation suggestions to help you to bring the routes into compliance. Optionally, if you don't want to have your route configurations monitored by Firewall Manager and receive these alerts, choose Off.

   **Note**
   Monitoring provides you with details about non-compliant resources due to faulty route configuration, and suggests remediation actions from the Firewall Manager GetViolationDetails API. For example, Network Firewall alerts you if traffic is not routed through the firewall endpoints that are created by your policy.

   **Warning**
   If you choose Monitor, you can't change it to Off in the future for the same policy. You must create a new policy.

13. For Traffic type, select Add to firewall policy to route traffic through the internet gateway.

14. AWS accounts affected by this policy allows you to narrow the scope of your policy by specifying accounts to include or exclude. For this tutorial, choose Include all accounts under my organization.

15. The Resource type for a Network Firewall policy is always VPC.

16. Resources allows you to narrow the scope of your policy by specifying resource tags for inclusion or exclusion. To use tagging, you need to first tag your resources. For more information about tagging your resources, see Working with Tag Editor. For this tutorial, choose Include all resources that match the selected resource type.
17. Choose Next.
18. Review your policy settings, and then choose Create policy.

   In the AWS Firewall Manager policies pane, your policy should be listed. The creation of a policy can take several minutes. Until the creation process is complete, the policy indicates that it's pending. When the policy is ready, the status updates with the count of in-scope accounts. You can choose the policy name to explore the compliance status of the accounts and resources. For information, see Viewing compliance information for an AWS Firewall Manager policy (p. 427)

19. When you are finished exploring, if you don't want to keep the policy that you created for this tutorial, choose the policy name, choose Delete, choose Clean up resources created by this policy, and finally choose Delete.

For more information about Firewall Manager Network Firewall policies, see AWS Network Firewall policies (p. 416).

Getting started with AWS Firewall Manager DNS Firewall policies

To use AWS Firewall Manager to enable Amazon Route 53 Resolver DNS Firewall across your organization, perform the following steps in sequence. For information about Firewall Manager DNS Firewall policies, see Amazon Route 53 Resolver DNS Firewall policies (p. 422).

Topics
- Step 1: Complete the general prerequisites (p. 373)
- Step 2: Create your DNS Firewall rule groups to use in your policy (p. 373)
- Step 3: Create and apply a DNS Firewall policy (p. 373)

Step 1: Complete the general prerequisites

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in AWS Firewall Manager prerequisites (p. 358). Complete all the prerequisites before proceeding to the next step.

Step 2: Create your DNS Firewall rule groups to use in your policy

To follow this tutorial, you should be familiar with Amazon Route 53 Resolver DNS Firewall and know how to configure its rule groups.

You must have least one rule group in DNS Firewall that will be used in your AWS Firewall Manager policy. If you haven't already created a rule group in DNS Firewall, do so now. For information about using DNS Firewall, see Amazon Route 53 Resolver DNS Firewall in the Amazon Route 53 Developer Guide.

Step 3: Create and apply a DNS Firewall policy

After completing the prerequisites, you create an AWS Firewall Manager DNS Firewall policy. A DNS Firewall policy provides a set of centrally controlled DNS Firewall rule group associations for your entire AWS organization. It also defines the AWS accounts and resources that the firewall applies to.

For more information about how Firewall Manager manages your DNS Firewall rule group associations, see Amazon Route 53 Resolver DNS Firewall policies (p. 422).
To create a Firewall Manager DNS Firewall policy (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

2. In the navigation pane, choose Security policies.

3. If you haven’t met the prerequisites, the console displays instructions about how to fix any issues. Follow the instructions, and then return to this step, to create a DNS Firewall policy.

4. Choose Create security policy.

5. For Policy type, choose Amazon Route 53 Resolver DNS Firewall.

6. For Region, choose an AWS Region.

7. Choose Next.

8. For Policy name, enter a descriptive name.

9. The policy configuration allows you to define the DNS Firewall rule group associations that you want to manage from Firewall Manager. You add the rule groups that you want to use in your policy. You can define an association to evaluate first for your VPCs and one to evaluate last. For this tutorial, add one or two rule group associations, depending on your needs.

10. Choose Next.

11. AWS accounts affected by this policy allows you to narrow the scope of your policy by specifying accounts to include or exclude. For this tutorial, choose Include all accounts under my organization.

12. The Resource type for a DNS Firewall policy is always VPC.

13. Resources allows you to narrow the scope of your policy by specifying resource tags for inclusion or exclusion. To use tagging, you need to first tag your resources. For more information about tagging your resources, see Working with Tag Editor. For this tutorial, choose Include all resources that match the selected resource type.

15. Review your policy settings, and then choose Create policy.

In the AWS Firewall Manager policies pane, your policy should be listed. The creation of a policy can take several minutes. Until the creation process is complete, the policy indicates that it’s pending. When the policy is ready, the status updates with the count of in-scope accounts. You can choose the policy name to explore the compliance status of the accounts and resources. For information, see Viewing compliance information for an AWS Firewall Manager policy (p. 427).

16. When you are finished exploring, if you don’t want to keep the policy that you created for this tutorial, choose the policy name, choose Delete, choose Clean up resources created by this policy, and finally choose Delete.

For more information about Firewall Manager DNS Firewall policies, see Amazon Route 53 Resolver DNS Firewall policies (p. 422).

Getting started with AWS Firewall Manager Palo Alto Networks Cloud Next Generation Firewall policies

To use AWS Firewall Manager to enable Palo Alto Networks Cloud Next Generation Firewall (NGFW) policies, perform the following steps in sequence. For information about Palo Alto Networks Cloud NGFW policies, see Palo Alto Networks Cloud NGFW policies (p. 423).

Topics
- Step 1: Complete the general prerequisites (p. 375)
• Step 2: Complete the Palo Alto Networks Cloud NGFW policy prerequisites (p. 375)
• Step 3: Create and apply a Palo Alto Networks Cloud NGFW policy (p. 375)

Step 1: Complete the general prerequisites

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in AWS Firewall Manager prerequisites (p. 358). Complete all the prerequisites before proceeding to the next step.

Step 2: Complete the Palo Alto Networks Cloud NGFW policy prerequisites

There are a couple of additional mandatory steps that you must complete in order to use Palo Alto Networks Cloud NGFW policies. Those steps are described in Palo Alto Networks Cloud Next Generation Firewall policy prerequisites (p. 361). Complete all the prerequisites before proceeding to the next step.

Step 3: Create and apply a Palo Alto Networks Cloud NGFW policy

After completing the prerequisites, you create an AWS Firewall Manager Palo Alto Networks Cloud NGFW policy.

For more information about Firewall Manager policies for Palo Alto Networks Cloud NGFW, see Palo Alto Networks Cloud NGFW policies (p. 423).

To create a Firewall Manager policy for Palo Alto Networks Cloud NGFW (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.
3. Choose Create policy.
4. For Policy type, choose Palo Alto Networks Palo Alto Networks Cloud NGFW. If you haven't already subscribed to the Palo Alto Networks Cloud NGFW service in the AWS Marketplace, you'll need to do that first. To subscribe in the AWS Marketplace, choose View AWS Marketplace details.
5. For Deployment model, choose either the Distributed model or Centralized model. The deployment model determines how Firewall Manager manages endpoints for the policy. With the distributed model, Firewall Manager maintains firewall endpoints in each VPC that's within policy scope. With the centralized model, Firewall Manager maintains a single endpoint in an inspection VPC.
6. For Region, choose an AWS Region. To protect resources in multiple Regions, you must create separate policies for each Region.
7. Choose Next.
8. For Policy name, enter a descriptive name.
9. In the policy configuration, choose the Palo Alto Networks Cloud NGFW firewall policy to associate with this policy. The list of Palo Alto Networks Cloud NGFW firewall policies contains all of the Palo Alto Networks Cloud NGFW firewall policies that are associated with your Palo Alto Networks Cloud NGFW tenant. For information about creating and managing Palo Alto Networks Cloud NGFW
firewall policies, see the Deploy Palo Alto Networks Cloud NGFW for AWS with the AWS Firewall Manager topic in the Palo Alto Networks Palo Alto Networks Cloud NGFW for AWS deployment guide.

10. For Palo Alto Networks Palo Alto Networks Cloud NGFW logging - optional, optionally choose which Palo Alto Networks Cloud NGFW log type(s) to log for your policy. For information about Palo Alto Networks Cloud NGFW log types, see Configure Logging for Palo Alto Networks Cloud NGFW on AWS in the Palo Alto Networks Palo Alto Networks Cloud NGFW for AWS deployment guide.

For log destination, specify when Firewall Manager should write logs to.

11. Choose Next.

12. Under Configure third-party firewall endpoint do one of the following, depending on whether you're using the distributed or centralized deployment model to create your firewall endpoints:

- If you're using the distributed deployment model for this policy, under Availability Zones, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by Availability Zone name or by Availability Zone ID.

- If you're using the centralized deployment model for this policy, in AWS Firewall Manager endpoint configuration under Inspection VPC configuration, enter the AWS account ID of the owner of the inspection VPC, and the VPC ID of the inspection VPC.

- Under Availability Zones, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by Availability Zone name or by Availability Zone ID.

13. Choose Next.

14. For Policy scope, under AWS accounts this policy applies to, choose the option as follows:

- If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.

- If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

- If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose Exclude the specified accounts and organizational units, and include all others, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

15. The Resource type for Network Firewall policies is VPC.

16. For Resources, if you want to protect (or exclude) only resources that have specific tags, select the appropriate option, then enter the tags to include or exclude. You can choose only one option. For more information about tags, see Working with Tag Editor.

If you enter more than one tag, a resource must have all of the tags to be included or excluded.

17. For Grant cross-account access, choose Download AWS CloudFormation template. This downloads a AWS CloudFormation template that you can use to create a AWS CloudFormation stack. This stack creates an AWS Identity and Access Management role that grants Firewall Manager cross-account permissions to manage Palo Alto Networks Cloud NGFW resources. For information about stacks, see Working with stacks in the AWS CloudFormation User Guide.
18. Choose Next.
19. For Policy tags, add any identifying tags that you want for the Firewall Manager policy. For more information about tags, see Working with Tag Editor.
20. Choose Next.
21. Review the new policy. To make any changes, choose Edit in the area that you want to change. This returns you to the corresponding step in the creation wizard. When you are satisfied with the policy, choose Create policy.

For more information about Firewall Manager Palo Alto Networks Cloud NGFW policies, see Palo Alto Networks Cloud NGFW policies (p. 423).

Getting started with AWS Firewall Manager Fortigate CNF policies

Fortigate Cloud Native Firewall (CNF) as a Service is a third-party firewall service that you can use for your AWS Firewall Manager policies. With Fortigate CNF for Firewall Manager, you can create and centrally deploy Fortigate CNF resources and policy sets across all of your AWS accounts. To use AWS Firewall Manager to enable Fortigate CNF policies, perform the following steps in sequence. For more information about Fortigate CNF policies, see Fortigate Cloud Native Firewall (CNF) as a Service policies (p. 424).

Topics
- Step 1: Complete the general prerequisites (p. 377)
- Step 2: Complete the Fortigate CNF policy prerequisites (p. 377)
- Step 3: Create and apply a Fortigate CNF policy (p. 377)

Step 1: Complete the general prerequisites

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in AWS Firewall Manager prerequisites (p. 358). Complete all the prerequisites before proceeding to the next step.

Step 2: Complete the Fortigate CNF policy prerequisites

There are additional mandatory steps that you must complete in order to use Fortigate CNF policies. Those steps are described in Fortigate Cloud Native Firewall (CNF) as a Service policy prerequisites (p. 361). Complete all the prerequisites before proceeding to the next step.

Step 3: Create and apply a Fortigate CNF policy

After completing the prerequisites, you create an AWS Firewall Manager Fortigate CNF policy.

For more information about Firewall Manager policies for Fortigate CNF, see Fortigate Cloud Native Firewall (CNF) as a Service policies (p. 424).

To create a Firewall Manager policy for Fortigate CNF (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).
2. In the navigation pane, choose **Security policies**.
3. Choose **Create policy**.
4. For **Policy type**, choose Fortigate CNF. If you haven't already subscribed to the Fortigate CNF service in the AWS Marketplace, you'll need to do that first. To subscribe in the AWS Marketplace, choose **View AWS Marketplace details**.
5. For **Deployment model**, choose either the **Distributed model** or **Centralized model**. The deployment model determines how Firewall Manager manages endpoints for the policy. With the distributed model, Firewall Manager maintains firewall endpoints in each VPC that's within policy scope. With the centralized model, Firewall Manager maintains a single endpoint in an inspection VPC.
6. For **Region**, choose an AWS Region. To protect resources in multiple Regions, you must create separate policies for each Region.
7. Choose **Next**.
8.
9. In the policy configuration, choose the Fortigate CNF firewall policy to associate with this policy. The list of Fortigate CNF firewall policies contains all of the Fortigate CNF firewall policies that are associated with your Fortigate CNF tenant. For information about creating and managing Fortigate CNF firewall policies, see the **Fortigate CNF documentation**.
10. Choose **Next**.
11. Under **Configure third-party firewall endpoint** do one of the following, depending on whether you're using the distributed or centralized deployment model to create your firewall endpoints:
   - If you're using the distributed deployment model for this policy, under **Availability Zones**, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by **Availability Zone name** or by **Availability Zone ID**.
   - If you're using the centralized deployment model for this policy, in **AWS Firewall Manager endpoint configuration** under **Inspection VPC configuration**, enter the AWS account ID of the owner of the inspection VPC, and the VPC ID of the inspection VPC.
   - Under **Availability Zones**, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by **Availability Zone name** or by **Availability Zone ID**.
12. Choose **Next**.
13. For **Policy scope**, under **AWS accounts this policy applies to**, choose the option as follows:
   - If you want to apply the policy to all accounts in your organization, leave the default selection, **Include all accounts under my AWS organization**.
   - If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose **Include only the specified accounts and organizational units**, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.
   - If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose **Exclude the specified accounts and organizational units, and include all others**, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.
14. The **Resource type** for Network Firewall policies is **VPC**.

15. For **Resources**, if you want to protect (or exclude) only resources that have specific tags, select the appropriate option, then enter the tags to include or exclude. You can choose only one option. For more information about tags, see Working with Tag Editor.

If you enter more than one tag, a resource must have all of the tags to be included or excluded.

16. For **Grant cross-account access**, choose **Download AWS CloudFormation template**. This downloads a AWS CloudFormation template that you can use to create a AWS CloudFormation stack. This stack creates an AWS Identity and Access Management role that grants Firewall Manager cross-account permissions to manage Fortigate CNF resources. For information about stacks, see Working with stacks in the **AWS CloudFormation User Guide**. To create a stack, you'll need the account ID from the Fortigate CNF portal.

17. Choose **Next**.

18. For **Policy tags**, add any identifying tags that you want for the Firewall Manager policy. For more information about tags, see Working with Tag Editor.

19. Choose **Next**.

20. Review the new policy. To make any changes, choose **Edit** in the area that you want to change. This returns you to the corresponding step in the creation wizard. When you are satisfied with the policy, choose **Create policy**.

For more information about Firewall Manager Fortigate CNF policies, see Fortigate Cloud Native Firewall (CNF) as a Service policies (p. 424).

---

**Working with AWS Firewall Manager policies**

AWS Firewall Manager provides the following types of policies:

- **AWS WAF policy** – Firewall Manager supports AWS WAF and AWS WAF Classic policies. For both versions, you define which resources are protected by the policy.
  - For the AWS WAF policy, you can define a set of rule groups to run first in the web ACL and a set of rule groups to run last. In the accounts where you apply the web ACL, the account owner can add rules and rule groups to run in between the two Firewall Manager rule group sets.
  - For AWS WAF Classic, you create a policy that defines a single rule group.
- **Shield Advanced policy** – This policy applies AWS Shield Advanced protection to specified accounts and resources.
- **Amazon VPC security group policy** – This type of policy gives you control over security groups that are in use throughout your organization in AWS Organizations and lets you enforce a baseline set of rules across your organization.
- **Network Firewall policy** – This policy applies AWS Network Firewall protection to your organization's VPCs.
- **Amazon Route 53 Resolver DNS Firewall policy** – This policy applies DNS Firewall protections to your organization's VPCs.
- **Palo Alto Networks Cloud NGFW policy** – This policy applies Palo Alto Networks Cloud Next Generation Firewall (NGFW) protections and Palo Alto Networks Cloud NGFW rulestacks to your organization's VPCs.
- **Fortigate Cloud Native Firewall (CNF) as a Service policy** – This policy applies Check Point Network Security as a Service (NSaaS) protections. Fortigate Cloud Native Firewall (CNF) as a Service is a cloud-centered solution which blocks Zero-Day threats and secures cloud infrastructures with industry-leading advanced threat prevention, smart web application firewalls (WAF), and API protection.
A Firewall Manager policy is specific to the individual policy type. If you want to enforce multiple policy types across accounts, you can create multiple policies. You can create more than one policy for each type.

If you add a new account to an organization that you created with AWS Organizations, Firewall Manager automatically applies the policy to the resources in that account that are within scope of the policy.

**General settings for AWS Firewall Manager policies**

AWS Firewall Manager managed policies have some common settings and behaviors. For all, you specify a name and define the scope of the policy, and you can use resource tagging to control policy scope. You can choose to view the accounts and resources that are out of compliance without taking corrective action or to automatically remediate noncompliant resources.

For information about policy scope, see [AWS Firewall Manager policy scope](p. 399).

**Creating an AWS Firewall Manager policy**

The steps for creating a policy vary between the different policy types. Make sure to use the procedure for the type of policy that you need.

**Important**

AWS Firewall Manager doesn't support Amazon Route 53 or AWS Global Accelerator. If you want to protect these resources with Shield Advanced, you can't use a Firewall Manager policy. Instead, follow the instructions in [Adding AWS Shield Advanced protection to AWS resources](p. 502).

**Topics**

- Creating an AWS Firewall Manager content audit security group policy (p. 387)
- Creating an AWS Firewall Manager usage audit security group policy (p. 389)
- Creating an AWS Firewall Manager policy for AWS Network Firewall (p. 391)
- Creating an AWS Firewall Manager policy for Amazon Route 53 Resolver DNS Firewall (p. 394)
- Creating an AWS Firewall Manager policy for Palo Alto Networks Palo Alto Networks Cloud NGFW (p. 395)
- Creating an AWS Firewall Manager policy for Fortigate Cloud Native Firewall (CNF) as a Service (p. 397)

**Creating an AWS Firewall Manager policy for AWS WAF**

In a Firewall Manager AWS WAF policy, you can use managed rule groups, which AWS and AWS Marketplace sellers create and maintain for you. You can also create and use your own rule groups. For more information about rule groups, see [Rule groups](p. 25).

**Note**

Firewall Manager supports the new AWS WAF Bot Control managed rule group. For information about Bot Control in AWS WAF, see [AWS WAF Bot Control](p. 151).

If you want to use your own rule groups, create those before you create your Firewall Manager AWS WAF policy. For guidance, see [Managing your own rule groups](p. 81). To use an individual custom rule, you must define your own rule group, define your rule within that, and then use the rule group in your policy.
For information about Firewall Manager AWS WAF policies, see AWS WAF policies (p. 404).

To create a Firewall Manager policy for AWS WAF (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.

3. Choose Create policy.

4. For Policy type, choose AWS WAF.

5. For Region, choose an AWS Region. To protect Amazon CloudFront distributions, choose Global.

   To protect resources in multiple Regions (other than CloudFront distributions), you must create separate Firewall Manager policies for each Region.

6. Choose Next.

7. For Policy name, enter a descriptive name. Firewall Manager includes the policy name in the names of the web ACLs that it manages. The web ACL names have FMManagedWebACLv2 - followed by the policy name that you enter here, -, and the web ACL creation timestamp, in UTC milliseconds. For example, FMManagedWebACLv2-MyWAFPolicyName-1621880374078.

8. Under Policy rules, add the rule groups that you want AWS WAF to evaluate first and last in the web ACL. To use AWS WAF managed rule group versioning, toggle Enable versioning. The individual account managers can add rules and rule groups in between your first rule groups and your last rule groups. For more information about using AWS WAF rule groups in Firewall Manager policies for AWS WAF, see AWS WAF policies (p. 404).

9. Set the default action for the web ACL. This is the action that AWS WAF takes when a web request doesn't match any of the rules in the web ACL. You can add custom headers with the Allow action, or custom responses for the Block action. For more information about default web ACL actions, see Deciding on the default action for a web ACL (p. 16). For information about setting custom web requests and responses, see Customized web requests and responses in AWS WAF (p. 126).

10. For Policy action, if you want to create a web ACL in each applicable account within the organization, but not apply the web ACL to any resources yet, choose Identify resources that don’t comply with the policy rules, but don’t auto remediate. You can change the option later.

   If instead you want to automatically apply the policy to existing in-scope resources, choose Auto remediate any noncompliant resources. This option creates a web ACL in each applicable account within the AWS organization and associates the web ACL with the resources in the accounts.

   When you choose Auto remediate any noncompliant resources, you can also choose to remove existing web ACL associations from in-scope resources, for the web ACLs that aren’t managed by another active Firewall Manager policy. If you choose this option, Firewall Manager first associates the policy’s web ACL with the resources, and then removes the prior associations. If a resource has an association with another web ACL that’s managed by a different active Firewall Manager policy, this choice doesn’t affect that association.

11. Choose Next.

12. For AWS accounts this policy applies to, choose the option as follows:

   • If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.

   • If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an
OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

- If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose **Exclude the specified accounts and organizational units, and include all others**, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

13. For **Resource type**, choose the types of resources that you want to protect.

14. For **Resources**, if you want to protect (or exclude) only resources that have specific tags, select the appropriate option, then enter the tags to include or exclude. You can choose only one option. For more information about tags, see **Working with Tag Editor**.

   If you enter more than one tag, a resource must have all of the tags to be included or excluded.

15. Choose **Next**.

16. For **Policy tags**, add any identifying tags that you want for the Firewall Manager policy. For more information about tags, see **Working with Tag Editor**.

17. Choose **Next**.

18. Review the new policy. To make any changes, choose **Edit** in the area that you want to change. This returns you to the corresponding step in the creation wizard. When you are satisfied with the policy, choose **Create policy**.

### Creating an AWS Firewall Manager policy for AWS WAF Classic

#### To create a Firewall Manager policy for AWS WAF Classic (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at [https://console.aws.amazon.com/wafv2/fmsv2](https://console.aws.amazon.com/wafv2/fmsv2).

   **Note**
   For information about setting up a Firewall Manager administrator account, see **AWS Firewall Manager prerequisites** (p. 358).

2. In the navigation pane, choose **Security policies**.

3. Choose **Create policy**.

4. For **Policy type**, choose **AWS WAF Classic**.

5. If you already created the AWS WAF Classic rule group that you want to add to the policy, choose **Create an AWS Firewall Manager policy and add existing rule groups**. If you want to create a new rule group, choose **Create a Firewall Manager policy and add a new rule group**.

6. For **Region**, choose an AWS Region. To protect Amazon CloudFront resources, choose **Global**.

   To protect resources in multiple Regions (other than CloudFront resources), you must create separate Firewall Manager policies for each Region.

7. Choose **Next**.

8. If you are creating a rule group, follow the instructions in **Creating an AWS WAF Classic rule group** (p. 316). After you create the rule group, continue with the following steps.
9. Enter a policy name.

10. If you are adding an existing rule group, use the dropdown menu to select a rule group to add, and then choose Add rule group.

11. A policy has two possible actions: Action set by rule group and Count. If you want to test the policy and rule group, set the action to Count. This action overrides any block action specified by the rules in the rule group. That is, if the policy’s action is set to Count, those requests are only counted and not blocked. Conversely, if you set the policy’s action to Action set by rule group, actions of the rule group rules are used. Choose the appropriate action.

12. Choose Next.

13. For AWS accounts this policy applies to, choose the option as follows:

- If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.
- If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.
- If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose Exclude the specified accounts and organizational units, and include all others, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn’t apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

14. Choose the type of resource that you want to protect.

15. If you want to protect only resources with specific tags, or alternatively exclude resources with specific tags, select Use tags to include/exclude resources, enter the tags, and then choose either Include or Exclude. You can choose only one option.

If you enter more than one tag (separated by commas), if a resource has any of those tags, it is considered a match.

For more information about tags, see Working with Tag Editor.

16. If you want to automatically apply the policy to existing resources, choose Create and apply this policy to existing and new resources.

This option creates a web ACL in each applicable account within an AWS organization and associates the web ACL with the resources in the accounts. This option also applies the policy to all new resources that match the preceding criteria (resource type and tags). Alternatively, if you choose Create policy but do not apply the policy to existing or new resources, Firewall Manager creates a web ACL in each applicable account within the organization, but doesn’t apply the web ACL to any resources. You must apply the policy to resources later. Choose the appropriate option.

17. For Replace existing associated web ACLs, you can choose to remove any web ACL associations that are currently defined for in-scope resources, and then replace them with associations to the web ACLs that you are creating with this policy. By default, Firewall Manager doesn’t remove existing web ACL associations before it adds the new ones. If you want to remove the existing ones, choose this option.
18. Choose **Next**.
19. Review the new policy. To make any changes, choose **Edit**. When you are satisfied with the policy, choose **Create and apply policy**.

## Creating an AWS Firewall Manager policy for AWS Shield Advanced

**To create a Firewall Manager policy for Shield Advanced (console)**

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at [https://console.aws.amazon.com/wafv2/fmsv2](https://console.aws.amazon.com/wafv2/fmsv2).

   **Note**
   For information about setting up a Firewall Manager administrator account, see **AWS Firewall Manager prerequisites** (p. 358).

2. In the navigation pane, choose **Security policies**.
3. Choose **Create policy**.
4. For **Policy type**, choose **Shield Advanced**.

   To create a Shield Advanced policy, you must be subscribed to Shield Advanced. If you are not subscribed, you are prompted to do so. For information about the cost for subscribing, see **AWS Shield Advanced Pricing**.

5. For **Region**, choose an AWS Region. To protect Amazon CloudFront distributions, choose **Global**.

   For Region choices other than **Global**, to protect resources in multiple Regions, you must create a separate Firewall Manager policy for each Region.

6. Choose **Next**.
7. For **Name**, enter a descriptive name.
8. For **Global** Region policies only, you can choose whether you want to manage Shield Advanced automatic application layer DDoS mitigation. For information about this Shield Advanced feature, see **Shield Advanced automatic application layer DDoS mitigation** (p. 489).

   You can choose to enable or disable automatic mitigation, or you can choose to ignore it. If you choose to ignore it, Firewall Manager doesn't manage automatic mitigation at all for the Shield Advanced protections. For more information about these policy options, see **Automatic application layer DDoS mitigation for Amazon CloudFront distributions** (p. 407).

9. For **Policy action**, we recommend creating the policy with the option that doesn't automatically remediate noncompliant resources. When you disable automatic remediation, you can assess the effects of your new policy before you apply it. When you are satisfied that the changes are what you want, then edit the policy and change the policy action to enable automatic remediation.

   If instead you want to automatically apply the policy to existing in-scope resources, choose **Auto remediate any noncompliant resources**. This option applies Shield Advanced protections for each applicable account within the AWS organization and each applicable resource in the accounts.

   For **Global** Region policies only, if you choose **Auto remediate any noncompliant resources**, you can also choose to have Firewall Manager automatically replace any existing AWS WAF Classic web ACL associations with new associations to web ACLs that were created using the latest version of AWS WAF (v2). If you choose this, Firewall Manager removes the associations with the earlier version web ACLs and creates new associations with latest version web ACLs, after creating new empty web ACLs in any in-scope accounts that don't already have them for the policy. For more information about this option, see **Replace AWS WAF Classic web ACLs with latest version web ACLs** (p. 408).

10. Choose **Next**.
11. For **AWS accounts this policy applies to**, choose the option as follows:
• If you want to apply the policy to all accounts in your organization, keep the default selection, 
Include all accounts under my AWS organization.

• If you want to apply the policy only to specific accounts or accounts that are in specific AWS 
Organizations organizational units (OUs), choose Include only the specified accounts and 
organizational units, and then add the accounts and OUs that you want to include. Specifying an 
OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any 
child OUs and accounts that are added at a later time.

• If you want to apply the policy to all but a specific set of accounts or AWS Organizations 
organizational units (OUs), choose Exclude the specified accounts and organizational units, and 
include all others, and then add the accounts and OUs that you want to exclude. Specifying an 
OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any 
child OUs and accounts that are added at a later time.

You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against 
your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the 
policy to any new accounts. As another example, if you include an OU, when you add an account 
to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new 
account.

12. Choose the type of resource that you want to protect.

Firewall Manager does not support Amazon Route 53 or AWS Global Accelerator. If you need to use 
Shield Advanced to protect resources from these services, you can't use a Firewall Manager policy. 
Instead, follow the Shield Advanced guidance at Adding AWS Shield Advanced protection to AWS 
resources (p. 502).

13. If you want to protect only resources with specific tags, or alternatively exclude resources with 
specific tags, select Use tags to include/exclude resources, enter the tags separated by commas, 
and then choose either Include or Exclude. You can choose only one option.

If you enter more than one tag, and if a resource has any of those tags, it is considered a match.

For more information about tags, see Working with Tag Editor.

15. For Policy tags, add any identifying tags that you want for the Firewall Manager policy. For more 
information about tags, see Working with Tag Editor.

16. Choose Next.

17. Review the new policy. To make any changes, choose Edit in the area that you want to change. This 
returns you to the corresponding step in the creation wizard. When you are satisfied with the policy, 
choose Create policy.

Creating an AWS Firewall Manager common security group policy

For information about how common security group policies work, see Common security group 
policies (p. 410).

To create a common security group policy, you must have a security group already created in your 
Firewall Manager administrator account that you want to use as the primary for your policy. You can 
manage security groups through Amazon Virtual Private Cloud (Amazon VPC) or Amazon Elastic 
Compute Cloud (Amazon EC2). For information, see Working with Security Groups in the Amazon VPC 
User Guide.
To create a common security group policy (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   **Note**
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.

3. Choose Create policy.

4. For Policy type, choose Security group.

5. For Security group policy type, choose Common security groups.

6. For Region, choose an AWS Region.

7. Choose Next.

8. For Policy name, enter a friendly name.

9. For Policy rules, do the following:
   a. From the rules options, choose the restrictions that you want to apply to the security group rules and the resources that are within policy scope. If you choose Distribute tags from the primary security group to the security groups created by this policy, then you must also select Identify and report when the security groups created by this policy become non-compliant.

      **Important**
      Firewall Manager won't distribute system tags added by AWS services into the replica security groups. System tags begin with the aws: prefix.

   b. For Primary security groups, choose Add primary security group, and then choose the security group that you want to use. Firewall Manager populates the list of primary security groups from all Amazon VPC instances in the Firewall Manager administrator account. The default maximum number of primary security groups for a policy is one. For information about increasing the maximum, see AWS Firewall Manager quotas (p. 457).

   c. For Policy action, we recommend creating the policy with the option that doesn't automatically remediate. This allows you to assess the effects of your new policy before you apply it. When you are satisfied that the changes are what you want, then edit the policy and change the policy action to enable automatic remediation of noncompliant resources.

10. Choose Next.

11. For AWS accounts this policy applies to, choose the option as follows:

   • If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.

   • If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

   • If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose Exclude the specified accounts and organizational units, and include all others, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

You can only choose one of the options.
After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

12. For Resource type, choose the types of resources that you want to protect.

If you choose EC2 instance, you can choose to include all elastic network interfaces in each Amazon EC2 instance or just the default interface in each instance. If you have more than one elastic network interface in any in-scope Amazon EC2 instance, choosing the option to include all interfaces allows Firewall Manager to apply the policy to all of them. When you enable automatic remediation, if Firewall Manager can't apply the policy to all elastic network interfaces in an Amazon EC2 instance, it marks the instance as noncompliant.

13. For Resources, if you want to apply the policy to all resources within the AWS accounts and resource type parameters, choose Include all resources that match the selected resource type. If you want to include or exclude specific resources, use tagging to specify the resources, and then choose the appropriate option and add the tags to the list. You can apply the policy either to all resources except those that have all the tags that you specify, or you can apply it to only those that have all the tags that you specify. For more information about tagging your resources, see Working with Tag Editor.

Note
If you enter more than one tag, a resource must have all the tags to be a match.

14. For Shared VPC resources, if you want to apply the policy to resources in shared VPCs, in addition to the VPCs that the accounts own, select Include resources from shared VPCs.

15. Choose Next.

16. Review the policy settings to be sure they're what you want, and then choose Create policy.

Firewall Manager creates a replica of the primary security group in every Amazon VPC instance contained within the in-scope accounts up to the supported Amazon VPC maximum quota per account. Firewall Manager associates the replica security groups to the resources that are within policy scope for each in-scope account. For more information about how this policy works, see Common security group policies (p. 410).

Creating an AWS Firewall Manager content audit security group policy

For information about how content audit security group policies work, see Content audit security group policies (p. 411).

For some content audit policy settings, you must provide an audit security group for Firewall Manager to use as a template. For example, you might have an audit security group that contains all of the rules that you don't allow in any security group. You must create these audit security groups using your Firewall Manager administrator account, before you can use them in your policy. You can manage security groups through Amazon Virtual Private Cloud (Amazon VPC) or Amazon Elastic Compute Cloud (Amazon EC2). For information, see Working with Security Groups in the Amazon VPC User Guide.

To create a content audit security group policy (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

Note
For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).
2. In the navigation pane, choose **Security policies**.
3. Choose **Create policy**.
4. For **Policy type**, choose **Security group**.
5. For **Security group policy type**, choose **Auditing and enforcement of security group rules**.
6. For **Region**, choose an AWS Region.
7. Choose **Next**.
8. For **Policy name**, enter a friendly name.
9. For **Policy rules**, choose the managed or custom policy rules option that you want to use.

a. For **Configure managed audit policy rules**, do the following:
   i. For **Configure security group rules to audit**, select the type of security group rules that you want your audit policy to apply to.
   ii. If you want to do things like restrict the protocols, ports, and CIDR range settings that you allow in your security groups, choose **Audit overly permissive security group rules** and select the options that you want.

   For selections that use protocol lists, you can use existing lists and you can create new lists. For information about protocol lists and how to use them in your policy, see [Managed lists](p. 401) and [Using managed lists](p. 402).
   iii. If you want to enforce restrictions on what specific applications can do, choose **Audit high risk applications** and select the options that you want.

   The following selections are mutually exclusive: **Applications that can access local CIDR ranges only** and **Applications that can use public CIDR ranges**. You can select at most one of them in any policy.

   For selections that use application lists, you can use existing lists and you can create new lists. For information about application lists and how to use them in your policy, see [Managed lists](p. 401) and [Using managed lists](p. 402).
   iv. Use the **Overrides** settings to explicitly override other settings in the policy. You can choose to always allow or always deny specific security group rules, regardless of whether they comply with the other options that you’ve set for the policy.

   For this option, you provide an audit security group as your allowed rules or denied rules template. For **Audit security groups**, choose **Add audit security groups**, and then choose the security group that you want to use. Firewall Manager populates the list of audit security groups from all Amazon VPC instances in the Firewall Manager administrator account. The default maximum quota for the number of audit security groups for a policy is one. For information about increasing the quota, see [AWS Firewall Manager quotas](p. 457).

b. For **Configure custom policy rules**, do the following:
   i. From the rules options, choose whether to allow only the rules defined in the audit security groups or deny all the rules. For information about this choice, see [Content audit security group policies](p. 411).
   ii. For **Audit security groups**, choose **Add audit security groups**, and then choose the security group that you want to use. Firewall Manager populates the list of audit security groups from all Amazon VPC instances in the Firewall Manager administrator account. The default maximum quota for the number of audit security groups for a policy is one. For information about increasing the quota, see [AWS Firewall Manager quotas](p. 457).
   iii. For **Policy action**, you must create the policy with the option that doesn’t automatically remediate. This allows you to assess the effects of your new policy before you apply it. When you are satisfied that the changes are what you want, edit the policy and change the policy action to enable automatic remediation of noncompliant resources.
10. Choose **Next**.

11. For **AWS accounts this policy applies to**, choose the option as follows:

- If you want to apply the policy to all accounts in your organization, leave the default selection, **Include all accounts under my AWS organization**.
- If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose **Include only the specified accounts and organizational units**, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.
- If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose **Exclude the specified accounts and organizational units, and include all others**, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

12. For **Resource type**, choose the types of resource that you want to protect.

13. For **Resources**, if you want to apply the policy to all resources within the AWS accounts and resource type parameters, choose **Include all resources that match the selected resource type**. If you want to include or exclude specific resources, use tagging to specify the resources, and then choose the appropriate option and add the tags to the list. You can apply the policy either to all resources except those that have all the tags that you specify, or you can apply it to only those that have all the tags that you specify. For more information about tagging your resources, see **Working with Tag Editor**.

**Note**

If you enter more than one tag, a resource must have all the tags to be a match.

14. Choose **Next**.

15. Review the policy settings to be sure they’re what you want, and then choose **Create policy**.

Firewall Manager compares the audit security group against the in-scope security groups in your AWS organization, according to your policy rules settings. You can review the policy status in the AWS Firewall Manager policy console. After the policy is created, you can edit it and enable automatic remediation to put your auditing security group policy into effect. For more information about how this policy works, see **Content audit security group policies** (p. 411).

### Creating an AWS Firewall Manager usage audit security group policy

For information about how usage audit security group policies work, see **Usage audit security group policies** (p. 413).

### To create a usage audit security group policy (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at [https://console.aws.amazon.com/wafv2/fmsv2](https://console.aws.amazon.com/wafv2/fmsv2).
2. In the navigation pane, choose Security policies.
3. Choose Create policy.
4. For Policy type, choose Security group.
5. For Security group policy type, choose Auditing and cleanup of unused and redundant security groups.
6. For Region, choose an AWS Region.
7. Choose Next.
8. For Policy name, enter a friendly name.
9. For Policy rules, choose one or both of the options available.
   - If you choose Security groups within this policy scope must be used by at least one resource., Firewall Manager removes any security groups that it determines are unused. By default, Firewall Manager considers security groups as noncompliant with this policy rule if they are unused for any length of time. You can optionally specify a number of minutes that a security group can exist unused before it is considered noncompliant. If you choose this rule, Firewall Manager runs it last when you save the policy.
   - If you choose Security groups within this policy scope must be unique., Firewall Manager consolidates redundant security groups, so that only one is associated with any resources. If you choose this, Firewall Manager runs it first when you save the policy.
10. For Policy action, we recommend creating the policy with the option that doesn’t automatically remediate. This allows you to assess the effects of your new policy before you apply it. When you are satisfied that the changes are what you want, then edit the policy and change the policy action to enable automatic remediation of noncompliant resources.
11. Choose Next.
12. For AWS accounts this policy applies to, choose the option as follows:
   - If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.
   - If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.
   - If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose Exclude the specified accounts and organizational units, and include all others, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn’t apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

13. For Resources, if you want to apply the policy to all resources within the AWS accounts and resource type parameters, choose Include all resources that match the selected resource type. If you want to include or exclude specific resources, use tagging to specify the resources, and then choose
the appropriate option and add the tags to the list. You can apply the policy either to all resources except those that have all the tags that you specify, or you can apply it to only those that have all the tags that you specify. For more information about tagging your resources, see Working with Tag Editor.

Note
If you enter more than one tag, a resource must have all the tags to be a match.

15. If you haven't excluded the Firewall Manager administrator account from the policy scope, Firewall Manager prompts you to do this. Doing this leaves the security groups in the Firewall Manager administrator account, which you use for common and audit security group policies, under your manual control. Choose the option you want in this dialogue.

16. Review the policy settings to be sure they're what you want, and then choose Create policy.

If you chose to require unique security groups, Firewall Manager scans for redundant security groups in each in-scope Amazon VPC instance. Then, if you chose to require that each security group be used by at least one resource, Firewall Manager scans for security groups that have remained unused for the minutes specified in the rule. You can review the policy status in the AWS Firewall Manager policy console. For more information about how this policy works, see Usage audit security group policies (p. 413).

Creating an AWS Firewall Manager policy for AWS Network Firewall

In a Firewall Manager Network Firewall policy, you use rule groups that you manage in AWS Network Firewall. For information about managing your rule groups, see AWS Network Firewall rule groups in the Network Firewall Developer Guide.

For information about Firewall Manager Network Firewall policies, see AWS Network Firewall policies (p. 416).

To create a Firewall Manager policy for AWS Network Firewall (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.

3. Choose Create policy.

4. For Policy type, choose AWS Network Firewall.

5. Under Firewall management type, choose how you'd like Firewall Manager to manage the policy's firewalls. Choose from the following options:

   • Distributed - Firewall Manager creates and maintains firewall endpoints in each VPC that's in the policy scope.
   • Centralized - Firewall Manager creates and maintains endpoints in a single inspection VPC.
   • Import existing firewalls - Firewall Manager imports existing firewalls from Network Firewall using resource sets. For information about resource sets, see Working with resource sets in Firewall Manager (p. 426).

6. For Region, choose an AWS Region. To protect resources in multiple Regions, you must create separate policies for each Region.

7. Choose Next.
8. For **Policy name**, enter a descriptive name. Firewall Manager includes the policy name in the names of the Network Firewall firewalls and firewall policies that it creates.

9. In the **AWS Network Firewall policy configuration**, configure the firewall policy as you would in Network Firewall. Add your stateless and stateful rule groups and specify the policy's default actions. You can optionally set the policy's stateful rule evaluation order and default actions, as well as logging configuration. For information about Network Firewall firewall policy management, see **AWS Network Firewall firewall policies** in the **AWS Network Firewall Developer Guide**.

When you create the Firewall Manager Network Firewall policy, Firewall Manager creates firewall policies for the accounts that are within scope. Individual account managers can add rule groups to the firewall policies, but they can't change the configuration that you provide here.

10. Choose **Next**.

11. Do one of the following, depending on the **Firewall management type** you selected in the previous step:

   - If you're using a **distributed** firewall management type, in **AWS Firewall Manager endpoint configuration** under **Firewall endpoint location**, choose one of the following options:
     
     - **Custom endpoint configuration**: Firewall Manager creates firewalls for each VPC within the policy scope, in the Availability Zones that you specify. Each firewall contains at least one firewall endpoint.
     
     - Under **Availability Zones**, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by **Availability Zone name** or by **Availability Zone ID**.
     
     - If you want to provide the CIDR blocks for Firewall Manager to use for firewall subnets in your VPCs, they must all be `/28` CIDR blocks. Enter one block per line. If you omit these, Firewall Manager chooses IP addresses for you from those that are available in the VPCs.

     **Note**
     Auto remediation happens automatically for AWS Firewall Manager Network Firewall policies, so you won't see an option to choose not to auto remediate here.

   - **Automatic endpoint configuration**: Firewall Manager automatically creates firewall endpoints in the Availability Zones with public subnets in your VPC.

     - For the **Firewall endpoints** configuration, specify how you want the firewall endpoints to be managed by Firewall Manager. We recommend using multiple endpoints for high availability.

   - If you're using a **centralized** firewall management type, in **AWS Firewall Manager endpoint configuration** under **Inspection VPC configuration**, enter the AWS account ID of the owner of the inspection VPC, and the VPC ID of the inspection VPC.

     - Under **Availability Zones**, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by **Availability Zone name** or by **Availability Zone ID**.

     - If you want to provide the CIDR blocks for Firewall Manager to use for firewall subnets in your VPCs, they must all be `/28` CIDR blocks. Enter one block per line. If you omit these, Firewall Manager chooses IP addresses for you from those that are available in the VPCs.

     **Note**
     Auto remediation happens automatically for AWS Firewall Manager Network Firewall policies, so you won't see an option to choose not to auto remediate here.

   - If you're using a **import existing firewalls** firewall management type, in **Resource sets** add one or more resource sets. A resource set defines the existing Network Firewall firewalls owned by your organization's account that you want to centrally manage in this policy. To add a resource set to the policy, you must first create a resource set using the console or the **PutResourceSet** API. For information about resource sets, see **Working with resource sets in Firewall Manager** (p. 426). For more information about importing existing firewalls from Network Firewall, see **import existing firewalls**. (p. 417)

12. Choose **Next**.
13. If your policy uses a distributed firewall management type, under Route management, choose whether or not Firewall Manager will monitor and alert on the traffic that must be routed through the respective firewall endpoints.

   **Note**
   If you choose Monitor, you can't change the setting to Off at a later date. Monitoring continues until you delete the policy.

14. For Traffic type, optionally add the traffic endpoints that you want to route traffic through for firewall inspection.

15. For Allow required cross-AZ traffic, if you enable this option then Firewall Manager treats as compliant routing that sends traffic out of an Availability Zone for inspection, for Availability Zones that don't have their own firewall endpoint. Availability Zones that have endpoints must always inspect their own traffic.

16. Choose Next.

17. For Policy scope, under AWS accounts this policy applies to, choose the option as follows:

   - If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.
   - If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.
   - If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose Exclude the specified accounts and organizational units, and include all others, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

   You can only choose one of the options.

   After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

18. The Resource type for Network Firewall policies is VPC.

19. For Resources, if you want to protect (or exclude) only resources that have specific tags, select the appropriate option, then enter the tags to include or exclude. You can choose only one option. For more information about tags, see Working with Tag Editor.

   If you enter more than one tag, a resource must have all of the tags to be included or excluded.

   Choose Next.

20. For Policy tags, add any identifying tags that you want for the Firewall Manager policy. For more information about tags, see Working with Tag Editor.

   Choose Next.

21. Review the new policy. To make any changes, choose Edit in the area that you want to change. This returns you to the corresponding step in the creation wizard. When you are satisfied with the policy, choose Create policy.
Creating an AWS Firewall Manager policy for Amazon Route 53 Resolver DNS Firewall

In a Firewall Manager DNS Firewall policy, you use rule groups that you manage in Amazon Route 53 Resolver DNS Firewall. For information about managing your rule groups, see Managing rule groups and rules in DNS Firewall in the Amazon Route 53 Developer Guide.

For information about Firewall Manager DNS Firewall policies, see Amazon Route 53 Resolver DNS Firewall policies (p. 422).

To create a Firewall Manager policy for Amazon Route 53 Resolver DNS Firewall (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.

3. Choose Create policy.

4. For Policy type, choose Amazon Route 53 Resolver DNS Firewall.

5. For Region, choose an AWS Region. To protect resources in multiple Regions, you must create separate policies for each Region.

6. Choose Next.

7. For Policy name, enter a descriptive name.

8. In the policy configuration, add the rule groups that you want DNS Firewall to evaluate first and last among your VPCs' rule group associations. You can add up to two rule groups to the policy.

   When you create the Firewall Manager DNS Firewall policy, Firewall Manager creates the rule group associations, with the association priorities that you've provided, for the VPCs and accounts that are within scope. The individual account managers can add rule group associations in between your first and last associations, but they can’t change the associations that you define here. For more information, see Amazon Route 53 Resolver DNS Firewall policies (p. 422).

9. Choose Next.

10. For AWS accounts this policy applies to, choose the option as follows:

   - If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.
   - If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.
   - If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose Exclude the specified accounts and organizational units, and include all others, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

   You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account
Creating a policy to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

11. The **Resource type** for DNS Firewall policies is **VPC**.
12. For **Resources**, if you want to protect (or exclude) only resources that have specific tags, select the appropriate option, then enter the tags to include or exclude. You can choose only one option. For more information about tags, see **Working with Tag Editor**.

    If you enter more than one tag, a resource must have all of the tags to be included or excluded.

13. Choose **Next**.
14. For **Policy tags**, add any identifying tags that you want for the Firewall Manager policy. For more information about tags, see **Working with Tag Editor**.
15. Choose **Next**.
16. Review the new policy. To make any changes, choose **Edit** in the area that you want to change. This returns you to the corresponding step in the creation wizard. When you are satisfied with the policy, choose **Create policy**.

Creating an AWS Firewall Manager policy for Palo Alto Networks Palo Alto Networks Cloud NGFW

With a Firewall Manager policy for Palo Alto Networks Cloud Next Generation Firewall (Palo Alto Networks Cloud NGFW), you use Firewall Manager to deploy Palo Alto Networks Cloud NGFW resources, and manage NGFW rulestacks centrally across all of your AWS accounts.

For information about Firewall Manager Palo Alto Networks Cloud NGFW policies, see **Palo Alto Networks Cloud NGFW policies** (p. 423). For information about how to configure and manage Palo Alto Networks Cloud NGFW for Firewall Manager, see the **Palo Alto Networks Palo Alto Networks Cloud NGFW on AWS** documentation.

Prerequisites

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in **AWS Firewall Manager prerequisites** (p. 358). Complete all the prerequisites before proceeding to the next step.

To create a Firewall Manager policy for Palo Alto Networks Cloud NGFW (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

    **Note**
    For information about setting up a Firewall Manager administrator account, see **AWS Firewall Manager prerequisites** (p. 358).

2. In the navigation pane, choose **Security policies**.
3. Choose **Create policy**.
4. For **Policy type**, choose **Palo Alto Networks Palo Alto Networks Cloud NGFW**. If you haven’t already subscribed to the Palo Alto Networks Cloud NGFW service in the AWS Marketplace, you’ll need to do that first. To subscribe in the AWS Marketplace, choose **View AWS Marketplace details**.
5. For **Deployment model**, choose either the **Distributed model** or **Centralized model**. The deployment model determines how Firewall Manager manages endpoints for the policy. With the distributed model, Firewall Manager maintains firewall endpoints in each VPC that’s within policy scope. With the centralized model, Firewall Manager maintains a single endpoint in an inspection VPC.
6. For **Region**, choose an AWS Region. To protect resources in multiple Regions, you must create separate policies for each Region.
7. Choose Next.
8. For Policy name, enter a descriptive name.
9. In the policy configuration, choose the Palo Alto Networks Cloud NGFW firewall policy to associate with this policy. The list of Palo Alto Networks Cloud NGFW firewall policies contains all of the Palo Alto Networks Cloud NGFW firewall policies that are associated with your Palo Alto Networks Cloud NGFW tenant. For information about creating and managing Palo Alto Networks Cloud NGFW firewall policies, see the Deploy Palo Alto Networks Cloud NGFW for AWS with the AWS Firewall Manager topic in the Palo Alto Networks Palo Alto Networks Cloud NGFW for AWS deployment guide.
10. For Palo Alto Networks Palo Alto Networks Cloud NGFW logging - optional, optionally choose which Palo Alto Networks Cloud NGFW log type(s) to log for your policy. For information about Palo Alto Networks Cloud NGFW log types, see Configure Logging for Palo Alto Networks Cloud NGFW on AWS in the Palo Alto Networks Palo Alto Networks Cloud NGFW for AWS deployment guide.

For log destination, specify when Firewall Manager should write logs to.
11. Choose Next.
12. Under Configure third-party firewall endpoint do one of the following, depending on whether you're using the distributed or centralized deployment model to create your firewall endpoints:
   - If you're using the distributed deployment model for this policy, under Availability Zones, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by Availability Zone name or by Availability Zone ID.
   - If you're using the centralized deployment model for this policy, in AWS Firewall Manager endpoint configuration under Inspection VPC configuration, enter the AWS account ID of the owner of the inspection VPC, and the VPC ID of the inspection VPC.
   - Under Availability Zones, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by Availability Zone name or by Availability Zone ID.
13. If you want to provide the CIDR blocks for Firewall Manager to use for firewall subnets in your VPCs, they must all be /28 CIDR blocks. Enter one block per line. If you omit these, Firewall Manager chooses IP addresses for you from those that are available in the VPCs.

Note
Auto remediation happens automatically for AWS Firewall Manager Network Firewall policies, so you won't see an option to choose not to auto remediate here.
15. For Policy scope, under AWS accounts this policy applies to, choose the option as follows:
   - If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.
   - If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.
   - If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose Exclude the specified accounts and organizational units, and include all others, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

You can only choose one of the options.

After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account
Creating an AWS Firewall Manager policy for Fortigate Cloud Native Firewall (CNF) as a Service

With a Firewall Manager policy for Fortigate CNF, you can use Firewall Manager to deploy and manage Fortigate CNF resources across all of your AWS accounts.

For information about Firewall Manager Fortigate CNF policies, see Fortigate Cloud Native Firewall (CNF) as a Service policies (p. 424). For information about how to configure Fortigate CNF for use with Firewall Manager, see the Fortinet documentation.

Prerequisites

There are several mandatory steps to prepare your account for AWS Firewall Manager. Those steps are described in AWS Firewall Manager prerequisites (p. 358). Complete all the prerequisites before proceeding to the next step.

To create a Firewall Manager policy for Fortigate CNF (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.

3. Choose Create policy.

4. For Policy type, choose Fortigate Cloud Native Firewall (CNF) as a Service. If you haven't already subscribed to the Fortigate CNF service in the AWS Marketplace, you'll need to do that first. To subscribe in the AWS Marketplace, choose View AWS Marketplace details.

5. For Deployment model, choose either the Distributed model or Centralized model. The deployment model determines how Firewall Manager manages endpoints for the policy. With the
distributed model, Firewall Manager maintains firewall endpoints in each VPC that's within policy scope. With the centralized model, Firewall Manager maintains a single endpoint in an inspection VPC.

6. For Region, choose an AWS Region. To protect resources in multiple Regions, you must create separate policies for each Region.

7. Choose Next.

8. For Policy name, enter a descriptive name.

9. In the policy configuration, choose the Fortigate CNF firewall policy to associate with this policy. The list of Fortigate CNF firewall policies contains all of the Fortigate CNF firewall policies that are associated with your Fortigate CNF tenant. For information about creating and managing Fortigate CNF tenants, see the Fortinet documentation.

10. Choose Next.

11. Under Configure third-party firewall endpoint do one of the following, depending on whether you're using the distributed or centralized deployment model to create your firewall endpoints:

   - If you're using the distributed deployment model for this policy, under Availability Zones, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by Availability Zone name or by Availability Zone ID.
   - If you're using the centralized deployment model for this policy, in AWS Firewall Manager endpoint configuration under Inspection VPC configuration, enter the AWS account ID of the owner of the inspection VPC, and the VPC ID of the inspection VPC.
   - Under Availability Zones, select which Availability Zones to create firewall endpoints in. You can select Availability Zones by Availability Zone name or by Availability Zone ID.

12. If you want to provide the CIDR blocks for Firewall Manager to use for firewall subnets in your VPCs, they must all be /28 CIDR blocks. Enter one block per line. If you omit these, Firewall Manager chooses IP addresses for you from those that are available in the VPCs.

   Note
   Auto remediation happens automatically for AWS Firewall Manager Network Firewall policies, so you won't see an option to choose not to auto remediate here.

13. Choose Next.

14. For Policy scope, under AWS accounts this policy applies to, choose the option as follows:

   - If you want to apply the policy to all accounts in your organization, leave the default selection, Include all accounts under my AWS organization.
   - If you want to apply the policy only to specific accounts or accounts that are in specific AWS Organizations organizational units (OUs), choose Include only the specified accounts and organizational units, and then add the accounts and OUs that you want to include. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.
   - If you want to apply the policy to all but a specific set of accounts or AWS Organizations organizational units (OUs), choose Exclude the specified accounts and organizational units, and include all others, and then add the accounts and OUs that you want to exclude. Specifying an OU is the equivalent of specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.

   You can only choose one of the options.

   After you apply the policy, Firewall Manager automatically evaluates any new accounts against your settings. For example, if you include only specific accounts, Firewall Manager doesn't apply the policy to any new accounts. As another example, if you include an OU, when you add an account to the OU or to any of its child OUs, Firewall Manager automatically applies the policy to the new account.

15. The Resource type for Network Firewall policies is VPC.
16. For **Resources**, if you want to protect (or exclude) only resources that have specific tags, select the appropriate option, then enter the tags to include or exclude. You can choose only one option. For more information about tags, see [Working with Tag Editor](#).

If you enter more than one tag, a resource must have all of the tags to be included or excluded.

17. For **Grant cross-account access**, choose [Download AWS CloudFormation template](#). This downloads a AWS CloudFormation template that you can use to create a AWS CloudFormation stack. This stack creates an AWS Identity and Access Management role that grants Firewall Manager cross-account permissions to manage Fortigate CNF resources. For information about stacks, see [Working with stacks](#) in the *AWS CloudFormation User Guide*. To create a stack, you'll need the account ID from the Fortigate CNF portal.

18. Choose **Next**.

19. For **Policy tags**, add any identifying tags that you want for the Firewall Manager policy. For more information about tags, see [Working with Tag Editor](#).

20. Choose **Next**.

21. Review the new policy. To make any changes, choose **Edit** in the area that you want to change. This returns you to the corresponding step in the creation wizard. When you are satisfied with the policy, choose **Create policy**.

### Deleting an AWS Firewall Manager policy

You can delete a Firewall Manager policy by performing the following steps.

**To delete a policy (console)**

1. In the navigation pane, choose **Security policies**.
2. Choose the option next to the policy that you want to delete.
3. Choose **Delete**.

**Note**

When you delete a Firewall Manager common security group policy, to remove the policy’s replica security groups, choose the option to clean up the resources created by the policy. Otherwise, after the primary is deleted, the replicas remain and require manual management in each Amazon VPC instance.

**Important**

When you delete a Firewall Manager Shield Advanced policy, the policy is deleted, but your accounts remain subscribed to Shield Advanced.

### AWS Firewall Manager policy scope

The policy scope defines where the policy applies. You can either apply centrally controlled policies to all of your accounts and resources within your organization in AWS Organizations, or to a subset of your accounts and resources. For instructions on how to set policy scope, see [Creating an AWS Firewall Manager policy](#) (p. 380).

### Policy scope options in AWS Firewall Manager

When you add a new account or resource to your organization, Firewall Manager automatically assesses it against your settings for each policy and applies the policy based on these settings. For example, you can choose to apply a policy to all accounts except the account numbers in a specified list; you can also choose to apply a policy only to resources that have all of the tags in a list.

**AWS accounts in scope**
The settings that you provide to define the AWS accounts affected by the policy determine which of the accounts in your AWS organization to apply the policy to. You can choose to apply the policy in one of the following ways:

- To all accounts in your organization
- To only a specific list of included account numbers and AWS Organizations organizational units (OUs)
- To all except a specific list of excluded account numbers and AWS Organizations organizational units (OUs)

For information about AWS Organizations, see AWS Organizations User Guide.

Resources in scope

Similarly to the settings for accounts in scope, the settings that you provide for resources determine which in-scope resource types to apply the policy to. You can choose one of the following:

- All resources
- Resources that have all of the tags that you specify
- All resources except those that have all of the tags that you specify

For more information about tagging your resources, see Working with Tag Editor.

Policy scope management in AWS Firewall Manager

When policies are in place, Firewall Manager manages them continuously and applies them to new AWS accounts and resources as they are added, in accordance with the policy scope.

How Firewall Manager manages AWS accounts and resources

If an account or resource goes out of scope for any reason, AWS Firewall Manager doesn't automatically remove protections or delete Firewall Manager-managed resources unless you select the Automatically remove protections from resources that leave the policy scope check box.

Note

The option Automatically remove protections from resources that leave the policy scope is not available for AWS Shield Advanced or AWS WAF Classic policies.

Selecting this check box directs AWS Firewall Manager to automatically clean up resources that Firewall Manager manages for accounts when those accounts leave the policy scope. For example, Firewall Manager will disassociate a Firewall Manager-managed web ACL from a protected customer resource when the customer resource leaves the policy scope.

To determine which resources should be removed from protection when a customer resource leaves the policy scope, Firewall Manager follows these guidelines:

- Default behavior:
  - The associated AWS Config managed rules are deleted. This behavior is independent of the check box.
  - Any associated AWS WAF web access control lists (web ACLs) that don't contain any resources are deleted. This behavior is independent of the check box.
  - Any protected resource that goes out of scope remains associated and protected. For example, an Application Load Balancer or API from API Gateway that's associated with a web ACL remains associated with the web ACL, and the protection remains in place.
- With the Automatically remove protections from resources that leave the policy scope check box selected:
  - The associated AWS Config managed rules are deleted. This behavior is independent of the check box.
Managed lists

Managed application and protocol lists streamline your configuration and management of AWS Firewall Manager content audit security group policies. You use managed lists to define the protocols and applications that your policy allows and disallows. For information about content audit security group policies, see Content audit security group policies (p. 411).

You can use the following types of managed lists in a content audit security group policy:

- **Firewall Manager application lists and protocol lists** – Firewall Manager manages these lists.
  - The application lists include FMS-Default-Public-Access-Apps-Allowed and FMS-Default-Public-Access-Apps-Denied, which describe commonly used applications that should be allowed or denied to the general public.
  - The protocol lists include FMS-Default-Protocols-Allowed, a list of commonly used protocols that should be allowed to the general public. You can use any list that Firewall Manager manages, but you can't edit or delete it.

- **Custom application lists and protocol lists** – You manage these lists. You can create lists of either type with the settings that you need. You have full control over your own custom managed lists, and you can create, edit, and delete them as needed.

  **Note**
  Currently, Firewall Manager doesn't check references to a custom managed list when you delete it. This means that you can delete a custom managed application list or protocol list even when it is in use by an active policy. This can cause the policy to stop functioning. Delete an application list or protocol list only after you have verified that it isn't referenced by any active policies.

Managed lists are AWS resources. You can tag a custom managed list. You can't tag a Firewall Manager managed list.

Managed list versioning

Custom managed lists don't have versions. When you edit a custom list, policies that reference the list automatically use the updated list.

Firewall Manager managed lists are versioned. The Firewall Manager service team publishes new versions as needed, in order to apply the best security practices to the lists.

When you use a Firewall Manager managed list in a policy, you choose your versioning strategy as follows:

- **Latest available version** – If you don't specify an explicit version setting for the list, then your policy automatically uses the latest version. This is the only option available through the console.
- **Explicit version** – If you specify a version for the list, then your policy uses that version. Your policy remains locked to the version that you specified until you modify the version setting. To specify the version, you must define the policy outside of the console, for example through the CLI or one of the SDKs.
For more information about choosing the version setting for a list, see Using managed lists in your content audit security group policies (p. 402).

Using managed lists in your content audit security group policies

When you create a content audit security group policy, you can choose to use managed audit policy rules. Some of the settings for this option require a managed application list or protocol list. Examples of these settings include protocols that are allowed in security group rules and applications can access the internet.

The following restrictions apply for each policy setting that uses a managed list:

- You can specify at most one Firewall Manager managed list for any setting. By default, you can specify at most one custom list. The custom list limit is a soft quota, so you can request an increase to it. For more information, see AWS Firewall Manager quotas (p. 457).
- In the console, if you select a Firewall Manager managed list, you can't specify the version. The policy will always use the latest version of the list. To specify the version, you must define the policy outside of the console, for example through the CLI or one of the SDKs. For information about versioning for Firewall Manager managed lists, see Managed list versioning (p. 401).

For information about creating a content audit security group policy through the console, see Creating a content audit security group policy (p. 387).

Creating a custom managed application list

To create a custom managed application list

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Application lists.

3. In the Application lists page, choose Create application list.

4. In the Create application list page, give your list a name. Don't use the prefix fms- as this is reserved for Firewall Manager.

5. Specify an application either by providing the protocol and port number or by selecting an application from the Type drop down. Give your application specification a name.

6. Choose Add another as needed and fill in the application information until you have completed your list.

7. (Optional) Apply tags to your list.

8. Choose Save to save your list and return to the Application lists page.

Creating a custom managed protocol list

To create a custom managed protocol list

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.
Note
For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Protocol lists.
3. In the Protocol lists page, choose Create protocol list.
4. In the protocol list creation page, give your list a name. Don't use the prefix fms- as this is reserved for Firewall Manager.
5. Specify a protocol.
6. Choose Add another as needed and fill in the protocol information until you have completed your list.
7. (Optional) Apply tags to your list.
8. Choose Save to save your list and return to the Protocol lists page.

Viewing a managed list

To view an application list or protocol list

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Application lists or Protocol lists.

   The page displays all of the lists of the selected type that are available for your use. The lists that Firewall Manager manages have a Y in the ManagedList column.

3. To see the details of a list, choose its name. The detail page displays the list's content and any tags.

   For Firewall Manager managed lists, you can also see the available versions by selecting the Version drop down.

Deleting a custom managed list

You can delete custom managed lists. You can't edit or delete lists that Firewall Manager manages.

Note
Currently, Firewall Manager doesn't check references to a custom managed list when you delete it. This means that you can delete a custom managed application list or protocol list even when it is in use by an active policy. This can cause the policy to stop functioning. Only delete an application list or protocol list after you have verified that it isn't referenced by any active policies.

To delete a custom managed application or protocol list

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. Make sure that the list that you want to delete isn't in use in any of your audit security group policies by doing the following:
a. In the navigation pane, choose **Security policies**.

b. In the **AWS Firewall Manager policies** page, select and edit your audit security groups, and remove any references to the custom list that you want to delete.

If you delete a custom managed list that's in use in an audit security group policy, the policy that's using it can stop functioning.

3. In the navigation pane, choose **Application lists** or **Protocol lists**, depending on the type of list you want to delete.

4. In the list page, select the custom list that you want to delete and choose **Delete**.

### AWS WAF policies

In a Firewall Manager AWS WAF policy, you specify the AWS WAF rule groups that you want to use across your resources. When you apply the policy, in each account that's within policy scope, Firewall Manager creates a web ACL that's managed by Firewall Manager. In the resulting web ACLs, individual account managers can add rules and rule groups, in addition to the rule groups that you defined through Firewall Manager.

When Firewall Manager creates a web ACL for the policy, it names the web ACL `FMManagedWebACLV2-policy name-timestamp`. The timestamp is in UTC milliseconds. For example, `FMManagedWebACLV2-MyWAFPolicyName-1621880374078`.

AWS Firewall Manager enables sampling and Amazon CloudWatch metrics for the web ACLs and rule groups that it creates for an AWS WAF policy.

### Rule groups in AWS WAF policies

The web ACLs that are managed by Firewall Manager AWS WAF policies contain three sets of rules. These sets provide a higher level of prioritization for the rules and rule groups in the web ACL:

- First rule groups, defined by you in the Firewall Manager AWS WAF policy. AWS WAF evaluates these rule groups first.
- Rules and rule groups that are defined by the account managers in the web ACLs. AWS WAF evaluates any account-managed rules or rule groups next.
- Last rule groups, defined by you in the Firewall Manager AWS WAF policy. AWS WAF evaluates these rule groups last.

Within each of these sets of rules, AWS WAF evaluates rules and rule groups as usual, according to their priority settings within the set.

In the policy's first and last rule groups sets, you can only add rule groups. You can use managed rule groups, which AWS Managed Rules and AWS Marketplace sellers create and maintain for you. You can also manage and use your own rule groups. For more information about all of these options, see [Rule groups](#).

**Note**

Firewall Manager supports the new AWS WAF Bot Control managed rule group. For information about Bot Control in AWS WAF, see [AWS WAF Bot Control](#).

If you want to use your own rule groups, you create those before you create your Firewall Manager AWS WAF policy. For guidance, see [Managing your own rule groups](#). To use an individual custom rule, you must define your own rule group, define your rule within that, and then use the rule group in your policy.
The first and last AWS WAF rule groups that you manage through Firewall Manager have names that begin with `PREFMManaged-` or `POSTFMManaged-`, respectively, followed by the Firewall Manager policy name, and the rule group creation timestamp, in UTC milliseconds. For example, `PREFMManaged-MyWAFPolicyName-162188055123`.

For information about how AWS WAF evaluates web requests, see Web ACL rule and rule group evaluation (p. 13).

For the procedure to create a Firewall Manager AWS WAF policy, see Creating an AWS Firewall Manager policy for AWS WAF (p. 380).

Firewall Manager enables sampling and Amazon CloudWatch metrics for the rule groups that you define for the AWS WAF policy.

Individual account owners have complete control over the metrics and sampling configuration for any rule or rule group that they add to the policy’s managed web ACLs.

### Configuring logging for an AWS WAF policy

You can enable centralized logging for your AWS WAF policies, to get detailed information about traffic within your organization. Information in the logs includes the time that AWS WAF received the request from your AWS resource, detailed information about the request, and the action for the rule that each request matched from all in-scope accounts. For more information about AWS WAF logging, see Logging web ACL traffic (p. 192).

**Note**
AWS Firewall Manager supports this option for the latest version of AWS WAF, and not for AWS WAF Classic.

When you enable centralized logging on an AWS WAF policy, Firewall Manager creates a web ACL for the policy in the Firewall Manager administrator account as follows:

- Firewall Manager creates the web ACL in the Firewall Manager administrator account regardless of whether the account is in scope of the policy.
- The web ACL has logging enabled, with a log name `FMManagedWebACLV2-Loggingpolicy name-timestamp`, where the timestamp is the UTC time that the log was enabled for the web ACL, in milliseconds. For example, `FMManagedWebACLV2-LoggingMyWAFPolicyName-1621880565180`. The web ACL has no rule groups and no associated resources.
- You are charged for the web ACL according to the AWS WAF pricing guidelines. For more information, see AWS WAF Pricing.
- Firewall Manager deletes the web ACL when you delete the policy.

**Note**
Firewall Manager doesn't modify any existing logging configurations in your organization's member accounts.

You send logs from your policy's web ACLs to an Amazon Kinesis Data Firehose where you've configured a storage destination. After you enable logging, AWS WAF delivers logs for each configured web ACL, through the HTTPS endpoint of Kinesis Data Firehose to the configured storage destination. Before you use it, test your delivery stream to be sure that it has enough throughput to accommodate your organization's logs. For more information about how to create an Amazon Kinesis Data Firehose and review the stored logs, see What Is Amazon Kinesis Data Firehose?

You must have the following permissions to successfully enable logging:

- `iam:CreateServiceLinkedRole`
- `firehose:ListDeliveryStreams`
• wafv2:PutLoggingConfiguration

For information about service-linked roles and the iam:CreateServiceLinkedRole permission, see Using service-linked roles for AWS WAF (p. 239).

To enable logging for an AWS WAF policy

1. Create an Amazon Kinesis Data Firehose using your Firewall Manager administrator account. Use a name starting with the prefix aws-waf-logs-. For example, aws-waf-logs-firewall-manager-central. Create the data firehose with a PUT source and in the region that you are operating. If you are capturing logs for Amazon CloudFront, create the firehose in US East (N. Virginia). Before you use it, test your delivery stream to be sure that it has enough throughput to accommodate your organization's logs. For more information, see Creating an Amazon Kinesis Data Firehose delivery stream.

2. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

3. In the navigation pane, choose Security Policies.
4. Choose the AWS WAF policy that you want to enable logging for. For more information about AWS WAF logging, see Logging web ACL traffic (p. 192).
5. On the Policy details tab, in the Policy rules section, choose Edit.
6. For Logging configuration status, choose Enabled.
7. Choose the Kinesis Data Firehose that you created for your logging. You must choose a firehose that begins with aws-waf-logs-.
8. (Optional) If you don't want certain fields and their values included in the logs, redact those fields. Choose the field to redact, and then choose Add. Repeat as necessary to redact additional fields. The redacted fields appear as XXX in the logs. For example, if you redact the URI field, the URI field in the logs will be XXX.
9. (Optional) If you don't want to send all requests to the logs, add your filtering criteria and behavior. Under Filter logs, for each filter that you want to apply, choose Add filter, then choose your filtering criteria and specify whether you want to keep or drop requests that match the criteria. When you finish adding filters, if needed, modify the Default logging behavior.
10. Choose Next.
11. Review your settings, then choose Save to save your changes to the policy.

To disable logging for an AWS WAF policy

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security Policies.
3. Choose the AWS WAF policy that you want to disable logging for.
4. On the Policy details tab, in the Policy rules section, choose Edit.
5. For Logging configuration status, choose Disabled.
6. Choose Next.
7. Review your settings, then choose Save to save your changes to the policy.

406
AWS Shield Advanced policies

When you apply a Firewall Manager Shield Advanced policy with auto remediation enabled, for each in-scope resource that's not already associated with an AWS WAF web ACL, Firewall Manager associates an empty AWS WAF web ACL. The empty web ACL is used only for Shield monitoring purposes. If you then associate any other web ACL to the resource, Firewall Manager removes the empty web ACL association.

How AWS Firewall Manager manages scope changes in Shield policies

Accounts and resources can go out of scope of an AWS Firewall Manager Shield Advanced policy due to a number of changes, such as changes to policy scope settings, changes to the tags on a resource, and the removal of an account from an organization. For general information about policy scope settings, see AWS Firewall Manager policy scope (p. 399).

With an AWS Firewall Manager Shield Advanced policy, if an account or resource goes out of scope, Firewall Manager stops monitoring the account or resource.

If an account goes out of scope by being removed from the organization, it will continue to be subscribed to Shield Advanced. Because the account is no longer part of the consolidated billing family, the account will incur a prorated Shield Advanced subscription fee. On the other hand, an account that goes out of scope but remains in the organization doesn’t incur additional fees.

If a resource goes out of scope, it continues to be protected by Shield Advanced and continues to incur Shield Advanced data transfer charges.

Automatic application layer DDoS mitigation for Amazon CloudFront distributions

When you apply a Shield Advanced policy to Amazon CloudFront distributions, you have the option of configuring Shield Advanced automatic application layer DDoS mitigation in the policy.

For information about Shield Advanced automatic mitigation, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

Shield Advanced automatic application layer DDoS mitigation has the following requirements:

- Automatic application layer DDoS mitigation works only with Amazon CloudFront resources.

  Because of this, you can only choose this option for Shield Advanced policies that you create for the Global Region, for use with Amazon CloudFront distributions.

- Automatic application layer DDoS mitigation works only with web ACLs that were created using the latest version of AWS WAF (v2).

  Because of this, if you have a policy that uses AWS WAF Classic web ACLs, you need to either replace the policy with a new policy, which will automatically use the latest version of AWS WAF, or have Firewall Manager create new version web ACLs for your existing policy and switch over to using them. For more information about the options, see Replace AWS WAF Classic web ACLs with latest version web ACLs (p. 408).

Automatic mitigation configuration

The automatic application layer DDoS mitigation option for Firewall Manager Shield Advanced policies applies Shield Advanced automatic mitigation functionality to your policy's in-scope accounts and
resources. For detailed information about this Shield Advanced feature, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

You can choose to have Firewall Manager enable or disable automatic mitigation for the CloudFront distributions that are in scope of the policy, or you can choose to have the policy ignore Shield Advanced automatic mitigation settings:

- **Enable** – If you choose to enable automatic mitigation, you also specify whether mitigating Shield Advanced rules should count or block matching web requests. Firewall Manager will mark in-scope resources as noncompliant if they either don’t have automatic mitigation enabled, or are using a rule action that doesn’t match the one you specify for the policy. If you configure the policy for automatic remediation, Firewall Manager updates noncompliant resources as needed.

- **Disable** – If you choose to disable automatic mitigation, Firewall Manager will mark in-scope resources as noncompliant if they have automatic mitigation enabled. If you configure the policy for automatic remediation, Firewall Manager updates noncompliant resources as needed.

- **Ignore** – If you choose to ignore automatic mitigation, Firewall Manager won’t consider any automatic mitigation settings when it performs remediation activities for the policy. This setting allows you to enable or disable automatic mitigation at the resource level, through Shield Advanced, without having those settings overwritten by Firewall Manager.

**Replace AWS WAF Classic web ACLs with latest version web ACLs**

Automatic application layer DDoS mitigation works only with web ACLs that were created using the latest version of AWS WAF (v2).

To determine the web ACL version for your Shield Advanced policy, see Determining the version of AWS WAF that’s used by a Shield Advanced policy (p. 409).

If you want to use automatic mitigation in your Shield Advanced policy, and your policy currently uses AWS WAF Classic web ACLs, you can either create a new Shield Advanced policy to replace your current one, or you can use the options described in this section to replace earlier version web ACLs with new (v2) web ACLs inside your current Shield Advanced policy. New policies always create web ACLs using the latest version of AWS WAF. If you replace the entire policy, when you delete it, you can have Firewall Manager delete all of the earlier version web ACLs as well. The rest of this section describes your options for replacing the web ACLs inside your existing policy.

When you modify an existing Shield Advanced policy for Amazon CloudFront resources, Firewall Manager can automatically create a new empty AWS WAF (v2) web ACL for the policy, in any in-scope account that doesn’t already have a v2 web ACL. When Firewall Manager creates a new web ACL, if the policy already has an AWS WAF Classic web ACL in the same account, Firewall Manager configures the new version web ACL with the same default action setting as the existing web ACL. If there is no existing AWS WAF Classic web ACL, Firewall Manager sets the default action to Allow in the new web ACL. After Firewall Manager creates a new web ACL, you can customize it as needed through the AWS WAF console.

When you choose any of the following policy configuration options, Firewall Manager creates new (v2) web ACLs for in-scope accounts that don’t already have them:

- When you enable or disable automatic application layer DDoS mitigation. This choice alone only causes Firewall Manager to create the new web ACLs, and not to replace any existing AWS WAF Classic web ACL associations on the policy’s in-scope resources.

- When you choose the policy action of automatic remediation and you choose the option to replace AWS WAF Classic web ACLs with AWS WAF (v2) web ACLs. You can choose to replace earlier version web ACLs regardless of your configuration choices for automatic application layer DDoS mitigation.

When you choose the replacement option, Firewall Manager creates the new version web ACLs as needed and then does the following for the policy’s in-scope resources:
• If a resource is associated with a web ACL from any other active Firewall Manager policy, Firewall Manager leaves the association alone.
• For any other case, Firewall Manager removes any association with an AWS WAF Classic web ACL and associates the resource with the policy's AWS WAF (v2) web ACL.

You can choose to have Firewall Manager replace the earlier version web ACLs with the new version web ACLs when you want to. If you've previously customized the policy's AWS WAF Classic web ACLs, you can update new version web ACLs to comparable settings before you choose to have Firewall Manager perform the replacement step.

You can access either version of web ACL for a policy through the same-version console for AWS WAF or AWS WAF Classic.

Firewall Manager doesn't delete any replaced AWS WAF Classic web ACLs until you delete the policy itself. After the AWS WAF Classic web ACLs are no longer used by the policy, you can delete them if you want to.

**Determining the version of AWS WAF that's used by a Shield Advanced policy**

You can determine which version of AWS WAF your Firewall Manager Shield Advanced policy uses by looking at the parameter keys in the policy's AWS Config service-linked rule. If the AWS WAF version that's in use is the latest, the parameter keys include `policyId` and `webAclArn`. If it's the earlier version, AWS WAF Classic, the parameter keys include `webAclId` and `resourceTypes`.

The AWS Config rule only lists keys for the web ACLs that the policy is currently using with in-scope resources.

**To determine which version of AWS WAF your Firewall Manager Shield Advanced policy uses**

1. Retrieve the policy ID for the Shield Advanced policy:
   a. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.
   b. In the navigation pane, choose Security Policies.
   c. Choose the Region for the policy. For CloudFront distributions, this is Global.
   d. Find the policy that you want and copy the value of its Policy ID.
      Example policy ID: 1111111-2222-3333-4444-a55aa5aa5555.

2. Create the policy's AWS Config rule name by appending the policy ID to the string FMManagedShieldConfigRule.
   Example AWS Config rule name: FMManagedShieldConfigRule1111111-2222-3333-4444-a55aa5aa5555.

3. Search the parameters for the associated AWS Config rule for keys named `policyId` and `webAclArn`:
   a. Open the AWS Config console at https://console.aws.amazon.com/config/.
   b. In the navigation pane, choose Rules.
   c. Find your Firewall Manager policy's AWS Config rule name in the list and select it. The rule's page opens.
   d. Under Rule details, in the Parameters section, look at the keys. If you find keys named `policyId` and `webAclArn`, the policy uses web ACLs that were created using the latest version of AWS WAF. If you find keys named `webAclId` and `resourceTypes`, the policy uses web ACLs that were created using the earlier version, AWS WAF Classic.
Security group policies

You can use AWS Firewall Manager security group policies to manage Amazon Virtual Private Cloud security groups for your organization in AWS Organizations. You can apply centrally controlled security group policies to your entire organization or to a select subset of your accounts and resources. You can also monitor and manage the security group policies that are in use in your organization, with auditing and usage security group policies.

Firewall Manager continuously maintains your policies and applies them to accounts and resources as they are added or updated across your organization. For information about AWS Organizations, see AWS Organizations User Guide. For information about Amazon Virtual Private Cloud security groups, see Security Groups for Your VPC in the Amazon VPC User Guide.

You can use Firewall Manager security group policies to do the following across your AWS organization:

- Apply common security groups to specified accounts and resources.
- Audit security group rules, to locate and remediate noncompliant rules.
- Audit usage of security groups, to clean up unused and redundant security groups.

This section covers how Firewall Manager security groups policies work and provides guidance for using them. For procedures to create security group policies, see Creating an AWS Firewall Manager policy (p. 380).

Common security group policies

With a common security group policy, Firewall Manager provides a centrally controlled association of security groups to accounts and resources across your organization. You specify where and how to apply the policy in your organization.

You can apply common security group policies to the following resource types:

- Amazon Elastic Compute Cloud (Amazon EC2) instance
- Elastic Network Interface
- Application Load Balancer
- Classic Load Balancer

For guidance on creating a common security group policy using the console, see Creating a common security group policy (p. 385).

Shared VPCs

In the policy scope settings for a common security group policy, you can choose to include shared VPCs. This choice includes VPCs that are owned by another account and shared with an in-scope account. VPCs that in-scope accounts own are always included. For information about shared VPCs, see Working with shared VPCs in the Amazon VPC User Guide.

The following caveats apply to including shared VPCs. These are in addition to the general caveats for security group policies at Security group policy limitations (p. 415).

- Firewall Manager replicates the primary security group into the VPCs for each in-scope account. For a shared VPC, Firewall Manager replicates the primary security group once for each in-scope account that the VPC is shared with. This can result in multiple replicas in a single shared VPC.
- When you create a new shared VPC, you won’t see it represented in the Firewall Manager security group policy details until after you create at least one resource in the VPC that’s within the scope of the policy.
• When you disable shared VPCs in a policy that had shared VPCs enabled, in the shared VPCs, Firewall Manager deletes the replica security groups that aren’t associated with any resources. Firewall Manager leaves the remaining replica security groups in place, but stops managing them. Removal of these remaining security groups requires manual management in each shared VPC instance.

Primary security groups

For each common security group policy, you provide AWS Firewall Manager with one or more primary security groups:

• Primary security groups must be created by the Firewall Manager administrator account and can reside in any Amazon VPC instance in the account.

• You manage your primary security groups through Amazon Virtual Private Cloud (Amazon VPC) or Amazon Elastic Compute Cloud (Amazon EC2). For information, see Working with Security Groups in the Amazon VPC User Guide.

• You can name one or more security groups as primaries for a Firewall Manager security group policy. By default, the number of security groups allowed in a policy is one, but you can submit a request to increase it. For information, see AWS Firewall Manager quotas (p. 457).

Policy rules settings

You can choose one or more of the following change control behaviors for the security groups and resources of your common security group policy:

• Identify and report on any changes made by local users to replica security groups.

• Disassociate any other security groups from the AWS resources that are within the policy scope.

• Distribute tags from the primary group to the replica security groups.

Important

Firewall Manager won’t distribute system tags added by AWS services into the replica security groups. System tags begin with the aws: prefix.

Policy creation and management

When you create your common security group policy, Firewall Manager replicates the primary security groups to every Amazon VPC instance within the policy scope, and associates the replicated security groups to accounts and resources that are in scope of the policy. When you modify a primary security group, Firewall Manager propagates the change to the replicas.

When you delete a common security group policy, you can choose whether to clean up the resources created by the policy. For Firewall Manager common security groups, these resources are the replica security groups. Choose the cleanup option unless you want to manually manage each individual replica after the policy is deleted. For most situations, choosing the cleanup option is the simplest approach.

How replicas are managed

The replica security groups in the Amazon VPC instances are managed like other Amazon VPC security groups. For information, see Security Groups for Your VPC in the Amazon VPC User Guide.

Content audit security group policies

Use AWS Firewall Manager content audit security group policies to check and manage the rules that are in use in your organization’s security groups. Content audit security group policies apply to all customer-created security groups in use in your AWS organization, according to the scope that you define in the policy.
For guidance on creating a content audit security group policy using the console, see Creating a content audit security group policy (p. 387).

**Policy scope resource type**

You can apply content audit security group policies to the following resource types:

- Amazon Elastic Compute Cloud (Amazon EC2) instance
- Elastic Network Interface
- Amazon VPC security group

Security groups are considered in scope of the policy if they explicitly are in scope or if they're associated with resources that are in scope.

**Policy rule options**

You can use either managed policy rules or custom policy rules for each content audit policy, but not both.

- **Managed policy rules** – In a policy with managed rules, you can use application and protocol lists to specify what's allowed and what's denied by the policy. You can use lists that are managed by Firewall Manager. You can also create and use your own application and protocol lists. For information about these types of lists and your management options for custom lists, see Managed lists (p. 401).

- **Custom policy rules** – In a policy with custom policy rules, you specify an existing security group as the audit security group for your policy. You can use the audit security group rules as a template that defines the rules that are allowed or denied by the policy.

**Audit security groups**

You must create audit security groups using your Firewall Manager administrator account, before you can use them in your policy. You can manage security groups through Amazon Virtual Private Cloud (Amazon VPC) or Amazon Elastic Compute Cloud (Amazon EC2). For information, see Working with Security Groups in the Amazon VPC User Guide.

A security group that you use for a content audit security group policy is used by Firewall Manager only as a comparison reference for the security groups that are in scope of the policy. Firewall Manager doesn't associate it with any resources in your organization.

The way that you define the rules in the audit security group depends on your choices in the policy rules settings:

- **Managed policy rules** – For managed policy rules settings, you use an audit security group to override other settings in the policy, to explicitly allow or deny rules that otherwise might have another compliance outcome.
  - If you choose to always *allow* the rules that are defined in the audit security group, any rule that matches one that's defined in the audit security group is considered compliant with the policy, regardless of the other policy settings.
  - If you choose to always *deny* the rules that are defined in the audit security group, any rule that matches one that's defined in the audit security group is considered noncompliant with the policy, regardless of the other policy settings.

- **Custom policy rules** – For custom policy rules settings, the audit security group provides the example of what is acceptable or not acceptable in the in-scope security group rules:
  - If you choose to *allow* the use of the rules, all in-scope security groups must only have rules that are within the allowed range of the policy's audit security group rules. *In this case, the policy's security group rules provide the example of what's acceptable to do.*
If you choose to *deny* the use of the rules, all in-scope security groups must only have rules that are *not within* the allowed range of the policy's audit security group rules. *In this case, the policy's security group provides the example of what's not acceptable to do.*

### Policy creation and management

When you create an audit security group policy, you must have automatic remediation disabled. The recommended practice is to review the effects of policy creation before enabling automatic remediation. After you review the expected effects, you can edit the policy and enable automatic remediation. When automatic remediation is enabled, Firewall Manager updates or removes rules that are noncompliant in in-scope security groups.

### Security groups affected by an audit security group policy

All security groups in your organization that are customer-created are eligible to be in scope of an audit security group policy.

Replica security groups are not customer-created and so aren't eligible to be directly in scope of an audit security group policy. However, they can be updated as a result of the policy's automatic remediation activities. A common security group policy's primary security group is customer-created and can be in scope of an audit security group policy. If an audit security group policy makes changes to a primary security group, Firewall Manager automatically propagates those changes to the replicas.

### Usage audit security group policies

Use AWS Firewall Manager usage audit security group policies to monitor your organization for unused and redundant security groups and optionally perform cleanup. When you enable automatic remediation for this policy, Firewall Manager does the following:

1. Consolidates redundant security groups, if you've chosen that option.
2. Removes unused security groups, if you've chosen that option.

You can apply usage audit security group policies to the following resource type:

- Amazon VPC security group

For guidance on creating a usage audit security group policy using the console, see *Creating a usage audit security group policy* (p. 389).

### How Firewall Manager remediates redundant security groups

For security groups to be considered redundant, they must have exactly the same rules set and be in the same Amazon VPC instance. To remediate a redundant security group set, Firewall Manager selects one of the security groups in the set to keep, and then associates it to all resources that are associated with the other security groups in the set. Firewall Manager then disassociates the other security groups from the resources they were associated with, which renders them unused.

**Note**

If you have also chosen to remove unused security groups, Firewall Manager does that next. This can result in the removal of the security groups that are in the redundant set.

### How Firewall Manager remediates unused security groups

For security groups to be considered unused, they must remain unused by any resource for the minimum number of minutes specified in the policy rule. By default, this number is zero. You can specify as many as 525,600 minutes (365 days) in order to allow yourself time to associate new security groups with
resources. Firewall Manager remediates unused security groups by deleting them from your account, according to your rules settings.

**Default account specification**

When you create a usage audit security group policy through the console, Firewall Manager automatically chooses *Exclude the specified accounts and include all others*. The service then puts the Firewall Manager administrator account in the list to exclude. This is the recommended approach, and allows you to manually manage the security groups that belong to the Firewall Manager administrator account.

**Best practices for security group policies**

This section lists recommendations for managing security groups using AWS Firewall Manager.

**Exclude the Firewall Manager administrator account**

When you set the policy scope, exclude the Firewall Manager administrator account. When you create a usage audit security group policy through the console, this is the default option.

**Start with automatic remediation disabled**

For content or usage audit security group policies, start with automatic remediation disabled. Review the policy details information to determine the effects that automatic remediation would have. When you are satisfied that the changes are what you want, edit the policy to enable automatic remediation.

**Avoid conflicts if you also use outside sources to manage security groups**

If you use a tool or service other than Firewall Manager to manage security groups, take care to avoid conflicts between your settings in Firewall Manager and the settings in your outside source. If you use automatic remediation and your settings conflict, you can create a cycle of conflicting remediation that consumes resources on both sides.

For example, say you configure another service to maintain a security group for a set of AWS resources, and you configure a Firewall Manager policy to maintain a different security group for some or all of the same resources. If you configure either side to disallow any other security group to be associated with the in-scope resources, that side will remove the security group association that's maintained by the other side. If both sides are configured in this way, you can end up with a cycle of conflicting disassociations and associations.

Additionally, say that you create a Firewall Manager audit policy to enforce a security group configuration that conflicts with the security group configuration from the other service. Remediation applied by the Firewall Manager audit policy can update or delete that security group, putting it out of compliance for the other service. If the other service is configured to monitor and automatically remediate any problems it finds, it will recreate or update the security group, putting it again out of compliance with the Firewall Manager audit policy. If the Firewall Manager audit policy is configured with automatic remediation, it will again update or delete the outside security group, and so on.

To avoid conflicts like these, create configurations that are mutually exclusive, between Firewall Manager and any outside sources.

You can use tagging to exclude outside security groups from automatic remediation by your Firewall Manager policies. To do this, add one or more tags to the security groups or other resources that are managed by the outside source. Then, when you define the Firewall Manager policy scope, in your resources specification, exclude resources that have the tag or tags that you've added.

Similarly, in your outside tool or service, exclude the security groups that Firewall Manager manages from any management or auditing activities. Either don't import the Firewall Manager resources or use Firewall Manager-specific tagging to exclude them from outside management.
Security group policy limitations

This section lists the limitations for using AWS Firewall Manager security group policies:

- Updating security groups for Amazon EC2 elastic network interfaces that were created using the Fargate service type is not supported. You can, however, update security groups for Amazon ECS elastic network interfaces with the Amazon EC2 service type.
- Firewall Manager doesn't support security groups for Amazon EC2 elastic network interfaces that were created by the Amazon Relational Database Service.
- Updating Amazon ECS elastic network interfaces is possible only for Amazon ECS services that use the rolling update (Amazon ECS) deployment controller. For other Amazon ECS deployment controllers such as CODE_DEPLOY or external controllers, Firewall Manager currently can't update the elastic network interfaces.
- With security groups for Amazon EC2 elastic network interfaces, changes to a security group aren't immediately visible to Firewall Manager. Firewall Manager usually detects changes within several hours, but detection can be delayed as much as six hours.
- Firewall Manager doesn't support updating security groups in elastic network interfaces for Network Load Balancers.
- Firewall Manager doesn't support security group references in common security group policies.

Security group policy use cases

You can use AWS Firewall Manager common security group policies to automate the host firewall configuration for communication between Amazon VPC instances. This section lists standard Amazon VPC architectures and describes how to secure each using Firewall Manager common security group policies. These security group policies can help you apply a unified set of rules to select resources in different accounts and avoid per-account configurations in Amazon Elastic Compute Cloud and Amazon VPC.

With Firewall Manager common security group policies, you can tag just the EC2 elastic network interfaces that you need for communication with instances in another Amazon VPC. The other instances in the same Amazon VPC are then more secure and isolated.

**Use case: Monitoring and controlling requests to Application Load Balancers and Classic Load Balancers**

You can use a Firewall Manager common security group policy to define which requests your in-scope load balancers should serve. You can configure this through the Firewall Manager console. Only requests that comply with the security group’s inbound rules can reach your load balancers, and the load balancers will only distribute requests that meet the outbound rules.

**Use case: Internet-accessible, public Amazon VPC**

You can use a Firewall Manager common security group policy to secure a public Amazon VPC, for example, to allow only inbound port 443. This is the same as only allowing inbound HTTPS traffic for a public VPC. You can tag public resources within the VPC (for example, as “PublicVPC”), and then set the Firewall Manager policy scope to only resources with that tag. Firewall Manager automatically applies the policy to those resources.

**Use case: Public and Private Amazon VPC instances**

You can use the same common security group policy for public resources as recommended in the prior use case for internet-accessible, public Amazon VPC instances. You can use a second common security group policy to limit communication between the public resources and the private ones. Tag the resources in the public and private Amazon VPC instances with something like “PublicPrivate” to apply
the second policy to them. You can use a third policy to define the allowed communication between the private resources and other corporation or private Amazon VPC instances. For this policy, you can use another identifying tag on the private resources.

**Use case: Hub and spoke Amazon VPC instances**

You can use a common security group policy to define communications between the hub Amazon VPC instance and spoke Amazon VPC instances. You can use a second policy to define communication from each spoke Amazon VPC instance to the hub Amazon VPC instance.

**Use case: Default network interface for Amazon EC2 instances**

You can use a common security group policy to allow only standard communications, for example internal SSH and patch/OS update services, and to disallow other insecure communication.

**Use case: Identify resources with open permissions**

You can use an audit security group policy to identify all resources within your organization that have permission to communicate with public IP addresses or that have IP addresses that belong to third-party vendors.

**AWS Network Firewall policies**

You can use AWS Firewall Manager Network Firewall policies to manage AWS Network Firewall firewalls for your Amazon Virtual Private Cloud VPCs across your organization in AWS Organizations. You can apply centrally controlled firewalls to your entire organization or to a select subset of your accounts and VPCs.

Network Firewall provides network traffic filtering protections for the public subnets in your VPCs. Firewall Manager creates and manages your firewalls based on the firewall management type defined by your policy. Firewall Manager provides the following firewall management models:

- **Distributed** - For each account and VPC that’s within policy scope, Firewall Manager creates a Network Firewall firewall and deploys firewall endpoints to VPC subnets, to filter network traffic.
- **Centralized** - Firewall Manager creates a single Network Firewall firewall in a single Amazon VPC.
- **Import existing firewalls** - Firewall Manager imports existing firewalls for management in a single Firewall Manager policy. You can apply additional rules to the imported firewalls managed by your policy to ensure that your firewalls meet your security standards.

**Note**

Firewall Manager Network Firewall policies are Firewall Manager policies that you use to manage Network Firewall protections for your VPCs across your organization. The Network Firewall protections are specified in resources in the Network Firewall service that are called firewall policies.

For information about using Network Firewall, see the [AWS Network Firewall Developer Guide](https://docs.aws.amazon.com/waf/latest/developerguide/what-is-network-firewall.html).

The following sections cover requirements for using Firewall Manager Network Firewall policies and describe how the policies work. For the procedure for creating the policy, see [Creating an AWS Firewall Manager policy for AWS Network Firewall](https://docs.aws.amazon.com/waf/latest/developerguide/creating-network-firewall-policy.html).

**You must enable resource sharing**

A Network Firewall policy shares Network Firewall rule groups across the accounts in your organization. For this to work, you must have resource sharing enabled for AWS Organizations. For information about how to enable resource sharing, see [Resource sharing for Network Firewall and DNS Firewall policies](https://docs.aws.amazon.com/waf/latest/developerguide/enable-resource-sharing.html).
You must have your Network Firewall rule groups defined

When you specify a new Network Firewall policy, you define the firewall policy the same as you do when you're using AWS Network Firewall directly. You specify the stateless rule groups to add, default stateless actions, and stateful rule groups. Your rule groups must already exist in the Firewall Manager administrator account for you to include them in the policy. For information about creating Network Firewall rule groups, see AWS Network Firewall rule groups.

How Firewall Manager creates firewall endpoints

The Firewall management type in your policy determines how Firewall Manager creates firewalls. Your policy can create distributed firewalls, a centralized firewall, or you can import existing firewalls:

- **Distributed** - With the distributed deployment model, Firewall Manager creates endpoints for each VPC that's within policy scope. You can either customize the endpoint location by specifying which Availability Zones to create firewall endpoints in, or Firewall Manager can automatically create endpoints in the Availability Zones with public subnets. If you manually choose the Availability Zones, you have the option to restrict the set of allowed CIDRs per Availability Zone. If you decide to let Firewall Manager automatically create the endpoints, you must also specify whether the service will create a single endpoint or multiple firewall endpoints within your VPCs.
  - For multiple firewall endpoints, Firewall Manager deploys a firewall endpoint in each Availability Zone where you have a subnet with an internet gateway or a Firewall Manager-created firewall endpoint route in the route table. This is the default option for a Network Firewall policy.
  - For a single firewall endpoint, Firewall Manager deploys a firewall endpoint in a single Availability Zone in any subnet that has an internet gateway route. With this option, traffic in other zones needs to cross zone boundaries in order to be filtered by the firewall.

  **Note**
  For both of these options, there must be a subnet associated to a route table that has an IPv4/prefixlist route in it. Firewall Manager does not check for any other resources.

- **Centralized** - With the centralized deployment model, Firewall Manager creates one or more firewall endpoints within an inspection VPC. An inspection VPC is a central VPC where Firewall Manager launches your endpoints. When you use the centralized deployment model, you also specify which Availability Zones to create firewall endpoints in. You can't change the inspection VPC after you create your policy. To use a different inspection VPC, you must create a new policy.

- **Import existing firewalls** - When you import existing firewalls, you choose the firewalls to manage in your policy by adding one or more resource sets to your policy. A resource set is a collection of resources, in this case existing firewalls in Network Firewall, that are managed by an account in your organization. Before you use resource sets in your policy, you must first create a resource set. For information about Firewall Manager resource sets, see Working with resource sets in Firewall Manager (p. 426).

Keep in mind the following considerations when working with imported firewalls:

- If an imported firewall become non-compliant, Firewall Manager will try to automatically resolve the violation, except for under the following circumstances:
  - If there's a mismatch between the Firewall Manager and Network Firewall policy's stateful or stateless default actions.
  - If a rule group in an imported firewall's firewall policy has the same priority as a rule group in the Firewall Manager policy.
  - If an imported firewall uses a firewall policy that's associated with a firewall that's not part of the policy's resource set. This can happen because a firewall can have exactly one firewall policy, but a single firewall policy can be associated with multiple firewalls.
  - If a pre-existing rule group belonging to an imported firewall's firewall policy that is also specified in the Firewall Manager policy is given a different priority.
  - If you enable resource cleanup in the policy, Firewall Manager removes the rule groups which have been in FMS import policy from the firewalls in scope of the resource set.
• Firewalls managed by that are managed by a Firewall Manager import existing firewall management
  type can only be managed by one policy at a time. If the same resource set is added to multiple
  import network firewall policies, the firewalls in the resource set will be managed by the first policy
  the resource set was added to and will be ignored by the second policy.

If you change the list of Availability Zones for policies using distributed or centralized firewall
management, Firewall Manager will try to clean up any endpoints that were created in the past, but that
aren't currently in policy scope. Firewall Manager will remove the endpoint only if there are no route
table routes that reference the out of scope endpoint. If Firewall Manager finds that it is unable to delete
these endpoints, it will mark the firewall subnet as being non-compliant and will continue attempting to
remove the endpoint until such time as it is safe to delete.

**How Firewall Manager manages your firewall subnets**

Firewall subnets are the VPC subnets that Firewall Manager creates for the firewall endpoints that
filter your network traffic. Each firewall endpoint must be deployed in a dedicated VPC subnet. Firewall
Manager creates at least one firewall subnet in each VPC that's within scope of the policy.

For policies that use the distributed deployment model with automatic endpoint configuration, Firewall
Manager only creates firewall subnets in Availability Zones that have a subnet with an internet gateway
route, or a subnet with a route to the firewall endpoints that Firewall Manager created for their policy.
For more information, see [VPCs and subnets](#) in the [Amazon VPC User Guide](#).

For policies that use either the distributed or centralized model where you specify which Availability
Zones Firewall Manager creates the firewall endpoints in, Firewall Manager creates an endpoint in those
specific Availability Zones irrespective of whether there are other resources in the Availability Zone.

When you first define a Network Firewall policy, you specify how Firewall Manager manages the firewall
subnets in each of the VPCs that are in scope. You cannot change this choice later.

For policies that use the distributed deployment model with automatic endpoint configuration, you can
choose between the following options:

- Deploy a firewall subnet for every Availability Zone that has public subnets. This is the default
  behavior. This provides high availability of your traffic filtering protections.

- Deploy a single firewall subnet in one Availability Zone. With this choice, Firewall Manager identifies
  a zone in the VPC that has the most public subnets and creates the firewall subnet there. The single
  firewall endpoint filters all network traffic for the VPC. This can reduce firewall costs, but it isn't highly
  available and it requires traffic from other zones to cross zone boundaries in order to be filtered.

For policies that use distributed deployment model with custom endpoint configuration or the
centralized deployment model, Firewall Manager creates the subnets in the specified Availability Zones
that are within the policy scope.

You can provide VPC CIDR blocks for Firewall Manager to use for the firewall subnets or you can leave
the choice of firewall endpoint addresses up to Firewall Manager to determine.

- If you don't provide CIDR blocks, Firewall Manager queries your VPCs for available IP addresses to use.
- If you provide a list of CIDR blocks, Firewall Manager searches for new subnets only in the CIDR blocks
  that you provide. You must use /28 CIDR blocks. For each firewall subnet that Firewall Manager
  creates, it walks your CIDR block list and uses the first one that it finds that is applicable to the
  Availability Zone and VPC and has available addresses. If Firewall Manager is unable to find open space
  in the VPC (with or without the restriction), the service won't create a firewall in the VPC.

If Firewall Manager can't create a required firewall subnet in an Availability Zone, it marks the subnet
as non-compliant with the policy. While the zone is in this state, traffic for the zone must cross zone
boundaries in order to be filtered by an endpoint in another zone. This is similar to the single firewall subnet scenario.

**How Firewall Manager manages your Network Firewall resources**

When you define the policy in Firewall Manager, you provide the network traffic filtering behavior of a standard AWS Network Firewall firewall policy. You add stateless and stateful Network Firewall rule groups and specify default actions for packets that don't match any stateless rules. For information on working with firewall policies in AWS Network Firewall, see the [AWS Network Firewall firewall policies](https://docs.aws.amazon.com/waf/latest/APIReference/)

For distributed and centralized policies, when you save the Network Firewall policy, Firewall Manager creates a firewall and firewall policy in each VPC that's within scope of the policy. Firewall Manager names these Network Firewall resources by concatenating the following values:

- A fixed string, either FMManagedNetworkFirewall or FMManagedNetworkFirewallPolicy, depending on the resource type.
- Firewall Manager policy name. This is the name you assign when you create the policy.
- Firewall Manager policy ID. This is the AWS resource ID for the Firewall Manager policy.
- Amazon VPC ID. This is the AWS resource ID for the VPC where Firewall Manager creates the firewall and firewall policy.

The following shows an example name for a firewall that's managed by Firewall Manager:

```
FMManagedNetworkFirewallEXAMPLENameEXAMPLEFirewallManagerPolicyIdEXAMPLEVPCId
```

The following shows an example firewall policy name:

```
FMManagedNetworkFirewallPolicyEXAMPLENameEXAMPLEFirewallManagerPolicyIdEXAMPLEVPCId
```

After you create the policy, member accounts in the VPCs can't override your firewall policy settings or your rule groups, but they can add rule groups to the firewall policy that Firewall Manager has created.

**How Firewall Manager manages and monitors VPC route tables for your policy**

**Note**

Route table management isn't currently supported for policies that use the centralized deployment model.

When Firewall Manager creates your firewall endpoints, it also creates the VPC route tables for them. However, Firewall Manager doesn't manage your VPC route tables. You must configure your VPC route tables to direct network traffic to the firewall endpoints that are created by Firewall Manager. Using Amazon VPC ingress routing enhancements, change your routing tables to route traffic through the new firewall endpoints. Your changes must insert the firewall endpoints between the subnets that you want to protect and outside locations. The exact routing that you need to do depends on your architecture and its components.

Currently, Firewall Manager allows monitoring of your VPC route table routes for any traffic destined to the internet gateway, that is bypassing the firewall. Firewall Manager doesn't support other target gateways like NAT gateways.

For information about managing route tables for your VPC, see [Managing route tables for your VPC](https://docs.aws.amazon.com/vpc/latest/userguide/route-tables.html) in the *Amazon Virtual Private Cloud User Guide*. For information about managing your route tables for Network Firewall, see [Route table configurations for AWS Network Firewall](https://docs.aws.amazon.com/waf/latest/APIReference/ROUTE_TABLE.html) in the *AWS Network Firewall Developer Guide*.

When you enable monitoring for a policy, Firewall Manager continuously monitors VPC route configurations and alerts you about traffic that bypasses firewall inspection for that VPC. If a subnet has a firewall endpoint route, Firewall Manager looks for the following routes:
• Routes to send traffic to the Network Firewall endpoint.
• Routes to forward the traffic from the Network Firewall endpoint to the internet gateway.
• Inbound routes from the internet gateway to the Network Firewall endpoint.
• Routes from the firewall subnet.

If a subnet has a Network Firewall route but there's asymmetric routing in Network Firewall and your internet gateway route table, Firewall Manager reports the subnet as non-compliant. Firewall Manager also detects routes to the internet gateway in the firewall route table that Firewall Manager created, as well as the route table for your subnet, and reports them as non-compliant. Additional routes in the Network Firewall subnet route table and your internet gateway route table are also reported as non-compliant. Depending on the violation type, Firewall Manager suggests remediation actions to bring the route configuration into compliance. Firewall Manager doesn't offer suggestions in all cases. For example, if your customer subnet has a firewall endpoint that was created outside of Firewall Manager, Firewall Manager doesn't suggest remediation actions.

By default, Firewall Manager will mark any traffic that crosses the Availability Zone boundary for inspection as being non-compliant. However, if you choose to automatically create a single endpoint in your VPC, Firewall Manager won't mark traffic that crosses the Availability Zone boundary as non-compliant.

For policies that use distributed deployment models with custom endpoint configuration, you can choose whether the traffic crossing the Availability Zone boundary from an Availability Zone without a firewall endpoint is marked as compliant or non-compliant.

**Note**

- Firewall Manager does not suggest remediation actions for non-IPv4 routes, such as IPv6 and prefix list routes.
- Calls made using the `DisassociateRouteTable` API call can take up to 12 hours to detect.
- Firewall Manager creates a Network Firewall route table for a subnet that contains the firewall endpoints. Firewall Manager assumes that this route table contains only valid internet gateway and VPC default routes. Any extra or invalid routes in this route table are considered to be non-compliant.

When you configure your Firewall Manager policy, if you choose **Monitor** mode, Firewall Manager provides resource violation and remediation details about your resources. You can use these suggested remediation actions to fix route issues in your route tables. If you choose **Off** mode, Firewall Manager doesn't monitor your route table content for you. With this option, you manage your VPC route tables for yourself. For more information about these resource violations, see Viewing compliance information for an AWS Firewall Manager policy (p. 427).

**Warning**

If you choose **Monitor** under **AWS Network Firewall route configuration** when creating your policy, you can't turn it off for that policy. However, if you choose **Off**, you can enable it later.

### Configuring logging for an AWS Network Firewall policy

You can enable centralized logging for your Network Firewall policies to get detailed information about traffic within your organization. You can select flow logging to capture network traffic flow, or alert logging to report traffic that matches a rule with the rule action set to DROP or ALERT. For more information about AWS Network Firewall logging, see Logging network traffic from AWS Network Firewall in the AWS Network Firewall Developer Guide.

You send logs from your policy's Network Firewall firewalls to an Amazon S3 bucket. After you enable logging, AWS Network Firewall delivers logs for each configured Network Firewall by updating the
firewall settings to deliver logs to your selected Amazon S3 buckets with the reserved AWS Firewall Manager prefix, `<policy-name>-<policy-id>`.

**Note**
This prefix is used by Firewall Manager to determine whether a logging configuration was added by Firewall Manager, or whether it was added by the account owner. If the account owner attempts to use the reserved prefix for their own custom logging, it is overwritten by the logging configuration in the Firewall Manager policy.

For more information about how to create an Amazon S3 bucket and review the stored logs, see What is Amazon S3? in the Amazon Simple Storage Service User Guide.

To enable logging you must meet the following requirements:

- The Amazon S3 that you specify in your Firewall Manager policy must exist.
- You must have the following permissions:
  - logs:CreateLogDelivery
  - s3:GetBucketPolicy
  - s3:PutBucketPolicy
- If the Amazon S3 bucket that's your logging destination uses server-side encryption with keys that are stored in AWS Key Management Service, you must add the following policy to your AWS KMS customer-managed key to allow Firewall Manager to log to your CloudWatch Logs log group:

```json
{
   "Effect": "Allow",
   "Principal": {
      "Service": "delivery.logs.amazonaws.com"
   },
   "Action": [
      "kms:Encrypt*",
      "kms:Decrypt*",
      "kms:ReEncrypt*",
      "kms:GenerateDataKey*",
      "kms:Describe*"
   ],
   "Resource": "*"
}
```

Note that only buckets in the Firewall Manager administrator account may be used for AWS Network Firewall central logging.

When you enable centralized logging on a Network Firewall policy, Firewall Manager takes these actions on your account:

- Firewall Manager updates the permissions on selected S3 buckets to allow for log delivery.
- Firewall Manager creates directories in the S3 bucket for each member account in the scope of the policy. The logs for each account can be found at `<bucket-name>/<policy-name>-<policy-id>/AWSLogs/<account-id>`.

**To enable logging for a Network Firewall policy**

1. Create an Amazon S3 bucket using your Firewall Manager administrator account. For more information, see Creating a bucket in the Amazon Simple Storage Service User Guide.
2. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.
DNS Firewall policies

3. In the navigation pane, choose Security Policies.
4. Choose the Network Firewall policy that you want to enable logging for. For more information about AWS Network Firewall logging, see Logging network traffic from AWS Network Firewall in the AWS Network Firewall Developer Guide.
5. On the Policy details tab, in the Policy rules section, choose Edit.
6. To enable and aggregate logs, choose one or more options under Logging configuration:
   - Enable and aggregate flow logs
   - Enable and aggregate alert logs
7. Choose the Amazon S3 bucket where you want your logs to be delivered. You must choose a bucket for each log type that you enable. You can use the same bucket for both log types.
8. (Optional) If you want custom member account-created logging to be replaced with the policy’s logging configuration, choose Override existing logging configuration.
9. Choose Next.
10. Review your settings, then choose Save to save your changes to the policy.

To disable logging for a Network Firewall policy
1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.
   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).
2. In the navigation pane, choose Security Policies.
3. Choose the Network Firewall policy that you want to disable logging for.
4. On the Policy details tab, in the Policy rules section, choose Edit.
5. Under Logging configuration status, deselect Enable and aggregate flow logs and Enable and aggregate alert logs if they are selected.
6. Choose Next.
7. Review your settings, then choose Save to save your changes to the policy.

Amazon Route 53 Resolver DNS Firewall policies

You can use AWS Firewall Manager DNS Firewall policies to manage associations between Amazon Route 53 Resolver DNS Firewall rule groups and your Amazon Virtual Private Cloud VPCs across your organization in AWS Organizations. You can apply centrally controlled rule groups to your entire organization, or to a select subset of your accounts and VPCs.

DNS Firewall provides filtering and regulation of outbound DNS traffic for your VPCs. You create reusable collections of filtering rules in DNS Firewall rule groups and you associate the rule groups to your VPCs. When you apply the Firewall Manager policy, for each account and VPC that's within policy scope, Firewall Manager creates an association between each DNS Firewall rule group in the policy and each VPC that's within scope of the policy, using the association priority settings that you specify in the Firewall Manager policy.

For information about using DNS Firewall, see Amazon Route 53 Resolver DNS Firewall in the Amazon Route 53 Developer Guide.
The following sections cover requirements for using Firewall Manager DNS Firewall policies and describe how the policies work. For the procedure for creating the policy, see Creating an AWS Firewall Manager policy for Amazon Route 53 Resolver DNS Firewall (p. 394).

You must enable resource sharing

A DNS Firewall policy shares DNS Firewall rule groups across the accounts in your organization. For this to work, you must have resource sharing enabled with AWS Organizations. For information about how to enable resource sharing, see Resource sharing for Network Firewall and DNS Firewall policies (p. 424).

You must have your DNS Firewall rule groups defined

When you specify a new DNS Firewall policy, you define the rule groups the same as you do when you're using Amazon Route 53 Resolver DNS Firewall directly. Your rule groups must already exist in the Firewall Manager administrator account for you to include them in the policy. For information about creating DNS Firewall rule groups, see DNS Firewall rule groups and rules.

You define the lowest and highest priority rule group associations

The DNS Firewall rule group associations that you manage through Firewall Manager DNS Firewall policies contain the lowest priority associations and the highest priority associations for your VPCs. In your policy configuration, these appear as first and last rule groups.

DNS Firewall filters DNS traffic for the VPC in the following order:

1. First rule groups, defined by you in the Firewall Manager DNS Firewall policy. Valid values are between 1 and 99.
2. DNS Firewall rule groups that are associated by individual account managers through DNS Firewall.
3. Last rule groups, defined by you in the Firewall Manager DNS Firewall policy. Valid values are between 9901 and 10000.

How Firewall Manager names the rule group associations that it creates

When you save the DNS Firewall policy, if you enabled autoremediation, Firewall Manager creates a DNS Firewall association between the rule groups that you provided in the policy and the VPCs that are in scope of the policy. Firewall Manager names these associations by concatenating the following values:

- The fixed string, FMManaged_.
- The Firewall Manager policy ID. This is the AWS resource ID for the Firewall Manager policy.

The following shows an example name for a firewall that's managed by Firewall Manager:

```
FMManaged_EXAMPLEDNSFirewallPolicyId
```

After you create the policy, if account owners in the VPCs override your firewall policy settings or your rule group associations then Firewall Manager will mark the policy as non-compliant and try to propose a remedial action. Account owners can associate other DNS Firewall rule groups to the VPCs that are in scope of the DNS Firewall policy. Any associations that are created by the individual account owners must have priority settings between your first and last rule group associations.

**Palo Alto Networks Cloud NGFW policies**

The Palo Alto Networks Cloud Next Generation Firewall (NGFW) is a third-party firewall service that you can use for your AWS Firewall Manager policies. With Palo Alto Networks Cloud NGFW for Firewall Manager, you can create and centrally deploy Palo Alto Networks Cloud NGFW resources and rulestacks across all of your AWS accounts.
To use Palo Alto Networks Cloud NGFW with Firewall Manager, you first subscribe to the Palo Alto Networks Cloud NGFW Pay-As-You-Go service in the AWS Marketplace. After subscribing, you perform a series of steps in the Palo Alto Networks Cloud NGFW service to configure your account and Cloud NGFW settings. Then, you create a Firewall Manager Cloud FMS policy to centrally deploy and manage Palo Alto Networks Cloud NGFW resources and rules across all of the accounts in your AWS Organizations.

For the procedure for creating the Firewall Manager policy, see Creating an AWS Firewall Manager policy for Palo Alto Networks Palo Alto Networks Cloud NGFW (p. 395). For information about how to configure and manage Palo Alto Networks Cloud NGFW for Firewall Manager, see the Palo Alto Networks Palo Alto Networks Cloud NGFW on AWS documentation.

Fortigate Cloud Native Firewall (CNF) as a Service policies

Fortigate Cloud Native Firewall (CNF) as a Service is a third-party firewall service that you can use for your AWS Firewall Manager policies. Fortigate CNF is a next generation firewall service that makes it easy for you to protect your cloud networks and manage your security policies. With Fortigate CNF for Firewall Manager, you can create and centrally deploy Fortigate CNF resources and policy sets across all of your AWS accounts.

To use Fortigate CNF with Firewall Manager, you first subscribe to the Fortigate Cloud Native Firewall (CNF) as a Service in the AWS Marketplace. After subscribing, you perform a series of steps in the Fortigate CNF service to configure your global policy sets and other settings. Then, you create a Firewall Manager policy to centrally deploy and manage Fortigate CNF resources across all of the accounts in your AWS Organizations.

For the procedure for creating a Fortigate CNF Firewall Manager policy, see Creating an AWS Firewall Manager policy for Fortigate Cloud Native Firewall (CNF) as a Service (p. 397). For information about how to configure and manage Fortigate CNF for use with Firewall Manager, see the Fortigate CNF documentation.

Resource sharing for Network Firewall and DNS Firewall policies

To manage Firewall Manager Network Firewall and DNS Firewall policies, you must enable resource sharing with AWS Organizations in AWS Resource Access Manager. This allows Firewall Manager to deploy protections across your accounts when you create these policy types.

To enable resource sharing, follow the instructions at Enable Sharing with AWS Organizations in the AWS Resource Access Manager User Guide.

Problems with resource sharing

You might encounter problems with resource sharing, either when you use AWS RAM to enable it, or when you're working on Firewall Manager policies that require it.

Examples of these problems include the following:

- When you follow the instructions to enable sharing, in the AWS RAM console, the choice Enable sharing with AWS Organizations is grayed out and not available for selection.
- When you work in Firewall Manager on a policy that requires resource sharing, the policy is marked as non-compliant and you see messages indicating that resource sharing or AWS RAM isn't enabled.

If you encounter problems with resource sharing, use the following procedure to try to enable it.
Try again to enable resource sharing

• Try again to enable sharing using one of the following options:

  • (Option) Through the AWS RAM console, follow the instructions at Enable Sharing with AWS Organizations in the AWS Resource Access Manager User Guide.
  • (Option) Using the AWS RAM API, call EnableSharingWithAwsOrganization. See the documentation at EnableSharingWithAwsOrganization.
Working with resource sets in Firewall Manager

An AWS Firewall Manager resource set is a collection of resources, such as firewalls, that you can group together and manage in a Firewall Manager policy. Resource sets enable members in your organization to have granular control over what resources to manage in a policy. To use resource sets, create a resource set in the console or using the `PutResourceSet` API, then add the resource set to your Firewall Manager policy.

You can create and manage resource sets for the following resource and security policy types:

<table>
<thead>
<tr>
<th>Resource type</th>
<th>Firewall Manager security policy type</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Network Firewall - firewalls</td>
<td>Network Firewall policy - Use resource sets to import existing firewalls from Network Firewall. For information about using resource sets in a Network Firewall policy, see the <em>Importing existing firewalls</em> (p. 417) step in the <em>Creating an AWS Firewall Manager policy for AWS Network Firewall</em> (p. 391) procedure.</td>
</tr>
</tbody>
</table>

The following sections cover requirements for creating and deleting resource sets.

**Topics**
- Considerations when working with resource sets in Firewall Manager (p. 426)
- Creating resource sets (p. 427)
- Deleting a resource set (p. 427)

**Considerations when working with resource sets in Firewall Manager**

Note the following considerations when working with resource sets:

**References to non-existent resources**

When you add a resource to a resource set, you create a reference to the resource using an Amazon Resource Name (ARN). Firewall Manager validates that Amazon Resource Name (ARN) is the correct format, but Firewall Manager doesn't check that the referenced resource exists. If the resource doesn't exist yet passes ARN validation, Firewall Manager includes the resource reference in the resource set. If a new resource with the same ARN is later created, Firewall Manager applies rule groups from the resource set's associated policy to the new resource.

**Deleted resources**

When a resource in a resource set is deleted, the reference to the resource remains in the resource set until it's removed by the Firewall Manager administrator.

**Resources owned by member account that leaves the AWS Organizations organization**

If a member account leaves the organization, any references to resources owned by that member account will remain in the resource set but will no longer be managed by any policies the resource set is associated with.

**Association to multiple policies**
Creating resource sets

Creating resource sets

To create a resource set (console)

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.
   
   Note
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).
2. In the navigation pane, choose Resource sets.
3. Choose Create resource set.
4. For Resource set name, enter a descriptive name.
5. (Optional) enter a Description for the resource set.
6. Choose Next.
7. For Choose resources, select an AWS account ID then select Choose resources to add resources owned and managed by this account to the resource set. After you select the resources, select Add to add the resources to the resource set.
8. Choose Next.
9. For Resource set tags, add any identifying tags that you want for the resource set. For more information about tags, see Working with Tag Editor.
10. Choose Next.
11. Review the new resource set. To make any changes, choose Edit in the area that you want to change. This returns you to the corresponding step in the creation wizard. When you are satisfied with the resource set, choose Create resource set.

Deleting a resource set

Before you can delete a resource set, the resource set must be disassociated from all policies using the resource set. You can disassociate resource groups in the policy detail page using the console, or with the PutPolicy API.

To delete a resource set (console)

1. In the navigation pane, choose Resource sets.
2. Choose the option next to the resource set that you want to delete.
3. Choose Delete.

Viewing compliance information for an AWS Firewall Manager policy

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, and HIPAA.

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.
You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.

- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

  **Note**
  Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.

- **Evaluating Resources with Rules** in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.

- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

- **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

For all AWS Firewall Manager policies, you can view the compliance status for accounts and resources that are in scope of the policy. An account or resource is in compliance with a Firewall Manager policy if the settings in the policy are reflected in the settings for the account or resource. Each policy type has its own compliance requirements, which you can tune when you define the policy. For some policies, you can also view detailed violation information for in scope resources, to help you to better understand and manage your security risk.

**To view the compliance information for a policy**

1. Sign in to the AWS Management Console using your Firewall Manager administrator account, and then open the Firewall Manager console at https://console.aws.amazon.com/wafv2/fmsv2.

   **Note**
   For information about setting up a Firewall Manager administrator account, see AWS Firewall Manager prerequisites (p. 358).

2. In the navigation pane, choose Security policies.

3. Choose a policy. In the Accounts and resources tab of the policy page, Firewall Manager lists the accounts in your organization, grouped by those that are within scope of the policy and those that are outside of scope.

   The Accounts within policy scope pane lists the compliance status for each account. A Compliant status indicates that the policy has successfully been applied to all of in-scope resources for the account. A Noncompliant status indicates that the policy hasn't been applied to one or more of the in-scope resources for the account.

4. Choose an account that's noncompliant. In the account page, Firewall Manager lists the ID and type for each noncompliant resource and the reason that the resource is in violation of the policy.
5. If the Firewall Manager policy type is a content audit security group policy, you can access detailed violation information for a resource.

To view violation details, choose the resource.

**Note**
Resources that Firewall Manager found to be noncompliant before the addition of the detailed resource violation page might not have violation details.

In the resource page, Firewall Manager lists specific details about the violation, according to resource type.

- **AWS::EC2::NetworkInterface (ENI)** – Firewall Manager displays information about the security group that the resource doesn't comply with. Choose the security group to see more detail about it.

- **AWS::EC2::Instance** – Firewall Manager displays the ENI attached to the EC2 instance that's noncompliant. It also displays information about the security group that the resources don't comply with. Choose the security group to see more detail about it.

- **AWS::EC2::SecurityGroup** – Firewall Manager displays the following violation details:
  - **Noncompliant security group rule** – The rule that's in violation, including its protocol, port range, IP CIDR range, and description.
  - **Referenced rule** – The audit security group rule that the noncompliant security group rule violates, with its details.
  - **Violation reasons** – Explanation of the noncompliance finding.
  - **Remediation action** – Suggested action to take. If Firewall Manager can't determine a safe remediation action, this field is blank.

- **AWS::EC2::Subnet** – This is used for Network Firewall policies. Firewall Manager displays the subnet ID, VPC ID, and Availability Zone. If applicable, Firewall Manager includes additional information about the violation, for example the reason the violation occurred, or the ID of the route table a subnet should be associated with. The violation description component contains a description of the expected state of the resource, the current, noncompliant state, and if available, a description of what caused the discrepancy.

For example, the expected state of a subnet might be “Subnet should contain a AWS Network Firewall subnet in its availability zone”, the current state might be “subnet with id subnet-1234 is missing a Network Firewall subnet in availability zone us-east-1e”, and the description might be “Firewall Manager was unable to create a subnet in this AZ because there are no available CIDR blocks.”

- **Route management violations** – For Network Firewall policies that use Monitor mode, Firewall Manager displays basic subnet information, as well as expected and actual routes in the subnet, internet gateway, and Network Firewall subnet route table. Firewall Manager alerts you that there's a violation if the actual routes don't match the expected routes in the route table.

- **Remediation actions for route management violations** – For Network Firewall policies that use Monitor mode, Firewall Manager suggests possible remediation actions on route configurations that have violations.

**Example – Route management violation and remediation suggestions**

A subnet is expected to send traffic through the firewall endpoints, but the current subnet is sending traffic directly to the internet gateway. This is a route management violation. The suggested remediation in this case might be a list of ordered actions. The first being a
recommendation to add the required routes to the Network Firewall subnet's route table to direct outgoing traffic to the internet gateway and to direct incoming traffic for destinations inside the VPC to `local`. The second recommendation is to replace the internet gateway route or the invalid Network Firewall route in the subnet's route table to direct outgoing traffic to the firewall endpoints. The third recommendation is to add required routes to the internet gateway's route table to direct incoming traffic to the firewall endpoints.

- **AWS::EC2::InternetGateway** – This is used for Network Firewall policies that have Monitor mode enabled.
- **Route management violations** – The internet gateway is noncompliant if the internet gateway is not associated with a route table, or if there is an invalid route in the internet gateway route table.
- **Remediation actions for route management violations** – Firewall Manager suggests possible remediation actions to remedy route management violations.

**Example 1 – Route management violation and remediation suggestions**

An internet gateway is not associated with a route table. The suggested remediation actions might be a list of ordered actions. The first action is to create a route table. The second action is to associate the route table with the internet gateway. The third action is to add the required route to the internet gateway route table.

**Example 2 – Route management violation and remediation suggestions**

The internet gateway is associated with a valid route table, but the route is configured improperly. The suggested remediation might be a list of ordered actions. The first suggestion is to remove the invalid route. The second is to add the required route to the internet gateway route table.

- **AWS::NetworkFirewall::FirewallPolicy** – This is used for Network Firewall policies. Firewall Manager displays information about a Network Firewall firewall policy that's been modified in a way that makes it noncompliant. The information provides the expected firewall policy and the policy that it found in the customer account, so you can compare stateless and stateful rule groups names and priority settings, custom action names, and default stateless actions settings. The violation description component contains a description of the expected state of the resource, the current, noncompliant state, and if available, a description of what caused the discrepancy.

- **AWS::EC2::VPC** – This is used for DNS Firewall policies. Firewall Manager displays information about a VPC that's in scope of a Firewall Manager DNS Firewall policy, and that is noncompliant with the policy. The information provided includes the expected rule groups that are expected to be associated with the VPC and the actual rule groups. The violation description component contains a description of the expected state of the resource, the current, noncompliant state, and if available, a description of what caused the discrepancy.

---

**AWS Firewall Manager findings**

AWS Firewall Manager creates findings for resources that are out of compliance and for attacks that it detects and sends them to AWS Security Hub. For information about Security Hub findings, see [Findings in AWS Security Hub](https://docs.aws.amazon.com/autoscaling指挥中心/latest/userguide/finding.html).

**How do I view my Firewall Manager findings?**

To view your Firewall Manager findings in Security Hub, follow the guidance at [Working with Findings in Security Hub](https://docs.aws.amazon.com/securityhub/latest/userguide/working-with-findings.html) and create a filter using the following settings:
AWS WAF policy findings

You can use Firewall Manager AWS WAF policies to apply AWS WAF rule groups to your resources in AWS Organizations. For more information, see Working with AWS Firewall Manager policies (p. 379).

Resource is missing Firewall Manager managed web ACL.

An AWS resource doesn’t have the AWS Firewall Manager managed web ACL association in accordance with the Firewall Manager policy. You can enable Firewall Manager remediation on the policy to correct this.

- Severity – 80
- Status settings – PASSED/FAILED
- Updates – If Firewall Manager performs the remediation action, it will update the finding and the severity will lower from HIGH to INFORMATIONAL. If you perform the remediation, Firewall Manager will not update the finding.

Firewall Manager managed web ACL has misconfigured rule groups.

The rule groups in a web ACL that’s managed by Firewall Manager are not configured correctly, according to the Firewall Manager policy. This means that the web ACL is missing the rule groups that the policy requires. You can enable Firewall Manager remediation on the policy to correct this.

- Severity – 80
- Status settings – PASSED/FAILED
- Updates – If Firewall Manager performs the remediation action, it will update the finding and the severity will lower from HIGH to INFORMATIONAL. If you perform the remediation, Firewall Manager will not update the finding.

AWS Shield Advanced policy findings

For information about AWS Shield Advanced policies, see Security group policies (p. 410).
Resource lacks Shield Advanced protection.

An AWS resource that should have Shield Advanced protection, according to the Firewall Manager policy, doesn't have it. You can enable Firewall Manager remediation on the policy, which will enable the protection for the resource.

- Severity – 60
- Status settings – PASSED/FAILED
- Updates – If Firewall Manager performs the remediation action, it will update the finding and the severity will lower from HIGH to INFORMATIONAL. If you perform the remediation, Firewall Manager will not update the finding.

Shield Advanced detected attack against monitored resource.

Shield Advanced detected an attack on a protected AWS resource. You can enable Firewall Manager remediation on the policy.

- Severity – 70
- Status settings – None
- Updates – Firewall Manager does not update this finding.

Security group common policy findings

For information about security group common policies, see Security group policies (p. 410).

Resource has misconfigured security group.

Firewall Manager has identified a resource that is missing the Firewall Manager managed security group associations that it should have, according to the Firewall Manager policy. You can enable Firewall Manager remediation on the policy, which creates the associations according to the policy settings.

- Severity – 70
- Status settings – PASSED/FAILED
- Updates – Firewall Manager updates this finding.

Firewall Manager replica security group is out of sync with primary security group.

A Firewall Manager replica security group is out of sync with its primary security group, according to their common security group policy. You can enable Firewall Manager remediation on the policy, which syncs the replica security groups with the primary.

- Severity – 80
- Status settings – PASSED/FAILED
- Updates – Firewall Manager updates this finding.

Security group content audit policy findings

For information about security group content audit policies, see Security group policies (p. 410).

Security group is not in compliance with content audit security group.

A Firewall Manager security group content audit policy has identified a noncompliant security group. This is a customer-created security group that's in scope of the content audit policy and that doesn't comply
with the settings defined by the policy and its audit security group. You can enable Firewall Manager remediation on the policy, which modifies the noncompliant security group to bring it into compliance.

- Severity – 70
- Status settings – PASSED/FAILED
- Updates – Firewall Manager updates this finding.

**Security group usage audit policy findings**

For information about security group usage audit policies, see Security group policies (p. 410).

**Firewall Manager found redundant security group.**

The Firewall Manager security group usage audit has identified a redundant security group. This is a security group with an identical rules set as another security group within the same Amazon Virtual Private Cloud instance. You can enable Firewall Manager automatic remediation on the usage audit policy, which replaces redundant security groups and with a single security group.

- Severity – 30
- Status settings – None
- Updates – Firewall Manager does not update this finding.

**Firewall Manager found unused security group.**

The Firewall Manager security group usage audit has identified an unused security group. This is a security group that’s not referenced by any Firewall Manager common security group policy. You can enable Firewall Manager automatic remediation on the usage audit policy, which removes unused security groups.

- Severity – 30
- Status settings – None
- Updates – Firewall Manager does not update this finding.

**Amazon Route 53 Resolver DNS Firewall policy findings**

For information about DNS Firewall policies, see Amazon Route 53 Resolver DNS Firewall policies (p. 422).

**Resource is missing DNS Firewall protection**

A VPC is missing a DNS Firewall rule group association that’s defined in the Firewall Manager DNS Firewall policy. The finding lists the rule group that’s specified by the policy.

- Severity – 80

**Security in AWS Firewall Manager**

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.
Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to Firewall Manager, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Firewall Manager. The following topics show you how to configure Firewall Manager to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Firewall Manager resources.

**Topics**

- Data protection in Firewall Manager (p. 434)
- Identity and access management in AWS Firewall Manager (p. 435)
- Logging and monitoring in Firewall Manager (p. 455)
- Compliance validation for Firewall Manager (p. 456)
- Resilience in Firewall Manager (p. 456)
- Infrastructure security in AWS Firewall Manager (p. 456)

**Data protection in Firewall Manager**

The AWS shared responsibility model applies to data protection in AWS Firewall Manager. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers’ email addresses, into tags or free-form fields such as a Name field. This includes when you work with Firewall Manager or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any
data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Firewall Manager entities—such as policies—are encrypted at rest, except in certain Regions where encryption is not available, including China (Beijing) and China (Ningxia). Unique encryption keys are used for each Region.

Identity and access management in AWS Firewall Manager

Access to AWS Firewall Manager requires credentials. Those credentials must have permissions to access AWS Firewall Manager resources, like policies. The following sections provide details on how you can use AWS Identity and Access Management (IAM) and Firewall Manager to help secure access to your resources.

- Authentication (p. 435)
- Access control (p. 436)

Authentication

You can access AWS as any of the following types of identities:

- **AWS account root user** – When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the AWS Account Management Reference Guide.

- **IAM user** – An IAM user is an identity within your AWS account that has specific custom permissions (for example, permissions to create a rule in Firewall Manager). You can use an IAM user name and password to sign in to secure AWS webpages like the AWS Management Console, AWS Discussion Forums, or the AWS Support Center.

In addition to a user name and password, you can also generate access keys for each user. You can use these keys when you access AWS services programmatically, either through one of the several SDKs or by using the AWS Command Line Interface (CLI). The SDK and CLI tools use the access keys to cryptographically sign your request. If you don't use AWS tools, you must sign the request yourself. Firewall Manager supports Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 Signing Process in the AWS General Reference.

- **IAM role** – An IAM role is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user in that it is an AWS identity with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. IAM roles with temporary credentials are useful in the following situations:
• **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see *Creating a role for a third-party Identity Provider* in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see *Permission sets* in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.

• **AWS service access** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see *Creating a role to delegate permissions to an AWS service* in the IAM User Guide.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see *Using an IAM role to grant permissions to applications running on Amazon EC2 instances* in the IAM User Guide.

**Access control**

You can have valid credentials to authenticate your requests, but unless you have permissions you can't create or access AWS Firewall Manager resources. For example, you must have permissions to create a Firewall Manager policy.

The following sections describe how to manage permissions for AWS Firewall Manager. We recommend that you read the overview first.

- Overview of managing access permissions to your AWS Firewall Manager resources (p. 437)
- Using identity-based policies (IAM policies) for AWS Firewall Manager (p. 440)
- Firewall Manager required permissions for API actions (p. 451)

**AWS Identity and Access Management**

Firewall Manager integrates with AWS Identity and Access Management (IAM), a service that lets your organization do the following:

- Create users and groups under your organization's AWS account
- Share your AWS account resources with users in the account
- Assign unique security credentials to each user
- Control user access to services and resources

For example, you can use IAM with Firewall Manager to control which users in your AWS account can create a new policy.

For general information about IAM, see the following documentation:

- AWS Identity and Access Management (IAM)
- IAM Getting Started Guide
Overview of managing access permissions to your AWS Firewall Manager resources

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles). Some services also support attaching permissions policies to resources.

**Note**
An account administrator (or administrator user) is a user with administrator privileges. For more information, see IAM Best Practices in the IAM User Guide.

When granting permissions, you decide who is getting the permissions, the resources they get permissions for, and the specific operations that you want to allow on those resources.

**Topics**

- AWS Firewall Manager resources and operations (p. 437)
- Understanding resource ownership (p. 438)
- Managing access to resources (p. 438)
- Specifying policy elements: Actions, effects, resources, and principals (p. 439)
- Specifying conditions in a policy (p. 440)

AWS Firewall Manager resources and operations

In AWS Firewall Manager, the resources are policy, applications list, and protocols list. The Amazon Resource Name (ARN) for Firewall Manager resources has the following format:

```
arn:aws:fms:region:account:resource/ID
```

The following table lists the format for each resource.

<table>
<thead>
<tr>
<th>Name in AWS Firewall Manager Console</th>
<th>Name in AWS Firewall Manager SDK/CLI</th>
<th>ARN Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applications list</td>
<td>AppsList</td>
<td>arn:aws:fms:region:account:applications-list/ID</td>
</tr>
</tbody>
</table>

To allow or deny access to a subset of Firewall Manager resources, include the ARNs of the resources in the resource element of your policy. Replace the account, resource, and ID variables with valid values. Valid values can be the following:

- **account**: The ID of your AWS account. You must specify a value.
• **resource**: The type of Firewall Manager resource.
• **ID**: The ID of the Firewall Manager resource, or a wildcard (*) to indicate all resources of the specified type that are associated with the specified AWS account.

For example, the following ARN specifies all policies for the account 111122223333 in Region us-east-1:

```
arn:aws:fms:us-east-1:111122223333:policy/*
```

For more information, see Resources in the IAM User Guide.

AWS Firewall Manager provides a set of operations to work with Firewall Manager resources. For a list of available operations, see Actions.

### Understanding resource ownership

A **resource owner** is the AWS account that creates the resource. That is, the resource owner is the AWS account of the principal entity (the root account, an IAM user, or an IAM role) that authenticates the request that creates the resource. The following examples illustrate how this works:

- If you use the root account credentials of your AWS account to create a Firewall Manager resource, your AWS account is the owner of the resource.
- If you create an IAM user in your AWS account and grant permissions to create a Firewall Manager resource to that user, the user can create a Firewall Manager resource. However, your AWS account, to which the user belongs, owns the Firewall Manager resource.
- If you create an IAM role in your AWS account with permissions to create a Firewall Manager resource, anyone who can assume the role can create a Firewall Manager resource. Your AWS account, to which the role belongs, owns the Firewall Manager resource.

### Managing access to resources

A **permissions policy** describes who has access to what. The following sections explain the available options for creating permissions policies.

**Note**
These sections discuss using IAM in the context of AWS Firewall Manager. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the IAM User Guide. For information about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

Policies that are attached to an IAM identity are known as identity-based policies, and policies that are attached to a resource are known as resource-based policies. AWS Firewall Manager supports only identity-based policies.

**Topics**

- Identity-based policies (IAM policies) (p. 438)
- Resource-based policies (p. 439)

### Identity-based policies (IAM policies)

You can attach policies to IAM identities. For example, you can do the following:

- **Attach a permissions policy to a user or a group in your account** – An account administrator can use a permissions policy that is associated with a particular user to grant permissions for that user to create a Firewall Manager resource.
• **Attach a permissions policy to a role (grant cross-account permissions)** – You can attach an identity-based permissions policy to an IAM role to grant cross-account permissions. For example, the administrator in Account A can create a role to grant cross-account permissions to another AWS account (for example, Account B) or an AWS service as follows:

1. Account A administrator creates an IAM role and attaches a permissions policy to the role that grants permissions on resources in Account A.
2. Account A administrator attaches a trust policy to the role identifying Account B as the principal who can assume the role.
3. Account B administrator can then delegate permissions to assume the role to any users in Account B. Doing this allows users in Account B to create or access resources in Account A. The principal in the trust policy also can be an AWS service principal if you want to grant an AWS service permissions to assume the role.

For more information about using IAM to delegate permissions, see Access Management in the IAM User Guide.

The following is an example policy that grants permissions for the `fms:GetPolicy` action on all policies in two specific regions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Deny",
            "Action": "fms:GetPolicy",
            "Resource": [
                "arn:aws:fms:us-east-1:*:policy/*",
                "arn:aws:fms:us-west-2:*:policy/*"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/stage": "prod"
                }
            }
        }
    ]
}
```

For more information about using identity-based policies with Firewall Manager, see Using identity-based policies (IAM policies) for AWS Firewall Manager (p. 440). For more information about users, groups, roles, and permissions, see Identities (Users, Groups, and Roles) in the IAM User Guide.

**Resource-based policies**

Other services, such as Amazon S3, also support resource-based permissions policies. For example, you can attach a policy to an S3 bucket to manage access permissions to that bucket. AWS Firewall Manager doesn't support resource-based policies.

**Specifying policy elements: Actions, effects, resources, and principals**

For each AWS Firewall Manager resource (see AWS Firewall Manager resources and operations (p. 437)), the service defines a set of API operations (see Firewall Manager required permissions for API actions (p. 451)). To grant permissions for these API operations, Firewall Manager defines a set of actions that you can specify in a policy. Note that performing an API operation can require permissions for more than one action. When granting permissions for specific actions, you also identify the resource on which the actions are allowed or denied.

The following are the most basic policy elements:
• **Resource** – In a policy, you use an Amazon Resource Name (ARN) to identify the resource to which the policy applies. For more information, see AWS Firewall Manager resources and operations (p. 437).

• **Action** – You use action keywords to identify resource operations that you want to allow or deny. For example, the `fms:CreatePolicy` permission, coupled with the `wafv2:ListRuleGroups` permission, allows the user permissions to perform the AWS Firewall Manager CreatePolicy operation.

• **Effect** – You specify the effect when the user requests the specific action. This can be either allow or deny. If you don't explicitly grant access to a resource, access is implicitly denied. You also can explicitly deny access to a resource, which you might do to make sure that a user cannot access it, even if a different policy grants access.

• **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. AWS Firewall Manager doesn't support resource-based policies.

To learn more about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

For a table that shows all the AWS Firewall Manager API actions and the resources that they apply to, see Firewall Manager required permissions for API actions (p. 451).

### Specifying conditions in a policy

When you grant permissions, you can use the IAM policy language to specify the conditions when a policy should take effect. For example, you might want a policy to be applied only after a specific date. For more information about specifying conditions in a policy language, see Condition in the IAM User Guide.

To express conditions, you use predefined condition keys. There are no condition keys specific to Firewall Manager. However, there are general AWS condition keys that you can use as appropriate. For a complete list of AWS keys, see Available Keys for Conditions in the IAM User Guide.

### Using identity-based policies (IAM policies) for AWS Firewall Manager

This section provides examples of identity-based policies that demonstrate how an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on AWS Firewall Manager resources.

**Important**

We recommend that you first review the introductory topics that explain the basic concepts and options available for you to manage access to your AWS Firewall Manager resources. For more information, see Overview of managing access permissions to your AWS Firewall Manager resources (p. 437).

For a table that shows all the AWS Firewall Manager API actions and the resources that they apply to, see Firewall Manager required permissions for API actions (p. 451).

### Topics

- Permissions required to use the AWS Firewall Manager console (p. 440)
- Customer managed policy examples (p. 443)

### Permissions required to use the AWS Firewall Manager console

The AWS Firewall Manager console provides an integrated environment for you to create and manage Firewall Manager resources. The console provides many features and workflows that often require permissions to create a Firewall Manager resource in addition to the API-specific permissions.
that are documented in the Firewall Manager required permissions for API actions (p. 451). For more information about these additional console permissions, see Customer managed policy examples (p. 443).

Granting full access to AWS Firewall Manager resources

Follow this guidance if you have difficulty creating or managing your Firewall Manager policies with the managed policy, AWSFMAdminFullAccess. For information about working with managed policies for AWS Firewall Manager, see ?? (p. 444).

This policy doesn't include permissions for setting up Amazon Simple Notification Service notifications in AWS Firewall Manager. For information about how to setting up access for Amazon Simple Notification Service, see Setting up access for Amazon Simple Notification Service.

Use the following policy to grant full administrative access to your account:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "fms:*",
        "waf:*",
        "waf-regional:*",
        "elasticloadbalancing:SetWebACL",
        "firehose:ListDeliveryStreams",
        "organizations:DescribeAccount",
        "organizations:DescribeOrganization",
        "organizations:ListRoots",
        "organizations:ListChildren",
        "organizations:ListAccounts",
        "organizations:ListAccountsForParent",
        "organizations:ListOrganizationalUnitsForParent",
        "shield:GetSubscriptionState",
        "route53resolver:ListFirewallRuleGroups",
        "route53resolver:GetFirewallRuleGroup",
        "wafv2:ListRuleGroups",
        "wafv2:ListAvailableManagedRuleGroups",
        "wafv2:CheckCapacity",
        "wafv2:PutLoggingConfiguration",
        "wafv2:ListAvailableManagedRuleGroupVersions",
        "network-firewall:DescribeRuleGroup",
        "network-firewall:DescribeRuleGroupMetadata",
        "network-firewall:ListRuleGroups",
        "ec2:DescribeAvailabilityZones",
        "ec2:DescribeRegions"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutBucketPolicy",
        "s3:GetBucketPolicy"
      ],
      "Resource": [
        "arn:aws:s3:::aws-waf-logs-*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": "iam:CreateServiceLinkedRole",
      "Resource": "*"
    }
  ]
}
```
Permission details

This policy includes the following permissions:

- **fms:**
  
  Lets you work with AWS Firewall Manager resources.

- **waf:***, waf-regional:***
  
  Lets you work with AWS WAF policies.

- **waf:***, waf-regional:***
  
  Lets you work with AWS WAF policies.

- **elasticloadbalancing:SetWebACL:**
  
  Lets you associate web access control lists (ACLs) to Elastic Load Balancers.

- **firehose:ListDeliveryStreams:**
  
  Lets you view AWS WAF logs.

- **organizations:DescribeAccount, organizations:DescribeOrganization, organizations:ListRoots, organizations:ListChildren, organizations:ListAccounts, organizations:ListAccountsForParent, organizations:ListOrganizationalUnitsForParent:**
  
  Lets you work with AWS Organizations.

- **shield:GetSubscriptionState:**
  
  Lets you view the subscription state for a AWS Shield policy.

- **route53resolver:ListFirewallRuleGroups, route53resolver:GetFirewallRuleGroup:**
  
  Lets you work with Route 53 Private DNS for VPCs rule groups in a Route 53 Private DNS for VPCs policy.
AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide
Identity and access management

  
  Lets you work with AWS WAFV2 policies.
- \texttt{network-firewall:DescribeRuleGroup}, \texttt{network-firewall:DescribeRuleGroupMetadata}, \texttt{network-firewall:ListRuleGroups}:
  
  Lets you work with AWS Network Firewall policies.
- \texttt{ec2:DescribeAvailabilityZones}:
  
  Lets you view an AWS Network Firewall policy's Availability Zones.
- \texttt{ec2:DescribeRegions}:
  
  Lets you view a policy's Region in the AWS Firewall Manager console.

\textbf{Customer managed policy examples}

The examples in this section provide a group of sample policies that you can attach to a user. If you are new to creating policies, we recommend that you first create an IAM user in your account and attach the policies to the user, in the sequence outlined in the steps in this section.

You can use the console to verify the effects of each policy as you attach the policy to the user. Initially, the user doesn't have permissions, and the user won't be able to do anything on the console. As you attach policies to the user, you can verify that the user can perform various operations on the console.

We recommend that you use two browser windows: one to create the user and grant permissions, and the other to sign in to the AWS Management Console using the user's credentials and verify permissions as you grant them to the user.

For examples that show how to create an IAM role that you can use as an execution role for your Firewall Manager resource, see \textit{Creating IAM Roles} in the \textit{IAM User Guide}.

\textbf{Example topics}

- Example: Give admin user read-only access to Firewall Manager security groups (p. 443)

\textbf{Create an IAM user}

First, you need to create an IAM user, add the user to an IAM group with administrative permissions, and then grant administrative permissions to the IAM user that you created. You then can access AWS using a special URL and the user's credentials.

For instructions, see \textit{Creating Your First IAM User and Administrators Group} in the \textit{IAM User Guide}.

\textbf{Example: Give admin user read-only access to Firewall Manager security groups}

The following policy grants admin users read-only access to Firewall Manager security groups and policies. These users can't create, update, or delete the Firewall Manager resources.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "fms:Get*",
                "fms:List*",
                "ec2:DescribeSecurityGroups"
            ]
        }
    ]
}
```

443
AWS managed policies for AWS Firewall Manager

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ViewOnlyAccess AWS managed policy provides read-only access to many AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

**AWS managed policy: AWSFMAdminFullAccess**

Use the AWSFMAdminFullAccess AWS managed policy to allow your administrators to access AWS Firewall Manager resources, including all Firewall Manager policy types. This policy doesn't include permissions for setting up Amazon Simple Notification Service notifications in AWS Firewall Manager. For information about how to setting up access for Amazon Simple Notification Service, see Setting up access for Amazon Simple Notification Service.

**Permission details**

This policy is grouped into statements based on the set of permissions.

- **AWS Firewall Manager policy resources** - Allows full administrative permissions to resources in AWS Firewall Manager, including all Firewall Manager policy types.
- **Write AWS WAF logs to Amazon Simple Storage Service** - Allows Firewall Manager to write and read AWS WAF logs in Amazon S3.
- **Create service linked role** – Allows the administrator to create a service-linked role, which allows Firewall Manager to access resources in other services on your behalf. This permission allows creating the service-linked role only for use by Firewall Manager. For information about how Firewall Manager uses service linked roles, see Using service-linked roles for Firewall Manager (p. 452).
- **AWS Organizations** – Allows administrators to use Firewall Manager for an organization in AWS Organizations. After enabling trusted access for Firewall Manager in AWS Organizations, members of the admin account can view findings across their organization. For information about using AWS Organizations with AWS Firewall Manager, see Using AWS Organizations with other AWS services in the AWS Organizations User Guide.

    "StringEquals":{

This policy includes the following permissions:

- **fms:**
  
  Lets you work with AWS Firewall Manager resources.

- **waf:**, **waf-regional:**
  
  Lets you work with AWS WAF policies.

- **elasticloadbalancing:**
  
  Lets you associate web access control lists (ACLs) to Elastic Load Balancers.

- **firehose:**
  
  Lets you view AWS WAF logs.

- **organizations:**
  
  Lets you work with AWS Organizations.

- **shield:**
  
  Lets you view the subscription state for a AWS Shield policy.

- **route53resolver:**
  
  Lets you work with Route 53 Private DNS for VPCs rule groups in an Route 53 Private DNS for VPCs policy.

- **ec2:**
  
  Lets you view a AWS Network Firewall policy's Availability Zones.

- **s3:**
  
  Lets you get the Amazon S3 bucket policy for AWS WAF logs.

- **ListDelegatedAdministrators**
  
  Lets you list Amazon OpenSearch Service delegated administrators.
AWS managed policy: FMSServiceRolePolicy

This policy allows AWS Firewall Manager to manage AWS resources on your behalf in Firewall Manager and in integrated services. This policy is attached to the service-linked role AWSServiceRoleForFMS. For more information about the service-linked role, see Using service-linked roles for Firewall Manager (p. 452).

For policy details, see the IAM console at FMSServiceRolePolicy.

AWS managed policy: AWSFMAadminReadOnlyAccess

Grants read-only access to all AWS Firewall Manager resources.

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Effect":"Allow",
      "Action":[

        "ec2:DescribeAvailabilityZones",
        "ec2:DescribeRegions"
      ],
      "Resource":"*
    },
    {
      "Effect":"Allow",
      "Action":[
        "s3:GetBucketPolicy"
      ],
      "Resource":[
        "arn:aws:s3:::aws-waf-logs-*"
      ]
    },
    {
      "Effect":"Allow",
      "Action":[
        "organizations:ListDelegatedAdministrators"
      ],
      "Resource":"
      "Condition":{
```
This policy includes the following permissions:

- **fms:**
  - Lets you view AWS Firewall Manager resources.

- **waf:Get*, waf-regional:Get***:
  - Lets you get AWS WAF policies.

- **waf:List*, waf-regional:List***:
  - Lets you list AWS WAF policies.

- **firehose:ListDeliveryStreams***:
  - Lets you list AWS WAF logs.

- **organizations:**
  - Lets you view AWS Organizations resources.

- **shield:GetSubscriptionState***:
  - Lets you get the subscription state for a AWS Shield policy.

- **route53resolver:**
  - Lets you get and list Route 53 Private DNS for VPCs rule groups in an Route 53 Private DNS for VPCs policy.

- **wafv2:**
  - Lets you list AWS WAFV2 rule groups, AWS Managed Rules rule groups in AWS WAFV2 policies, AWS WAFV2 rule group capacity, and AWS WAFV2 AWS Managed Rules rule groups versions.

- **network-firewall:**
  - Lets you view AWS Network Firewall rule groups and rule group metadata.

- **ec2:**
  - Lets you view a AWS Network Firewall policy's Availability Zones.

- **s3:GetBucketPolicy***:
  - Lets you get the Amazon S3 bucket policy for AWS WAF logs.
• **ListDelegatedAdministrators:**

  Lets you list delegated administrators in AWS Organizations.

**AWS managed policy: AWSFMMemberReadOnlyAccess**

Grants read-only access to AWS Firewall Manager member resources. For policy details, see the IAM console at [AWSFMMemberReadOnlyAccess](#).

---

### Firewall Manager updates to AWS managed policies

View details about updates to AWS managed policies for Firewall Manager since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Firewall Manager document history page at [Document history](#) (p. 566).

### Firewall Manager required permissions for API actions

When you set up Access control (p. 436) and writing permissions policies that you can attach to an IAM identity (identity-based policies), use the information in this section as a guide. For each AWS Firewall Manager API operation, you need to know the actions for which to grant permissions, and the AWS resource for which you grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

**Note**

To specify an action, use the fms: prefix followed by the API operation name (for example, fms:CreatePolicy).

This topic only list actions that require explicit resource permissions.

You can use AWS-wide condition keys in your AWS Firewall Manager policies to express conditions. For a complete list of AWS-wide keys, see Available Keys for Conditions in the IAM User Guide.

To use the following Firewall Manager API actions, you need permissions on the resource: arn:aws:fms:region:account:policy/ID.

- DeletePolicy
- GetComplianceDetail
- GetPolicy
- GetProtectionStatus
- ListComplianceStatus
- PutPolicy

Additionally, to use the Firewall Manager API action PutNotificationChannel, the Amazon SNS topic that you specify must allow the Firewall Manager service-linked role to publish messages to it. The following shows an example SNS topic permission setting:

```json
{
    "Sid": "AWSFirewallManagerSNSPolicy",
    "Effect": "Allow",
    "Principal": {
```
For more information about Firewall Manager actions and resources, see the AWS Identity and Access Management guide topic Actions Defined by AWS Firewall Manager.

For the full list of the API actions available for Firewall Manager, see AWS Firewall Manager API Reference.

### Using service-linked roles for Firewall Manager

AWS Firewall Manager uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Firewall Manager. Service-linked roles are predefined by Firewall Manager and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Firewall Manager easier because you don't have to manually add the necessary permissions. Firewall Manager defines the permissions of its service-linked roles, and unless defined otherwise, only Firewall Manager can assume its roles. The defined permissions include the trust policy and the permissions policy. That permissions policy can't be attached to any other IAM entity.

You can delete a service-linked role only after first deleting the role's related resources. This protects your Firewall Manager resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

### Service-linked role permissions for Firewall Manager

Firewall Manager uses the service-linked role AWSServiceRoleForFMS.

AWS Firewall Manager uses this service-linked role to write logs to Amazon Kinesis Data Firehose. This role is used only if you enable logging in AWS Firewall Manager. For more information, see Logging web ACL traffic (p. 192).

The AWSServiceRoleForFMS service-linked role trusts the service to assume the role fms.amazonaws.com.

The permissions policies of the role allows Firewall Manager to complete the following actions on the specified resources:

- Action: firehose:PutRecord and firehose:PutRecordBatch on Amazon Kinesis Data Firehose data stream resources with a name that starts with "aws-fms-logs-". For example, aws-fms-logs-us-east-2-analytics.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.
Creating a service-linked role for Firewall Manager

You don't need to manually create a service-linked role. When you enable Firewall Manager logging on the AWS Management Console, or you make a PutLoggingConfiguration request in the Firewall Manager CLI or the Firewall Manager API, Firewall Manager creates the service-linked role for you.

You must have the iam:CreateServiceLinkedRole permission to enable logging.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable Firewall Manager logging, Firewall Manager creates the service-linked role for you again.

Editing a service-linked role for Firewall Manager

Firewall Manager doesn't allow you to edit the AWSServiceRoleForFMS service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

Deleting a service-linked role for Firewall Manager

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

Note

If the Firewall Manager service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the service-linked role using IAM

Use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForFMS service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Supported Regions for Firewall Manager service-linked roles

Firewall Manager supports using service-linked roles in all of the regions where the service is available. For more information, see Firewall Manager endpoints and quotas.

Cross-service confused deputy prevention

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource policies to limit the permissions that AWS Firewall Manager gives another service to the resource. Use aws:SourceArn if you want only one resource to be associated with the cross-service access. Use aws:SourceAccount if you want to allow any resource in that account to be associated with the cross-service use.

The most effective way to protect against the confused deputy problem is to use the aws:SourceArn global condition context key with the full ARN of the resource. If you don't know the full ARN of
the resource or if you are specifying multiple resources, use the `aws:SourceArn` global context condition key with wildcard characters (*) for the unknown portions of the ARN. For example, 

```
arn:aws:fms:Region:account-id:*.
```

If the `aws:SourceArn` value does not contain the account ID, such as an Amazon S3 bucket ARN, you must use both global condition context keys to limit permissions.

The value of `aws:SourceArn` must be the AWS Firewall Manager administrator's AWS account.

The following examples show how you can use the `aws:SourceArn` global condition context key in Firewall Manager to prevent the confused deputy problem.

The following example shows how to prevent the confused deputy problem by using the `aws:SourceArn` global condition context key in the Firewall Manager role trust policy. Replace `Region` and `account-id` with your own information.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "servicename.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": [
          "arn:aws:fms:Region:account-id:*",
          "arn:aws:fms:Region:account-id:policy/*"
        ],
        "StringEquals": {
          "aws:SourceAccount": "account-id"
        }
      }
    }
  }
}
```
Logging and monitoring in Firewall Manager

Monitoring is an important part of maintaining the reliability, availability, and performance of Firewall Manager and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Firewall Manager resources and responding to potential events:

**Amazon CloudWatch Alarms**

Using CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, CloudWatch sends a notification to an Amazon SNS topic or AWS Auto Scaling policy. For more information, see Monitoring with Amazon CloudWatch (p. 541).

**AWS CloudTrail Logs**

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Firewall Manager. Using the information collected by CloudTrail, you can determine the request that was made to Firewall Manager, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging API calls with AWS CloudTrail (p. 548).
Compliance validation for Firewall Manager

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, and HIPAA.

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.

- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

  **Note**
  Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.

- **Evaluating Resources with Rules** in the AWS Config Developer Guide – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.

- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

- **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

Resilience in Firewall Manager

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Infrastructure security in AWS Firewall Manager

As a managed service, AWS Firewall Manager is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use AWS published API calls to access Firewall Manager through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.
Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

## AWS Firewall Manager quotas

AWS Firewall Manager is subject to the following quotas (formerly referred to as limits).

AWS Firewall Manager has default quotas that you might be able to increase and fixed quotas.

The security group policies managed by Firewall Manager are subject to standard Amazon VPC quotas. For more information, see [Amazon VPC Quotas](https://docs.aws.amazon.com/vpc/latest/userguide/amazon-vpc-quotas.html) in the Amazon VPC User Guide.

Each Firewall Manager Network Firewall policy creates a Network Firewall firewall with an associated firewall policy and its rule groups. These Network Firewall resources are subject to the quotas listed at [AWS Network Firewall quotas](https://docs.aws.amazon.com/network-firewall/latest/developerguide/awswaf-quotas.html) in the Network Firewall Developer Guide.

### Soft quotas

AWS Firewall Manager has default quotas on the number of entities per Region. You can request an increase in these quotas.

#### All policy types

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default quota per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accounts per organization in AWS Organizations</td>
<td>Varies. An invitation sent to an account counts against this quota. The count is returned if the invited account declines, the management account cancels the invitation, or the invitation expires.</td>
</tr>
<tr>
<td>Firewall Manager policies per organization in AWS Organizations</td>
<td>20. The Region specifications Global and US East (N. Virginia) Region refer to the same Region, so this limit applies to the total combined policies for the two of them.</td>
</tr>
<tr>
<td>Organizational units in scope per Firewall Manager policy</td>
<td>20</td>
</tr>
<tr>
<td>Accounts in scope of a Firewall Manager policy if you explicitly include and exclude individual accounts</td>
<td>200</td>
</tr>
<tr>
<td>Accounts in scope of a Firewall Manager policy if you do not explicitly include or exclude individual accounts</td>
<td>2,500</td>
</tr>
<tr>
<td>Tags that include or exclude resources per Firewall Manager policy</td>
<td>8</td>
</tr>
<tr>
<td>Maximum number of resource sets per account.</td>
<td>20</td>
</tr>
</tbody>
</table>

AWS Shield

Protection against Distributed Denial of Service (DDoS) attacks is of primary importance for your internet-facing applications. When you build your application on AWS, you can make use of protections that AWS provides at no additional cost. Additionally, you can use the AWS Shield Advanced managed threat protection service to improve your security posture with additional DDoS detection, mitigation, and response capabilities.

AWS is committed to providing you with the tools, best practices, and services to help ensure high availability, security, and resiliency in your defense against bad actors on the internet. This guide is provided to help IT decision makers and security engineers understand how to use Shield and Shield Advanced to better protect their applications from DDoS attacks and other external threats.

When you build your application on AWS, you receive automatic protection by AWS against common volumetric DDoS attack vectors, like UDP reflection attacks and TCP SYN floods. You can leverage these protections to ensure the availability of the applications that you run on AWS by designing and configuring your architecture for DDoS resiliency.

This guide provides recommendations that can help you design, create, and configure your application architectures for DDoS resiliency. Applications that adhere to the best practices provided in this guide can benefit from an improved continuity of availability when they are targeted by larger DDoS attacks and by wider ranges of DDoS attack vectors. Additionally, this guide shows you how to use Shield Advanced to implement an optimized DDoS protection posture for your critical applications. These include applications for which you've guaranteed a certain level of availability to your customers and those that require operational support from AWS during DDoS events.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to Shield Advanced, see [AWS Services in Scope by Compliance Program](#).

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.
How AWS Shield works

AWS Shield Standard and AWS Shield Advanced provide protections against Distributed Denial of Service (DDoS) attacks for AWS resources at the network and transport layers (layer 3 and 4) and the application layer (layer 7). A DDoS attack is an attack in which multiple compromised systems try to flood a target with traffic. A DDoS attack can prevent legitimate end users from accessing the target services and can cause the target to crash due to overwhelming traffic volume.

AWS Shield provides protection against a wide range of known DDoS attack vectors and zero-day attack vectors. Shield detection and mitigation is designed to provide coverage against threats even if they are not explicitly known to the service at the time of detection.

Classes of attacks that Shield detects include the following:

- **Network volumetric attacks (layer 3)** – This is a sub category of infrastructure layer attack vectors. These vectors attempt to saturate the capacity of the targeted network or resource, to deny service to legitimate users.

- **Network protocol attacks (layer 4)** – This is a sub category of infrastructure layer attack vectors. These vectors abuse a protocol to deny service to the targeted resource. A common example of a network protocol attack is a TCP SYN flood, which can exhaust connection state on resources like servers, load balancers, or firewalls. A network protocol attack can also be volumetric. For example, a larger TCP SYN flood may intend to saturate the capacity of a network while also exhausting the state of the targeted resource or intermediate resources.

- **Application layer attacks (layer 7)** – This category of attack vector attempts to deny service to legitimate users by flooding an application with queries that are valid for the target, such as web request floods.

Contents

- AWS Shield Standard overview (p. 462)
- AWS Shield Advanced overview (p. 462)
  - AWS Shield Advanced protected resources (p. 463)
AWS Shield Standard overview

AWS Shield is a managed threat protection service that protects the perimeter of your application. The perimeter is the first point of entry for application traffic coming from outside the AWS network.

To determine where your application perimeter lies, consider how users access your application from the internet. If the first point of entry is in an AWS Region, then the application perimeter is your Amazon Virtual Private Cloud (VPC). If users are directed to your application by Amazon Route 53, and first access the application using Amazon CloudFront or AWS Global Accelerator, then the application perimeter begins at the edge of the AWS network.

Shield provides DDoS detection and mitigation benefits for all applications running on AWS, but the decisions that you make when you design your application architecture will influence your level of DDoS resiliency. DDoS Resiliency is your application’s ability to continue operating within expected parameters during an attack.

All AWS customers benefit from the automatic protection of Shield Standard, at no additional charge. Shield Standard defends against the most common, frequently occurring network and transport layer DDoS attacks that target your website or applications. While Shield Standard helps protect all AWS customers, you get particular benefit with Amazon Route 53 hosted zones, Amazon CloudFront distributions, and AWS Global Accelerator standard accelerators. These resources receive comprehensive availability protection against all known network and transport layer attacks.

AWS Shield Advanced overview

AWS Shield Advanced is a managed service that helps you protect your application against external threats, like DDoS attacks, volumetric bots, and vulnerability exploitation attempts. For higher levels of protection against attacks, you can subscribe to AWS Shield Advanced. For information about Shield Advanced pricing, see AWS Shield Advanced Pricing.

Note
For accounts that are members of an AWS Organizations organization, AWS bills Shield Advanced subscriptions against the organization's payer account, regardless of whether the payer account itself is subscribed.

When you subscribe to Shield Advanced and add protection to your resources, Shield Advanced provides expanded DDoS attack protection for those resources. The protections that you receive from Shield Standard are enhanced with Shield Advanced.
Advanced can vary depending on your architecture and configuration choices. Use the information in this guide to build and protect resilient applications using Shield Advanced, and to escalate when you need expert help.

**Topics**
- AWS Shield Advanced protected resources (p. 463)
- AWS Shield Advanced capabilities and options (p. 463)
- Deciding whether to subscribe to AWS Shield Advanced and apply additional protections (p. 464)

### AWS Shield Advanced protected resources

**Note**

Shield Advanced protections are only enabled for resources that you have explicitly specified in Shield Advanced or that you protect through an AWS Firewall Manager Shield Advanced policy. Shield Advanced doesn’t automatically protect your resources.

You can use Shield Advanced for advanced monitoring and protection with the following resource types:

- Amazon CloudFront distributions.
- Amazon Route 53 hosted zones.
- AWS Global Accelerator standard accelerators.
- Amazon EC2 Elastic IP addresses. Shield Advanced protects the resources that are associated with protected Elastic IP addresses.
- Amazon EC2 instances, through association to Amazon EC2 Elastic IP addresses.
- The following Elastic Load Balancing (ELB) load balancers:
  - Application Load Balancers.
  - Classic Load Balancers.
  - Network Load Balancers, through associations to Amazon EC2 Elastic IP addresses.

For additional information about protections for these resource types, see [AWS Shield Advanced protections by resource type (p. 487)](p. 487).

### AWS Shield Advanced capabilities and options

AWS Shield Advanced subscription includes the following capabilities and options. These supplement the DDoS detection and mitigation capabilities that you already receive with AWS.

- **AWS WAF integration** – Shield Advanced uses AWS WAF web ACLs, rules, and rule groups as part of its application layer protections. Your subscription to Shield Advanced covers the basic AWS WAF fees for web ACLs, rules, and web requests.

  For more information about AWS WAF, see [How AWS WAF works (p. 6)](p. 6). For information about the basic AWS WAF costs, see [AWS WAF Pricing](p. 463). Your subscription to Shield Advanced does not cover any additional AWS WAF costs, such as those for the optional intelligent threat mitigation capabilities of Bot Control or the rule actions CAPTCHA and Challenge. For information about Shield Advanced pricing, see [AWS Shield Advanced Pricing](p. 463).

- **Automatic application layer DDoS mitigation** – You can configure Shield Advanced to respond automatically to mitigate application layer (layer 7) attacks against your protected resources. With automatic mitigation, Shield Advanced responds to a detected DDoS attack by creating, evaluating, and deploying custom AWS WAF rules for your protected resource. You can configure automatic mitigation to count or block the web requests that are part of an attack.

  For more information, see [Shield Advanced automatic application layer DDoS mitigation (p. 489)](p. 489).
• **Health-based detection** – You can use Amazon Route 53 health checks with Shield Advanced to inform event detection and mitigation. Health checks monitor your application according to your specifications, reporting healthy when your specifications are met and unhealthy when they aren't. Using health checks with Shield Advanced helps prevent false positives and provides faster detection and mitigation when a protected resource is unhealthy. You can use health-based detection for any resource type except Route 53 hosted zones. Shield Advanced proactive engagement is available only for resources that have health-based detection enabled.

For more information, see *Configuring health-based detection using health checks* (p. 495).

• **Protection groups** – You can use protection groups to create logical groupings of your protected resources, for enhanced detection and mitigation of the group as a whole. You can define the criteria for membership in a protection group so that newly protected resources are automatically included. A protected resource can belong to multiple protection groups.

For more information, see *AWS Shield Advanced protection groups* (p. 506).

• **Enhanced visibility into DDoS events and attacks** – Shield Advanced gives you access to advanced, real-time metrics and reports for extensive visibility into events and attacks on your protected AWS resources. You can access this information through the Shield Advanced API and console, and through Amazon CloudWatch metrics.

For more information, see *Visibility into DDoS events* (p. 508).

• **Centralized management of Shield Advanced protections by AWS Firewall Manager** – You can use Firewall Manager to automatically apply Shield Advanced protections to your new accounts and resources and to deploy AWS WAF rules to your web ACLs. Firewall Manager Shield Advanced protection policies are included at no additional charge for Shield Advanced customers. You can also centralize your Shield Advanced monitoring activities for your accounts by using Firewall Manager with an Amazon Simple Notification Service (SNS) topic or AWS Security Hub.

For more information about using Firewall Manager with Shield Advanced, see *AWS Firewall Manager* (p. 358) and *AWS Shield Advanced policies* (p. 407). For information about Firewall Manager pricing, see *AWS Firewall Manager Pricing*.

• **AWS Shield Response Team (SRT)** – The SRT has deep experience in protecting AWS, Amazon.com, and its subsidiaries. As an AWS Shield Advanced customer, you can contact the SRT at any time for assistance during a DDoS attack that affects the availability of your application. You can also work with the SRT to create and manage custom mitigations for your resources. To use the services of the SRT, you must also be subscribed to the Business Support plan or the Enterprise Support plan.

For more information, see *Shield Response Team (SRT) support* (p. 483).

• **Proactive engagement** – With proactive engagement, the Shield Response Team (SRT) contacts you directly if the Amazon Route 53 health check that you have associated with your protected resource becomes unhealthy during an event that's detected by Shield Advanced. This gives you quicker engagement with experts when the availability of your application might be affected by a suspected attack.

For more information, see *Configuring proactive engagement* (p. 485).

• **Cost protection opportunities** – Shield Advanced offers some cost protection against spikes in your AWS bill that might result from a DDoS attack against your protected resources.

For more information, see *Requesting a credit in AWS Shield Advanced* (p. 521).

**Deciding whether to subscribe to AWS Shield Advanced and apply additional protections**

Review the scenarios in this section for help deciding which accounts to subscribe to AWS Shield Advanced and where to apply additional protections. With Shield Advanced, you pay one monthly
subscription fee for all accounts created under a consolidated billing account, plus usage fees based on GB of data transferred out. For information about Shield Advanced pricing, see AWS Shield Advanced Pricing.

**Note**
For accounts that are members of an AWS Organizations organization, AWS bills Shield Advanced subscriptions against the organization's payer account, regardless of whether the payer account itself is subscribed.

To protect an application and its resources with Shield Advanced, you subscribe the accounts that manage the application to Shield Advanced and then you add protections to the application's resources. For information about subscribing accounts and protecting resources, see Getting started with AWS Shield Advanced (p. 477).

**Identifying the applications to protect**
Consider implementing Shield Advanced protections for applications where you need any of the following:

- Guaranteed availability for the users of the application.
- Rapid access to DDoS mitigation experts if the application is affected by a DDoS attack.
- Awareness by AWS that the application might be affected by a DDoS attack and notification of attacks from AWS and escalation to your security or operations teams.
- Predictability in your cloud costs, including when a DDoS attack affects your use of AWS services.

If an application or its resources require any of the above, consider creating subscriptions for the related accounts.

**Identifying the resources to protect**
For each subscribed account, consider adding a Shield Advanced protection to each resource that has any of the following characteristics:

- The resource serves external users on the internet.
- The resource is exposed to the internet and is also part of a critical application. Consider every exposed resource, regardless of whether you intend it to be accessed by users on the internet.
- The resource is protected by an AWS WAF web ACL.

To learn more about creating and managing protections for your resources, see Resource protections in AWS Shield Advanced (p. 487).

Additionally, follow the recommendations in this guide to help ensure that you architect your application for DDoS resiliency and that you have properly configured the features of Shield Advanced for optimal protections.

**Examples of DDoS attacks**
AWS Shield Advanced provides expanded protection against many types of attacks.

The following list describes some common attack types:

**User Datagram Protocol (UDP) reflection attacks**
In UDP reflection attacks, an attacker can spoof the source of a request and use UDP to elicit a large response from the server. The extra network traffic directed towards the spoofed, attacked...
IP address can slow the targeted server and prevent legitimate end users from accessing needed resources.

TCP SYN flood

The intent of a TCP SYN flood attack is to exhaust the available resources of a system by leaving connections in a half-open state. When a user connects to a TCP service like a web server, the client sends a TCP SYN packet. The server returns an acknowledgment, and the client returns its own acknowledgment, completing the three-way handshake. In a TCP SYN flood, the third acknowledgment is never returned, and the server is left waiting for a response. This can prevent other users from connecting to the server.

DNS query flood

In a DNS query flood, an attacker uses multiple DNS queries to exhaust the resources of a DNS server. AWS Shield Advanced can help provide protection against DNS query flood attacks on Route 53 DNS servers.

HTTP flood/cache-busting (layer 7) attacks

With an HTTP flood, including GET and POST floods, an attacker sends multiple HTTP requests that appear to be from a real user of the web application. Cache-busting attacks are a type of HTTP flood that uses variations in the HTTP request's query string that prevent use of edge-located cached content and forces the content to be served from the origin web server, causing additional and potentially damaging strain on the origin web server.

How AWS Shield detects events

AWS operates service-level detection systems for the AWS network and individual AWS services, to ensure that they remain available during a DDoS attack. Additionally, resource-level detection systems monitor each individual AWS resource to ensure that traffic toward the resource remains within expected parameters. This combination protects both the targeted AWS resource and AWS services, by applying mitigations that drop known bad packets, highlight potentially malicious traffic, and prioritize traffic from end users.

Detected events appear in your Shield Advanced event summaries, attack details, and Amazon CloudWatch metrics as either the name of the DDoS attack vector or as Volumetric if the evaluation was based on traffic volume instead of signature. For more information on the attack vector dimensions that are available within the DDoSDetected CloudWatch metric, see AWS Shield Advanced metrics and alarms (p. 545)

Topics

- Detection logic for infrastructure layer threats (p. 466)
- Detection logic for application layer threats (p. 467)
- Detection logic for multiple resources in an application (p. 468)

Detection logic for infrastructure layer threats

The detection logic used to protect targeted AWS resources against DDoS attacks in the infrastructure layers (layer 3 and layer 4) depends on the resource type and whether the resource is protected with AWS Shield Advanced.

Detection for Amazon CloudFront and Amazon Route 53

When you serve your web application with CloudFront and Route 53, all packets to the application are inspected by a fully inline DDoS mitigation system, which does not introduce any observable latency. DDoS attacks against CloudFront distributions and Route 53 hosted zones are mitigated in real time. These protections apply regardless of whether you use AWS Shield Advanced.
Follow the best practice of using CloudFront and Route 53 as the entry point of your web application wherever possible for the fastest detection and mitigation of DDoS events.

**Detection for AWS Global Accelerator and regional services**

Resource-level detection protects AWS Global Accelerator standard accelerators and resources that are launched in AWS Regions, like Classic Load Balancers, Application Load Balancers, and Elastic IP addresses (EIPs). These resource types are monitored for traffic elevations that may indicate the presence of a DDoS attack that requires a mitigation. Every minute, traffic to each AWS resource is evaluated. If traffic to a resource is elevated, additional checks are performed to measure the capacity of the resource.

Shield performs the following standard checks:

- **Amazon Elastic Compute Cloud (Amazon EC2) instances, EIPs attached to Amazon EC2 instances** – Shield retrieves capacity from the protected resource. The capacity depends on the target's instance type, instance size, and other factors such as whether the instance is using enhanced networking.

- **Classic Load Balancers and Application Load Balancers** – Shield retrieves capacity from the targeted load balancer node.

- **EIPs attached to Network Load Balancers** – Shield retrieves capacity from the targeted load balancer.

  The capacity is independent of the target load balancer's group configuration.

- **AWS Global Accelerator standard accelerators** – Shield retrieves capacity, which is based on the endpoint configuration.

These evaluations occur across multiple dimensions of network traffic, such as port and protocol. If the capacity of the targeted resource is exceeded, Shield places a DDoS mitigation. The mitigations placed by Shield will reduce DDoS traffic, but might not eliminate it. Shield may also place a mitigation if a fraction of the resource's capacity is exceeded on a traffic dimension that's consistent with known DDoS attack vectors. Shield places this mitigation with a limited time to live (TTL), which it extends as long as the attack is ongoing.

**Note**

Mitigations placed by Shield will reduce DDoS traffic, but may not eliminate it. You can augment Shield with solutions like AWS Network Firewall or an on-host firewall like iptables to prevent your application from processing traffic that is not valid for your application or was not generated by legitimate end users.

Shield Advanced protections add the following to the existing Shield detection activities:

- **Lower detection thresholds** – Shield Advanced places mitigations at one half of the calculated capacity. This can provide faster mitigations for attacks that ramp up slowly and mitigation of attacks that have a more ambiguous volumetric signature.

- **Intermittent attack protection** – Shield Advanced places mitigations with an exponentially increasing time to live (TTL), based on the frequency and duration of attacks. This keeps mitigations in place longer when a resource is frequently targeted and when an attack occurs in short bursts.

- **Health-based detection** – When you associate a Route 53 health check with a Shield Advanced protected resource, the status of the health check is used in the detection logic. During a detected event, if the health check is healthy, Shield Advanced requires greater confidence that the event is an attack before placing a mitigation. If instead the health check is unhealthy, Shield Advanced might place a mitigation even before confidence has been established. This feature helps avoid false positives and provides quicker reactions to attacks that affect your application. For information about health checks with Shield Advanced, see Configuring health-based detection using health checks (p. 495).

**Detection logic for application layer threats**

AWS Shield Advanced provides web application layer detection for protected Amazon CloudFront distributions and Application Load Balancers. When you protect these resource types with Shield
AWS WAF, AWS Firewall Manager, and  
AWS Shield Advanced Developer Guide  
How Shield detects events

Advanced, you can associate an AWS WAF web ACL with your protection to enable web application layer detection. Shield Advanced consumes request data for the associated web ACL and builds a traffic baseline for your application. Web application layer detection relies on the native integration between Shield Advanced and AWS WAF. To learn more about application layer protections, including associating an AWS WAF web ACL to a Shield Advanced protected resource, see AWS Shield Advanced application layer (layer 7) protections (p. 488).

For web application layer detection, Shield Advanced monitors application traffic and compares it to historic baselines looking for anomalies. This monitoring covers total volume and the composition of traffic. During a DDoS attack, we expect both the volume and composition of traffic to change, and Shield Advanced requires a statistically significant deviation in both to declare an event.

Shield Advanced performs its measurements against historical time windows. This approach reduces false positive notifications from legitimate changes in traffic volume or from changes in traffic that match an expected pattern, such as a sale that's offered at the same time each day.

**Note**
Avoid false positives in your Shield Advanced protections by giving Shield Advanced time to establish baselines that represent normal, legitimate traffic patterns. Associate a web ACL with your protected resource at least 24 hours before any planned event that might cause unusual patterns in your web traffic. Shield Advanced web application layer detection is most accurate when it has observed 30 days of normal traffic.

The time that Shield Advanced takes to detect an event is affected by how much change it observes in the volume of traffic. For lower volume changes, Shield Advanced observes traffic for a longer period, in order to build confidence that an event is occurring. For higher volume changes, Shield Advanced detects and reports an event more quickly.

**Note**
You can architect your application to scale in response to elevated traffic or load to ensure that it is not affected by smaller request floods. With Shield Advanced, your protected resources are covered by cost protection. This helps protect you against unexpected increases in your cloud bill that might occur as the result of a DDoS attack. To learn more about Shield Advanced cost protection, see Requesting a credit in AWS Shield Advanced (p. 521).

**Detection logic for multiple resources in an application**

You can use AWS Shield Advanced protection groups to create collections of protected resources that are part of the same application. You can choose which protected resources to place in a group or indicate that all resources of the same type should be treated as one group. For example, you might create a group of all Application Load Balancers. When you create a protection group, Shield Advanced detection aggregates all traffic for the protected resources within the group. This is useful if you have many resources that each have a small amount of traffic, but with a large aggregated volume. You can also use protection groups to preserve application baselines, for the case of blue-green deployments where traffic is transferred between protected resources.

You can choose to aggregate the traffic in your protection group in one of the following ways:

- **Sum** – This aggregation combines all traffic across resources in the protection group. You can use this aggregation to ensure that newly created resources have an existing baseline and to reduce detection sensitivity, which can help prevent false positives.

- **Mean** – This aggregation uses the average of all traffic across the protection group. You can use this aggregation for applications where traffic across resources is uniform, like load balancers.

- **Max** – This aggregation uses the highest traffic of any resource in the protection group. You can use this aggregation when there are multiple tiers of an application in a protection group. For example, you may have a protection group that includes a CloudFront distribution, its Application Load Balancer origin, and the Application Load Balancer’s Amazon EC2 instance targets.
You can also use protection groups to improve the speed at which Shield Advanced places mitigations, for attacks that targets multiple internet-facing Elastic IPs or AWS Global Accelerator standard accelerators. When one resource in a protection group is targeted, Shield Advanced establishes confidence for the other resources in the group. This places Shield Advanced detection on alert and can reduce the time required to create additional mitigations.

To learn more about protection groups, see AWS Shield Advanced protection groups (p. 506).

How AWS Shield mitigates events

The mitigation logic that protects your application can vary depending on your application architecture. When you protect a web application with Amazon CloudFront and Amazon Route 53, you benefit from mitigations that are specific to web and DNS use cases and that protect all traffic for the services. When your application's entry point is a resource that runs in an AWS Region, the mitigation logic varies depending on the service, the resource type, and your use of AWS Shield Advanced.

AWS DDoS mitigation systems are developed by Shield engineers and they’re closely integrated with AWS services. The engineers take into account aspects of your architecture such as the capacity and health of targeted resources. Shield engineers continually monitor the efficacy and performance of DDoS mitigation systems and are able to respond quickly when new threats are discovered or anticipated.

You can architect your application to scale in response to elevated traffic or load, to help ensure that it’s not affected by smaller request floods. If you use Shield Advanced to protect your resources, you receive coverage against unexpected increases in your cloud bill that might occur as the result of a DDoS attack.

Infrastructure mitigations

For infrastructure layer attacks, AWS Shield DDoS mitigation systems are present at the AWS network border and at AWS edge locations. The placement of multiple levels of security controls throughout the AWS infrastructure provides defense-in-depth to your cloud applications.

Shield maintains DDoS mitigation systems at all points of ingress from the internet. When Shield detects a DDoS attack, for each point of ingress, it reroutes the traffic through the DDoS mitigation systems in the same location. This doesn’t introduce any observable additional latency, and provides a mitigation capacity of more than 100 TeraBits Per Second (Tbps) across all AWS Regions and all edge locations. Shield protects your resource availability without rerouting traffic to external or remote scrubbing centers, which could increase latency.

- At the AWS network border, for any AWS service or resource, DDoS mitigation systems mitigate infrastructure layer attacks coming from the internet. The systems perform their mitigations when signaled by Shield detection or by an engineer on the Shield Response Team (SRT).
- At AWS edge locations, DDoS mitigation systems continuously inspect every packet that’s forwarded to Amazon CloudFront distributions and Amazon Route 53 hosted zones, regardless of their origin. When needed, the systems apply mitigations that are specifically designed for web and DNS traffic. An added benefit of using Amazon CloudFront and Amazon Route 53 to protect your web applications is that DDoS attacks are immediately mitigated, without requiring a signal from Shield detection.

Application layer mitigations

Shield Advanced provides web application layer mitigations for the Amazon CloudFront distributions and Application Load Balancers where you’ve enabled Shield Advanced protections. When you enable protection, you associate an AWS WAF web ACL with the resource, to enable web application layer detection. Additionally, you have the option of enabling automatic applicaton layer mitigation, which instructs Shield Advanced to manage protections for you during a DDoS attack.

Shield only provides mitigations for application layer attacks on resources for which you’ve enabled Shield Advanced and automatic application layer mitigation. With automatic mitigation, Shield Advanced automatically mitigates attacks with AWS WAF protections, and then removes the mitigations when
they're no longer needed. For detailed information about mitigations of this type, see How Shield Advanced manages automatic mitigation (p. 491).

Mitigation features

The main features of AWS Shield DDoS mitigation are the following:

- **Packet validation** – This ensures that every inspected packet conforms to an expected structure and is valid for its protocol. Supported protocol validations include IP, TCP (including header and options), UDP, ICMP, DNS, and NTP.

- **Access Control Lists (ACLs) and shapers** – An ACL evaluates traffic against specific attributes and either drops matching traffic or maps it to a shaper. The shaper limits the packet rate for the matching traffic, dropping excess packets in order to contain the volume that reaches the destination. AWS Shield detection and Shield Response Team (SRT) engineers can provide dedicated rate allocations to expected traffic and more restrictive rate allocations to traffic with attributes that match known DDoS attack vectors. The attributes that an ACL can match include the port, protocol, TCP flags, destination address, source country, and arbitrary patterns in the packet payload.

- **Suspicion scoring** – This uses the knowledge that Shield has of expected traffic to apply a score to every packet. Packets that more closely adhere to patterns of known good traffic are assigned a lower suspicion score. Observation of known bad traffic attributes can increase the suspicion score for a packet. When it’s necessary to rate limit packets, Shield drops packets with higher suspicion scores first. This helps Shield to mitigate both known and zero-day DDoS attacks while avoiding false positives.

- **TCP SYN proxy** – This provides protection against TCP SYN floods by sending TCP SYN cookies to challenge new connections before allowing them to pass to the protected service. The TCP SYN proxy provided by Shield DDoS mitigation is stateless, which allows it to mitigate the largest known TCP SYN flood attacks without reaching state exhaustion. This is achieved by integrating with AWS services to hand off connection state instead of maintaining a continuous proxy between the client and the protected service. TCP SYN proxy is currently available on Amazon CloudFront and Amazon Route 53.

- **Rate distribution** – This continuously adjusts per-location shaper values based on the ingress pattern of traffic toward a protected resource. This prevents rate limiting of customer traffic that might not enter the AWS network evenly.

AWS Shield mitigation logic for CloudFront and Route 53

Shield DDoS mitigation continually inspects traffic for CloudFront and Route 53. These services operate from a globally distributed network of AWS edge locations that provide you with broad access to Shield’s DDoS mitigation capacity and deliver your application from infrastructure that’s closer to your end users.

- **CloudFront** – Shield DDoS mitigations only allow traffic that’s valid for web applications to pass through to the service. This provides automatic protection against many common DDoS vectors, like UDP reflection attacks.

  CloudFront maintains persistent connections to your application origin, TCP SYN floods are automatically mitigated through integration with the Shield TCP SYN proxy feature, and Transport Layer Security (TLS) is terminated at the edge. These combined features ensure that your application origin only receives well-formed web requests and that it’s protected against lower-layer DDoS attacks, connection floods, and TLS abuse.

  CloudFront uses a combination of DNS traffic direction and anycast routing. These techniques improve the resilience of your application by mitigating attacks close to the source, providing fault isolation, and ensuring access to capacity to mitigate the largest known attacks.

- **Route 53** – Shield mitigations only allow valid DNS requests to reach the service. Shield mitigates DNS query floods using suspicion scoring that prioritizes known good queries and deprioritizes queries that contain suspicious or known DDoS attack attributes.
Route 53 uses shuffle sharding to provide a unique set of four resolver IP addresses to every hosted zone, for both IPv4 and IPv6. Each IP address corresponds to a different subset of Route 53 locations. Each location subset consists of authoritative DNS servers that only partially overlap with infrastructure in any other subset. This ensures that if a user query fails for any reason, it will be successfully served on retry.

Route 53 uses anycast routing to direct DNS queries to the nearest edge location, based on network proximity. Anycast also fans out DDoS traffic to many edge locations, which prevents attacks from focusing on a single location.

In addition to the speed of mitigation, CloudFront and Route 53 provide broad access to the globally distributed capacity of Shield. To take advantage of these capabilities, use these services as the entry point of your dynamic or static web applications.

To learn more about using CloudFront and Route 53 to protect web applications, see How to Help Protect Dynamic Web Applications Against DDoS Attacks by Using Amazon CloudFront and Amazon Route 53. To learn more about fault isolation on Route 53, see A Case Study in Global Fault Isolation.

AWS Shield mitigation logic for AWS Regions

Resources that are launched in AWS Regions are protected by AWS Shield DDoS mitigation systems placed by Shield resource-level detection. Regional resources include Elastic IPs (EIPs), Classic Load Balancers, and Application Load Balancers.

Prior to placing a mitigation, Shield identifies the targeted resource and its capacity. Shield uses the capacity to determine the maximum total traffic that its mitigations should allow to be forwarded to the resource. Access control lists (ACLs) and other shapers within the mitigation might decrease the allowed volumes for some traffic, for example traffic that matches known DDoS attack vectors or that isn't expected to come in large volume. This further limits the amount of traffic that the mitigations allow for UDP reflection attacks or for TCP traffic that has TCP SYN or FIN flags.

Shield determines capacity and places mitigations differently for each resource type.

- For an Amazon EC2 instance, or an EIP that's attached to an Amazon EC2 instance, Shield calculates the capacity based on the instance type and other instance attributes, such as whether the instance has enhanced networking enabled.
- For an Application Load Balancer or Classic Load Balancer, Shield calculates capacity individually for each targeted node of the load balancer. DDoS attack mitigations for these resources are provided by a combination of Shield DDoS mitigations and automatic scaling by the load balancer. When the Shield Response Team (SRT) is engaged on an attack against an Application Load Balancer or Classic Load Balancer resource, they might accelerate scaling as an additional protection measure.
- Shield calculates capacity for some AWS resources is based on the available capacity of the underlying AWS infrastructure. These resource types include Network Load Balancers (NLBs) and resources that route traffic through Gateway Load Balancers or AWS Network Firewall.

**Note**

Protect your Network Load Balancers by attaching EIPs that are protected by Shield Advanced. You can work with SRT to build custom mitigations that are based on the expected traffic and capacity of the underlying application.

When Shield places a mitigation, the initial rate limits that Shield defines in the mitigation logic are applied equally to every Shield DDoS mitigation system. For example, if Shield places a mitigation with a 100,000 packets per second (pps) limit, it will initially allow 100,000 pps at every location. Then, Shield continuously aggregates mitigation metrics to determine the actual ratio of traffic, and uses the ratio to adapt the rate limit for each location. This prevents false positives and ensures that the mitigations are not overly permissive.
AWS Shield mitigation logic for AWS Global Accelerator standard accelerators

Shield mitigations only allow valid traffic to reach the listener endpoints of a Global Accelerator standard accelerator. Standard accelerators are deployed globally, and they provide you with IP addresses that you can use to route traffic to AWS resources in any AWS Region. The rate limits that Shield enforces for a Global Accelerator mitigation are based on the capacities of the resources to which the standard accelerator routes traffic. Shield places mitigations when the total traffic exceeds the determined rate, and also when a fraction of that rate is exceeded for known DDoS vectors.

When you configure a standard accelerator, you define endpoint groups for each AWS Region where you'll route traffic for your application. When Shield places a mitigation, it calculates the capacity of each endpoint group and updates rate limits at each Shield DDoS mitigation system accordingly. The rate varies for each location, based on assumptions made by Shield about how traffic will route from the internet to your AWS resources. The capacity for an endpoint group is calculated as the number of resources in the group multiplied by the lowest capacity for any resource in the group. At regular intervals, Shield recalculates the capacity for your application and updates the rate limits as needed.

**Note**
Using traffic dials to change the percentage of traffic that's directed to an endpoint group doesn't change how Shield calculates or distributes rate limits to its DDoS mitigation systems. If you use traffic dials, configure your endpoint groups to mirror one another in terms of resource type and quantity. This helps ensure that the capacity calculated by Shield is representative of the resources that are serving traffic for your application.

For more information about endpoint groups and traffic dials in Global Accelerator, see [Endpoint groups in AWS Global Accelerator standard accelerators](#).

AWS Shield Advanced mitigation logic for Elastic IPs

When you protect an Elastic IP (EIP) with AWS Shield Advanced, Shield Advanced enhances the mitigations that Shield places during a DDoS event. Shield Advanced DDoS mitigation systems replicate the Network ACL (NACL) configuration for the public subnet to which the EIP is associated. For example, if your NACL is configured to block all UDP traffic, Shield Advanced merges that rule into the mitigations that Shield places.

This additional functionality can help you to avoid availability risks due to traffic that's not valid for your application. You can also use NACLs to block individual source IP addresses or source IP address CIDR ranges. This can be a useful mitigation tool for DDoS attacks that aren't distributed. It also lets you easily manage your own allow lists or to block IP addresses that shouldn't communicate with your application, without relying on intervention by AWS engineers.

AWS Shield Advanced mitigation logic for web applications

AWS Shield Advanced uses AWS WAF to mitigate web application layer attacks. AWS WAF is included with Shield Advanced at no additional cost. When you protect an Amazon CloudFront distribution or Application Load Balancer with Shield Advanced, you can use Shield Advanced to associate an AWS WAF web ACL with your protected resource, if you don't already have one associated. If you haven't already configured a web ACL, you can use the Shield Advanced console wizard to create one and add a rate-based rule to it. A rate-based rule limits the number of requests per five minute time window for each IP address, providing basic protections against web application layer request floods. You can configure the rate, starting as low as 100. For more information, see [Shield Advanced application layer AWS WAF web ACLs and rate-based rules](#).

For enhanced protection, enable Shield Advanced automatic application layer mitigation. With this option, when Shield Advanced detects an attack on a protected resource, it attempts to identify an attack signature that isolates the attack traffic from the normal traffic to your application. Shield
Advanced evaluates the identified attack signature against the historical traffic patterns for the resource that's under attack, as well as for any other resource that's associated with the same web ACL.

If Shield Advanced determines that the attack signature isolates only the traffic that's involved in the DDoS attack, it implements the signature in AWS WAF rules inside the associated web ACL. You can instruct Shield Advanced to place mitigations that only count the traffic that they match against, or that block it, and you can change the setting at any time. When Shield Advanced determines that its mitigating rules are no longer needed, it removes them from the web ACL.

For more information, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

Examples of basic DDoS resilient architectures

DDoS resiliency is the ability of your application architecture to withstand Distributed Denial of Service (DDoS) attacks while continuing to serve legitimate end users. An application that is highly resilient can remain available during an attack with minimal impact on performance metrics such as errors or latency. This section shows some common example architectures and describes how to use the DDoS detection and mitigation capabilities that are provided by AWS and Shield Advanced to increase their DDoS resiliency.

The example architectures in this section highlight the AWS services that provide the greatest DDoS resiliency benefits for your deployed applications. The benefits of the highlighted services include the following:

- **Access to globally distributed network capacity** – The services Amazon CloudFront, AWS Global Accelerator, and Amazon Route 53 provide you with access to internet and DDoS mitigation capacity across the AWS global edge network. This is useful in mitigating larger volumetric attacks, which can reach terabits in scale. You can run your application in any AWS Region and use these services to protect availability and optimize performance for your legitimate users.

- **Protection against web application layer DDoS attack vectors** – Web application layer DDoS attacks are best mitigated using a combination of application scale and a web application firewall (WAF). Shield Advanced uses web request inspection logs from AWS WAF to detect anomalies that can be mitigated either automatically or via engagement with the AWS Shield Response Team (SRT). Automatic mitigation is available through deployed AWS WAF rate-based rules and also through the Shield Advanced automatic application layer DDoS mitigation.

In addition to reviewing these examples, review and follow the applicable best practices at AWS Best Practices for DDoS Resiliency.

**DDoS resiliency example for common web applications**

You can build a web application in any AWS Region and receive automatic DDoS protection from the detection and mitigation capabilities that AWS provides in the Region.

This example is for architectures that route users to a web application using resources like Classic Load Balancers, Application Load Balancers, Network Load Balancers, AWS Marketplace solutions, or a your own proxy layer. You can improve DDoS resiliency by inserting Amazon Route 53 hosted zones, Amazon CloudFront distributions, and AWS WAF web ACLs between these web application resources and your users. These insertions can obfuscate the application origin, serve requests closer to your end users, and detect and mitigate application layer request floods. Applications that serve static or dynamic content to your users with CloudFront and Route 53 are protected by an integrated, fully inline DDoS mitigation system that mitigates infrastructure layer attacks in real time.
With these architectural improvements in place, you can then protect your Route 53 hosted zones and your CloudFront distributions with Shield Advanced. When you protect CloudFront distributions, Shield Advanced prompts you to associate AWS WAF web ACLs and create rate-based rules for them, and gives you the option of enabling automatic application layer DDoS mitigation or proactive engagement. Proactive engagement and automatic application layer DDoS mitigation use Route 53 health checks that you associate with the resource. To learn more about these options, see Resource protections in AWS Shield Advanced (p. 487).

The following reference diagram depicts this DDoS resilient architecture for a web application.

The benefits that this approach provides to your web application include the following:

- Protection against frequently used infrastructure layer (layer 3 and layer 4) DDoS attacks, without detection delay. In addition, if a resource is frequently targeted, Shield Advanced places mitigations for longer periods of time. Shield Advanced also uses application context inferred from Network ACLs (NACLs) to block unwanted traffic further upstream. This isolates failures closer to their source, minimizing the effect on legitimate users.

- Protection against TCP SYN floods. The DDoS mitigation systems that are integrated with CloudFront, Route 53, and AWS Global Accelerator provide a TCP SYN proxy capability that challenges new connection attempts and only serves legitimate users.

- Protection against DNS application layer attacks, because Route 53 is responsible for serving authoritative DNS responses.

- Protection against web application layer request floods. The rate-based rule that you configure in your AWS WAF web ACL blocks source IPs when they are sending more requests than the rule allows.

- Automatic application layer DDoS mitigation for your CloudFront distributions, if you choose to enable this option. When Shield Advanced detects an event that affects the health of your application, it automatically creates, tests, and manages mitigating rules in the distribution’s associated AWS WAF web ACL.

- Proactive engagement with the Shield Response Team (SRT), if you choose to enable this option. When Shield Advanced detects an event that affects the health of your application, the SRT responds and proactively engages with your security or operations teams using the contact information that you
provide. The SRT analyzes patterns in your traffic and can update your AWS WAF rules to block the attack.

**DDoS resiliency example for TCP and UDP applications**

This example shows a DDoS resilient architecture for TCP and UDP applications in an AWS Region that uses Amazon Elastic Compute Cloud (Amazon EC2) instances or Elastic IP (EIP) addresses.

You can follow this general example to improve DDoS resiliency for the following application types:

- TCP or UDP applications. For example, applications used for gaming, IoT, and voice over IP.
- Web applications that require static IP addresses or that use protocols that Amazon CloudFront doesn't support. For example, your application might require IP addresses that your users can add to their firewall allow lists, and that aren't used by any other AWS customers.

You can improve DDoS resiliency for these application types by introducing Amazon Route 53 and AWS Global Accelerator. These services can route users to your application and they can provide your application with static IP addresses that are anycast routed across the AWS global edge network. Global Accelerator standard accelerators can improve user latency by up to 60%. If you have a web application, you can detect and mitigate web application layer request floods by running the application on an Application Load Balancer, and then protecting the Application Load Balancer with an AWS WAF web ACL.

After you’ve built your application, protect your Route 53 hosted zones, Global Accelerator standard accelerators, and any Application Load Balancers with Shield Advanced. When you protect your Application Load Balancers, you can associate AWS WAF web ACLs and create rate-based rules for them. You can configure proactive engagement with the SRT for both your Global Accelerator standard accelerators and your Application Load Balancers by associating new or existing Route 53 health checks. To learn more about the options, see Resource protections in AWS Shield Advanced (p. 487).

The following reference diagram depicts an example DDoS resilient architecture for TCP and UDP applications.
The benefits that this approach provides to your application include the following:

- Protection against the largest known infrastructure layer (layer 3 and layer 4) DDoS attacks. If the volume of an attack causes congestion upstream from AWS, the failure will be isolated closer to its source and will have a minimized effect on your legitimate users.
- Protection against DNS application layer attacks, because Route 53 is responsible for serving authoritative DNS responses.
- If you have a web application, this approach provides protection against web application layer request floods. The rate-based rule that you configure in your AWS WAF web ACL blocks source IPs while they are sending more requests than the rule allows.
- Proactive engagement with the Shield Response Team (SRT), if you choose to enable this option for eligible resources. When Shield Advanced detects an event that affects the health of your application, the SRT responds and proactively engages with your security or operations teams using the contact information that you provide.

### Example Shield Advanced use cases

You can use Shield Advanced to protect your resources in many types of scenarios. However, in some cases you should use other services or combine other services with Shield Advanced to offer the best protection. Following are examples of how to use Shield Advanced or other AWS services to help protect your resources.

<table>

For example, if you use Shield Advanced to protect an Elastic IP address, Shield Advanced protects whatever resource is associated with it. During an attack, Shield Advanced automatically deploys your network ACLs to the border of the AWS network. When your network ACLs are at the border of the network, Shield Advanced can provide protection against larger DDoS events. Typically, network ACLs are applied near your Amazon EC2 instances within your Amazon VPC. The network ACL can mitigate attacks only as large as your Amazon VPC and instance can handle. If the network interface attached to your Amazon EC2 instance can process up to 10 Gbps, volumes over 10 Gbps slow down and possibly block traffic to that instance. During an attack, Shield Advanced promotes your network ACL to the AWS border, which can process multiple terabytes of traffic. Your network ACL is able to provide protection for your resource well beyond your network's typical capacity. For more information about network ACLs, see Network ACLs.

Getting started with AWS Shield Advanced

This tutorial walks you through getting started with AWS Shield Advanced. Shield Advanced provides advanced DDoS detection and mitigation protection for network layer (layer 3), transport layer (layer 4), and application layer (layer 7) attacks.

For more information about Shield Advanced, see AWS Shield Advanced overview (p. 462).

Note

It's important that you fully configure Shield Advanced prior to a Distributed Denial of Service (DDoS) event. Complete the following steps to help ensure that your application is protected and that you are ready to respond if your application is affected by a DDoS attack.

Perform the following steps in sequence.

Contents

- Subscribe to AWS Shield Advanced (p. 477)
- Add resources to protect and configure protections (p. 478)
  - Configure application layer (layer 7) DDoS protections with AWS WAF (p. 479)
  - Configure health-based detection for your protections (p. 480)
  - Configure alarms and notifications (p. 481)
  - Review and finish your protection configuration (p. 481)
- Configure AWS SRT support (p. 481)
- Create a DDoS dashboard in CloudWatch and set CloudWatch alarms (p. 482)

Subscribe to AWS Shield Advanced

You must subscribe to Shield Advanced for each AWS account that you want to protect.
For accounts that are members of an AWS Organizations organization, AWS bills Shield Advanced subscriptions against the organization's payer account, regardless of whether the payer account itself is subscribed.

**Subscribing multiple accounts**

When you subscribe multiple accounts that are in the same AWS Organizations consolidated billing account family, one subscription price covers all subscribed accounts in the family. The organization must own all of the AWS accounts and their resources. Exceptions apply for AWS Channel Resellers. For detailed pricing information and examples, see AWS Shield Advanced Pricing.

If your accounts are part of an organization, we recommend that you use AWS Firewall Manager if you can, to automate your subscriptions and protections for the organization. Firewall Manager supports all protected resource types except for Amazon Route 53 and AWS Global Accelerator. To use Firewall Manager, see AWS Firewall Manager (p. 358) and Getting started with AWS Firewall Manager AWS Shield Advanced policies (p. 366).

If you don't use Firewall Manager, for each account with resources to protect, subscribe and add protections using the following procedures.

**To subscribe an account to AWS Shield Advanced**

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the AWS Shield navigation bar, choose Getting started. Choose Subscribe to Shield Advanced.
3. In the Subscribe to Shield Advanced page, read each term of the agreement, and then select all of the check boxes to indicate that you accept the terms. For accounts in a consolidated billing family, you must agree to the terms for each account.

   **Important**
   By choosing Subscribe to Shield Advanced, you subscribe to Shield Advanced and activate the service. To unsubscribe, you must contact AWS Support.

   Choose Subscribe to Shield Advanced.

Your account is subscribed. Continue through the following steps to protect your account's resources with Shield Advanced.

**Note**
Shield Advanced doesn't automatically protect your resources after you subscribe. You must specify the resources you want Shield Advanced to protect configure the protections.

**Add resources to protect and configure protections**

Shield Advanced only protects the resources that you specify, either through Shield Advanced or in a Firewall Manager Shield Advanced policy. It doesn't automatically protect the resources of a subscribed account.

If you use an AWS Firewall Manager Shield Advanced policy for your protections, you don't need to do this step. You configure the policy with the types of resource to protect, and Firewall Manager automatically adds protections to resources that are within scope of the policy.

If you don't use Firewall Manager, go through the following procedures for each account that has resources to protect.

**To choose the resources to protect using Shield Advanced**

1. Choose Add resources to protect from the subscription confirmation page of the prior procedure, or from the Protected resources or Overview page.
2. In the Choose resources to protect with Shield Advanced page, in Specify the Region and resource types, provide the Region and resource type specifications for the resources that you want to protect. You can protect resources in multiple Regions by selecting All Regions and you can narrow the selection to global resources by selecting Global. You can deselect any resource types that you do not want to protect. For information about protections for your resource types, see AWS Shield Advanced protections by resource type (p. 487).

3. Choose Load resources. Shield Advanced populates the Select Resources section with the AWS resources that match your criteria.

4. In the Select Resources section, you can filter the list of resources by entering a string to search for in the resource listings.

5. In the Tags section, if you want to add tags to the Shield Advanced protections that you are creating, specify those. For information about tagging AWS resources, see Working with Tag Editor.

6. Choose Protect with Shield Advanced. This adds Shield Advanced protections to the resources.

Continue through the console wizard screens to complete the configuration of your resource protections.

Topics

- Configure application layer (layer 7) DDoS protections with AWS WAF (p. 479)
- Configure health-based detection for your protections (p. 480)
- Configure alarms and notifications (p. 481)
- Review and finish your protection configuration (p. 481)

Configure application layer (layer 7) DDoS protections with AWS WAF

To protect an application layer resource, Shield Advanced uses an AWS WAF web ACL with a rate-based rule as a starting point. AWS WAF is a web application firewall that lets you monitor the HTTP and HTTPS requests that are forwarded to your application layer resources, and lets you control access to your content based on the characteristics of the requests. A rate-based rule limits the volume of traffic from any single IP address, providing basic DDoS protection to your application. For more information, see How AWS WAF works (p. 6) and Rate-based rule statement (p. 100).

The base costs for using the AWS WAF web ACL with Shield Advanced is covered by your Shield Advanced subscription. For pricing information and examples, see AWS Shield Advanced Pricing.

You can also optionally enable Shield Advanced automatic application layer DDoS mitigation, to have Shield Advanced automatically provide incident-specific protections for you.

Important

If you manage your Shield Advanced protections through AWS Firewall Manager using a Shield Advanced policy, you can't manage application layer protections here. You must manage them in your Firewall Manager Shield Advanced policy.

To configure layer 7 DDoS protections for a Region

Shield Advanced gives you the option to configure layer 7 DDoS mitigation for each Region where your chosen resources are located. If you're adding protections in multiple regions, the wizard walks you through the following procedure for each Region.

1. The Configure layer 7 DDoS protections page lists each resource that isn't yet associated with a web ACL. For each of these, either choose an existing web ACL or create a new web ACL. For any resource that already has an associated web ACL, you can change web ACLs by first disassociating the current
one through AWS WAF. For more information, see Associating or disassociating a web ACL with an AWS resource (p. 23).

For web ACLs that don't already have a rate-based rule, the configuration wizard prompts you to add one. A rate-based rule limits traffic from IP addresses when they are sending a high volume of requests. Rate-based rules help protect your application against web request floods and can provide alerts about sudden spikes in traffic that might indicate a potential DDoS attack. Add a rate-based rule to a web ACL by choosing Add rate limit rule and then providing a rate limit and rule action. You can configure additional protections in the web ACL through AWS WAF.

For information about using web ACLs and rate-based rules in your Shield Advanced protections, including additional configuration options for rate-based rules, see Shield Advanced application layer AWS WAF web ACLs and rate-based rules (p. 489).

2. For **Automatic application layer DDoS mitigation**, if you want to have Shield Advanced automatically mitigate DDoS attacks against your application layer resources, choose Enable and then select the AWS WAF rule action that you want Shield Advanced to use in its custom rules. This setting applies to all of the web ACLs for the resources that you are managing in this wizard session.

   With automatic application layer DDoS mitigation, Shield Advanced compares current traffic patterns against historic traffic baselines to detect deviations that might indicate a DDoS attack. If automatic mitigation is enabled for a resource, when Shield Advanced detects a DDoS attack, it responds by creating, evaluating, and deploying custom AWS WAF rules to respond. You specify whether the custom rules count or block attacks on your behalf.

   **Note**
   Automatic application layer DDoS mitigation works only with web ACLs that were created using the latest version of AWS WAF (v2).

   For more information about Shield Advanced automatic application layer DDoS mitigation, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

3. Choose Next. The console wizard advances to the health-based detection page.

### Configure health-based detection for your protections

You can optionally configure Shield Advanced to use health-based detection, which can improve responsiveness and accuracy in attack detection and mitigation. You can use this option with any resource type except for Route 53 hosted zones.

To use health-based detection, you first need to define a health check for your resource in Route 53 and then associate the health check with your Shield Advanced protection. It's important that the health check that you configure accurately reflect the health of the resource. For information and examples for configuring health checks to use with Shield Advanced, see Configuring health-based detection using health checks (p. 495).

Health checks are required for Shield Response Team (SRT) proactive engagement support. For information about proactive engagement, see Configuring proactive engagement (p. 485).

**Note**
Health checks must be reporting healthy when you associate them with your Shield Advanced protections.

**To configure health-based detection**

1. Under **Associated Health Check**, choose the ID of the health check that you want to associate with the protection.

   **Note**
   If you do not see the health check you need, go to the Route 53 console and verify the health check and its ID. For information, see Creating and Updating Health Checks.
2. Choose **Next**. The console wizard advances to the alarms and notifications page.

### Configure alarms and notifications

You can optionally configure Amazon Simple Notification Service notifications for detected Amazon CloudWatch alarms and rate-based rule activity. You can use these to receive notification when Shield detects an event on a protected resource or when a rate-limit configured in a rate-based rule is exceeded.

For information about Shield Advanced CloudWatch metrics, see the section called “Metrics” (p. 517). For information about Amazon SNS, see the *Amazon Simple Notification Service Developer Guide*.

#### To configure alarms and notifications

1. Select the Amazon SNS topics that you want notification for. You can use a single Amazon SNS topic for all protected resources and rate-based rules, or you can choose different topics, customized to your organization. For example, you can create an SNS topic for each team that’s responsible for incident response for a specific set of resources.
2. Choose **Next**. The console wizard advances to the resource protection review page.

### Review and finish your protection configuration

#### To review and configure your settings

1. In the **Review and configure DDoS mitigation and visibility** page, review your settings. To make modifications, choose **Edit** in the area that you want to modify. This takes you back to the associated page in the console wizard. Make your changes, then choose **Next** in the subsequent pages until you return to the **Review and configure DDoS mitigation and visibility** page.
2. Choose **Finish configuration**. The **Protected resources** page lists your newly protected resources.

### Configure AWS SRT support

The Shield Response Team (SRT) are security engineers who specialize in DDoS event response. You can optionally add permissions that allow the SRT to manage resources on your behalf during a DDoS event. In addition, you can configure the SRT to proactively engage with you if the Route 53 health checks associated with your protected resources are unhealthy during a detected event. Both of these additions to your protections enable quicker responses to DDoS events.

#### Note

To use the services of the Shield Response Team (SRT), you must be subscribed to the Business Support plan or the Enterprise Support plan.

The SRT can monitor AWS WAF request data and logs during application layer events to identify anomalous traffic. They can help craft custom AWS WAF rules to mitigate offending traffic sources. As needed, the SRT might make architectural recommendations to help you better align your resources with AWS recommendations.

For more information about the SRT, see *Shield Response Team (SRT) support* (p. 483).

#### To grant permissions to the SRT

1. In the AWS Shield console **Overview** page, under **Configure AWS SRT support**, choose **Edit SRT access**. The **Edit AWS Shield Response Team (SRT) access** page opens.
2. For **SRT access setting** select one of the options:
Create a DDoS dashboard in CloudWatch and set CloudWatch alarms

- **Do not grant the SRT access to my account** – Shield removes any permissions you previously gave to the SRT to access your account and resources.

- **Create a new role for the SRT to access my account** – Shield creates the role and automatically configures it for use. The role allows the SRT to access your AWS Shield Advanced and AWS WAF resources using the service principal `drt.shield.amazonaws.com`, which represents the SRT.

- **Choose an existing role for the SRT to access my accounts** – For this option, you must modify the configuration of the role in AWS Identity and Access Management (IAM) as follows:
  - Attach the managed policy `AWSShieldDRTAccessPolicy` to the role. This managed policy allows the SRT to make AWS Shield Advanced and AWS WAF API calls on your behalf and to access your AWS WAF logs. For more information about attaching the managed policy to your role, see [Attaching and Detaching IAM Policies](#).
  - Modify the role to trust the service principal `drt.shield.amazonaws.com`. This is the service principal that represents the SRT. For more information, see [IAM JSON Policy Elements: Principal](#).

3. Choose **Save** to save your changes.

For more information about giving the SRT access to your protections and data, see [Configuring access for the Shield Response Team (SRT)](#) (p. 484).

**To enable SRT proactive engagement**

1. In the AWS Shield console **Overview** page, under **Proactive engagement and contacts**, in the contacts area, choose **Edit**.

   In the **Edit contacts** page, provide the contact information for the people that you want the SRT to contact for proactive engagement.

   If you provide more than one contact, in the **Notes**, indicate the circumstances under which each contact should be used. Include primary and secondary contact designations, and provide the hours of availability and time zones for each contact.

   Example contact notes:
   - This is a hotline that's staffed 24x7x365. Please work with the responding analyst and they will get the appropriate person on the call.
   - Please contact me if the hotline doesn't respond within 5 minutes.

2. Choose **Save**.

   The **Overview** page reflects the updated contact information.

3. Choose **Edit proactive engagement feature**, choose **Enable**, and then choose **Save** to enable proactive engagement.

For more information about proactive engagement, see [Configuring proactive engagement](#) (p. 485).

**Create a DDoS dashboard in CloudWatch and set CloudWatch alarms**

You can monitor potential DDoS activity using Amazon CloudWatch, which collects raw data from Shield Advanced and processes it into readable, near real-time metrics. You can use statistics in CloudWatch to gain a perspective on how your web application or service is performing. For more information about using CloudWatch, see [What is CloudWatch](#) in the *Amazon CloudWatch User Guide*. 
• For instructions for creating a CloudWatch dashboard, see Monitoring with Amazon CloudWatch (p. 541).
• For descriptions of the Shield Advanced metrics that you can add to your dashboard, see AWS Shield Advanced metrics and alarms (p. 545).

Shield Advanced reports resource metrics to CloudWatch more frequently during DDoS events than while no events are underway. Shield Advanced reports metrics once a minute during an event, and then once right after the event ends. While no events are underway, Shield Advanced reports metrics once a day, at a time assigned to the resource. This periodic report keeps the metrics active and available for use in your custom CloudWatch alarms.

This completes the tutorial for getting started with Shield Advanced. To take full advantage of the protections you’ve chosen, continue exploring the features and options of Shield Advanced. To start, familiarize yourself with your options for viewing and responding to events at Visibility into DDoS events (p. 508) and Responding to DDoS events (p. 519).

Shield Response Team (SRT) support

The Shield Response Team (SRT) provides added support for Shield Advanced customers. The SRT are security engineers who specialize in DDoS event response. As an additional layer of support to your AWS Support plan, you can work directly with the SRT, leveraging their expertise as part of your event response workflow. For information about the options and for configuration guidance, see the topics that follow.

Note
To use the services of the Shield Response Team (SRT), you must be subscribed to the Business Support plan or the Enterprise Support plan.

SRT support activities

The primary goal in an engagement with the SRT is to protect the availability and performance of your application. Depending on the type of DDoS event and the architecture of your application, the SRT may take one or more of the following actions:

• AWS WAF log analysis and rules – For resources that use an AWS WAF web ACL, the SRT can analyze your AWS WAF logs to identify attack characteristics in your application web requests. With your approval during engagement, the SRT can apply changes to your web ACL to block the attacks that they’ve identified.
• Build custom network mitigations – The SRT can write custom mitigations for you for infrastructure layer attacks. The SRT can work with you to understand traffic that’s expected for your application, to block unexpected traffic, and to optimize packet per second rate limits. For more information, see Configuring custom mitigations with the Shield Response Team (SRT) (p. 486).
• Network traffic engineering – The SRT works closely with AWS networking teams to protect Shield Advanced customers. When required, AWS can change how internet traffic arrives on the AWS network in order to allocate more mitigation capacity to your application.
• Architectural recommendations – The SRT may determine that the best mitigation for an attack requires architectural changes to better align with the AWS best practices, and they will help support your implementation of these practices. For information, see AWS Best Practices for DDoS Resiliency.

Topics
• Configuring access for the Shield Response Team (SRT) (p. 484)
• Configuring proactive engagement (p. 485)
• Contacting the Shield Response Team (SRT) (p. 486)
• Configuring custom mitigations with the Shield Response Team (SRT) (p. 486)
Configuring access for the Shield Response Team (SRT)

You can grant permission to the Shield Response Team (SRT) to act on your behalf, accessing your AWS WAF logs and making calls to the AWS Shield Advanced and AWS WAF APIs to manage protections. With API access, SRT engineers can directly manage AWS WAF rules used to mitigate application-layer DDoS attacks. Additionally, you can grant the SRT access to other data that you have stored in Amazon S3 buckets, such as packet captures or logs from an Application Load Balancer, Amazon CloudFront, or from third party sources.

Note
To use the services of the Shield Response Team (SRT), you must be subscribed to the Business Support plan or the Enterprise Support plan.

To manage permissions for the SRT

1. In the AWS Shield console Overview page, under Configure AWS SRT support, choose Edit SRT access. The Edit AWS Shield Response Team (SRT) access page opens.

2. For SRT access setting select one of the options:
   - **Do not grant the SRT access to my account** – Shield removes any permissions you previously gave to the SRT to access your account and resources.
   - **Create a new role for the SRT to access my account** – Shield creates the role and automatically configures it for use. The role allows the SRT to access your AWS Shield Advanced and AWS WAF resources using the service principal drt.shield.amazonaws.com, which represents the SRT.
   - **Choose an existing role for the SRT to access my accounts** – For this option, you must modify the configuration of the role in AWS Identity and Access Management (IAM) as follows:
     - Attach the managed policy AWSShieldDRTAccessPolicy to the role. This managed policy allows the SRT to make AWS Shield Advanced and AWS WAF API calls on your behalf and to access your AWS WAF logs. For more information about attaching the managed policy to your role, see Attaching and Detaching IAM Policies.
     - Modify the role to trust the service principal drt.shield.amazonaws.com. This is the service principal that represents the SRT. For more information, see IAM JSON Policy Elements: Principal.

3. For (Optional): Grant SRT access to an Amazon S3 bucket, if you need to share data that isn't in your AWS WAF web ACL logs, configure this. For example, Application Load Balancer access logs, Amazon CloudFront logs, or logs from third party sources.

   Note
   You don't need to do this for your AWS WAF web ACL logs. The SRT gains access to those when you grant access to your account.

   a. Configure the Amazon S3 buckets according to the following guidelines:
      - The bucket locations must be in the same AWS account as the one you gave the SRT general access to, in the prior step AWS Shield Response Team (SRT) access.
      - The buckets can be either plaintext or SSE-S3 encrypted. For more information about Amazon S3 SSE-S3 encryption, see Protecting Data Using Server-Side Encryption with Amazon S3-Managed Encryption Keys (SSE-S3) in the Amazon S3 User Guide.
      - The SRT cannot view or process logs that are stored in buckets that are encrypted with keys stored in AWS Key Management Service (AWS KMS).
   b. In the Shield Advanced (Optional): Grant SRT access to an Amazon S3 bucket section, for each Amazon S3 bucket where your data or logs are stored, enter the name of the bucket and choose Add Bucket. You can add up to 10 buckets.
This grants the SRT the following permissions on each bucket: s3:GetBucketLocation, s3:GetObject, and s3:ListBucket.

If you want to give the SRT permission to access more than 10 buckets, you can do this by editing the additional bucket policies and manually granting the permissions listed here for the SRT.

4. Choose Save to save your changes.

The SRT can monitor AWS WAF request data and logs during application layer events to identify anomalous traffic. They can also help craft custom AWS WAF rules to mitigate offending traffic sources.

Configuring proactive engagement

With proactive engagement, the Shield Response Team (SRT) contacts you directly when the availability or performance of your application is affected because of a possible attack. We recommend this engagement model because it provides the quickest SRT response and it allows the SRT to begin troubleshooting even before they've established contact with you.

Proactive engagement is available for network-layer and transport-layer events on Elastic IP addresses and AWS Global Accelerator standard accelerators, and for web request floods on Amazon CloudFront distributions and Application Load Balancers. Proactive engagement is available only for Shield Advanced resource protections that have an associated Amazon Route 53 health check. For information about managing and using health checks, see Configuring health-based detection using health checks (p. 495).

During an event that's detected by Shield Advanced, the SRT uses the state of your health checks to determine whether the event qualifies for proactive engagement. If so, the SRT will contact you within 15 minutes, according to the contact guidance that you provide in your proactive engagement configuration.

You can configure up to ten contacts for proactive engagement, and you can provide notes to guide the SRT in reaching out to you. Your proactive engagement contacts should be available to engage with the SRT within 15 minutes of contact, as you might provide in a 24/7 operations center. If you don't have a 24/7 operations center, you can provide a pager contact and indicate this contact preference in your contact notes.

Proactive engagement requires you to do the following:

- You must be subscribed to the Business Support plan or the Enterprise Support plan.
- You must associate an Amazon Route 53 health check with any resource that you want to protect with proactive engagement. The SRT uses the status of your health checks to help determine whether an event requires proactive engagement, so it's important that your health checks accurately reflect the state of your protected resources. For more information and guidance, see Configuring health-based detection using health checks (p. 495).
- For a resource that has an AWS WAF web ACL associated, you must create the web ACL using AWS WAF (v2), which is the latest version of AWS WAF.
- You must provide at least one contact for the SRT to use for proactive engagement during an event. Keep your contact information complete and up to date.

To enable SRT proactive engagement

1. In the AWS Shield console Overview page, under Proactive engagement and contacts, in the contacts area, choose Edit.
In the **Edit contacts** page, provide the contact information for the people that you want the SRT to contact for proactive engagement.

If you provide more than one contact, in the **Notes**, indicate the circumstances under which each contact should be used. Include primary and secondary contact designations, and provide the hours of availability and time zones for each contact.

Example contact notes:

- This is a hotline that's staffed 24x7x365. Please work with the responding analyst and they will get the appropriate person on the call.
- Please contact me if the hotline doesn't respond within 5 minutes.

2. Choose **Save**.

   The **Overview** page reflects the updated contact information.

3. Choose **Edit proactive engagement feature**, choose **Enable**, and then choose **Save** to enable proactive engagement.

## Contacting the Shield Response Team (SRT)

You can contact the Shield Response Team (SRT) in one of the following ways:

- **Support case** – You can open a case under **AWS Shield** in the **AWS Support Center**. Select the severity appropriate to your situation and provide your contact details. In the description, provide as much detail as possible. Provide information about any protected resources that you think might be affected, and the current state of your end-user experience. For example, if your user experience is degraded or parts of your application are currently unavailable, provide that information.

   If the availability or performance of your application is currently affected by a possible DDoS attack, choose the following severity and contact options:

   - For severity, choose the highest severity available for your support plan:
     - For Business support this is **Production system down: < 1 hour**.
     - For Enterprise support this is **Business-critical system down: < 15 minutes**.
   - For contact option, select either **Phone** or **Chat** and provide your details. Using a live contact method provides the fastest response.

- **Proactive engagement** – With **AWS Shield Advanced** proactive engagement, the SRT contacts you directly if the Amazon Route 53 health check associated with your protected resource becomes unhealthy during a detected event. For more information about this option, see **Configuring proactive engagement** (p. 485).

## Configuring custom mitigations with the Shield Response Team (SRT)

For your Elastic IPs (EIPs) and your AWS Global Accelerator standard accelerators, you can work with the Shield Response Team (SRT) to configure custom mitigations. This is useful in case you know of specific logic that should be enforced when a mitigation is placed. For example, you may wish to only allow traffic from certain countries, enforce specific rate limits, configure optional validations, disallow fragments, or only allow traffic that matches a specific pattern in the packet payload.

Examples of common custom mitigations include the following:
Resource protections in AWS Shield Advanced

You can add and configure AWS Shield Advanced protections for your resources. You can manage protections for a single resource and you can group your protected resources into logical collections for better event management. You can also track changes to your Shield Advanced protections using AWS Config.

Topics
- AWS Shield Advanced protections by resource type (p. 487)
- AWS Shield Advanced application layer (layer 7) protections (p. 488)
- Configuring health-based detection using health checks (p. 495)
- Managing resource protections in AWS Shield Advanced (p. 502)
- AWS Shield Advanced protection groups (p. 506)
- Tracking resource protection changes in AWS Config (p. 507)

AWS Shield Advanced protections by resource type

Shield Advanced protects AWS resources in the network and transport layers (layers 3 and 4) and in the application layer (layer 7). You can protect some resources directly and others through association with protected resources. This section provides information about Shield Advanced protections for each resource type.

Note
Shield Advanced protects only resources that you have specified either in Shield Advanced or through an AWS Firewall Manager Shield Advanced policy. It doesn't automatically protect your resources.

You can use Shield Advanced for advanced monitoring and protection with the following resource types:
- Amazon CloudFront distributions.
- Amazon Route 53 hosted zones.
- AWS Global Accelerator standard accelerators.
- Amazon EC2 Elastic IP addresses. Shield Advanced protects the resources that are associated with protected Elastic IP addresses.
- Amazon EC2 instances, through association to Amazon EC2 Elastic IP addresses.
- The following Elastic Load Balancing (ELB) load balancers:
• Application Load Balancers.
• Classic Load Balancers.
• Network Load Balancers, through associations to Amazon EC2 Elastic IP addresses.

You can't use Shield Advanced to protect any other resource type. For example you can't protect AWS Global Accelerator custom routing accelerators or Gateway Load Balancers.

You can monitor and protect up to 1,000 resources for each resource type per AWS account. For example, in a single account, you could protect 1,000 Amazon EC2 Elastic IP addresses, 1,000 CloudFront distributions, and 1,000 Application Load Balancers. You can request an increase to the number of resources that you can protect with Shield Advanced through the Service Quotas console at https://console.aws.amazon.com/servicequotas/.

Protecting Amazon EC2 instances and Network Load Balancers with Shield Advanced

You can protect Amazon EC2 instances and Network Load Balancers by first attaching these resources to Elastic IP addresses, and then protecting the Elastic IP addresses in Shield Advanced.

When you protect Elastic IP addresses, Shield Advanced identifies and protects the resources that they're attached to. Shield Advanced automatically identifies the type of resource that's attached to an Elastic IP address and applies the appropriate detections and mitigations for that resource. This includes configuring network ACLs that are specific to the Elastic IP address. For more information about using Elastic IP addresses with your AWS resources, see the following guides: Amazon Elastic Compute Cloud documentation or Elastic Load Balancing documentation.

During an attack, Shield Advanced automatically deploys your network ACLs to the border of the AWS network. When your network ACLs are at the border of the network, Shield Advanced can provide protection against larger DDoS events. Typically, network ACLs are applied near your Amazon EC2 instances within your Amazon VPC. The network ACL can mitigate attacks only as large as your Amazon VPC and instance can handle. For example, if the network interface attached to your Amazon EC2 instance can process up to 10 Gbps, then volumes over 10 Gbps will slow down and possibly block traffic to that instance. During an attack, Shield Advanced promotes your network ACL to the AWS border, which can process multiple terabytes of traffic. Your network ACL is able to provide protection for your resource well beyond your network's typical capacity. For more information about network ACLs, see Network ACLs.

Some scaling tools, like AWS Elastic Beanstalk, don't let you to automatically attach an Elastic IP address to a Network Load Balancer. For those cases, you need to manually attach the Elastic IP address.

AWS Shield Advanced application layer (layer 7) protections

To protect your application layer resources with Shield Advanced, you start by associating an AWS WAF web ACL with the resource and adding one or more rate-based rules to it. You can additionally enable automatic application layer DDoS mitigation, which causes Shield Advanced to automatically create and manage web ACL rules on your behalf in response to DDoS attacks.

When you protect an application layer resource with Shield Advanced, Shield Advanced analyzes traffic over time to establish and maintain baselines. Shield Advanced uses these baselines to detect anomalies in traffic patterns that might indicate a DDoS attack. The point at which Shield Advanced detects an attack depends on the traffic that Shield Advanced has been able to observe prior to the attack and on the architecture you use for your web applications. The architectural variations that can affect Shield Advanced behavior include the type of instance you use, your instance size, and whether the instance type supports enhanced networking. You can also configure Shield Advanced to automatically place mitigations for application layer attacks.

Topics
Shield Advanced application layer AWS WAF web ACLs and rate-based rules

To protect an application layer resource with Shield Advanced, you start by associating an AWS WAF web ACL with the resource. AWS WAF is a web application firewall that lets you monitor the HTTP and HTTPS requests that are forwarded to your application layer resources, and lets you control access to your content based on the characteristics of the requests. You can configure a web ACL to monitor and manage requests based on factors such as where the request originated, the contents of query strings and cookies, and the rate of requests coming from a single IP address. At a minimum, your Shield Advanced protection requires you to associate a web ACL with a rate-based rule, which limits the rate of requests for each IP address.

If the associated web ACL doesn’t have a rate-based rule defined, Shield Advanced prompts you to define at least one. Rate-based rules automatically block traffic from source IPs when they exceed the thresholds that you define. They help protect your application against web request floods and can provide alerts about sudden spikes in traffic that might indicate a potential DDoS attack.

With your web ACL in place, if a DDoS attack occurs, you apply mitigations by adding and managing rules in the web ACL. You can do this directly, with the assistance of the Shield Response Team (SRT), or automatically through automatic application layer DDoS mitigation.

How rate-based rules work

When you use a rate-based rule, every 30 seconds, AWS WAF evaluates traffic for the prior five minutes. AWS WAF blocks requests from any source IP address that exceeds the threshold until the request rate drops down to an acceptable level. When you configure a rate-based rule, configure its rate threshold to a value that’s greater than the normal traffic rate that you expect from any one source IP in any five minute time window.

You might want to use more than one rate-based rule in a web ACL. For example, you could have one rate-based rule for all traffic that has a high threshold plus one or more additional rules that are configured to match select parts of your web application and that have lower thresholds. For example, you might match on the URI /login.html with a lower threshold, to mitigate abuse against a login page.

For additional information and guidance, see the security blog post The three most important AWS WAF rate-based rules.

Expanded configuration options through AWS WAF

The Shield Advanced console enables you to add a rate-based rule and configure it with the essential settings. You can define additional configuration options by managing your rate-based rules through AWS WAF. For example, you can configure the rule to aggregate on a forwarded IP address and you can add a scope-down statement to filter out some requests from evaluation. For all of the configuration options, see Rate-based rule statement (p. 100). For information about using AWS WAF to manage your web request monitoring and management rules, see Creating a web ACL (p. 18).

Shield Advanced automatic application layer DDoS mitigation

You can configure Shield Advanced to respond automatically to mitigate application layer (layer 7) attacks against your protected application layer resources, by counting or blocking web requests that are part of the attack. This option is an addition to the application layer protection that you add through Shield Advanced with an AWS WAF web ACL and rate-based rule. For information about the console steps, see Configure application layer DDoS protections (p. 503).
Shield Advanced compares current traffic patterns against historic traffic baselines to detect deviations that might indicate a DDoS attack. When you enable automatic application layer DDoS mitigation for a resource, Shield Advanced responds to detected DDoS attacks by creating, evaluating, and deploying custom AWS WAF rules.

**Shield Advanced automatic application layer DDoS mitigation caveats**

The following list describes the caveats of Shield Advanced automatic application layer DDoS mitigation, and describes steps that you might want to take in response.

- Automatic application layer DDoS mitigation works only with web ACLs that were created using the latest version of AWS WAF (v2).
- For detection and automatic mitigation of application layer attacks, Shield Advanced leverages the historical traffic to your protected resource. Awareness of the normal traffic patterns to your application is what enables Shield Advanced to isolate attack traffic from the normal traffic to your application. If your protected resource doesn’t yet have a history of normal application traffic, such as before the application is launched, or if it lacks production traffic for extended periods of time, we recommend enabling the automatic mitigation in COUNT mode until a history of normal application traffic has been established for the resource.
- Shield Advanced requires from 24 hours to 30 days to establish a baseline of your application traffic.
- Automatic application layer DDoS mitigation only places rules to mitigate a DDoS attack after testing them against historical traffic to verify that they mitigate the attack traffic and don't impact the normal traffic to your application.
- The time between the start of a DDoS attack and when Shield Advanced places automatic mitigation rules varies with each event. Some DDoS attacks might end before mitigation rules are deployed. Other attacks might happen when a mitigation is already in place, and so might be mitigated from the start of the event.
- For Application Load Balancers that receive any traffic through a content delivery network (CDN), such as Amazon CloudFront, the application-layer automatic mitigation capabilities of Shield Advanced for those Application Load Balancer resources will be reduced. Shield Advanced uses client traffic attributes to identify and isolate attack traffic from normal traffic to your application, and CDNs may not preserve or forward the original client traffic attributes. If you use CloudFront, we recommend enabling automatic mitigation on the CloudFront distribution.
- Automatic application layer DDoS mitigation does not interact with protection groups. You can enable automatic mitigation for resources that are in protection groups, but Shield Advanced does not automatically apply attack mitigations based on protection group findings. Shield Advanced applies automatic attack mitigations for individual resources.

Best practices for using automatic mitigation

Adhere to the guidance provided here when you use automatic mitigation.

- Manage all of your automatic mitigation protections either through Shield Advanced or, if you're using AWS Firewall Manager to manage your Shield Advanced automatic mitigation settings, through Firewall Manager. Don't mix your use of Shield Advanced and Firewall Manager to manage these protections.

- Manage similar resources using the same web ACLs and protection settings, and manage dissimilar resources using different web ACLs. When Shield Advanced mitigates a DDoS attack on a protected resource, it defines rules for the web ACL that's associated with the resource and then tests the rules against traffic of all resources that are associated with the web ACL. Shield Advanced will only apply the rules if they don't negatively impact any of the associated resources. For more information, see How Shield Advanced manages automatic mitigation (p. 491).

- Don't delete any rule group from your web ACLs whose name starts with ShieldMitigationRuleGroup. If you do, you disable the protections provided by Shield Advanced automatic mitigation for every resource that's associated with the web ACL. Additionally, it can take Shield Advanced some time to receive notice of the change and to update its settings. During this time, the Shield Advanced console pages will provide incorrect information. For more information, see The Shield Advanced rule group reference statement (p. 493).

- For Application Load Balancers that have all their internet traffic proxied through a Amazon CloudFront distribution, only enable automatic mitigation on the CloudFront distribution. The CloudFront distribution will always have the greatest number of original traffic attributes, which Shield Advanced leverages to mitigate attacks.

Configuration required to enable automatic mitigation

You enable Shield Advanced automatic mitigation as part of the application layer DDoS protections for your resource. For information about doing this through the console, see Configure application layer DDoS protections (p. 503).

The automatic mitigation functionality requires you to do the following:

- **Associate a web ACL with the resource** – This is required for any Shield Advanced application layer protection. You can use the same web ACL for multiple resources. We recommend doing this only for resources that have similar traffic. For information about web ACLs, including the requirements for using them with multiple resources, see How AWS WAF works (p. 8).

- **Enable and configure Shield Advanced automatic application layer DDoS mitigation** – When you enable this, you specify whether you want Shield Advanced to automatically block or count web requests that it determines to be part of a DDoS attack. Shield Advanced adds a rule group to the associated web ACL and uses it to dynamically manage its response to DDoS attacks on the resource. For information about the rule action settings, see AWS WAF rule action (p. 84).

- **(Optional, but recommended) Add a rate-based rule to the web ACL** – The rate-based rule provides your resource with basic protection against DDoS attacks by preventing any individual IP address from sending too many requests in a short time. For information about rate-based rules, see Rate-based rule statement (p. 100).

How Shield Advanced manages automatic mitigation

The topics in section describe how Shield Advanced handles your configuration changes for automatic application layer DDoS mitigation and how it handles DDoS attacks when automatic mitigation is enabled.
What happens when you enable automatic mitigation

Shield Advanced does the following when you enable automatic mitigation:

- **As needed, adds a rule group for Shield Advanced use** – If the AWS WAF web ACL that you have associated with the resource doesn't already have an AWS WAF rule group reference statement that's dedicated to automatic application layer DDoS mitigation, Shield Advanced adds one. The name of the rule group reference statement starts with `ShieldMitigationRuleGroup`. For additional details about this rule group, see The Shield Advanced rule group reference statement (p. 493).

- **Starts responding to DDoS attacks against the resource** – Shield Advanced automatically responds to DDoS attacks for the protected resource. Shield Advanced uses the rule group to deploy AWS WAF rules for DDoS attack mitigation. Shield Advanced tailors these rules to your application and to the attacks that your application experiences, and tests them against the resource's historical traffic before deploying them. The sections that follow provide more information about how Shield Advanced does this.

Shield Advanced uses a single rule group reference statement in any web ACL that you use for automatic mitigation. If you're already using the web ACL for automatic mitigation, Shield Advanced doesn't add another rule group to it. Automatic application layer DDoS mitigation depends on the presence of the rule group to mitigate attacks. If the rule group is removed from the AWS WAF web ACL for any reason, the removal disables automatic mitigation for all resources that are associated with the web ACL.

How Shield Advanced responds to DDoS attacks with automatic mitigation

When Shield Advanced detects an attack on a protected resource that has automatic mitigation enabled, it does the following:

1. Attempts to identify an attack signature that isolates the attack traffic from the normal traffic to your application. The goal is to produce high quality DDoS mitigation rules that, when placed, affect only the attack traffic and don't impact normal traffic to your application.

2. Evaluates the identified attack signature against the historical traffic patterns for the resource that's under attack as well as for any other resource that's associated with the same web ACL. Shield Advanced does this before it deploys any rules in response to the event.

Depending on the evaluation results, Shield Advanced does one of the following:

- If Shield Advanced determines that the attack signature isolates only the traffic that is involved in the DDoS attack, it implements the signature in AWS WAF rules under the Shield Advanced mitigation rule group in the web ACL. Shield Advanced gives these rules the action setting that you've configured for the resource's automatic mitigation - either COUNT or BLOCK.

- Otherwise, Shield Advanced doesn't place a mitigation.

Throughout an attack, Shield Advanced sends the same notifications and provides the same event information as for basic Shield Advanced application layer protections. You can see the information about events and DDoS attacks, and about any Shield Advanced mitigations for attacks, in the Shield Advanced event console. For information, see Visibility into DDoS events (p. 508).
If you've configured automatic mitigation to use the BLOCK rule action and you experience false positives from the mitigation rules that Shield Advanced has deployed, you can change the rule action to COUNT. For information about how to do this, see Changing the action used for automatic application layer DDoS mitigation (p. 495).

What happens when you change the rule action setting

When you change the automatic mitigation rule action setting for a protected resource, Shield Advanced updates all rule settings for the resource. It updates any rules that are currently in place for the resource in the managed rule group and it uses the new action setting when it creates new rules.

Changing the action setting can take a few seconds to propagate. During this time, you might see the old setting in some places where the rule group is in use, and the new setting in other places.

You can change the rule action setting for your automatic mitigation configuration in the events page of the console, and through the application layer configuration page. For information about the events page, see Responding to DDoS events (p. 519). For information about the configuration page, see Configure application layer DDoS protections (p. 503).

How Shield Advanced manages mitigations when an attack subsides

When Shield Advanced determines that mitigation rules that were deployed for a particular attack are no longer needed, it removes them from the Shield Advanced mitigation rule group.

The removal of mitigating rules won't necessarily coincide with the end of an attack. Shield Advanced monitors patterns of attack that it detects on your protected resources. It might proactively defend against the recurrence of an attack with a specific signature by keeping the rules that it has deployed against the initial occurrence of that attack in place. As needed, Shield Advanced increases the window of time that it keeps rules in place. This way, Shield Advanced might mitigate repeated attacks with a specific signature before they impact your protected resources.

What happens when you disable automatic mitigation

Shield Advanced does the following when you disable automatic mitigation for a resource:

- **Stops automatically responding to DDoS attacks** – Shield Advanced discontinues its automatic response activities for the resource.
- **Removes unneeded rules from the Shield Advanced rule group** – If Shield Advanced is maintaining any rules in its managed rule group on behalf of the protected resource, it removes them.
- **Removes the Shield Advanced rule group, if it's no longer in use** – If the web ACL that you have associated with the resource isn't associated to any other resource that has automatic mitigation enabled, Shield Advanced removes its rule group reference statement from the web ACL.

The Shield Advanced rule group reference statement

Shield Advanced manages automatic application layer DDoS mitigation activities using a rule group in the web ACL that you have associated with your resource.

The Shield Advanced rule group reference statement in your web ACL has following properties:

- **Name** – ShieldMitigationRuleGroup_account-id_web-acl-id_unique-identifier
- **Web ACL capacity units (WCU)** – 150. These WCUs count against the WCU usage in your web ACL.
- **Priority** – 10,000,000. This high priority setting leaves you room to run your other rules and rule groups in the web ACL before the Shield Advanced rule group. AWS WAF runs the rules in a web ACL from the lowest numeric priority setting on up.
The automatic mitigation functionality doesn't consume any additional AWS WAF resources in your account, outside of the rule group WCUs in your web ACL. For example, the Shield Advanced rule group isn't counted as one of your account's rule groups. For information about account limits in AWS WAF, see AWS WAF quotas (p. 243).

Managing automatic application layer DDoS mitigation

Use the guidance in this section to manage your automatic application layer DDoS mitigation configurations. For information about how automatic mitigation works, see the preceding topics.

Topics

- Viewing the automatic application layer DDoS mitigation configuration for a resource (p. 494)
- Enabling and disabling automatic application layer DDoS mitigation (p. 494)
- Changing the action used for automatic application layer DDoS mitigation (p. 495)

Viewing the automatic application layer DDoS mitigation configuration for a resource

You can view the automatic application layer DDoS mitigation configuration for a resource in the Protected resources page and in the individual protections pages.

To view the automatic application layer DDoS mitigation configuration

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the AWS Shield navigation pane, choose Protected resources. In the list of protected resources, the column Automatic application layer DDoS mitigation indicates whether automatic mitigation is enabled and, where enabled, the action that Shield Advanced is to use in its mitigations.

   You can also select any application layer resource to see the same information listed on the protections page for the resource.

Enabling and disabling automatic application layer DDoS mitigation

The following procedure shows how to enable or disable automatic response for a protected resource.

To enable or disable automatic application layer DDoS mitigation for a single resource

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the AWS Shield navigation pane, choose Protected resources.
3. In the Protections tab, select the application layer resource that you want to enable automatic mitigation for. The protections page opens for the resource.
4. In the resource's protections page, choose Edit.
5. In the page Configure layer 7 DDoS mitigation for global resources - optional, for Automatic application layer DDoS mitigation, choose the option that you want to use for automatic mitigations. The options in the console are the following:
   - Keep current settings – Make no changes to the automatic mitigation settings of the protected resource.
   - Enable – Enable automatic mitigation for the protected resource. When you choose this, also select the rule action that you want the automatic mitigations to use in the web ACL rules. For information about the rule action settings, see AWS WAF rule action (p. 84).
   - Disable – Disable automatic mitigation for the protected resource.
6. Walk through the rest of the pages until you finish and save the configuration.

In the Protections page, the automatic mitigation settings are updated for the resource.

Changing the action used for automatic application layer DDoS mitigation

You can change the action that Shield Advanced uses for its application layer automatic response in multiple locations in the console:

- **Automatic mitigation configuration** – Change the action when you configure automatic mitigation for your resource. For the procedure, see the preceding section Enabling and disabling automatic application layer DDoS mitigation (p. 494).
- **Event details page** – Change the action in the event details page, when you're viewing the event information in the console. For information, see AWS Shield Advanced event details (p. 514).

Configuring health-based detection using health checks

You can configure Shield Advanced to use health-based detection for improved responsiveness and accuracy in attack detection and mitigation. You can use this option with any resource type except for Route 53 hosted zones.

To configure health-based detection, you define a health check for your resource in Route 53, verify that it's reporting healthy, and then associate it with your Shield Advanced protection. For information about Route 53 health checks, see How Amazon Route 53 checks the health of your resources and Creating, updating, and deleting health checks in the Amazon Route 53 Developer Guide.

**Note**

Health checks are required for Shield Response Team (SRT) proactive engagement support. For information about proactive engagement, see Configuring proactive engagement (p. 485).

Health checks measure the health of your resources based on the requirements that you define. The health check status provides input to the Shield Advanced detection mechanisms, which gives them greater sensitivity to the current state of your specific applications.

You can enable health-based detection for any resource type except for Route 53 hosted zones.

- **Network and transport layer (layer 3/layer 4) resources** – Health-based detection improves the accuracy of network-layer and transport-layer event detection and mitigation for Network Load Balancers, Elastic IP addresses, and Global Accelerator standard accelerators. When you protect these resource types with Shield Advanced, Shield Advanced can provide mitigations for smaller attacks and faster mitigation for attacks, even when traffic is within the application's capacity.

  When you add health-based detection, during periods when the associated health check is unhealthy, Shield Advanced can place mitigations even more quickly and at even lower thresholds.

- **Application layer (layer 7) resources** – Health-based detection improves the accuracy of web request flood detection for CloudFront distributions and Application Load Balancers. When you protect these resource types with Shield Advanced, you receive web request flood detection alerts when there's a statistically significant deviation in traffic volume that's combined with significant changes in traffic patterns, based on request characteristics.

  With health-based detection, when the associated Route 53 health check is unhealthy, Shield Advanced requires smaller deviations to alert and it reports events more quickly. Conversely, when the associated Route 53 health check is healthy, Shield Advanced requires larger deviations to alert.

**Contents**
Best practices for using health checks with Shield Advanced

Follow the best practices in this section when you create and use health checks with Shield Advanced.

- Plan your health checks by identifying the components of your infrastructure that you want to monitor. Consider the following resource types for health checks:
  - Critical resources.
  - Any resources where you want higher sensitivity in Shield Advanced detection and mitigation.
  - Resources for which you want Shield Advanced to proactively reach out to you. Proactive engagement is informed by the status of your health checks.

Examples of resources that you might want to monitor include Amazon CloudFront distributions, internet-facing load balancers, and Amazon EC2 instances.

- Define health checks that accurately reflect the health of your application origin with as few notifications as possible.
  - Write health checks so that they're only unhealthy when your application is unavailable or isn't performing within acceptable parameters. You are responsible for defining and maintaining health checks based on your application's specific requirements.
  - Use as few health checks as possible while still accurately reporting on the health of your application. For example, multiple alarms from multiple areas of your application that all report the same problem might add overhead to your response activities without adding informational value.
  - Use calculated health checks to monitor application health using a combination of Amazon CloudWatch metrics. For example, you can calculate combined health based on the latency of your application servers and their 5xx error rates, which indicate that the origin server didn't fulfill the request.
  - Create and publish your own application health indicators to CloudWatch custom metrics as needed and use them in a calculated health check.

- Implement and manage your health checks to improve detection and reduce unnecessary maintenance activities.
  - Before you associate a health check with a Shield Advanced protection, make sure that it's in a healthy state. Associating a health check that's reporting unhealthy can skew the Shield Advanced detection mechanisms for your protected resources.
  - Keep your health checks available for use by Shield Advanced. Don't delete a health check in Route 53 that you're using for a Shield Advanced protection.
  - Use staging and test environments only to test your health checks. Only maintain health check associations for environments that require production-level performance and availability. Don't maintain health check association in Shield Advanced for staging and test environments.
### Metrics commonly used for health checks

This section lists the Amazon CloudWatch metrics that are commonly used in health checks to measure application health during distributed denial of service (DDoS) events. For full information about the CloudWatch metrics for each resource type, see the list that follows the table.

**Topics**
- Metrics used to monitor application health (p. 497)
- Amazon CloudWatch metrics for each resource type (p. 498)

### Metrics used to monitor application health

<table>
<thead>
<tr>
<th>Resource</th>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Route 53</td>
<td>HealthCheckStatus</td>
<td>The status of the health check endpoint.</td>
</tr>
<tr>
<td>CloudFront</td>
<td>TotalErrorRate</td>
<td>The percentage of all requests for which the HTTP status code is 4xx or 5xx.</td>
</tr>
<tr>
<td>Application Load Balancer</td>
<td>ActiveConnectionCount</td>
<td>The number of concurrent TCP connections that are active from clients to the load balancer, and from the load balancer to targets.</td>
</tr>
<tr>
<td>Application Load Balancer</td>
<td>ConsumedLCUs</td>
<td>The number of load balancer capacity units (LCU) used by your load balancer.</td>
</tr>
<tr>
<td>Application Load Balancer</td>
<td>HTTPCode_ELB_4XX_Count, HTTPCode_ELB_5XX_Count</td>
<td>The number of HTTP 4xx or 5xx client error codes generated by the load balancer.</td>
</tr>
<tr>
<td>Application Load Balancer</td>
<td>NewConnectionCount</td>
<td>The number of new TCP connections established from clients to the load balancer, and from the load balancer to targets.</td>
</tr>
<tr>
<td>Application Load Balancer</td>
<td>ProcessedBytes</td>
<td>The number of bytes processed by the load balancer.</td>
</tr>
<tr>
<td>Application Load Balancer</td>
<td>RejectedConnectionCount</td>
<td>The number of connections that were rejected because the load balancer reached its maximum number of connections.</td>
</tr>
<tr>
<td>Application Load Balancer</td>
<td>TargetConnectionErrorCount</td>
<td>The number of connections that were not successfully established between the load balancer and the target.</td>
</tr>
<tr>
<td>Application Load Balancer</td>
<td>TargetResponseTime</td>
<td>The time elapsed in seconds after the request leaves the load balancer.</td>
</tr>
</tbody>
</table>
### Configuring health-based detection using health checks

</table>

#### Amazon CloudWatch metrics for each resource type

For additional information about the metrics that are available for your protected resources, see the following sections in the resource guides:

- Amazon Route 53 – [Monitoring your resources with Amazon Route 53 health checks and Amazon CloudWatch](https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/) in the Amazon Route 53 Developer Guide.
- Amazon CloudFront – [Monitoring CloudFront with Amazon CloudWatch](https://docs.aws.amazon.com/CloudFront/latest/DeveloperGuide/) in the Amazon CloudFront Developer Guide.
Managing health check associations

You'll benefit the most from using a health check with Shield Advanced if the health check only reports healthy when your application is running within acceptable parameters and only reports unhealthy when it's not. Use the guidance in this section to manage your health check associations in Shield Advanced.

**Note**

Shield Advanced doesn't automatically manage your health checks.

The following are required to use a health check with Shield Advanced:

- The health check must report healthy when you associate it with your Shield Advanced protection.
- The health check must be relevant to the health of your protected resource. You are responsible for defining and maintaining health checks that accurately report the health of your application, based on your application's specific requirements.
- The health check must remain available for use by the Shield Advanced protection. Don't delete a health check in Route 53 that you're using for a Shield Advanced protection.

**Topics**

- Associating a health check with your resource (p. 499)
- Disassociating a health check from your resource (p. 500)
- The health check association status (p. 500)

**Associating a health check with your resource**

The following procedure shows how to associate an Amazon Route 53 health check with a protected resource.

**Note**

Before you associate a health check with a Shield Advanced protection, make sure that it's in a healthy state. For information, see Monitoring health check status and getting notifications in the Amazon Route 53 Developer Guide.

**To associate a health check**

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the AWS Shield navigation pane, choose **Protected resources**.
3. On the **Protections** tab, select the resource that you want to associate with a health check.
4. Choose **Configure protections**.
5. Choose **Next** until you get to the page Configure health check based DDoS detection - optional.
6. Under **Associated Health Check**, choose the ID of the health check that you want to associate with the protection.

   **Note**
   If you do not see the health check you need, go to the Route 53 console and verify the health check and its ID. For information, see [Creating and Updating Health Checks](#).

7. Walk through the rest of the pages until you finish the configuration. On the **Protections** page, your updated health check association is listed for the resource.

8. On the **Protections** page, check that your newly associated health check is reporting healthy.

   You can’t successfully begin using a health check in Shield Advanced while the health check is reporting unhealthy. Doing so causes Shield Advanced to detect false positives at very low thresholds and can also negatively impact the ability of the Shield Response Team (SRT) to provide proactive engagement for the resource.

   If the newly associated health check is reporting unhealthy, do the following:
   
   a. Disassociate the health check from your protection in Shield Advanced.
   
   b. Revisit your health check specifications in Amazon Route 53 and verify your overall application performance and availability.
   
   c. When your application is performing within your parameters for good health and your health check is reporting healthy, try again to associate the health check in Shield Advanced.

The health check association procedure is complete when you've established your new health check association and it reports healthy in Shield Advanced.

**Disassociating a health check from your resource**

The following procedure shows how to disassociate an Amazon Route 53 health check from a protected resource.

**To disassociate a health check**

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at [https://console.aws.amazon.com/wafv2/](https://console.aws.amazon.com/wafv2/).
2. In the AWS Shield navigation pane, choose **Protected resources**.
3. On the **Protections** tab, select the resource that you want to disassociate from a health check.
4. Choose **Configure protections**.
5. Choose **Next** until you get to the page **Configure health check based DDoS detection - optional**.
6. Under **Associated Health Check**, choose the empty option, listed as `-`.
7. Walk through the rest of the pages until you finish the configuration.

On the **Protections** page, the health check field for your resource is set to `-`, indicating no health check association.

**The health check association status**

You can see the status of the health check that's associated with a protection on the AWS WAF & Shield console **Protected resources** page and on the details page of each resource.

- **Healthy** – The health check is available and is reporting healthy.
- **Unhealthy** – The health check is available and is reporting unhealthy.
- **Unavailable** – The health check is not available for use by Shield Advanced.
To resolve an Unavailable health check

Create and use a new health check. Don't try to associate a health check again after it has had a status of unavailable in Shield Advanced.

For detailed guidance on following these steps, see the preceding topics.

1. In Shield Advanced, disassociate the health check from the resource.
2. In Route 53, create a new health check for the resource and note its ID. For information, see Creating and Updating Health Checks in the Amazon Route 53 Developer Guide.
3. In Shield Advanced, associate the new health check with the resource.

Health check examples

This section shows examples of health checks that you could use in a calculated health check. A calculated health check uses a number of individual health checks to determine a combined status. The status of each individual health check is based on the health of an endpoint or on the state of an Amazon CloudWatch metric. You combine health checks into a calculated health check and then configure your calculated health check to report health based on the combined health status of the individual health checks. Tune the sensitivity of your calculated health checks according to your requirements for application performance and availability.

For information about calculated health checks, see Monitoring other health checks (calculated health checks) in the Amazon Route 53 Developer Guide. For additional information, see the blog post Route 53 Improvements – Calculated Health Checks and Latency Checks.

Topics

- Amazon CloudFront distributions (p. 501)
- Load balancers (p. 501)
- Amazon EC2 elastic IP address (EIP) (p. 502)

Amazon CloudFront distributions

The following examples describe health checks that could be combined into a calculated health check for a CloudFront distribution:

- Monitor an endpoint by specifying a domain name to a path on the distribution that's serving dynamic content. A healthy response would include HTTP response codes 2xx and 3xx.
- Monitor the state of a CloudWatch alarm that's measuring the health of the CloudFront origin. For example, you can maintain a CloudWatch alarm on the Application Load Balancer metric TargetResponseTime, and create a health check that reflects the status of the alarm. The health check can be unhealthy when the response time, between request leaving the load balancer and when the load balancer receives a response from the target, exceeds the threshold configured in the alarm.
- Monitor the state of a CloudWatch alarm that measures the percentage of requests for which the response's HTTP status code is 5xx. If the CloudFront distribution's 5xx error rate is higher than the threshold defined in the CloudWatch alarm, the status of this health check will switch to unhealthy.

Load balancers

The following examples describe health checks that could be used in calculated health checks for an Application Load Balancer, Network Load Balancer, or Global Accelerator standard accelerator.

- Monitor the state of a CloudWatch alarm that measures the number of new connections established by clients to the load balancer. You can set the alarm threshold for the average number of new
connections at some degree higher than your every day average. The metrics for each resource type are the following:

- Application Load Balancer: NewConnectionCount
- Network Load Balancer: ActiveFlowCount
- Global Accelerator: NewFlowCount
- For Application Load Balancer and Network Load Balancer, monitor the state of a CloudWatch alarm that measures the number of load balancers that are considered healthy. You can set the alarm threshold either on Availability Zone or on the minimum number of healthy hosts that your load balancer requires. The available metrics for the load balancer resources are as follows:
  - Application Load Balancer: HealthyHostCount
  - Network Load Balancer: HealthyHostCount
- For Application Load Balancer, monitor the state of a CloudWatch alarm that measures the number of HTTP 5xx response codes generated by the load balancer targets. For an Application Load Balancer, you can use the metric HTTPCode_Target_5XX_Count and base the alarm threshold on the sum of all 5xx errors for the load balancer.

Amazon EC2 elastic IP address (EIP)

The following example health checks could be combined into a calculated health check for an Amazon EC2 elastic IP address:

- Monitor an endpoint by specifying an IP address to the Elastic IP address. The health check will remain healthy as long as a TCP connection can be established with the resource behind the IP address.
- Monitor the state of a CloudWatch alarm that measures the percentage of allocated Amazon EC2 compute units that are currently in use on the instance. You can use the Amazon EC2 metric CPUUtilization and base the alarm threshold on what you consider to be a high CPU utilization rate for your application, such as 90%.

Managing resource protections in AWS Shield Advanced

Use the guidance in this section to manage Shield Advanced protections for your resources.

**Note**

Shield Advanced protects only resources that you have specified either in Shield Advanced or through an AWS Firewall Manager Shield Advanced policy. It doesn't automatically protect your resources.

If you're using an AWS Firewall Manager Shield Advanced policy, you don't need to manage protections for resources that are in scope of the policy. Firewall Manager automatically manages protections for accounts and resources that are in scope of a policy, according to the policy configuration. For more information, see AWS Shield Advanced policies (p. 407).

**Topics**

- Adding AWS Shield Advanced protection to AWS resources (p. 502)
- Configuring AWS Shield Advanced protections (p. 503)
- Removing AWS Shield Advanced protection from an AWS resource (p. 505)

**Adding AWS Shield Advanced protection to AWS resources**

Follow the guidance in this section to add Shield Advanced protection to one or more resources.
To add protection for an AWS resource

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the navigation pane, under AWS Shield choose Protected resources.
3. Choose Add resources to protect.
4. In the Choose resources to protect with Shield Advanced page, in Specify the Region and resource types, provide the Region and resource type specifications for the resources that you want to protect. You can protect resources in multiple Regions by selecting All Regions and you can narrow the selection to global resources by selecting Global. You can deselect any resource types that you do not want to protect. For information about protections for your resource types, see AWS Shield Advanced protections by resource type (p. 487).
5. Choose Load resources. Shield Advanced populates the Select Resources section with the AWS resources that match your criteria.
6. In the Select Resources section, you can filter the list of resources by entering a string to search for in the resource listings.
7. Select the resources that you want to protect.
8. In the Tags section, if you want to add tags to the Shield Advanced protections that you are creating, specify those. For information about tagging AWS resources, see Working with Tag Editor.
9. Choose Protect with Shield Advanced. This adds Shield Advanced protections to the resources.

Configuring AWS Shield Advanced protections

You can change the settings for your AWS Shield Advanced protections at any time. To do this, walk through the options for your selected protections and modify the settings that you need to change.

To manage protected resources

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the AWS Shield navigation pane, choose Protected resources.
3. In the Protections tab, select the resources that you want to protect.
4. Choose Configure protections and the resource specification option that you want.
5. Walk through each of the resource protection options, making changes as needed.

Configure application layer DDoS protections

For protection against attacks on Amazon CloudFront and Application Load Balancer resources, you can add AWS WAF web ACLs and add rate-based rules. For information about this, see Shield Advanced application layer AWS WAF web ACLs and rate-based rules (p. 489).

You can also enable the Shield Advanced automatic application layer DDoS mitigation. For information about how AWS WAF works, see AWS WAF (p. 6). For information about the automatic mitigation feature, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

Important
If you manage your Shield Advanced protections through AWS Firewall Manager using a Shield Advanced policy, you can't manage the application layer protections here. For all other resources, we recommend that, at a minimum, you attach a web ACL to each resource, even if web ACL doesn't contain any rules.

Note
When you enable automatic application layer DDoS mitigation for a resource, if needed, the operation automatically adds a service-linked role to your account to give Shield Advanced the
permissions it needs to manage your web ACL protections. For information, see Using service-linked roles for Shield Advanced (p. 533).

**To configure application layer DDoS protections**

1. In the **Configure layer 7 DDoS protections** page, if the resource isn’t already associated with a web ACL, you can choose an existing web ACL or create your own.

   To create a web ACL, follow these steps:
   a. Choose **Create web ACL**.
   b. Enter a name. You can’t change the name after you create the web ACL.
   c. Choose **Create**.

   **Note**
   If a resource is already associated with a web ACL, you can’t change to a different web ACL. If you want to change the web ACL, you must first remove the associated web ACLs from the resource. For more information, see Associating or disassociating a web ACL with an AWS resource (p. 23).

2. If the web ACL doesn’t have a rate-based rule defined, you can add one by choosing **Add rate limit rule** and then performing the following steps:
   a. Enter a name.
   b. Enter a rate limit. This is the maximum number of requests allowed in any five minute period from any single IP address before the rate-based rule action is applied to the IP address. When the requests from the IP address fall below the limit, the action is discontinued.
   c. Set the rule action to count or block requests from IP addresses while their request counts are over the limit. The application and removal of the rule action might take effect a minute or two after the IP address request rate changes.
   d. Choose **Add rule**.

3. For **Automatic application layer DDoS mitigation**, choose whether you want Shield Advanced to automatically mitigate DDoS attacks on your behalf, as follows:
   - To enable automatic mitigation, choose **Enable** and then select the AWS WAF rule action that you want Shield Advanced to use in its custom rules. Your choices are Count and Block. For information about these actions, see AWS WAF rule action (p. 84).
   - To disable automatic mitigation, choose **Disable**.
   - To leave the automatic mitigation settings unchanged for the resources that you’re managing, leave the default choice **Keep current settings**.

   For information about Shield Advanced automatic application layer DDoS mitigation, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

4. Choose **Next**.

**Create alarms and notifications**

The following procedure shows how to manage CloudWatch alarms for protected resources.

**Note**
CloudWatch incurs additional costs. For CloudWatch pricing, see Amazon CloudWatch Pricing.
To create alarms and notifications

1. In the protections page Create alarms and notifications - optional, configure the SNS topics for the alarms and notifications that you want to receive. For resources that you don’t want notifications for, choose No topic. You can add an Amazon SNS topic or create a new topic.

2. To create an Amazon SNS topic, follow these steps:
   a. In the dropdown list, choose Create an SNS topic.
   b. Enter a topic name.
   c. Optionally enter an email address that the Amazon SNS messages will be sent to, and then choose Add email. You can enter more than one.
   d. Choose Create.

3. Choose Next.

Removing AWS Shield Advanced protection from an AWS resource

You can remove AWS Shield Advanced protection from any of your AWS resources at any time.

Important
Deleting an AWS resource doesn't remove the resource from AWS Shield Advanced. You must also remove the protection on the resource from AWS Shield Advanced, as described in this procedure.

Remove AWS Shield Advanced protection from an AWS resource

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the AWS Shield navigation pane, choose Protected resources.
3. In the Protections tab, select the resources whose protections you want to remove.
4. Choose Delete protections.

   • If you have an Amazon CloudWatch alarm configured for a protection, you are given the option to delete the alarm along with the protection. If you choose not to delete the alarm at this point, you can instead delete it later using the CloudWatch console.

   Note
   For protections that have an Amazon Route 53 health check configured, if you add the protection again later, the protection still includes the health check.

The preceding steps remove AWS Shield Advanced protection from specific AWS resources. They don’t cancel your AWS Shield Advanced subscription. You will continue to be charged for the service. For information about your AWS Shield Advanced subscription, contact the AWS Support Center.

Removing a CloudWatch alarm from your Shield Advanced protections

To remove a CloudWatch alarm from your Shield Advanced protections, do one of the following:

• Delete the protection as described in Removing AWS Shield Advanced protection from an AWS resource (p. 505). Be sure to select the check box next to Also delete related DDoSDetection alarm.
• Delete the alarm using the CloudWatch console. The name of the alarm to delete starts with DDoSDetectedAlarmForProtection.
AWS Shield Advanced protection groups

Use protection groups to create logical collections of your protected resources and manage their protections as a group. For information about managing resource protections, see Configuring AWS Shield Advanced protections (p. 503).

**Note**
Automatic application layer DDoS mitigation does not interact with protection groups. You can enable automatic mitigation for resources that are in protection groups, but Shield Advanced does not automatically apply attack mitigations based on protection group findings. Shield Advanced applies automatic attack mitigations for individual resources.

AWS Shield Advanced protection groups give you a self-service way to customize the scope of detection and mitigation by treating multiple protected resources as a single unit. Resource grouping can provide a number of benefits.

- Improve accuracy of detection.
- Reduce unactionable event notifications.
- Increase coverage of mitigation actions to include protected resources that also might be affected during an event.
- Accelerate time to mitigation of attacks with multiple similar targets.
- Facilitate automatic protection of newly created protected resources.

Protection groups can help reduce false positives in situations such as blue/green swap, where resources alternate between being near zero load and fully loaded. Another example is when you create and delete resources frequently while maintaining a load level that's shared among the members of the group. For situations such as these, monitoring individual resources can lead to false positives, while monitoring the health of the group of resources does not.

You can configure protection groups to include all protected resources, all resources of specific resource types, or individually specified resources. Newly protected resources that satisfy your protection group criteria are automatically included in your protection group. A protected resource can belong to multiple protection groups.

**Managing AWS Shield Advanced protection groups**

Use the guidance in this section to manage your protection group configurations.

**Creating a Shield Advanced protection group**

**To create a protection group**

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the AWS Shield navigation pane, choose Protected resources.
3. Choose the Protection groups tab, then choose Create protection group.
4. In the Create protection group page, provide a name for your group. You'll use this name to identify the group in your list of protected resources. You can't change the name of a protection group after you create it.
5. For Protection grouping criteria, select the criteria that you want Shield Advanced to use to identify the protected resources to include in the group. Make your additional selections based on the criteria that you've chosen.
6. For **Aggregation**, select how you want Shield Advanced to combine resource data for the group in order to detect, mitigate, and report events.

   - **Sum** – Use the total traffic across the group. This is a good choice for most cases. Examples include Elastic IP addresses for Amazon EC2 instances that scale manually or automatically.
   - **Mean** – Use the average of the traffic across the group. This is a good choice for resources that share traffic uniformly. Examples include accelerators and load balancers.
   - **Max** – Use the highest traffic from each resource. This is useful for resources that don't share traffic, and for resources that share traffic in a non-uniform way. Examples include Amazon CloudFront distributions and origin resources for CloudFront distributions.

7. Choose **Save** to save your protection group and return to the **Protected resources** page.

In the **Shield Events** page, you can view events for your protection group and drill down to see additional information for the protected resources that are in the group.

### Updating a Shield Advanced protection group

**To update a protection group**

2. In the AWS Shield navigation pane, choose **Protected resources**.
3. In the **Protection groups** tab, select the check box next to the protection group that you want to modify.
4. In the protection group's page, choose **Edit**. Make your changes to the protection group settings.
5. Choose **Save** to save your changes.

### Deleting a Shield Advanced protection group

**To delete a protection group**

2. In the AWS Shield navigation pane, choose **Protected resources**.
3. In the **Protection groups** tab, select the check box next to the protection group that you want to remove.
4. In the protection group's page, choose **Delete** and confirm the action.

### Tracking resource protection changes in AWS Config

You can record changes to the AWS Shield Advanced protection of your resources using AWS Config. You can then use this information to maintain a configuration change history for audit and troubleshooting purposes.

To record protection changes, enable AWS Config for each resource that you want to track. For more information, see **Getting Started with AWS Config** in the **AWS Config Developer Guide**.

You must enable AWS Config for each AWS Region that contains the tracked resources. You can enable AWS Config manually, or you can use the AWS CloudFormation template "Enable AWS Config" at **AWS CloudFormation StackSets Sample Templates** in the **AWS CloudFormation User Guide**.

If you enable AWS Config, you're charged as detailed on the **AWS Config Pricing** page.
Note
If you already have AWS Config enabled for the necessary Regions and resources, you don’t need to do anything. AWS Config logs regarding protection changes to your resources start populating automatically.

After enabling AWS Config, use the US East (N. Virginia) Region in the AWS Config console to view the configuration change history for AWS Shield Advanced global resources.

View the change history for AWS Shield Advanced regional resources via the AWS Config console in the US East (N. Virginia), US East (Ohio), US West (Oregon), US West (N. California), Europe (Ireland), Europe (Frankfurt), Asia Pacific (Tokyo), and Asia Pacific (Sydney) Regions.

Visibility into DDoS events

AWS Shield provides visibility into the following categories of events and event activities:

- **Global** – All customers can access an aggregated view of global threat activity over the last two weeks. You can see this information under the Getting Started and Global threat dashboard pages of the AWS Shield console. For more information, see AWS Shield global and account activity (p. 508).

- **Account** – All customers can access a summary of the events for their account over the prior year. You can see this information under the Getting Started page of the AWS Shield console. For more information, see AWS Shield global and account activity (p. 508).

When you subscribe to Shield Advanced and add protections to your resources, you gain access to additional information about the events and DDoS attacks on the protected resources:

- **Events on protected resources** – Shield Advanced provides detailed information for each event through the Events page of the AWS Shield console. For more information, see AWS Shield Advanced events (p. 511).

- **Event metrics for protected resources** – Shield Advanced publishes Amazon CloudWatch metrics for all resources that it protects that you can use to configure CloudWatch dashboards and alarms. For more information, see AWS Shield Advanced Amazon CloudWatch metrics (p. 517).

- **Cross-account event visibility for protected resources** – If you use AWS Firewall Manager to manage your Shield Advanced protections, you can enable visibility into protections across multiple accounts by using Firewall Manager combined with AWS Security Hub. For more information, see Event visibility across accounts (p. 517).

AWS Shield global and account activity

You can access an aggregated view of global threat activity and a per-account event summary in the AWS Shield console Getting Started and Global threat dashboard pages.

The following screenshot shows an example Getting Started page.
Global and account activity

To access the AWS Shield console

- Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.

You don't need a subscription to Shield Advanced to access global activity and account event summary information.

Global activity

This information is available through the AWS Shield console Global threat dashboard and Getting Started pages. The following screenshot shows an example of the global activity pane.
Global activity describes DDoS events observed across all AWS customers. Once per hour, AWS updates the information for the prior two weeks. In the console pane, you can see the results, partitioned by AWS Region and displayed on a world heat map. Next to the map, Shield displays summary information such as the largest packet attack, largest bit rate, most common vector, total number of attacks, and threat level. The threat level is an assessment of the current global activity compared to what AWS typically observes. The default threat level value is Normal. AWS automatically updates the value to High for elevated DDoS activity.

The Global threat dashboard also provides time-series metrics and gives you the ability to change between time durations. To view the history of significant DDoS attacks, you can customize the dashboard for views from the last day to the last two weeks. Time-series metrics provide a view of the largest bit rate, packet rate, or request rate for all events detected by AWS Shield for applications running on AWS during the time window that you select.

Account activity

This information is available in the AWS Shield console Getting Started page.

The following screenshot shows an example account activity pane.

Account activity describes DDoS events that Shield detected for your resources that are eligible for protection by Shield Advanced. Each day, Shield creates summary metrics for the year ending at 00:00
UTC the prior day, and then displays total events, largest bit rate, largest packet rate, and largest request rate.

- The total events metric reflects every time that Shield observed suspicious attributes in traffic that was destined to your application. Suspicious attributes can include traffic that is at a higher than normal volume, traffic that does not match your application’s historical profile, or traffic that does not match heuristics that are defined by Shield for valid application traffic.
- Largest bit rate and largest packet rate statistics are available for every resource.
- The largest request rate statistic is available only for Amazon CloudFront distributions and Application Load Balancers that have an associated AWS WAF web ACL.

**Note**

You can also access the account level event summary through the AWS Shield API operation `DescribeAttackStatistics`.

### AWS Shield Advanced events

When you subscribe to Shield Advanced, and protect your resources, you gain access to additional visibility features for the resources. These include near real-time notification of events that are detected by Shield Advanced and additional information about detected events and mitigations.

AWS Shield evaluates traffic to your protected resource along multiple dimensions. When an anomaly is detected, Shield Advanced creates a separate event for each resource that's affected.

You can access event summaries and details through the **Events** page of the Shield console. The top level **Events** page provides an overview of current and past events.

The following screenshot shows an example **Events** page with a single ongoing event. This active event is also flagged in the left navigation pane.

![Example Events Page](image)

Shield Advanced might also automatically place mitigations against attacks, depending on the traffic type and on your configured protections. These mitigations can protect your resource from receiving excess traffic or traffic that matches a known DDoS attack signature.

The following screenshot shows an example **Events** listing where all events have been mitigated by Shield Advanced or have subsided on their own.
Protect your resources before an event

Improve the accuracy of event detection by protecting resources with Shield Advanced while they are receiving the normal expected traffic, before they are subject to a DDoS attack.

In order to accurately report events for a protected resource, Shield Advanced must first establish a baseline of expected traffic patterns for it.

- Shield Advanced reports infrastructure layer events for resources after they've been protected for at least 15 minutes.
- Shield Advanced reports web application layer events for resources after they've been protected for at least 24 hours. The accuracy of detection for application layer events is best after Shield Advanced has observed expected traffic for 30 days.

To access events information in the AWS Shield console

1. Sign in to the AWS Management Console and open the AWS WAF & Shield console at https://console.aws.amazon.com/wafv2/.
2. In the AWS Shield navigation pane, choose Events. The console shows the Events page.
3. From the Events page, you can select any event in the list to see additional summary information and details for the event.

AWS Shield Advanced event summaries

You can view summary and detail information for an event in the event's console page. To open the page for an event, select its AWS resource name from the Events page list.

The following screenshot shows an example event summary for a network layer event.
The event page summary information includes the following.

- **Current status** – Values that indicate the state of the event and the actions that Shield Advanced has taken on the event. Status values apply to infrastructure layer (layer 3 or 4) and application layer (layer 7) events.
  - **Identified (ongoing)** and **Identified (subsided)** – These indicate that Shield Advanced detected an event, but has taken no action on it so far. **Identified (subsided)** indicates that the suspicious traffic that Shield detected has stopped without intervention.
  - **Mitigation in progress** and **Mitigated** – These indicate that Shield Advanced detected an event and has taken action on it. **Mitigated** is also used when the targeted resource is an Amazon CloudFront distribution or Amazon Route 53 hosted zone, which have their own automatic inline mitigations.

- **Attack vectors** – DDoS attack vectors like TCP SYN floods and Shield Advanced detection heuristics like request flood. These can be indicators of a DDoS attack.

- **Start time** – The date and time that the first anomalous traffic data point was detected.

- **Duration or end time** – Indicates the time elapsed between the event start time and the last observed anomalous data point that Shield Advanced observed. While an event is ongoing, these values will continue to increase.

- **Protection** – Names the Shield Advanced protection that's in associated with the resource, and provides a link to its protection page. This is available in the individual event's page.

- **Automatic application layer DDoS mitigation** – Used for application layer protections, to indicate whether the Shield Advanced automatic application layer DDoS mitigation is enabled for the resource. If it is enabled, this provides a link to access and manage the configuration. This is available in the individual event's page.

- **Network layer automatic mitigation** – Indicates whether the resource has automatic mitigation at the network layer. If a resource has a network layer component, it will have this enabled. This information is available in the individual event's page.

For resources that are frequently targeted, Shield may leave mitigations in place after excess traffic has subsided, to prevent further recurring events.

**Note**

You can also access event summaries for protected resources through the AWS Shield API operation **ListAttacks**.
AWS Shield Advanced event details

You can see details about an event's detection, mitigation, and top contributors in the bottom section of the console page for the event. This section can include a mix of legitimate and potentially unwanted traffic, and may represent both traffic that was passed to your protected resource and traffic that was blocked by Shield mitigations.

- **Detection and mitigation** – Provides information about the observed event and any applied mitigations against it. For information about event mitigation, see Responding to DDoS events (p. 519).

- **Top contributors** – Categorizes the traffic that's involved in the event, and lists the primary sources of traffic for each category.

Mitigation metrics aren't included for Amazon CloudFront or Amazon Route 53 resources, because these services are protected by a mitigation system that's always enabled and doesn't require mitigations for individual resources.

The details sections vary according to whether the information is for an infrastructure layer or application layer event.

**Application layer event details**

For an application layer (layer 7) event, the Detection and mitigation tab shows detection metrics that are based on information obtained from the AWS WAF logs. Mitigation metrics are based on AWS WAF rules in the associated web ACL that are configured to block the unwanted traffic.

The following screenshot shows an example of the detection metrics for an application layer event that subsided after a number of hours.

Event traffic that subsides before a mitigating rule takes effect isn't represented in mitigation metrics. This can result in a difference between the web request traffic shown in the detection graphs and the allow and block metrics shown in the mitigation graphs.

For Amazon CloudFront distributions, you can configure Shield Advanced to apply automatic mitigations for you. With any application layer resources, you can choose to define your own mitigating rules in your web ACL and you can request help from the Shield Response Team (SRT). For information about these options, see Responding to DDoS events (p. 519).

The Top contributors tab for application layer events displays the top 5 contributors to the event, categorized by dimensions such as source IP, source country, and destination URL.

The following screenshot shows an example Top contributors tab for an application layer event.
Contributor information is based on requests for both legitimate and potentially unwanted traffic. Larger volume events and events where the request sources aren't highly distributed are more likely to have identifiable top contributors. A significantly distributed attack could have any number of sources, making it hard to identify top contributors to the attack. If Shield Advanced doesn't identify significant contributors for a specific category, it displays the data as unavailable.

**Infrastructure layer event details**

For an infrastructure layer (layer 3 or 4) event, the Detection and mitigation tab shows detection metrics that are based on sampled network flows and mitigation metrics that are based on traffic observed by the mitigation systems. Mitigation metrics are a more precise measurement of the traffic into your resource.

The following screenshot shows an example Detection and mitigation tab for an infrastructure layer event.

Event traffic that subsides before Shield places a mitigation isn't represented in the mitigation metrics. This can result in a difference between the traffic shown in the detection graphs and the pass and drop metrics shown in the mitigation graphs.

Shield automatically creates a mitigation for the protected resource types Elastic IP (EIP), Classic Load Balancer (CLB), Application Load Balancer (ALB), and AWS Global Accelerator standard accelerator. Mitigation metrics for EIP addresses and AWS Global Accelerator standard accelerators indicate the number of passed and dropped packets.
The **Top contributors** tab for infrastructure layer events lists metrics for up to 100 top contributors on several traffic dimensions. The details include network layer properties for any dimension where at least five significant sources of traffic could be identified. Examples of sources of traffic are source IP and source ASN.

The following screenshot shows an example **Top contributors** tab for an infrastructure layer event.

![Top contributors screenshot](image)

Contributor metrics are based on sampled network flows for both legitimate and potentially unwanted traffic. Larger volume events and events where the traffic sources aren't highly distributed are more likely to have identifiable top contributors. A significantly distributed attack could have any number of sources, making it hard to identify top contributors to the attack. If Shield doesn't identify any significant contributors for a specific metric or category, it displays the data as unavailable.

In an infrastructure layer DDoS attack, traffic sources might be spoofed or reflected. A spoofed source is intentionally forged by the attacker. A reflected source is the real source of detected traffic, but it's not a willing participant in the attack. For example, an attacker might generate a large, amplified flood of traffic to a target by reflecting the attack off of services on the internet that are usually legitimate. In this case, the source information might be valid while it's not the actual source of the attack. These factors can limit the viability of mitigation techniques that block sources based on packet headers.
AWS Shield Advanced Amazon CloudWatch metrics

Shield Advanced publishes Amazon CloudWatch event metrics for all resources that it protects. These metrics improve your ability to monitor your resources by making it possible to create and configure CloudWatch dashboards and alarms for them.

### Shield Advanced Amazon CloudWatch metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDoSDetected</td>
<td>Indicates a DDoS event for a specific Amazon Resource Name (ARN). This metric has a value of 1 during an event and a value of 0 otherwise.</td>
</tr>
<tr>
<td>DDoSA OrbitBitsPerSecond</td>
<td>The number of bytes observed during a DDoS event for a specific ARN. This metric is available only for network and transport layer (layer 3 or 4) DDoS events. The unit of this metric is bits.</td>
</tr>
<tr>
<td>DDoSA OrbitPacketsPerSecond</td>
<td>The number of packets observed during a DDoS event for a specific ARN. This metric is available only for network and transport layer (layer 3 or 4) DDoS events. The unit of this metric is packets.</td>
</tr>
<tr>
<td>DDoSA OrbitRequestsPerSecond</td>
<td>The number of requests observed during a DDoS event for a specific ARN. This metric is available only for application layer (layer 7) DDoS events. The unit of this metric is requests.</td>
</tr>
</tbody>
</table>

If there are no events to record to a CloudWatch metric, once each day, Shield Advanced publishes a zero value metric. This keeps the metric active and available for use in custom CloudWatch alarms and dashboards.

We recommend that you create alarms to notify you of circumstances that require attention. As a starting point, you could create an alarm for each protected resource that reports when the DDoSDetected metric is non zero. A non-zero value in this metric doesn't necessarily imply that a DDoS attack is underway, but we recommend looking closer at the resource status when the metric is in this state.

For request floods, we recommend that you create alarms for composite checks that also consider factors such as application health and web request volume. You may choose to alarm on the other three metrics that report on the volume of traffic for various attack vector dimensions. By considering the capacity of your application and alarming when traffic is approaching your application limitations, you can create a set of rules that notify you as needed, without too much unwanted noise.

For additional information about Shield Advanced metrics, including mitigation and top contributor metrics, metric dimensions, and information about creating alarms, see [AWS Shield Advanced metrics and alarms](p. 545).

### Event visibility across accounts

You can use AWS Firewall Manager and AWS Security Hub to manage and monitor AWS Shield Advanced protected resources across multiple accounts.

With Firewall Manager, you can create a Shield Advanced security policy that reports and enforces DDoS protection compliance across all of your accounts. Firewall Manager monitors your protected resources, including adding protections to new resources that come into scope of the Shield Advanced policy.
You can integrate Firewall Manager with AWS Security Hub to get a single dashboard that reports DDoS events that are detected by Shield Advanced and Firewall Manager compliance findings, when Firewall Manager identifies a resource that’s out of compliance with your Shield Advanced security policy.

The following figure depicts a typical architecture for monitoring Shield Advanced protected resources with Firewall Manager and Security Hub.

When you integrate Firewall Manager with Security Hub, you can view security findings in a single place, alongside other alerts and compliance status information for the applications that you run on AWS.

The following screenshot highlights the information that you can see for a Shield Advanced event inside the Security Hub console when you have an integration of this type.
Responding to DDoS events

AWS automatically mitigates network and transport layer (layer 3 and layer 4) Distributed Denial of Service (DDoS) attacks. If you use Shield Advanced to protect your Amazon EC2 instances, during an attack Shield Advanced automatically deploys your Amazon VPC network ACLs to the border of the AWS network. This allows Shield Advanced to provide protection against larger DDoS events. For more information about network ACLs, see Network ACLs.

For application layer (layer 7) DDoS attacks, AWS attempts to detect and notify AWS Shield Advanced customers through CloudWatch alarms. By default, it doesn't automatically apply mitigations, to avoid inadvertently blocking valid user traffic.

For application layer (layer 7) resources, you have the following options available for responding to an attack.

- **Provide your own mitigations** – You can investigate and mitigate the attack on your own. For information, see Manually mitigating an application layer DDoS attack (p. 520).
- **Contact support** – If you're a Shield Advanced customer, you can contact the AWS Support Center to get help with mitigations. Critical and urgent cases are routed directly to DDoS experts. For information, see Contacting the support center during an application layer DDoS attack (p. 519).

Additionally, before an attack occurs, you can proactively enable the following mitigation options:

- **Automatic mitigations on Amazon CloudFront distributions** – With this option, Shield Advanced defines and manages mitigating rules for you in your web ACL. For information about automatic application layer mitigation, see Shield Advanced automatic application layer DDoS mitigation (p. 489).
- **Proactive engagement** – When AWS Shield Advanced detects a large application layer attack against one of your applications, the SRT can proactively contact you. The SRT triages the DDoS event and creates AWS WAF mitigations. The SRT contacts you and, with your consent, can apply the AWS WAF rules. For more information about this option, see Configuring proactive engagement (p. 485).

**Contacting the support center during an application layer DDoS attack**

If you're an AWS Shield Advanced customer, you can contact the AWS Support Center to get help with mitigations. Critical and urgent cases are routed directly to DDoS experts. With AWS Shield Advanced, complex cases can be escalated to the AWS Shield Response Team (SRT), which has deep experience in protecting AWS, Amazon.com, and its subsidiaries. For more information about the SRT, see Shield Response Team (SRT) support (p. 483).

To get Shield Response Team (SRT) support, contact the AWS Support Center. The response time for your case depends on the severity that you select and the response times, which are documented on the AWS Support Plans page.

Select the following options:

- Case type: Technical Support
- Service: Distributed Denial of Service (DDoS)
When discussing with our representative, explain that you’re an AWS Shield Advanced customer experiencing a possible DDoS attack. Our representative will direct your call to the appropriate DDoS experts. If you open a case with the AWS Support Center using the Distributed Denial of Service (DDoS) service type, you can speak directly with a DDoS expert by chat or telephone. DDoS support engineers can help you identify attacks, recommend improvements to your AWS architecture, and provide guidance in the use of AWS services for DDoS attack mitigation.

For application layer attacks, the SRT can help you analyze the suspicious activity. If you have automatic mitigation enabled for your resource, the SRT can review the mitigations that Shield Advanced is automatically placing against the attack. In any case, the SRT can assist you to review and mitigate the issue. Mitigations that the SRT recommends often require the SRT to create or update AWS WAF web access control lists (web ACLs) in your account. The SRT will need your permission to do this work.

Important
We recommend that as part of enabling AWS Shield Advanced, you follow the steps in Configuring access for the Shield Response Team (SRT) (p. 484) to proactively provide the SRT with the permissions that they need to assist you during an attack. Providing permission ahead of time helps to prevent any delays in the event of an actual attack.

The SRT helps you triage the DDoS attack to identify attack signatures and patterns. With your consent, the SRT creates and deploys AWS WAF rules to mitigate the attack.

You can also contact the SRT before or during a possible attack to review mitigations and to develop and deploy custom mitigations. For example, if you're running a web application and need only ports 80 and 443 open, you can work with the SRT to preconfigure a web ACL to "allow" only ports 80 and 443.

You authorize and contact the SRT at the account level. That is, if you use Shield Advanced within a Firewall Manager Shield Advanced policy, the account owner, not the Firewall Manager administrator, must contact the SRT for support. The Firewall Manager administrator can contact the SRT only for accounts that they own.

Manually mitigating an application layer DDoS attack

If you determine that the activity in the events page for your resource represents a DDoS attack, you can create your own AWS WAF rules in your web ACL to mitigate the attack. This is the only option available if you aren’t a Shield Advanced customer. AWS WAF is included with AWS Shield Advanced at no additional cost. For information about creating rules in your web ACL, see Web access control lists (web ACLs) (p. 12).

If you use AWS Firewall Manager, you can add your AWS WAF rules to a Firewall Manager AWS WAF policy.

To manually mitigate a potential application layer DDoS attack

1. Create rule statements in your web ACL with criteria that matches the unusual behavior. To start with, configure them to count matching requests. For information about configuring your web ACL and rule statements, see Web ACL rule and rule group evaluation (p. 13) and Testing and tuning your AWS WAF protections (p. 212).

   Note
   Always test your rules first by initially using the rule action Count instead of Block. After you’re comfortable that your new rules are identifying the correct requests, you can modify them to block the requests.

2. Monitor the request counts to determine whether you want to block the matching requests. If the volume of requests continues to be unusually high and you’re confident that your rules are
Requesting a credit after an attack

Capturing the requests that are causing the high volume, change the rules in your web ACL to block the requests.

3. Continue monitoring the events page to ensure that your traffic is being handled as you want it to be.

AWS provides preconfigured templates to get you started quickly. The templates include a set of AWS WAF rules that you can customize and use to block common web-based attacks. For more information, see AWS WAF Security Automations.

Requesting a credit in AWS Shield Advanced

If you're subscribed to AWS Shield Advanced and you experience a DDoS attack that increases utilization of a Shield Advanced protected resource, you can request a credit for charges related to the increased utilization to the extent that it is not mitigated by Shield Advanced. Credits are available only for the following types of charges: Amazon CloudFront HTTP/HTTPS requests, CloudFront data transfer out, Amazon Route 53 queries, AWS Global Accelerator standard accelerator data transfer, load balancer capacity units for Application Load Balancer, and usage spikes on protected Amazon Elastic Compute Cloud (Amazon EC2) instances.

Prerequisites for requesting a credit

To be eligible to receive a credit, before the attack began, you must have done the following:

- You must have added Shield Advanced protection to the resources for which you want to request a credit. Protected resources added during an attack are not eligible for cost protection.

  **Note**
  Enabling Shield Advanced on your AWS account does not automatically enable Shield Advanced protection for individual resources.

  For more information about how to protect AWS resources using Shield Advanced, see Adding AWS Shield Advanced protection to AWS resources (p. 502).

- For applicable CloudFront and Application Load Balancer protected resources, you must have associated an AWS WAF web ACL and implemented a rate-based rule in the web ACL. For information about how to create AWS WAF rate-based rules, see Rate-based rule statement (p. 100). For information about how to associate web ACLs with AWS resources, see Web access control lists (web ACLs) (p. 12).

- You must have implemented the appropriate best practices in AWS Best Practices for DDoS Resiliency to configure your application in a way that minimizes cost during a DDoS attack.

How to apply for a credit

To be eligible for a credit, you must submit your credit request within 15 days of the end of the billing month in which the attack occurred.

To apply for a credit, submit a billing case through the AWS Support Center. Include the following in your request:

- The words "DDoS Concession" in the subject line
- The dates and times of each event or availability interruption for which you're requesting a credit
- The AWS services and specific resources that were affected

After you submit a request, the AWS Shield Response Team (SRT) will validate whether a DDoS attack occurred and, if so, whether any protected resources scaled to absorb the DDoS attack.
Security in your use of the AWS Shield service

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Note
This section provides standard AWS security guidance for using the AWS Shield service and its AWS resources, such as Shield Advanced protections.

For guidance using Shield and Shield Advanced to protect your AWS resources such as Amazon CloudFront distributions and Application Load Balancers from Distributed Denial of Service (DDoS) attacks, see the rest of the AWS Shield guide.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to Shield, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Shield. The following topics show you how to configure Shield to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Shield resources.

Topics

- Data protection in Shield (p. 522)
- Identity and access management in AWS Shield Advanced (p. 523)
- Logging and monitoring in Shield (p. 536)
- Compliance validation for Shield (p. 537)
- Resilience in Shield (p. 537)
- Infrastructure security in AWS Shield (p. 537)

Data protection in Shield

The AWS shared responsibility model applies to data protection in AWS Shield. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:
• Use multi-factor authentication (MFA) with each account.
• Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
• Set up API and user activity logging with AWS CloudTrail.
• Use AWS encryption solutions, along with all default security controls within AWS services.
• Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
• If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers’ email addresses, into tags or free-form fields such as a Name field. This includes when you work with Shield or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Shield entities—such as protections—are encrypted at rest, except in certain Regions where encryption is not available, including China (Beijing) and China (Ningxia). Unique encryption keys are used for each Region.

Identity and access management in AWS Shield Advanced

Access to AWS Shield Advanced requires credentials. Those credentials must have permissions to access AWS resources, such as an AWS Shield Advanced resource or an Amazon S3 bucket. The following sections provide details on how you can use AWS Identity and Access Management (IAM) and Shield Advanced to help secure access to your resources.

• Authentication (p. 523)
• Access control (p. 524)

Authentication

You can access AWS as any of the following types of identities:

• AWS account root user – When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the AWS Account Management Reference Guide.

• IAM user – An IAM user is an identity within your AWS account that has specific custom permissions (for example, permissions to create a rule in Shield Advanced). You can use an IAM user name and password to sign in to secure AWS webpages like the AWS Management Console, AWS Discussion Forums, or the AWS Support Center.

In addition to a user name and password, you can also generate access keys for each user. You can use these keys when you access AWS services programmatically, either through one of the several SDKs or by using the AWS Command Line Interface (CLI). The SDK and CLI tools use the access keys
to cryptographically sign your request. If you don't use AWS tools, you must sign the request yourself. Shield Advanced supports **Signature Version 4**, a protocol for authenticating inbound API requests. For more information about authenticating requests, see **Signature Version 4 Signing Process** in the **AWS General Reference**.

**IAM role** – An IAM role is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user in that it is an AWS identity with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see **Creating a role for a third-party Identity Provider** in the **IAM User Guide**. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see **Permission sets** in the **AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide**.

- **AWS service access** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see **Creating a role to delegate permissions to an AWS service** in the **IAM User Guide**.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see **Using an IAM role to grant permissions to applications running on Amazon EC2 instances** in the **IAM User Guide**.

**Access control**

You can have valid credentials to authenticate your requests, but unless you have permissions you can't create or access AWS Shield Advanced resources. For example, you must have permissions to create a Shield Advanced protection or list attacks.

The following sections describe how to manage permissions for AWS Shield Advanced. We recommend that you read the overview first.

- **Overview of managing access permissions to your AWS Shield Advanced resources** (p. 525)
- **Using identity-based policies (IAM policies) for AWS Shield Advanced** (p. 529)
- **Shield Advanced required permissions for API actions** (p. 533)
AWS Identity and Access Management

Shield Advanced integrates with AWS Identity and Access Management (IAM), a service that lets your organization do the following:

- Create users and groups under your organization's AWS account
- Share your AWS account resources with users in the account
- Assign unique security credentials to each user
- Control user access to services and resources

For example, you can use IAM with Shield Advanced to control which users in your AWS account can create a new web ACL.

For general information about IAM, see the following documentation:

- AWS Identity and Access Management (IAM)
- IAM Getting Started Guide
- IAM User Guide

Overview of managing access permissions to your AWS Shield Advanced resources

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles). Some services also support attaching permissions policies to resources.

Note

An account administrator (or administrator user) is a user with administrator privileges. For more information, see IAM Best Practices in the IAM User Guide.

When granting permissions, you decide who is getting the permissions, the resources they get permissions for, and the specific operations that you want to allow on those resources.

Topics

- AWS Shield Advanced resources and operations (p. 525)
- Understanding resource ownership (p. 526)
- Managing access to resources (p. 526)
- Specifying policy elements: Actions, effects, resources, and principals (p. 528)
- Specifying conditions in a policy (p. 528)

AWS Shield Advanced resources and operations

In AWS Shield Advanced, the resources are protections and attacks. These resources have unique Amazon Resource Names (ARNs) associated with them, as shown in the following table.

<table>
<thead>
<tr>
<th>Name in AWS Shield Advanced Console</th>
<th>Name in AWS Shield Advanced SDK/CLI</th>
<th>ARN Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event or attack</td>
<td>AttackDetail</td>
<td>arn:aws:shield::account:attack/ID</td>
</tr>
</tbody>
</table>
Identity and access management

<table>
<thead>
<tr>
<th>Name in AWS Shield Advanced Console</th>
<th>Name in AWS Shield Advanced SDK/CLI</th>
<th>ARN Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protection</td>
<td>Protection</td>
<td>arn:aws:shield::account:protection/</td>
</tr>
</tbody>
</table>

To allow or deny access to a subset of Shield Advanced resources, include the ARN of the resource in the resource element of your policy. The ARNs for Shield Advanced have the following format:

```
arn:aws:shield::account:resource/ID
```

Replace the `account`, `resource`, and `ID` variables with valid values. Valid values can be the following:

- **account**: The ID of your AWS account. You must specify a value.
- **resource**: The type of Shield Advanced resource.
- **ID**: The ID of the Shield Advanced resource, or a wildcard (*) to indicate all resources of the specified type that are associated with the specified AWS account.

For example, the following ARN specifies all protections for the account 111122223333:

```
arn:aws:shield::111122223333:protection/*
```

For more information, see Resources in the IAM User Guide.

AWS Shield Advanced provides a set of operations to work with Shield Advanced resources. For a list of available operations, see Actions.

**Understanding resource ownership**

A resource owner is the AWS account that creates the resource. That is, the resource owner is the AWS account of the principal entity (the root account, an IAM user, or an IAM role) that authenticates the request that creates the resource. The following examples illustrate how this works:

- If you use the root account credentials of your AWS account to create a Shield Advanced resource, your AWS account is the owner of the resource.
- If you create an IAM user in your AWS account and grant permissions to create a Shield Advanced resource to that user, the user can create a Shield Advanced resource. However, your AWS account, to which the user belongs, owns the Shield Advanced resource.
- If you create an IAM role in your AWS account with permissions to create a Shield Advanced resource, anyone who can assume the role can create a Shield Advanced resource. Your AWS account, to which the role belongs, owns the Shield Advanced resource.
- With AWS Shield Advanced, to create a protection or describe an attack associated with a specific resource, a user must have an access to the resource itself in addition to having access to the Shield Advanced resource. For example to create a protection for an Amazon CloudFront distribution, the user needs read access for the distribution to protect. To describe an attack against a CloudFront distribution, the user needs read access to the distribution.

**Managing access to resources**

A permissions policy describes who has access to what. The following sections explain the available options for creating permissions policies.
Note
These sections discuss using IAM in the context of AWS Shield Advanced. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the IAM User Guide. For information about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

Policies that are attached to an IAM identity are known as identity-based policies, and policies that are attached to a resource are known as resource-based policies. AWS Shield Advanced supports only identity-based policies.

Topics

- Identity-based policies (IAM policies) (p. 527)
- Resource-based policies (p. 528)

Identity-based policies (IAM policies)

You can attach policies to IAM identities. For example, you can do the following:

- **Attach a permissions policy to a user or a group in your account** – An account administrator can use a permissions policy that is associated with a particular user to grant permissions for that user to create an Shield Advanced resource.

- **Attach a permissions policy to a role (grant cross-account permissions)** – You can attach an identity-based permissions policy to an IAM role to grant cross-account permissions. For example, the administrator in Account A can create a role to grant cross-account permissions to another AWS account (for example, Account B) or an AWS service as follows:
  1. Account A administrator creates an IAM role and attaches a permissions policy to the role that grants permissions on resources in Account A.
  2. Account A administrator attaches a trust policy to the role identifying Account B as the principal who can assume the role.
  3. Account B administrator can then delegate permissions to assume the role to any users in Account B. Doing this allows users in Account B to create or access resources in Account A. The principal in the trust policy also can be an AWS service principal if you want to grant an AWS service permissions to assume the role.

For more information about using IAM to delegate permissions, see Access Management in the IAM User Guide.

AWS Shield allows cross-account resource access, but it doesn't allow you to create cross-account resource protections. You can only create protections for resources from within the account that owns those resources.

The following is an example policy that grants permissions for the shield:ListProtections action on all resources. Shield Advanced doesn't support identifying specific resources using the resource ARNs (also referred to as resource-level permissions) for some of the API actions, so you must specify a wildcard character (*):

```json
{
    "Version": "2016-06-02",
    "Statement": [
        {
            "Sid": "ListProtections",
            "Effect": "Allow",
            "Action": [
                "shield:ListProtections"
            ]
        }
    ]
}
```
For more information about using identity-based policies with Shield Advanced, see Using identity-based policies (IAM policies) for AWS Shield Advanced (p. 529). For more information about users, groups, roles, and permissions, see Identities (Users, Groups, and Roles) in the IAM User Guide.

Resource-based policies

Other services, such as Amazon S3, also support resource-based permissions policies. For example, you can attach a policy to an S3 bucket to manage access permissions to that bucket. AWS Shield Advanced doesn't support resource-based policies.

Specifying policy elements: Actions, effects, resources, and principals

For each AWS Shield Advanced resource (see AWS Shield Advanced resources and operations (p. 525)), the service defines a set of API operations (see Shield Advanced required permissions for API actions (p. 533)). To grant permissions for these API operations, Shield Advanced defines a set of actions that you can specify in a policy. Note that performing an API operation can require permissions for more than one action. When granting permissions for specific actions, you also identify the resource on which the actions are allowed or denied.

The following are the most basic policy elements:

- **Resource** – In a policy, you use an Amazon Resource Name (ARN) to identify the resource to which the policy applies. For more information, see AWS Shield Advanced resources and operations (p. 525).
- **Action** – You use action keywords to identify resource operations that you want to allow or deny. For example, the shield:CreateRuleGroup permission allows the user permissions to perform the AWS Shield Advanced CreateRuleGroup operation.
- **Effect** – You specify the effect when the user requests the specific action. This can be either allow or deny. If you don't explicitly grant access to a resource, access is implicitly denied. You also can explicitly deny access to a resource, which you might do to make sure that a user cannot access it, even if a different policy grants access.
- **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. AWS Shield Advanced doesn't support resource-based policies.

To learn more about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

For a table that shows all the AWS Shield Advanced API actions and the resources that they apply to, see Shield Advanced required permissions for API actions (p. 533).

Specifying conditions in a policy

When you grant permissions, you can use the IAM policy language to specify the conditions when a policy should take effect. For example, you might want a policy to be applied only after a specific date. For more information about specifying conditions in a policy language, see Condition in the IAM User Guide.

To express conditions, you use predefined condition keys. There are no condition keys specific to Shield Advanced. However, there are general AWS condition keys that you can use as appropriate. For a complete list of AWS keys, see Available Keys for Conditions in the IAM User Guide.
Using identity-based policies (IAM policies) for AWS Shield Advanced

This section provides examples of identity-based policies that demonstrate how an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on AWS Shield Advanced resources.

**Important**
We recommend that you first review the introductory topics that explain the basic concepts and options available for you to manage access to your AWS Shield Advanced resources. For more information, see Overview of managing access permissions to your AWS Shield Advanced resources (p. 525).

For a table that shows all the AWS Shield Advanced API actions and the resources that they apply to, see Shield Advanced required permissions for API actions (p. 533).

**Topics**
- Permissions required to use the AWS Shield Advanced console (p. 529)
- AWS managed (predefined) policies for AWS Shield Advanced (p. 529)
- Customer managed policy examples (p. 530)

**Permissions required to use the AWS Shield Advanced console**

The AWS Shield Advanced console provides an integrated environment for you to create and manage Shield Advanced resources. The console provides many features and workflows that often require permissions to create an Shield Advanced resource in addition to the API-specific permissions that are documented in the Shield Advanced required permissions for API actions (p. 533). For more information about these additional console permissions, see Customer managed policy examples (p. 530).

**AWS managed (predefined) policies for AWS Shield Advanced**

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. Managed policies grant necessary permissions for common use cases so you can avoid having to investigate what permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

AWS Shield uses the AWS managed policy AWSShieldDRTAccessPolicy that you can use to grant the Shield Response Team (SRT) access to your account. This allows the SRT to perform actions on your account, to manage your AWS WAF rules and Shield protections. To use this, you create a role and pass it to the Shield API operation, associate SRT role. In the API, this is AssociateDRTRole. In the CLI, it's associate-drt-role. For more information about this policy, see Configure AWS SRT support (p. 481).

Shield Advanced uses the AWS managed policy AWSShieldServiceRolePolicy for the permissions it needs to manage automatic application layer DDoS mitigation resources for your account. This allows Shield Advanced to create and apply AWS WAF rules and rule groups in the web ACLs that you’ve associated with your protected resources, to automatically respond to DDoS attacks. To use this, you create a role and pass it to the Shield Advanced API operation, enable application layer automatic response. In the API, this is EnableApplicationLayerAutomaticResponse. In the CLI, it's enable-application-layer-automatic-response. For more information about the use of this policy, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

**Note**
You can review AWS managed permissions policies by signing in to the IAM console and searching for the policies.
You also can create your own custom IAM policies to allow permissions for AWS Shield Advanced API operations and resources. You can attach these custom policies to the IAM users or groups that require those permissions or to custom execution roles (IAM roles) that you create for your Shield Advanced resources.

Customer managed policy examples

The examples in this section provide a group of sample policies that you can attach to a user. If you are new to creating policies, we recommend that you first create an IAM user in your account and attach the policies to the user, in the sequence outlined in the steps in this section.

You can use the console to verify the effects of each policy as you attach the policy to the user. Initially, the user doesn't have permissions, and the user won't be able to do anything on the console. As you attach policies to the user, you can verify that the user can perform various operations on the console.

We recommend that you use two browser windows: one to create the user and grant permissions, and the other to sign in to the AWS Management Console using the user’s credentials and verify permissions as you grant them to the user.

For examples that show how to create an IAM role that you can use as an execution role for your Shield Advanced resource, see Creating IAM Roles in the IAM User Guide.

Example topics

- Example 1: Give users read-only access to Shield Advanced, CloudFront, and CloudWatch
- Example 2: Give users full access to Shield Advanced, CloudFront, and CloudWatch

Create an IAM user

First, you need to create an IAM user, add the user to an IAM group with administrative permissions, and then grant administrative permissions to the IAM user that you created. You then can access AWS using a special URL and the user’s credentials.

For instructions, see Creating Your First IAM User and Administrators Group in the IAM User Guide.

Example 1: Give users read-only access to Shield Advanced, CloudFront, and CloudWatch

The following policy grants users read-only access to Shield Advanced an associated resources, including Amazon CloudFront resources, and Amazon CloudWatch metrics. It's useful for users who need permission to view the settings in Shield Advanced protections and attacks and to monitor metrics in CloudWatch. These users can't create, update, or delete Shield Advanced resources.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ProtectedResourcesReadAccess",
            "Effect": "Allow",
            "Action": [
                "cloudfront:List*",
                "elasticloadbalancing:List*",
                "route53:List*",
                "cloudfront:Describe*",
                "elasticloadbalancing:Describe*",
                "route53:Describe*",
                "cloudwatch:Describe*",
                "cloudwatch:Get*",
                "cloudwatch:List*",
                "cloudfront:GetDistribution*",
            ]
        }
    ]
}
```
Example 2: Give users full access to Shield Advanced, CloudFront, and CloudWatch

The following policy lets users perform any Shield Advanced operation, perform any operation on CloudFront web distributions, and monitor metrics and a sample of requests in CloudWatch. It's useful for users who are Shield Advanced administrators.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ProtectedResourcesReadAccess",
            "Effect": "Allow",
            "Action": [
                "cloudfront:List*",
                "elasticloadbalancing:List*",
                "route53:List*",
                "cloudfront:Describe*",
                "elasticloadbalancing:Describe*",
                "route53:Describe*",
                "cloudwatch:Describe*",
                "cloudwatch:Get*",
                "cloudwatch:List*",
                "cloudfront:GetDistribution*",
                "globalaccelerator:ListAccelerators",
                "globalaccelerator:DescribeAccelerator"
            ],
            "Resource": [
                "arn:aws:elasticloadbalancing:*:*:*",
                "arn:aws:cloudfront::*:*",
                "arn:aws:route53::*:*:hostedzone/*",
                "arn:aws:cloudfront::*:*:*",
                "arn:aws:globalaccelerator::*:*"
            ]
        },
        {
            "Sid": "ShieldFullAccess",
            "Effect": "Allow",
            "Action": [
                "shield:*"
            ],
            "Resource": "*"
        }
    ]
}
```
We strongly recommend that you configure multi-factor authentication (MFA) for users who have administrative permissions. For more information, see Using Multi-Factor Authentication (MFA) Devices with AWS in the IAM User Guide.

AWS managed policies for AWS Shield Advanced

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ViewOnlyAccess AWS managed policy provides read-only access to many AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

Shield Advanced updates to AWS managed policies

View details about updates to AWS managed policies for Shield Advanced since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Shield Advanced document history page at Document history (p. 566).

AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide
Identity and access management

Policy | Description of change | Date
---|---|---
The service-linked role AWSServiceRoleForAWSShield uses this policy. For information, see Using service-linked roles for Shield Advanced (p. 533). | | 
Shield Advanced started tracking changes | Shield Advanced started tracking changes for its AWS managed policies. | March 1, 2021

Shield Advanced required permissions for API actions

When you set up Access control (p. 524) and writing permissions policies that you can attach to an IAM identity (identity-based policies), use the information in this section as a guide. For each AWS Shield Advanced API operation, you need to know the actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

**Note**  
To specify an action, use the shield: prefix followed by the API operation name (for example, shield:CreateProtection).

You can use AWS condition keys in your AWS Shield Advanced policies to express conditions. For a complete list of AWS keys, see Available Keys for Conditions in the IAM User Guide.

To see Shield Advanced actions, resource types, and condition keys, see Actions, resources, and condition keys for AWS Shield Advanced in the Service Authorization Reference.

For more information about Shield actions and resources, see the AWS Identity and Access Management guide topic Actions Defined by AWS Shield.

For a full list of the API actions available for Shield, see AWS Shield Advanced API Reference.

Using service-linked roles for Shield Advanced

AWS Shield Advanced uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Shield Advanced. Service-linked roles are predefined by Shield Advanced and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Shield Advanced easier because you don’t have to manually add the necessary permissions. Shield Advanced defines the permissions of its service-linked roles, and unless defined otherwise, only Shield Advanced can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Shield Advanced resources because you can’t inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-Linked Role Permissions for Shield Advanced

Shield Advanced uses the service-linked role named AWSServiceRoleForAWSShield. This role allows Shield Advanced to access and manage AWS resources in order to automatically respond to application
layer DDoS attacks on your behalf. For more information about this functionality, see Shield Advanced automatic application layer DDoS mitigation (p. 489).

The AWSServiceRoleForAWSShield service-linked role trusts the following services to assume the role:

- shield.amazonaws.com

The role permissions policy named AWSShieldServiceRolePolicy allows Shield Advanced to complete the following actions on all AWS resources:

- wafv2:GetWebACL
- wafv2:UpdateWebACL
- wafv2:GetWebACLForResource
- wafv2:ListResourcesForWebACL
- cloudfront:ListDistributions
- cloudfront:GetDistribution

When actions are permitted on all AWS resources, it's indicated in the policy as "Resource": "*". This means that the service-linked role can take each indicated action on all AWS resources that the action supports. For example, the action wafv2:GetWebACL is supported only for wafv2 web ACL resources.

Shield Advanced only makes resource-level API calls for protected resources for which you've enabled the application layer protections feature and for web ACLs that are associated with those protected resources.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

Creating a Service-Linked Role for Shield Advanced

You don't need to manually create a service-linked role. When you enable automatic application layer DDoS mitigation for a resource in the AWS Management Console, the AWS CLI, or the AWS API, Shield Advanced creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable automatic application layer DDoS mitigation for a resource, Shield Advanced creates the service-linked role for you again.

Editing a Service-Linked Role for Shield Advanced

Shield Advanced does not allow you to edit the AWSServiceRoleForAWSShield service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

Deleting a Service-Linked Role for Shield Advanced

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

**Note**

If Shield Advanced is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.
To delete the Shield Advanced resources that are used by the AWSServiceRoleForAWSShield

For all of your resources that have application layer DDoS protections configured, disable automatic application layer DDoS mitigation. For console instructions, see Configure application layer DDoS protections (p. 503).

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAWSShield service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Supported Regions for Shield Advanced Service-Linked Roles

Shield Advanced supports using service-linked roles in all of the Regions where the service is available. For more information, see Shield Advanced endpoints and quotas.
Logging and monitoring in Shield

Monitoring is an important part of maintaining the reliability, availability, and performance of Shield and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Shield resources and responding to potential events:

Amazon CloudWatch Alarms

Using CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, CloudWatch sends a notification to an Amazon SNS topic or AWS Auto Scaling policy. For more information, see Monitoring with Amazon CloudWatch (p. 541).

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Shield. Using the information collected by CloudTrail, you can determine the request that was made to Shield, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging API calls with AWS CloudTrail (p. 548).
Compliance validation for Shield

Third-party auditors assess the security and compliance of Shield as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using Shield is determined by the sensitivity of your data, your organization’s compliance objectives, and applicable laws and regulations. If your use of Shield is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA Security and Compliance Whitepaper** – This publication describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Well-Architected Framework** – The AWS Well-Architected Framework helps you build secure cloud applications.

Resilience in Shield

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Infrastructure security in AWS Shield

As a managed service, AWS Shield is protected by the AWS global network security procedures that are described in Amazon Web Services: Overview of Security Processes.

You use AWS published API calls to access Shield through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.
AWS Shield Advanced quotas

AWS Shield Advanced has default quotas on the number of entities per Region. You can request an increase in these quotas.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of protected resources for each resource type that AWS Shield Advanced offers protection for, per account.</td>
<td>1,000</td>
</tr>
<tr>
<td>Maximum number of protection groups, per account.</td>
<td>100</td>
</tr>
<tr>
<td>Maximum number of individual protected resources that you can specifically include in a protection group. In the API, this applies to the Members that you specify when you set the protection group Pattern to ARBITRARY. In the console, this applies to the resources that you select for the protection grouping Choose from protected resources.</td>
<td>1,000</td>
</tr>
</tbody>
</table>
Monitoring AWS WAF, AWS Firewall Manager, and AWS Shield Advanced

Monitoring is an important part of maintaining the reliability, availability, and performance of your services.

**Note**
For information about monitoring your Shield Advanced resources and identifying possible DDoS events using Shield Advanced, see [AWS Shield](p. 460).

As you start monitoring these services, you should create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

The next step is to establish a baseline for normal performance in your environment, by measuring performance at various times and under different load conditions. As you monitor AWS WAF, Firewall Manager, Shield Advanced and related services, store historical monitoring data so that you can compare it with current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

For AWS WAF, you should monitor the following items at a minimum to establish a baseline:

- The number of allowed web requests
- The number of blocked web requests

**Topics**
- Monitoring tools (p. 539)
- Logging API calls with AWS CloudTrail (p. 548)

## Monitoring tools

AWS provides various tools that you can use to monitor AWS WAF and AWS Shield Advanced. You can configure some of these tools to do the monitoring for you, while other tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

### Automated monitoring tools

You can use the following automated monitoring tools to watch AWS WAF and AWS Shield Advanced and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon
SNS) topic or Amazon EC2 Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms will not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring CloudFront Activity Using CloudWatch.

**Note**
CloudWatch metrics and alarms are not enabled for AWS Firewall Manager.

Not only can you use CloudWatch to monitor AWS WAF and Shield Advanced metrics as described in Monitoring with Amazon CloudWatch (p. 541), you also should use CloudWatch to monitor activity for your protected resources. For more information, see the following:
- Monitoring CloudFront Activity Using CloudWatch in the Amazon CloudFront Developer Guide
- Logging and monitoring in Amazon API Gateway in the API Gateway Developer Guide
- CloudWatch Metrics for Your Application Load Balancer in the Elastic Load Balancing User Guide
- Monitoring and Logging in the AWS AppSync Developer Guide
- Logging and monitoring in Amazon Cognito in the Amazon Cognito Developer Guide
- **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see What is Amazon CloudWatch Logs?
- **Amazon CloudWatch Events** – Automate your AWS services and respond automatically to system events. Events from AWS services are delivered to CloudWatch Events in near real time, and you can specify automated actions to take when an event matches a rule that you write. For more information, see What is Amazon CloudWatch Events?
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log-processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Logging API calls with AWS CloudTrail (p. 548) and Working with CloudTrail Log Files in the AWS CloudTrail User Guide.
- **AWS Config** – View the configuration of AWS resources in your AWS account, including how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.

## Manual monitoring tools

Another important part of monitoring AWS WAF and AWS Shield Advanced involves manually monitoring those items that the CloudWatch alarms don't cover. You can view the AWS WAF, Shield Advanced, CloudWatch, and other AWS Management Console dashboards to see the state of your AWS environment. We recommend that you also check the log files for your web ACLs and rules.

- For example, to view the AWS WAF dashboard:
  - On the **Requests** tab of the AWS WAF **Web ACLs** page, view a graph of total requests and requests that match each rule that you have created. For more information, see Viewing a sample of web requests (p. 219).
- View the CloudWatch home page for the following:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

In addition, you can use CloudWatch to do the following:
- Create customized dashboards to monitor the services that you care about.
- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all of your AWS resource metrics.
- Create and edit alarms to be notified of problems.
Monitoring with Amazon CloudWatch

You can monitor web requests and web ACLs and rules using Amazon CloudWatch, which collects and processes raw data from AWS WAF and AWS Shield Advanced into readable, near real-time metrics. You can use statistics in Amazon CloudWatch to gain a perspective on how your web application or service is performing. For more information, see What is CloudWatch in the Amazon CloudWatch User Guide.

**Note**
CloudWatch metrics and alarms are not enabled for Firewall Manager.

Creating Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify, and performs one or more actions based on the value of the metric relative to a specified threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods.

AWS WAF and AWS Shield Advanced metrics and dimensions

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

- The AWS WAF namespace is AWS/WAFV2
- The Shield Advanced namespace is AWS/DDoSProtection

**Note**
AWS WAF reports metrics once a minute.
Shield Advanced reports metrics once a minute during an event and less frequently other times.

Use the following procedures to view the metrics for AWS WAF and AWS Shield Advanced.

**To view metrics using the CloudWatch console**

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to the one where your AWS resources are located. For CloudFront, choose the US East (N. Virginia) Region.
3. In the navigation pane, under **Metrics**, choose **All metrics** and then search under the **Browse** tab for the service.

**To view metrics using the AWS CLI**

- For AWS/WAFV2, at a command prompt use the following command:

  ```bash
  aws cloudwatch list-metrics --namespace "AWS/WAFV2"
  ```

  For Shield Advanced, at a command prompt use the following command:

  ```bash
  aws cloudwatch list-metrics --namespace "AWS/DDoSProtection"
  ```

541
AWS WAF metrics and dimensions

AWS WAF reports metrics once a minute. AWS WAF provides the following metrics and dimensions in the AWS/WAFV2 namespace.

### Web ACL, rule group, and rule metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllowedRequests</td>
<td>The number of allowed web requests.</td>
</tr>
<tr>
<td></td>
<td>Reporting criteria: There is a nonzero value.</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>BlockedRequests</td>
<td>The number of blocked web requests.</td>
</tr>
<tr>
<td></td>
<td>Reporting criteria: There is a nonzero value.</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>CountedRequests</td>
<td>The number of counted web requests.</td>
</tr>
<tr>
<td></td>
<td>Reporting criteria: There is a nonzero value.</td>
</tr>
<tr>
<td></td>
<td>A counted web request is one that matches at least one of the rules. Request counting is typically used for testing.</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>CaptchaRequests</td>
<td>The number of web requests that had CAPTCHA controls applied.</td>
</tr>
<tr>
<td></td>
<td>Reporting criteria: There is a nonzero value.</td>
</tr>
<tr>
<td></td>
<td>A CAPTCHA web request is one that matches a rule that has a CAPTCHA action setting. This metric records all requests that match, regardless of whether they have a valid CAPTCHA token.</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>RequestsWithValidCaptchaToken</td>
<td>The number of web requests that had CAPTCHA controls applied and that had a valid CAPTCHA token.</td>
</tr>
<tr>
<td></td>
<td>Reporting criteria: There is a nonzero value.</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>ChallengeRequests</td>
<td>The number of web requests that had challenge controls applied.</td>
</tr>
<tr>
<td></td>
<td>Reporting criteria: There is a nonzero value.</td>
</tr>
<tr>
<td></td>
<td>A challenge web request is one that matches a rule that has a Challenge action setting. This metric records all requests that match, regardless of whether they have a valid challenge token.</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
</tbody>
</table>
### Metric Description

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequestsWithValidChallengeToken</td>
<td>The number of web requests that had challenge controls applied and that had a valid challenge token. Reporting criteria: There is a nonzero value. Valid statistics: Sum</td>
</tr>
<tr>
<td>PassedRequests</td>
<td>The number of passed requests. This is only used for requests that go through a rule group evaluation without matching any of the rule group rules. Reporting criteria: There is a nonzero value. Passed requests are requests that don't match any of the rules in the rule group. Valid statistics: Sum</td>
</tr>
</tbody>
</table>

### Web ACL, rule group, and rule dimensions

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>Required for all protected resource types except for Amazon CloudFront distributions.</td>
</tr>
<tr>
<td>Rule</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• The metric name of the Rule.</td>
</tr>
<tr>
<td></td>
<td>• ALL, which represents all rules within a WebACL or RuleGroup.</td>
</tr>
<tr>
<td></td>
<td>• Default_Action (only when combined with the WebACL dimension), which represents the action assigned to any request whose evaluation wasn't terminated by the action of a rule in the web ACL.</td>
</tr>
<tr>
<td>RuleGroup</td>
<td>The metric name of the RuleGroup.</td>
</tr>
<tr>
<td>WebACL</td>
<td>The metric name of the WebACL.</td>
</tr>
</tbody>
</table>

**Note**

For any single web request, AWS WAF emits metrics for at most 100 labels. Your web ACL evaluation can apply more than 100 labels and match against more than 100 labels, but only the first 100 will be reflected in these metrics.

### Label and AWS WAF Bot Control metrics

<table>
<thead>
<tr>
<th>Metric</th>

### AWS Shield Advanced metrics and alarms

This section discusses the metrics and alarms available with AWS Shield Advanced.

#### AWS Shield Advanced metrics

Shield Advanced reports metrics to Amazon CloudWatch on an AWS resource more frequently during DDoS events than while no events are underway. Shield Advanced reports metrics once a minute during an event, and then once right after the event ends. While no events are underway, Shield Advanced reports metrics once a day, at a time assigned to the resource. This periodic report keeps the metrics active and available for use in custom CloudWatch alarms.

Shield Advanced reports metrics in the US East (N. Virginia) Region, us-east-1 for the following:

- The global services Amazon CloudFront and Amazon Route 53.
- Protection groups. For information about protection groups, see [AWS Shield Advanced protection groups](#).

#### Detection metrics

Shield Advanced provides the following detection metrics and dimensions in the AWS/DDoSProtection namespace.

### Detection metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDoSDetected</td>
<td>Indicates whether a DDoS event is underway for a particular Amazon Resource Name (ARN). This metric has a non-zero value during an event.</td>
</tr>
<tr>
<td>DDoSAttackBitsPerSecond</td>
<td>The number of bits observed during a DDoS event for a particular Amazon Resource Name (ARN).</td>
</tr>
</tbody>
</table>
### Metric | Description
--- | ---
| DDoSAvoidPacketsPerSecond | The number of packets observed during a DDoS event for a particular Amazon Resource Name (ARN). This metric is available only for network and transport layer (layer 3 and layer 4) DDoS events. This metric has a non-zero value during an event. Units: Packets
| DDoSAvoidRequestsPerSecond | The number of requests observed during a DDoS event for a particular Amazon Resource Name (ARN). This metric is available only for layer 7 DDoS events. The metric is reported only for the most significant layer 7 events. This metric has a non-zero value during an event. Units: Requests

Shield Advanced posts the DDoSDetected metric with no other dimensions. The remaining detection metrics include the AttackVector dimensions that correspond to the type of attack, from the following list:

- ACKFlood
- ChargenReflection
- DNSReflection
- GenericUDPReflection
- MemcachedReflection
- MSSQLReflection
- NetBIOSReflection
- NTPReflection
- PortMapper
- RequestFlood
- RIPReflection
- SNMPReflection
- SSDPReflection
- SYNFlode
- UDPFragment
- UDPPtraffic
- UDPReflection
### Mitigation metrics

Shield Advanced provides the following mitigation metrics and dimensions in the AWS/DDoSProtection namespace.

#### Mitigation metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VolumePacketsPerSecond</td>
<td>The number of packets per second that were dropped or passed by a mitigation that was deployed in response to a detected event.</td>
</tr>
<tr>
<td></td>
<td>Units: packets</td>
</tr>
</tbody>
</table>

#### Mitigation dimensions

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceArn</td>
<td>Amazon Resource Name (ARN)</td>
</tr>
<tr>
<td>MitigationAction</td>
<td>The outcome of an applied mitigation. Possible values are Pass or Drop.</td>
</tr>
</tbody>
</table>

### Top contributors metrics

Shield Advanced provides the following mitigation metrics and dimensions in the AWS/DDoSProtection namespace.

#### Top contributors metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VolumePacketsPerSecond</td>
<td>The number of packets per second for a top contributor.</td>
</tr>
<tr>
<td></td>
<td>Units: packets</td>
</tr>
<tr>
<td>VolumeBitsPerSecond</td>
<td>The number of bits per second for a top contributor.</td>
</tr>
<tr>
<td></td>
<td>Units: bits</td>
</tr>
</tbody>
</table>

Shield Advanced posts top contributors metrics by dimension combinations that characterize the event contributors. You can use any of the following combinations of dimensions for any of the top contributors metrics:

- ResourceArn, Protocol
- ResourceArn, Protocol, SourcePort
- ResourceArn, Protocol, DestinationPort
- ResourceArn, Protocol, SourceIp
- ResourceArn, Protocol, SourceAsn
- ResourceArn, TcpFlags
Top contributors dimensions

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceArn</td>
<td>Amazon Resource Name (ARN).</td>
</tr>
<tr>
<td>Protocol</td>
<td>IP protocol name, either TCP or UDP.</td>
</tr>
<tr>

Creating AWS Shield Advanced alarms

You can use AWS Shield Advanced metrics for Amazon CloudWatch alarms. CloudWatch sends notifications or automatically make changes to the resources that you are monitoring based on rules that you define.

For detailed instructions on creating a CloudWatch alarm, see the Amazon CloudWatch User Guide. When creating the alarm on the CloudWatch console, to use the Shield Advanced metrics, after choosing Create an alarm, choose AWSDDOSProtectionMetrics. You can then create an alarm based on a specific volume of traffic, or you can trigger an alarm whenever a metric is non-zero. The second option triggers an alarm for any potential attack that Shield Advanced observes.

Note
The AWSDDOSProtectionMetrics are available only to Shield Advanced customers.

For more information, see What is CloudWatch in the Amazon CloudWatch User Guide.

AWS Firewall Manager notifications

AWS Firewall Manager doesn’t record metrics, so you can’t create Amazon CloudWatch alarms specifically for Firewall Manager. However, you can configure Amazon SNS notifications to alert you to potential attacks. To create Amazon SNS notifications in Firewall Manager, see Step 4: Configure Amazon SNS notifications and Amazon CloudWatch alarms (p. 368).

Logging API calls with AWS CloudTrail

AWS WAF, AWS Shield Advanced, and AWS Firewall Manager are integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures a subset of API calls for these services as events, including calls from the AWS WAF, Shield Advanced or Firewall Manager consoles and from code calls to the AWS WAF, Shield Advanced, or Firewall Manager APIs. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for AWS WAF, Shield Advanced, or Firewall Manager. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to these services, the
AWS WAF, AWS Firewall Manager, and AWS Shield Advanced Developer Guide
AWS WAF information in AWS CloudTrail

IP address that the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, including how to configure and enable it, see the AWS CloudTrail User Guide.

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in AWS WAF, Shield Advanced, or Firewall Manager, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for AWS WAF, Shield Advanced, or Firewall Manager, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail on the console, the trail applies to all Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

AWS WAF information in AWS CloudTrail

All AWS WAF actions are logged by AWS CloudTrail and are documented in the AWS WAF API Reference. For example, calls to ListWebACL, UpdateWebACL, and DeleteWebACL generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials
- Whether the request was made with temporary security credentials for a role or federated user
- Whether the request was made by another AWS service

For more information, see CloudTrail userIdentity Element.

Example: AWS WAF log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. AWS CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following are examples of CloudTrail log entries for AWS WAF web ACL operations.

Example: CloudTrail log entry for CreateWebACL

```json
{
  "eventVersion": "1.05",
  "userIdentity": {

AWS Shield Advanced information in CloudTrail

AWS Shield Advanced supports logging the following actions as events in CloudTrail log files:

- ListAttacks
- DescribeAttack
- CreateProtection
- DescribeProtection
- DeleteProtection
- ListProtections
- CreateSubscription
- DescribeSubscription
- GetSubscriptionState
- DeleteSubscription

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Example: Shield Advanced log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the DeleteProtection and ListProtections actions.

```json
[
  {
    "eventVersion": "1.05",
    "userIdentity": {
      "type": "IAMUser",
      "principalId": "1234567890987654321231",
      "arn": "arn:aws:iam::123456789012:user/SampleUser",
      "accountId": "123456789012",

```
AWS Firewall Manager information in CloudTrail

AWS Firewall Manager supports logging the following actions as events in CloudTrail log files:

- AssociateAdminAccount
- DeleteNotificationChannel
- DeletePolicy
- DisassociateAdminAccount
- PutNotificationChannel
- PutPolicy
- GetAdminAccount
- GetComplianceDetail
- GetNotificationChannel
- GetPolicy
- ListComplianceStatus
- ListPolicies

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:
• Whether the request was made with root or IAM user credentials.
• Whether the request was made with temporary security credentials for a role or federated user.
• Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Example: Firewall Manager log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the GetAdminAccount--> action.

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "1234567890987654321231",
        "arn": "arn:aws:sts::123456789012:assumed-role/Admin/SampleUser",
        "accountId": "123456789012",
        "accessKeyId": "1AFGDT647FHU83JHFI81H",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",

```
Using the AWS WAF and AWS Shield Advanced API

This section describes how to make requests to the AWS WAF and Shield Advanced API for creating and managing match sets, rules, and web ACLs in AWS WAF as well as your subscription and protections in Shield Advanced. This section will acquaint you with the components of requests, the content of responses, and how to authenticate requests.

Topics
- Using the AWS SDKs (p. 560)
- Making HTTPS requests to AWS WAF or Shield Advanced (p. 560)
- HTTP responses (p. 562)
- Authenticating requests (p. 563)

Using the AWS SDKs

If you use a language that AWS provides an SDK for, use the SDK rather than trying to work your way through the APIs. The SDKs make authentication simpler, integrate easily with your development environment, and provide easy access to AWS WAF and Shield Advanced commands. For more information about the AWS SDKs, see Step 3: Download tools (p. 5) in the topic Setting up (p. 3).

Making HTTPS requests to AWS WAF or Shield Advanced

AWS WAF and Shield Advanced requests are HTTPS requests, as defined by RFC 2616. Like any HTTP request, a request to AWS WAF or Shield Advanced contains a request method, a URI, request headers, and a request body. The response contains an HTTP status code, response headers, and sometimes a response body.

Request URI

The request URI is always a single forward slash, /.

HTTP headers

AWS WAF and Shield Advanced require the following information in the header of an HTTP request:

**Host (Required)**

The endpoint that specifies where your resources are created. For information about endpoints, see AWS service endpoints. For example, the value of the Host header for AWS WAF for a CloudFront distribution is waf.amazonaws.com:443.

**x-amz-date or Date (Required)**

The date used to create the signature that is contained in the Authorization header. Specify the date in ISO 8601 standard format, in UTC time, as shown in the following example:
HTTP request body

Many AWS WAF and Shield Advanced API actions require you to include JSON-formatted data in the body of the request.

The following example request uses a simple JSON statement to update an IPSet to include the IP address 192.0.2.44 (represented in CIDR notation as 192.0.2.44/32):

```json
{
    "IPSet": {
        "name": "example-set",
        "values": [192.0.2.44/32]
    }
}
```
HTTP responses

All AWS WAF and Shield Advanced API actions include JSON-formatted data in the response.

Here are some important headers in the HTTP response and how you should handle them in your application, if applicable:

**HTTP/1.1**

This header is followed by a status code. Status code 200 indicates a successful operation.

- **Type:** String
  - **x-amzn-RequestId**
    - A value created by AWS WAF or Shield Advanced that uniquely identifies your request, for example, K2QH8DNOU907H97FNA26DLL80B8V4K0QS5AEXMVJF6GQ9ASUAAJG. If you have a problem with AWS WAF, AWS can use this value to troubleshoot the problem.
    - **Type:** String
  - **Content-Length**
    - The length of the response body in bytes.
    - **Type:** String
  - **Date**
    - The date and time that AWS WAF or Shield Advanced responded, for example, Wed, 07 Oct 2015 12:00:00 GMT.
    - **Type:** String
Error responses

If a request results in an error, the HTTP response contains the following values:

- A JSON error document as the response body
- Content-Type
- The applicable 3xx, 4xx, or 5xx HTTP status code

The following is an example of a JSON error document:

HTTP/1.1 400 Bad Request
x-amzn-RequestId: b0e91dc8-3807-11e2-83c6-5912bf8ad066
x-amzn-ErrorType: ValidationException
Content-Type: application/json
Content-Length: 125
Date: Mon, 26 Nov 2012 20:27:25 GMT

{"message":"1 validation error detected: Value null at 'TargetString' failed to satisfy constraint: Member must not be null"}

Authenticating requests

If you use a language that AWS provides an SDK for, we recommend that you use the SDK. All the AWS SDKs greatly simplify the process of signing requests and save you a significant amount of time when compared with using the AWS WAF or Shield Advanced API. In addition, the SDKs integrate easily with your development environment and provide easy access to related commands.

AWS WAF and Shield Advanced require that you authenticate every request that you send by signing the request. To sign a request, you calculate a digital signature using a cryptographic hash function, which returns a hash value based on the input. The input includes the text of your request and your secret access key. The hash function returns a hash value that you include in the request as your signature. The signature is part of the Authorization header of your request.

After receiving your request, AWS WAF or Shield Advanced recalculates the signature using the same hash function and input that you used to sign the request. If the resulting signature matches the signature in the request, AWS WAF or Shield Advanced processes the request. If not, the request is rejected.

AWS WAF and Shield Advanced supports authentication using AWS Signature Version 4. The process for calculating a signature can be broken into three tasks:

Task 1: Create a Canonical Request

Create your HTTP request in canonical format as described in Task 1: Create a Canonical Request For Signature Version 4 in the Amazon Web Services General Reference.

Task 2: Create a String to Sign

Create a string that you will use as one of the input values to your cryptographic hash function. The string, called the string to sign, is a concatenation of the following values:

- Name of the hash algorithm
- Request date
- Credential scope string
- Canonicalized request from the previous task
The credential scope string itself is a concatenation of date, region, and service information.

For the `X-Amz-Credential` parameter, specify the following:

- The code for the endpoint to which you're sending the request, `us-east-2`
- `waf` for the service abbreviation

For example:

```
X-Amz-Credential=AKIAIOSFODNN7EXAMPLE/20130501/us-east-2/waf/aws4_request
```

**Task 3: Create a Signature**

Create a signature for your request by using a cryptographic hash function that accepts two input strings:

- Your string to sign, from Task 2.
- A derived key. The derived key is calculated by starting with your secret access key and using the credential scope string to create a series of hash-based message authentication codes (HMACs).
Related information

The following related resources can help you as you work with this service.

The following resources are available for AWS WAF, AWS Shield Advanced, and AWS Firewall Manager.

- **Guidelines for Implementing AWS WAF** – Technical publication with current recommendations for implementing AWS WAF to protect existing and new web applications.
- **AWS discussion forums** – A community-based forum for discussing technical questions related to this and other AWS services.
- **AWS WAF Discussion Forum** – A community-based forum for developers to discuss technical questions related to AWS WAF.
- **Shield Advanced Discussion Forum** – A community-based forum for developers to discuss technical questions related to Shield Advanced.
- **AWS WAF product information** – The primary web page for information about AWS WAF, including features, pricing, and more.
- **Shield Advanced product information** – The primary web page for information about Shield Advanced, including features, pricing, and more.

The following resources are available for Amazon Web Services.

- **Classes & Workshops** – Links to role-based and specialty courses, in addition to self-paced labs to help sharpen your AWS skills and gain practical experience.
- **AWS Developer Center** – Explore tutorials, download tools, and learn about AWS developer events.
- **AWS Developer Tools** – Links to developer tools, SDKs, IDE toolkits, and command line tools for developing and managing AWS applications.
- **Getting Started Resource Center** – Learn how to set up your AWS account, join the AWS community, and launch your first application.
- **Hands-On Tutorials** – Follow step-by-step tutorials to launch your first application on AWS.
- **AWS Whitepapers** – Links to a comprehensive list of technical AWS whitepapers, covering topics such as architecture, security, and economics and authored by AWS Solutions Architects or other technical experts.
- **AWS Support Center** – The hub for creating and managing your AWS Support cases. Also includes links to other helpful resources, such as forums, technical FAQs, service health status, and AWS Trusted Advisor.
- **AWS Support** – The primary webpage for information about AWS Support, a one-on-one, fast-response support channel to help you build and run applications in the cloud.
- **Contact Us** – A central contact point for inquiries concerning AWS billing, account, events, abuse, and other issues.
- **AWS Site Terms** – Detailed information about our copyright and trademark; your account, license, and site access; and other topics.
Document history

This page lists significant changes to this documentation.

Service features are sometimes rolled out incrementally to the AWS Regions where a service is available. We update this documentation for the first release only. We don't provide information about Region availability or announce subsequent Region rollouts. For information about Region availability of service features and to subscribe to notifications about updates, see What's New with AWS?

</tr>
<tr>
<td>Update Description</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Firewall Manager updates to content audit security group policies (p. 411)</td>
<td>AWS Firewall Manager has expanded functionality for content audit security group policies including a managed rules option, that uses managed application and protocol lists, and details for resource violations.</td>
<td>July 7, 2020</td>
</tr>
<tr>
<td>Firewall Manager managed lists (p. 401)</td>
<td>AWS Firewall Manager now supports managed application and protocol lists. Firewall Manager manages some lists and you can create and manage your own.</td>
<td>July 7, 2020</td>
</tr>
<tr>
<td>Firewall Manager supports shared VPCs in common security group policies (p. 410)</td>
<td>AWS Firewall Manager now supports using common security group policies in shared VPCs. You can do this in addition to using them in the VPCs owned by in-scope accounts.</td>
<td>May 26, 2020</td>
</tr>
<tr>
<td>Updated AWS Managed Rules for AWS WAF (p. 35)</td>
<td>Added documentation for each rule in the AWS Managed Rules for AWS WAF.</td>
<td>May 20, 2020</td>
</tr>
<tr>
<td>Updated AWS Managed Rules for AWS WAF (p. 70)</td>
<td>AWS Managed Rules for AWS WAF updated the Linux operating system rule group.</td>
<td>May 19, 2020</td>
</tr>
<tr>
<td>Add support for migrating AWS WAF Classic resources to AWS WAF (v2) (p. 245)</td>
<td>You can now use the console or API to export your AWS WAF Classic resources for migration to the latest version of AWS WAF.</td>
<td>April 27, 2020</td>
</tr>
<tr>
<td>Add support for AWS Organizations organizational units in policy scope (p. 379)</td>
<td>AWS Firewall Manager now supports using AWS Organizations organizational units (OUs) to specify policy scope. You can use OUs to include or exclude accounts from the scope, in addition to including or excluding specific accounts. Specifying an OU is the same as specifying all accounts in the OU and in any of its child OUs, including any child OUs and accounts that are added at a later time.</td>
<td>April 6, 2020</td>
</tr>
<tr>
<td>Add support for AWS WAF (v2) to AWS Firewall Manager (p. 379)</td>
<td>AWS Firewall Manager now supports the latest version of AWS WAF, in addition to the prior version, AWS WAF Classic.</td>
<td>March 31, 2020</td>
</tr>
<tr>
<td><strong>Update to AWS Firewall Manager common security group policies</strong></td>
<td>AWS Firewall Manager common security group policy now has the option to apply the policy to all elastic network interfaces in your in-scope Amazon EC2 instances. You can still choose to only apply the policy to the default elastic network interface.</td>
<td>March 11, 2020</td>
</tr>
<tr>
<td><strong>Updated AWS Managed Rules for AWS WAF</strong></td>
<td>AWS Managed Rules for AWS WAF added an AWSManagedRulesAnonymousIpList rule group.</td>

<td>AWS Firewall Manager integrated with AWS Security Hub</td>
<td>AWS Firewall Manager now creates findings for resources that are out of compliance and for attacks and sends them to AWS Security Hub.</td>
<td>December 18, 2019</td>
</tr>
<tr>
<td>Release of AWS WAF version 2</td>
<td>New version of the AWS WAF developer guide. You can manage a web ACL or rule group in JSON format. Expanded capabilities include logical rule statements, rule statement nesting, and full CIDR support for IP addresses and address ranges. Rules are no longer AWS resources, but exist only in the context of a web ACL or rule group. For existing customers, the prior version of the service is now called AWS WAF Classic. In the APIs, SDKs, and CLIs, AWS WAF Classic retains its naming schemes and this latest version of AWS WAF is referred to with an added &quot;V2&quot; or &quot;v2&quot;, depending on the context. AWS WAF can't access AWS resources that were created in AWS WAF Classic. To use those resources in AWS WAF, you need to migrate them.</td>
<td>November 25, 2019</td>
</tr>
<tr>
<td>AWS Managed Rules rule groups for AWS WAF</td>
<td>Added AWS Managed Rules rule groups. These are free of charge for AWS WAF customers.</td>
<td>November 25, 2019</td>
</tr>
<tr>
<td>AWS Firewall Manager support for Amazon Virtual Private Cloud security groups</td>
<td>Added support for Amazon VPC security groups to Firewall Manager.</td>
<td>October 10, 2019</td>
</tr>
<tr>
<td>AWS Firewall Manager support for AWS Shield Advanced</td>
<td>Added support for Shield Advanced to Firewall Manager.</td>
<td>March 15, 2019</td>
</tr>
<tr>
<td>Tutorial: Creating hierarchical policies</td>
<td>Added tutorial on creating hierarchical policies in AWS Firewall Manager.</td>
<td>February 11, 2019</td>
</tr>
<tr>
<td>Rule-level control in rule groups</td>
<td>You can now exclude individual rules from AWS Marketplace rule groups, as well as your own rule groups.</td>
<td>December 12, 2018</td>
</tr>
<tr>
<td>AWS Shield Advanced support for AWS Global Accelerator standard accelerators</td>
<td>Shield Advanced can now protect AWS Global Accelerator standard accelerators.</td>
<td>November 26, 2018</td>
</tr>
<tr>
<td>AWS WAF support for Amazon API Gateway</td>
<td>AWS WAF now protects Amazon API Gateway APIs.</td>
<td>October 25, 2018</td>
</tr>
</tbody>
</table>
### Updated Features

- **Expanded AWS shield advanced getting started wizard**: New wizard provides opportunity to create rate-based rules and Amazon CloudWatch Events.

- **AWS WAF logging**: Enable logging to get detailed information about traffic that is analyzed by your web ACL.

- **Support for query parameters in conditions**: When creating a condition, you can now search the requests for specific parameters.

- **Shield advanced getting started wizard**: Introduces a new streamlined process for subscribing to AWS Shield Advanced.

- **Expanded allowed CIDR ranges**: When creating an IP match condition, AWS WAF now supports IPv4 address ranges: /8 and any range between /16 through /32.

### Updates before 2018

The following table describes important changes in each release of the *AWS WAF Developer Guide* that were made before 2018.

<table>
<thead>

<tr>
<td>New Features</td>
<td>2015-08-24</td>
<td>You can now log all your API calls to AWS WAF through AWS CloudTrail, the AWS service that records API calls for your account and delivers log files to your S3 bucket. CloudTrail logs can be used to enable security</td>
<td>April 28, 2016</td>
</tr>
</tbody>
</table>
analysis, track changes to your AWS resources, and aid in compliance auditing. Integrating AWS WAF and CloudTrail lets you determine which requests were made to the AWS WAF API, the source IP address from which each request was made, who made the request, when it was made, and more.

If you are already using AWS CloudTrail, you will start seeing AWS WAF API calls in your CloudTrail log. If you haven’t enabled CloudTrail for your account, you can enable it on CloudTrail from the AWS Management Console. There is no additional charge for enabling CloudTrail, but standard rates for Amazon S3 and Amazon SNS usage apply.

<tbody>
<tr>
<td>New Features</td>
<td>2015-08-24</td>
<td>You can now use AWS WAF to allow, block, or count web requests that appear to contain malicious scripts, known as cross-site scripting or XSS. Attackers sometimes insert malicious scripts into web requests in an effort to exploit vulnerabilities in web applications. For more information, see Cross-site scripting attack rule statement (p. 107).</td>
<td>March 29, 2016</td>
</tr>
</tbody>
</table>
| New Features            | 2015-08-24    | With this release, AWS WAF adds the following features:  

  - You can configure AWS WAF to allow, block, or count web requests based on the lengths of specified parts of the requests, such as query strings or URLs. For more information, see Size constraint rule statement (p. 104).

  - You can configure AWS WAF to allow, block, or count web requests based on the content in the request body. This is the part of a request that contains any additional data that you want to send to your web server as the HTTP request body, such as data from a form. This feature applies to string match conditions, SQL injection match conditions, and the new size constraint conditions mentioned in the first bullet. For more information, see Web request components (p. 108). | January 27, 2016|
| New Feature             | 2015-08-24    | You can now use the AWS WAF console to choose the CloudFront distributions that you want to associate a web ACL with. For more information, see Associating or Disassociating a Web ACL and a CloudFront Distribution.                                                                                                                                                                                                                                                                   | November 16, 2015|
| Initial Release         | 2015-08-24    | This is the first release of the AWS WAF Developer Guide.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | October 6, 2015|
AWS glossary

For the latest AWS terminology, see the AWS glossary in the AWS General Reference.
