```python
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {'Name': 'FeatureGroupName',
             'Operator': 'Contains',
             'Value': 'ver' },
            {'Name': 'FeatureName',
             'Operator': 'Contains',
             'Value': 'wha' },
            {'Name': 'Parameters.org',
             'Operator': 'Contains',
             'Value': 'Sage' },
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is "And"
    }
)
```
• Description – A searchable description of the feature.
• Parameters – Searchable key-value pairs.

The description can have up to 255 characters.

For parameters, you must specify a key-value pair in your search. You can add up to 25 parameters.

To update the metadata of a feature, you can use either Amazon SageMaker Studio or the `UpdateFeatureMetadata` operation.

Use the following procedure to update the metadata using Amazon SageMaker Studio.

To update the feature metadata with Studio, do the following.

1. In Amazon SageMaker Studio, navigate to SageMaker resources.
2. On the navigation pane, choose Feature Store.
3. Choose Feature catalog.
4. In the Feature name column, choose a feature name.
5. Choose Edit metadata.
6. In the Description field, add or update the description.
7. In the Parameters field under Parameters, specify a key-value pair for the parameter.
8. (Optional) Choose Add new parameter to add another parameter.
9. Choose Save changes.
10. Choose Confirm.

The following describes how you can use the `UpdateFeatureMetadata` operation for different scenarios.

Add a list of parameters to a feature

To add a list of parameters to a feature, specify values for the following fields:

• FeatureGroupName
• Feature
• Parameters

The following example code uses the AWS SDK for Python (Boto3) to add two parameters.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterAdditions=[
        {
            "Key": "example-key-0", "Value": "example-value-0"
        },
        {
            "Key": "example-key-1", "Value": "example-value-1"
        },
    ]
)
```

Add a description to a feature

To add a description to a feature, specify values for the following fields:
Adding Searchable Metadata to Your Features

- FeatureGroupName
- Feature
- Description

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description="description"
)
```

Remove parameters for a feature

To remove all parameters for a feature, do the following.

Specify values for the following fields:

- FeatureGroupName
- Feature

Specify the keys for the parameters that you're removing under ParameterRemovals.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterRemovals=[
        {"Key": "example-key-0"},
        {"Key": "example-key-1"},
    ]
)
```

Remove the description for a feature

To remove the description for a feature, do the following.

Specify values for the following fields:

- FeatureGroupName
- Feature

Specify an empty string for Description.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description=""
)
```

After you've updated the metadata for a feature, you can use the DescribeFeatureMetadata operation to see the updates that you've made.

The following code goes through an example workflow using the AWS SDK for Python (Boto3).
Example Code

The example code does the following:

1. Sets up your SageMaker environment.
2. Creates a feature group.
3. Adds features to the group.
4. Adds metadata to the features.

Step 1: Setup

To start using Feature Store, create SageMaker, boto3 and Feature Store sessions. Then set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

**Note**
The role that you use must have the following managed policies attached to it: AmazonS3FullAccess and AmazonSageMakerFeatureStoreAccess.

```python
# SageMaker Python SDK version 2.x is required
!pip install 'sagemaker>=2.0.0'
import sagemaker
import sys
import boto3
import pandas as pd
import numpy as np
import io
from sagemaker.session import Session
from sagemaker import get_execution_role
from botocore.exceptions import ClientError

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()
sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()
```

Step 2: Create a Feature Group and Add Features

```python
feature_group_name = "test-for-feature-metadata"
feature_definitions = [
    {"FeatureName": "feature-1", "FeatureType": "String"},
    {"FeatureName": "feature-2", "FeatureType": "String"},
    {"FeatureName": "feature-3", "FeatureType": "String"},
    {"FeatureName": "feature-4", "FeatureType": "String"},
    {"FeatureName": "feature-5", "FeatureType": "String"}
]
try:
    sagemaker_client.create_feature_group(
        FeatureGroupName=feature_group_name,
        RecordIdentifierFeatureName="feature-1",
        EventTimeFeatureName="feature-2",
```
FeatureDefinitions=feature_definitions,
OnlineStoreConfig={"EnableOnlineStore": True}
)
except ClientError as e:
    if e.response["Error"]["Code"] == "ResourceInUse":
        pass
    else:
        raise e

Step 3: Add Metadata

Before you add metadata, use the DescribeFeatureGroup operation to make sure that the status of the feature group is Created.

sagemaker_client.describe_feature_group(  
    FeatureGroupName=feature_group_name
)

Add a description to the feature.

sagemaker_client.update_feature_metadata(  
    FeatureGroupName=feature_group_name,  
    FeatureName="feature-1",  
    Description="new description"
)

You can use the DescribeFeatureMetadata operation to see if you have successfully updated the description for the feature group.

sagemaker_client.describe_feature_metadata(  
    FeatureGroupName=feature_group_name,  
    FeatureName="feature-1"
)

You can also use it to add parameters to the feature group.

sagemaker_client.update_feature_metadata(  
    FeatureGroupName=feature_group_name,  
    FeatureName="feature-1",  
    ParameterAdditions=[  
        {"Key": "team", "Value": "featurestore"},  
        {"Key": "org", "Value": "sagemaker"},  
    ]
)

You can use the DescribeFeatureMetadata operation again to see if you have successfully added the parameters.

sagemaker_client.describe_feature_metadata(  
    FeatureGroupName=feature_group_name,  
    FeatureName="feature-1"  
)
Query Feature Store with Athena and AWS Glue

After a Feature Store feature group has been created in an offline feature store, you can choose to run queries using Amazon Athena on an AWS Glue catalog. This requires data to be registered in a data catalog with other catalog details which is auto-registered for you in Feature Store. In other words, Feature Store automatically builds an AWS Glue data catalog when feature groups are created and you can turn them off. This is particularly useful when you want to build a dataset by executing SQL queries and then train a model for inference.

After your FeatureStore has been created and populated with your data in the offline store, you have the capability to write SQL queries to join data stored in the offline store from different FeatureGroups. To do this, you can use Amazon Athena to write and execute SQL queries. You can set up a AWS Glue crawler to run on a schedule to ensure your catalog is always up to date as well.

If you want to do this please define a role which can be used by the AWS Glue crawler to access the offline store's S3 buckets. For more information, see Create an IAM role.

For more information on how to use AWS Glue and Athena to build a training dataset for model training and inference, see Build Training Dataset: Create Feature Groups.

Sample Athena Queries

Below we provide some sample queries that act as a template for you to quickly write queries using Athena.

Interactive Exploration

This query selects the first 1000 records.

```
SELECT *
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>
LIMIT 1000
```

Latest snapshot without duplicates

This query selects the latest non-duplicate records.

```
SELECT *
FROM (SELECT *,
        row_number()
    OVER (PARTITION BY <RecordIdentifierFeatureName>
          ORDER BY  <EventTimeFeatureName> desc, Api_Invocation_Time DESC, write_time DESC) AS row_num
    FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>)
WHERE row_num = 1;
```

Latest snapshot without duplicates and deleted records in the offline store

This query filters out any deleted records and selects non-duplicate records from the offline store.

```
SELECT *
FROM (SELECT *
        , row_number()
    FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>
WHERE row_num = 1)
```

1034
Cross-Account Offline Store Access

Amazon SageMaker Feature Store allows users to create a feature group in one account (Account A) and configure it with an offline store using an Amazon S3 bucket in another account (Account B). This can be set up using the steps in the following section.

Topics

- Step 1: Set Up the Offline Store Access Role in Account A (p. 1035)
- Step 2: Set up an Offline Store S3 Bucket in Account B (p. 1036)
- Step 3: Set up an Offline Store KMS Encryption Key in Account A (p. 1037)
- Step 4: Create a Feature Group in Account A (p. 1038)

Step 1: Set Up the Offline Store Access Role in Account A

First, set up a role for Amazon SageMaker Feature Store to write the data into the offline store. The simplest way to accomplish this is to create a new role using the AmazonSageMakerFeatureStoreAccess policy or to use an existing role that already has the AmazonSageMakerFeatureStoreAccess policy attached. This document refers to this policy as Account-A-Offline-Feature-Store-Role-ARN.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```
Step 2: Set up an Offline Store S3 Bucket in Account B

Create an S3 bucket in Account B. If you are using the default AmazonSageMakerFeatureStoreAccess policy, the bucket name must include SageMaker, Sagemaker, or sagemaker. Edit the bucket policy as shown in the following example to allow Account A to read and write objects.

This document refers to the following example bucket policy as Account-B-Offline-Feature-Store-Bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": ["s3:PutObject",
                  "s3:GetBucketAcl",
                  "s3:PutObjectAcl"
                ],
      "Resource": ["arn:aws:s3:::*SageMaker*",
                   "arn:aws:s3:::*Sagemaker*",
                   "arn:aws:s3:::*sagemaker*"
                 ]
    }
  ]
}
```

The preceding code snippet shows the AmazonSageMakerFeatureStoreAccess policy. The Resource section of the policy is scoped down by default to S3 buckets with names that contain SageMaker, Sagemaker, or sagemaker. This means the offline store S3 bucket being used must follow this naming convention. If this is not your case, or if you want to further scope down the resource, you can copy and paste the policy to your S3 bucket policy in the console, customize the Resource section to be `arn:aws:s3:::your-offline-store-bucket-name`, and then attach to the role.

Additionally, this role must have KMS permissions attached. At a minimum, it requires the `kms:GenerateDataKey` permission to be able to write to the offline store using your customer managed key. See Step 3 to learn about why a customer managed key is needed for the cross-account scenario and how to set it up. The following example shows an inline policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3CrossAccountBucketAccess",
      "Effect": "Allow",
      "Action": ["s3:ListBucket",
                 "s3:GetObject"
               ],
      "Resource": "arn:aws:s3:::your-offline-store-bucket-name"
    }
  ]
`
```

The Resource section of this policy is scoped to any key in Account A. To further scope this down, after setting up the offline store KMS key in Step 3, return to this policy and replace it with the key ARN.

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": ["kms:GenerateDataKey"
                 ],
    }
  ]
}
```

The Resource section of this policy is scoped to any key in Account A. To further scope this down, after setting up the offline store KMS key in Step 3, return to this policy and replace it with the key ARN.

Step 2: Set up an Offline Store S3 Bucket in Account B

Create an S3 bucket in Account B. If you are using the default AmazonSageMakerFeatureStoreAccess policy, the bucket name must include SageMaker, Sagemaker, or sagemaker. Edit the bucket policy as shown in the following example to allow Account A to read and write objects.

This document refers to the following example bucket policy as Account-B-Offline-Feature-Store-Bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3CrossAccountBucketAccess",
      "Effect": "Allow",
```
Step 3: Set up an Offline Store KMS Encryption Key in Account A

Amazon SageMaker Feature Store ensures that server-side encryption is always enabled for S3 objects in the offline store. For cross-account use cases, you must provide a customer managed key so that you are in control of who can write to the offline store (in this case, Account-A-Offline-Feature-Store-Role-ARN from Account A) and who can read from the offline store (in this case, identities from Account B).

This document refers to the following example key policy as Account-A-Offline-Feature-Store-KMS-Key-ARN.

```
{
  "Version": "2012-10-17",
  "Id": "key-consolepolicy-3",
  "Statement": [
    {
      "Sid": "Enable IAM User Permissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::Account-A-Account-Id:root"
      },
      "Action": "kms:*",
      "Resource": "*"
    },
    {
      "Sid": "Allow access for Key Administrators",
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::Account-A-Account-Id:role/Administrator",
          "arn:aws:iam::Account-A-Account-Id:root"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

In the preceding policy, the principal is Account-A-Offline-Feature-Store-Role-ARN, which is the role created in Account A in Step 1 and provided to Amazon SageMaker Feature Store to write to the offline store. You can provide multiple ARN roles under Principal.
Step 4: Create a Feature Group in Account A

Next, create the feature group in Account A, with an offline store S3 bucket in Account B. To do this, provide the following parameters for RoleArn, OfflineStoreConfig.S3StorageConfig.KmsKeyId and OfflineStoreConfig.S3StorageConfig.S3Uri respectively:

- Provide Account-A-Offline-Feature-Store-Role-ARN as the RoleArn.
- Provide Account-A-Offline-Feature-Store-KMS-Key-ARN for OfflineStoreConfig.S3StorageConfig.KmsKeyId.
- Provide Account-B-Offline-Feature-Store-Bucket for OfflineStoreConfig.S3StorageConfig.S3Uri.
Security and Access Control

Amazon SageMaker Feature Store enables you to create two types of stores: an online store or offline store. The online store is used for low latency real-time inference use cases whereas the offline store is used for training and batch inference use cases. When you create a feature group for online or offline use you can provide a AWS Key Management Service customer managed key to encrypt all your data at rest. In case you do not provide a AWS KMS key then we ensure that your data is encrypted on the server side using an AWS owned AWS KMS key or AWS managed AWS KMS key. While creating a feature group, you can select storage type and optionally provide a AWS KMS key for encrypting data, then you can call various APIs for data management such as PutRecord, GetRecord, DeleteRecord.

Feature Store allows you to grant or deny access to individuals at the feature group-level and enables cross-account access to Feature Store. For example, you can set up developer accounts to access the offline store for model training and exploration that do not have write access to production accounts. You can set up production accounts to access both online and offline stores. Feature Store uses unique customer AWS KMS keys for offline and online store data at-rest encryption. Access control is enabled through both API and AWS KMS key access. You can also create feature group-level access control.

For more information about customer managed key, see customer managed keys. For more information about AWS KMS, see AWS KMS.

Using AWS KMS Permissions for Amazon SageMaker Feature Store

Encryption at rest protects Feature Store under an AWS KMS customer managed key. By default, it uses an AWS owned customer managed key for OnlineStore and AWS managed customer managed key for OfflineStore. Feature Store supports an option to encrypt your online or offline store under customer managed key. You can select the customer managed key for Feature Store when you create your online or offline store, and they can be different for each store.

Feature Store supports only symmetric customer managed keys. You cannot use an asymmetric customer managed key to encrypt your data in your online or offline store. For help determining whether a customer managed key is symmetric or asymmetric, see Identifying symmetric and asymmetric customer managed keys.

When you use a customer managed key, you can take advantage of the following features:

- You create and manage the customer managed key, including setting the key policies, IAM policies and grants to control access to the customer managed key. You can enable and disable the customer managed key, enable and disable automatic key rotation, and delete the customer managed key when it is no longer in use.
- You can use a customer managed key with imported key material or a customer managed key in a custom key store that you own and manage.
- You can audit the encryption and decryption of your online or offline store by examining the API calls to AWS KMS in AWS CloudTrail logs.

You do not pay a monthly fee for AWS owned customer managed keys. Customer managed keys will incur a charge for each API call and AWS Key Management Service quotas apply to each customer managed key.
Authorizing Use of a Customer Managed Key for Your Online Store

If you use a customer managed key to protect your online store, the policies on that customer managed key must give Feature Store permission to use it on your behalf. You have full control over the policies and grants on a customer managed key.

Feature Store does not need additional authorization to use the default AWS owned KMS key to protect your online or offline stores in your AWS account.

Customer managed key policy

When you select a customer managed key to protect your Online Store, Feature Store must have permission to use the customer managed key on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the customer managed key that Feature Store requires. You can provide these permissions in a key policy, an IAM policy, or a grant. At a minimum, Feature Store requires the following permissions on a customer managed key:

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows Feature Store to use the customer managed key in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use your Feature Store. If the principals specified in the policy statement don't have permission to use your Feature Store, the call fails, even when it comes from the Feature Store service.
- The kms:ViaService condition key allows the permissions only when the request comes from FeatureStore on behalf of the principals listed in the policy statement. These principals can't call these operations directly. The value for kms:ViaService should be sagemaker.*.amazonaws.com.

Note
The kms:ViaService condition key can only be used for the online store customer managed AWS KMS key, and cannot be used for the offline store. If you add this special condition to your customer managed key, and use the same AWS KMS key for both the online and offline store, then it will fail the CreateFeatureGroup API operation.

- Gives the customer managed key administrators read-only access to the customer managed key and permission to revoke grants, including the grants that Feature Store uses to protect your data.

Before using an example key policy, replace the example principals with actual principals from your AWS account.

```
{"Id": "key-policy-feature-store",
 "Version":"2012-10-17",
 "Statement": [
  {"Sid" : "Allow access through Amazon SageMaker Feature Store for all principals in the account that are authorized to use Amazon SageMaker Feature Store",
   "Effect": "Allow",
   "Principal": {"AWS": "arn:aws:iam::111122233333:user/featurestore-user"},
   "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:DescribeKey",
    
```
Using Grants to Authorize Feature Store

In addition to key policies, Feature Store uses grants to set permissions on the customer managed key. To view the grants on a customer managed key in your account, use the `ListGrants` operation. Feature Store does not need grants, or any additional permissions, to use the AWS owned customer managed key to protect your online store.

Feature Store uses the grant permissions when it performs background system maintenance and continuous data protection tasks.

Each grant is specific to an online store. If the account includes multiple stores encrypted under the same customer managed key, there will be unique grants per `FeatureGroup` using the same customer managed key.

The key policy can also allow the account to revoke the grant on the customer managed key. However, if you revoke the grant on an active encrypted online store, Feature Store won't be able to protect and maintain the store.

Monitoring Feature Store interaction with AWS KMS

If you use a customer managed key to protect your online or offline store, you can use AWS CloudTrail logs to track the requests that Feature Store sends to AWS KMS on your behalf.
Accessing Data in Your Online Store

The caller (either IAM user or IAM role) to ALL DataPlane operations (Put, Get, DeleteRecord) must have below permissions on the customer managed key:

```
"kms:Decrypt"
```

Authorizing Use of a Customer Managed Key for your Offline Store

The roleArn that is passed as a parameter to createFeatureGroup must have below permissions to the OfflineStore KmsKeyId:

```
"kms:GenerateDataKey"
```

Note
The key policy for the online store also works for the offline store, only when the kms:ViaService condition is not specified.

Important
You can specify a AWS KMS encryption key to encrypt the Amazon S3 location used for your offline feature store when you create a feature group. If AWS KMS encryption key is not specified, by default we encrypt all data at rest using AWS KMS key. By defining your bucket-level key for SSE, you can reduce AWS KMS requests costs by up to 99 percent.

Quotas, Naming Rules and Data Types

Limits and Quotas

Note
Soft limits can be increased based on your needs.

- **Maximum number of feature groups per AWS account**: Soft limit of 100.
- **Maximum number of feature definitions per feature group**: 2500.
- **Maximum Transactions per second (TPS) per API per AWS account**: Soft limit of 10000 TPS per API excluding the BatchGetRecord API call, which has a soft limit of 500 TPS.
- **Maximum size of a record**: 350KB.
- **Maximum size of a record identifier**: 2KB.
- **Maximum size of a feature value**: 350KB.
- **Maximum number of concurrent feature group creation workflows**: 4.
- **BatchGetRecord API**: Can contain as many as 100 records and can query up to 10 feature groups.

Naming Rules

- **Reserved Words**: The following are reserved words and cannot be used as feature names in feature definitions: is_deleted, write_time, and api_invocation_time.
Data Types

- **String Feature Type**: Strings are Unicode with UTF-8 binary encoding. The minimum length of a string can be zero, the maximum length is constrained by the maximum size of a record.
- **Fractional Feature Type**: Fractional feature values must conform to a double precision floating point number as defined by the IEEE 754 standard.
- **Integral Feature Type**: Feature Store supports integral values in the range of a 64-bit signed integer. Minimum value of \( -2^{63} \) and a maximum value: \( 2^{63} - 1 \).
- **Event Time Features**: All feature groups have an event time feature. The feature can have a feature type of either String or Fractional. A string event time is accepted in ISO-8601 format, in UTC time, conforming to the pattern(s): \([yyyy-MM-dd'T'HH:mm:ssZ, yyyy-MM-dd'T'HH:mm:ss.SSSZ]\). A fractional event time value is accepted as seconds from unix epoch, with millisecond precision. Event times must be in the range of \([0000-01-00T00:00:00.000Z, 9999-12-31T23:59:59.999Z]\).

Amazon SageMaker Feature Store Offline Store

Data Format

Amazon SageMaker Feature Store offline store data is stored in an Amazon S3 bucket within your account. When you call `PutRecord`, your data is buffered, batched, and written into Amazon S3 within 15 minutes. Feature Store only supports the Parquet file format. Specifically, when your data is written to your offline store, the data can only be retrieved from your Amazon S3 bucket in Parquet format. Each file can contain multiple `Records`.

Files are organized with the following naming convention:

```
```

Records in the offline store are partitioned by event time into hourly partitions as shown in the preceding example. The partitioning scheme is not configurable. The following code shows an example of a Parquet file:

```
s3://my-bucket/my-prefix/123456789012/sagemaker/us-east-1/offline-store/customer-purchase-history-patterns-1593511200/data/year=2020/month=06/day=31/hour=00/20200631T064401Z_108934320012Az11.parquet
```

Feature Store also exposes the `OfflineStoreConfig.S3StorageConfig.ResolvedOutputS3Uri` field, which can be found from in the `DescribeFeatureGroup` API call. This is the S3 path under which the files for the specific feature group are written.

Example value of `ResolvedOutputS3Uri`:

```
```

The following additional fields are added by Feature Store to each Record when they persist in the offline store:

- **api_invocation_time** – The timestamp when the service receives the `PutRecord` or `DeleteRecord` call. If using managed ingestion (e.g. Data Wrangler), this is the timestamp when data was written into the offline store.
write_time – The timestamp when data was written into the offline store. Can be used for constructing time-travel related queries.

is_deleted – False by default. If DeleteRecord is called, a new Record is inserted into RecordIdentifierValue and set to True in the offline store.

Amazon SageMaker Feature Store Notebook Examples

To get started using Amazon SageMaker Feature Store, you can choose from a variety of example Jupyter notebooks in the table below. If this is your first time using Feature Store, try out the Introduction to Feature Store notebook. To run any these notebooks, you must attach this policy to your IAM execution role: AmazonSageMakerFeatureStoreAccess.

See IAM Roles to access your role and attach this policy. For a walkthrough see Adding policies to your IAM role. The following screenshot illustrates how the policy appears under your IAM role after it has been attached.

Feature Store sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker Feature Store.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduction to Feature Store</td>
<td>An introduction to key Feature Store capabilities such as how to create, configure a feature group, and how to ingest data into an online or offline feature store.</td>
</tr>
<tr>
<td>Fraud Detection with Feature Store</td>
<td>An advanced example on how to train a fraud detection model by ingesting data into a Feature Store, querying it to form a training dataset, and how to train a simple model for inference.</td>
</tr>

Train Models

For an overview on training models with Amazon SageMaker, see Train a Model with Amazon SageMaker (p. 9).

SageMaker provides features to monitor and manage the training and validation of machine learning models. For guidance on metrics available, incremental training, automatic model tuning, and the use of augmented manifest files to label training data, see the following topics.

- For guidance on choosing a machine learning algorithm and its implementation for your task or problem, see Choose an Algorithm (p. 1047).
- For guidance on debugging and profiling the training of machine learning models, see Amazon SageMaker Debugger (p. 2191).
- For guidance on distributed training of deep learning models, see Amazon SageMaker Distributed Training Libraries (p. 2387).
- For guidance on compiling and training deep learning models, see Amazon SageMaker Training Compiler (p. 2495).
- For guidance on metrics used to monitor and train models, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics (p. 2612).
- For guidance on metrics used to detect model post-processing bias, see Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify (p. 2547).
- For guidance on model explainability, see Amazon SageMaker Clarify Model Explainability (p. 2569).
- For guidance on incremental training in SageMaker, see Incremental Training in Amazon SageMaker (p. 2587).
- For guidance on using managed spot training in SageMaker, see Managed Spot Training in Amazon SageMaker (p. 2603).
- For guidance on using training checkpoints in SageMaker, see Use Checkpoints in Amazon SageMaker (p. 2604).
- For guidance on automatic model tuning, also known as hyperparameter tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).
- For guidance on using an augmented manifest file to label training data, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2608).

Choose an Algorithm

Machine learning can help you accomplish empirical tasks that require some sort of inductive inference. This task involves induction as it uses data to train algorithms to make generalizable inferences. This means that the algorithms can make statistically reliable predictions or decisions, or complete other tasks when applied to new data that was not used to train them.

To help you select the best algorithm for your task, we classify these tasks on various levels of abstraction. At the highest level of abstraction, machine learning attempts to find patterns or relationships between features or less structured items, such as text in a data set. Pattern recognition techniques can be classified into distinct machine learning paradigms, each of which address specific problem types. There are currently three basic paradigms for machine learning used to address various problem types:

- Supervised learning (p. 1050)
- Unsupervised learning (p. 1050)
- Reinforcement learning (p. 1051)

The types of problems that each learning paradigm can address are identified by considering the inferences (or predictions, decisions, or other tasks) you want to make from the type of data that you have or could collect. Machine learning paradigms use algorithmic methods to address their various problem types. The algorithms provide recipes for solving these problems.

However, many algorithms, such as neural networks, can be deployed with different learning paradigms and on different types of problems. Multiple algorithms can also address a specific problem type. Some algorithms are more generally applicable and others are quite specific for certain kinds of objectives and data. So the mapping between machine learning algorithms and problem types is many-to-many. Also, there are various implementation options available for algorithms.

The following sections provide guidance concerning implementation options, machine learning paradigms, and algorithms appropriate for different problem types.

Topics

- Choose an algorithm implementation (p. 1047)
- Problem types for the basic machine learning paradigms (p. 1049)
- Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1051)
- Use Reinforcement Learning with Amazon SageMaker (p. 2157)

Choose an algorithm implementation

After choosing an algorithm, you must decide which implementation of it you want to use. Amazon SageMaker supports three implementation options that require increasing levels of effort.

- **Pre-trained models** require the least effort and are models ready to deploy or to fine-tune and deploy using SageMaker JumpStart.
- **Built-in algorithms** require more effort and scale if the data set is large and significant resources are needed to train and deploy the model.
- If there is no built-in solution that works, try to develop one that uses pre-made images for machine and deep learning frameworks for supported frameworks such as Scikit-Learn, TensorFlow, PyTorch, MXNet, or Chainer.
- If you need to run custom packages or use any code which isn’t a part of a supported framework or available via PyPi, then you need to build your own custom Docker image that is configured to install the necessary packages or software. The custom image must also be pushed to an online repository like the Amazon Elastic Container Registry.

**Topics**
- Use a built-in algorithm (p. 1048)
- Use script mode in a supported framework (p. 1049)
- Use a custom Docker image (p. 1049)

**Use a built-in algorithm**

When choosing an algorithm for your type of problem and data, the easiest option is to use one of Amazon SageMaker’s built-in algorithms. These built-in algorithms come with two major benefits.

- The built-in algorithms require no coding to start running experiments. The only inputs you need to provide are the data, hyperparameters, and compute resources. This allows you to run experiments more quickly, with less overhead for tracking results and code changes.
- The built-in algorithms come with parallelization across multiple compute instances and GPU support right out of the box for all applicable algorithms (some algorithms may not be included due to inherent limitations). If you have a lot of data with which to train your model, most built-in algorithms can easily scale to meet the demand. Even if you already have a pre-trained model, it may still be easier to use its corollary in SageMaker and input the hyper-parameters you already know than to port it over, using script mode on a supported framework.
For more information on the built-in algorithms provided by SageMaker, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1051).

For important information about docker registry paths, data formats, recommended EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms (p. 1057).

**Use script mode in a supported framework**

If the algorithm you want to use for your model is not supported by a built-in choice and you are comfortable coding your own solution, then you should consider using an Amazon SageMaker supported framework. This is referred to as "script mode" because you write your custom code (script) in a text file with a .py extension. As the table above indicates, SageMaker supports most of the popular machine learning frameworks. These frameworks come preloaded with the corresponding framework and some additional Python packages, such as Pandas and NumPy, so you can write your own code for training an algorithm. These frameworks also allow you to install any Python package hosted on PyPi by including a requirements.txt file with your training code or to include your own code directories. R is also supported natively in SageMaker notebook kernels. Some frameworks, like scikit-learn and Spark ML, have pre-coded algorithms you can use easily, while other frameworks like TensorFlow and PyTorch may require you to implement the algorithm yourself. The only limitation when using a supported framework image is that you cannot import any software packages that are not hosted on PyPi or that are not already included with the framework's image.

For more information on the frameworks supported by SageMaker, see Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 13).

**Use a custom Docker image**

Amazon SageMaker's built-in algorithms and supported frameworks should cover most use cases, but there are times when you may need to use an algorithm from a package not included in any of the supported frameworks. You might also have a pre-trained model picked or persisted somewhere which you need to deploy. SageMaker uses Docker images to host the training and serving of all models, so you can supply your own custom Docker image if the package or software you need is not included in a supported framework. This may be your own Python package or an algorithm coded in a language like Stan or Julia. For these images you must also configure the training of the algorithm and serving of the model properly in your Dockerfile. This requires intermediate knowledge of Docker and is not recommended unless you are comfortable writing your own machine learning algorithm. Your Docker image must be uploaded to an online repository, such as the Amazon Elastic Container Registry (ECR) before you can train and serve your model properly.

For more information on custom Docker images in SageMaker, see Using Docker containers with SageMaker (p. 2999).

**Problem types for the basic machine learning paradigms**

The following three sections describe the main problem types addressed by the three basic paradigms for machine learning. For a list of the built-in algorithms that SageMaker provides to address these problem types, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1051).

**Topics**

- Supervised learning (p. 1050)
- Unsupervised learning (p. 1050)
- Reinforcement learning (p. 1051)
Supervised learning

If your data set consists of features or attributes (inputs) that contain target values (outputs), then you have a supervised learning problem. If your target values are categorical (mathematically discrete), then you have a classification problem. It is a standard practice to distinguish binary from multiclass classification.

- **Binary classification** is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.

- **Multiclass classification** is a type of supervised learning that assigns an individual to one of several classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about religion, politics, or finance, or as about one of several other predefined topic classes.

If the target values you are trying to predict are mathematically continuous, then you have a regression problem. Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms and the square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

For more information on the built-in supervised learning algorithms provided by SageMaker, see Supervised Learning (p. 1055).

Unsupervised learning

If your data set consists of features or attributes (inputs) that do not contain labels or target values (outputs), then you have an unsupervised learning problem. In this type of problem, the output must be predicted based on the pattern discovered in the input data. The goal in unsupervised learning problems is to discover patterns such as groupings within the data. There are a large variety of tasks or problem types to which unsupervised learning can be applied. Principal component and cluster analyses are two of the main methods commonly deployed for preprocessing data. Here is a short list of problem types that can be addressed by unsupervised learning:

- **Dimension reduction** is typically part of a data exploration step used to determine the most relevant features to use for model construction. The idea is to transform data from a high-dimensional, sparsely populated space into a low-dimensional space that retains most significant properties of the original data. This provides relief for the curse of dimensionality that can arise with sparsely populated, high-dimensional data on which statistical analysis becomes problematic. It can also be used to help understand data, reducing high-dimensional data to a lower dimensionality that can be visualized.

- **Cluster analysis** is a class of techniques that are used to classify objects or cases into groups called clusters. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the features or attributes that you want the algorithm to use to determine similarity, select a distance function to measure similarity, and specify the number of clusters to use in the analysis.

- **Anomaly detection** is the identification of rare items, events, or observations in a data set which raise suspicions because they differ significantly from the rest of the data. The identification of anomalous items can be used, for example, to detect bank fraud or medical errors. Anomalies are also referred to as outliers, novelties, noise, deviations, and exceptions.

- **Density estimation** is the construction of estimates of unobservable underlying probability density functions based on observed data. A natural use of density estimates is for data exploration. Density
estimates can discover features such as skewness and multimodality in the data. The most basic form of density estimation is a rescaled histogram.

SageMaker provides several built-in machine learning algorithms that you can use for these unsupervised learning tasks. For more information on the built-in unsupervised algorithms provided by SageMaker, see Unsupervised Learning (p. 1056).

**Reinforcement learning**

Reinforcement learning is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

For more information on SageMaker’s frameworks, toolkits, and environments for reinforcement learning, see Use Reinforcement Learning with Amazon SageMaker (p. 2157).

**Use Amazon SageMaker Built-in Algorithms or Pre-trained Models**

Amazon SageMaker provides a suite of built-in algorithms, pre-trained models, and pre-built solution templates to help data scientists and machine learning practitioners get started on training and deploying machine learning models quickly. For someone who is new to SageMaker, choosing the right algorithm for your particular use case can be a challenging task. The following table provides a quick cheat sheet that shows how you can start with an example problem or use case and find an appropriate built-in algorithm offered by SageMaker that is valid for that problem type. Additional guidance organized by learning paradigms (supervised and unsupervised) and important data domains (text and images) is provided in the sections following the table.

For important information about Docker registry paths, data formats, recommended Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms (p. 1057).

The following sections provide additional guidance for the Amazon SageMaker built-in algorithms grouped by the supervised and unsupervised learning paradigms to which they belong. For descriptions of these learning paradigms and their associated problem types, see Choose an Algorithm (p. 1047). Sections are also provided for the SageMaker built-in algorithms available to address two important machine learning domains: textual analysis and image processing.

- Pre-trained Models and Solution Templates (p. 1055)
- Supervised Learning (p. 1055)
- Unsupervised Learning (p. 1056)
- Textual Analysis (p. 1056)
- Image Processing (p. 1057)

### Pre-trained Models and Solution Templates

SageMaker JumpStart provides a wide range of pre-trained models, pre-built solution templates, and examples for popular problem types that use the SageMaker SDK as well as Studio. For more information about these models, solutions, and the example notebooks provided by SageMaker JumpStart, see SageMaker JumpStart (p. 45).

### Supervised Learning

Amazon SageMaker provides several built-in general purpose algorithms that can be used for either classification or regression problems.

- **AutoGluon-Tabular (p. 1923)**—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- **CatBoost (p. 1930)**—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- **Factorization Machines Algorithm (p. 1938)**—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- **K-Nearest Neighbors (k-NN) Algorithm (p. 1948)**—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
- **LightGBM (p. 1957)**—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).
• Linear Learner Algorithm (p. 1966)—learns a linear function for regression or a linear threshold function for classification.
• TabTransformer (p. 1983)—a novel deep tabular data modeling architecture built on self-attention-based Transformers.
• XGBoost Algorithm (p. 1990)—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

Amazon SageMaker also provides several built-in supervised learning algorithms that are used for more specialized tasks during feature engineering and forecasting from time series data.
• Object2Vec Algorithm (p. 2039)—a new highly customizable multi-purpose algorithm used for feature engineering. It can learn low-dimensional dense embeddings of high-dimensional objects to produce features that improve training efficiencies for downstream models. While this is a supervised algorithm, as it requires labeled data for training, there are many scenarios in which the relationship labels can be obtained purely from natural clusterings in data, without any explicit human annotation.
• DeepAR Forecasting Algorithm (p. 2068)—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).

Unsupervised Learning

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.
• Principal Component Analysis (PCA) Algorithm (p. 2100)—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
• K-Means Algorithm (p. 2092)—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
• IP Insights (p. 2083)—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
• Random Cut Forest (RCF) Algorithm (p. 2104)—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

Textual Analysis

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.
• BlazingText algorithm (p. 2018)—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
• Sequence-to-Sequence Algorithm (p. 2055)—a supervised algorithm commonly used for neural machine translation.
• Latent Dirichlet Allocation (LDA) Algorithm (p. 2028)—an algorithm suitable for determining topics in a set of documents. It is an unsupervised algorithm, which means that it doesn't use example data with answers during training.
• Neural Topic Model (NTM) Algorithm (p. 2033)—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
Image Processing

SageMaker also provides image processing algorithms that are used for image classification, object detection, and computer vision.

- **Image Classification - MXNet (p. 2113)** — uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- **Image Classification - TensorFlow (p. 2124)** — uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- **Semantic Segmentation Algorithm (p. 2147)** — provides a fine-grained, pixel-level approach to developing computer vision applications.
- **Object Detection (p. 2137)** — detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.

Algorithms that are parallelizable can be deployed on multiple compute instances for distributed training.

The following topics provide information about Docker registry paths, data formats, recommended Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by Amazon SageMaker.

**Topics**
- Docker Registry Paths and Example Code (p. 1060)
- Common Data Formats for Built-in Algorithms (p. 1911)
Docker Registry Paths and Example Code

The following topics list the Docker registry path and other parameters for each of the Amazon SageMaker provided algorithms and Deep Learning Containers (DLC).

Use the path as follows:

- To create a training job (create_training_job), specify the Docker registry path (TrainingImage) and the training input mode (TrainingInputMode) for the training image. You create a training job to train a model using a specific dataset.
- To create a model (create_model), specify the Docker registry path (Image) for the inference image (PrimaryContainer Image). SageMaker launches machine learning compute instances that are based on the endpoint configuration and deploys the model, which includes the artifacts (the result of model training).

**Note**
For the registry path, use the :1 version tag to ensure that you are using a stable version of the algorithm/DLC. You can reliably host a model trained using an image with the :1 tag on an inference image that has the :1 tag. Using the :latest tag in the registry path provides you with the most up-to-date version of the algorithm/DLC, but might cause problems with backward compatibility. Avoid using the :latest tag for production purposes.

**Important**
When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 1991) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

To find the registry path, choose the AWS Region, then choose the algorithm or DLC.

### MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='us-east-2', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```
### Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor',region='us-east-2')
```

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ntm',region='us-east-2')
```

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo',region='us-east-2')
```
## Use Built-in Algorithms

## Use Built-in Algorithms

### Registry path  | Version  | Job types (image scope) | Processor types | Python versions
---|---|---|---|---
520713654638.dkr.ecr.us-east-2.amazonaws.com/sagemaker-pytorch:<tag> | | training | CPU, GPU | py2, py3
520713654638.dkr.ecr.us-east-2.amazonaws.com/sagemaker-pytorch:<tag> | | inference | CPU, GPU | py2, py3
520713654638.dkr.ecr.us-east-2.amazonaws.com/sagemaker-pytorch:<tag> | | training | CPU, GPU | py2, py3

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest',region='us-east-2')
```

### Ray PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch',region='us-east-2',version='0.8.5',instance_type='ml.c5.4xlarge')
```

### Registry path  | Version  | Job types (image scope) | Processor types | Python versions
---|---|---|---|---
404615174143.dkr.ecr.us-east-2.amazonaws.com/randomcutforest:<tag> | | inference, training | | |
462105765813.dkr.ecr.us-east-2.amazonaws.com/sagemaker-rl-ray-container:ray-1.6.0-torch:<tag> | | training | CPU, GPU | py36
462105765813.dkr.ecr.us-east-2.amazonaws.com/sagemaker-rl-ray-container:ray-0.8.5-torch:<tag> | | training | CPU, GPU | py36
Scikit-learn (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='us-east-2',version='0.23-1',image_scope='inference')
```

Docker Registry Paths and Example Code for US East (N. Virginia) (us-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1097)
- BlazingText (algorithm) (p. 1099)
- Chainer (DLC) (p. 1099)
- Clarify (algorithm) (p. 1100)
- Data Wrangler (algorithm) (p. 1100)
Use Built-in Algorithms

- Debugger (algorithm) (p. 1100)
- DeepAR Forecasting (algorithm) (p. 1101)
- Factorization Machines (algorithm) (p. 1101)
- Hugging Face (algorithm) (p. 1101)
- IP Insights (algorithm) (p. 1105)
- Image classification (algorithm) (p. 1105)
- Inferentia MXNet (DLC) (p. 1105)
- Inferentia PyTorch (DLC) (p. 1106)
- K-Means (algorithm) (p. 1106)
- KNN (algorithm) (p. 1107)
- LDA (algorithm) (p. 1107)
- Linear Learner (algorithm) (p. 1107)
- MXNet (DLC) (p. 1108)
- MXNet Coach (DLC) (p. 1111)
- Model Monitor (algorithm) (p. 1111)
- NTM (algorithm) (p. 1111)
- Neo Image Classification (algorithm) (p. 1112)
- Neo MXNet (DLC) (p. 1112)
- Neo PyTorch (DLC) (p. 1112)
- Neo Tensorflow (DLC) (p. 1113)
- Neo XGBoost (algorithm) (p. 1114)
- Object Detection (algorithm) (p. 1114)
- Object2Vec (algorithm) (p. 1114)
- PCA (algorithm) (p. 1115)
- PyTorch (DLC) (p. 1115)
- Random Cut Forest (algorithm) (p. 1119)
- Ray PyTorch (DLC) (p. 1119)
- Scikit-learn (algorithm) (p. 1119)
-Semantic Segmentation (algorithm) (p. 1120)
- Seq2Seq (algorithm) (p. 1120)
- Spark (algorithm) (p. 1121)
-SparkML Serving (algorithm) (p. 1121)
- Tensorflow (DLC) (p. 1121)
- Tensorflow Coach (DLC) (p. 1130)
- Tensorflow Inferentia (DLC) (p. 1131)
- Tensorflow Ray (DLC) (p. 1131)
- VW (algorithm) (p. 1132)
- XGBoost (algorithm) (p. 1133)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='us-east-1',image_scope='inference',version='0.4')
```
# Output path
'763104351884.dkr.ecr.us-east-1.amazonaws.com/autogluon-inference:0.4-cpu-py38'

--- | --- | ---
785573368785.dkr.ecr.us-east-1.amazonaws.com/xgboost-neo:tag | latest | inference

**Object Detection (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection',region='us-east-1')
# Output path
'811284229777.dkr.ecr.us-east-1.amazonaws.com/object-detection:1'
```

### Registry path | Version | Job types (image scope)
--- | --- | ---
811284229777.dkr.ecr.us-east-1.amazonaws.com/object-detection:tag | 1 | inference, training

**Object2Vec (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec',region='us-east-1')
# Output path
'382416733822.dkr.ecr.us-east-1.amazonaws.com/object2vec:1'
```
### PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='pca', region='us-east-1')

# Output path
'382416733822.dkr.ecr.us-east-1.amazonaws.com/pca:1'
```

Docker Registry Paths and Example Code for US West (N. California) (us-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1135)
- BlazingText (algorithm) (p. 1136)
- Chainer (DLC) (p. 1136)
- Clarify (algorithm) (p. 1137)
- Data Wrangler (algorithm) (p. 1137)
- Debugger (algorithm) (p. 1138)
- DeepAR Forecasting (algorithm) (p. 1138)
- Factorization Machines (algorithm) (p. 1138)
- Hugging Face (algorithm) (p. 1138)
- IP Insights (algorithm) (p. 1142)
- Image classification (algorithm) (p. 1142)
- Inferentia MXNet (DLC) (p. 1142)
- Inferentia PyTorch (DLC) (p. 1143)
- K-Means (algorithm) (p. 1143)
- KNN (algorithm) (p. 1143)
- LDA (algorithm) (p. 1144)
- Linear Learner (algorithm) (p. 1144)
- MXNet (DLC) (p. 1144)
- MXNet Coach (DLC) (p. 1147)
- Model Monitor (algorithm) (p. 1148)
- NTM (algorithm) (p. 1148)
- Neo Image Classification (algorithm) (p. 1148)
- Neo MXNet (DLC) (p. 1149)
- Neo PyTorch (DLC) (p. 1149)
- Neo Tensorflow (DLC) (p. 1150)
- Neo XGBoost (algorithm) (p. 1150)
- Object Detection (algorithm) (p. 1150)
- Object2Vec (algorithm) (p. 1151)
- PCA (algorithm) (p. 1151)
- PyTorch (DLC) (p. 1151)
- Random Cut Forest (algorithm) (p. 1155)
- Ray PyTorch (DLC) (p. 1155)
- Scikit-learn (algorithm) (p. 1155)
- Semantic Segmentation (algorithm) (p. 1156)
- Seq2Seq (algorithm) (p. 1156)
- Spark (algorithm) (p. 1156)
- SparkML Serving (algorithm) (p. 1157)
- Tensorflow (DLC) (p. 1157)
- Tensorflow Coach (DLC) (p. 1166)
- Tensorflow Inferentia (DLC) (p. 1167)
- Tensorflow Ray (DLC) (p. 1167)
- VW (algorithm) (p. 1168)
- XGBoost (algorithm) (p. 1168)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

### Docker Registry Paths and Example Code for US West (Oregon) (us-west-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1170)
- BlazingText (algorithm) (p. 1172)
- Chainer (DLC) (p. 1172)
- Clarify (algorithm) (p. 1172)
- Data Wrangler (algorithm) (p. 1173)
- Debugger (algorithm) (p. 1173)
- DeepAR Forecasting (algorithm) (p. 1173)
• Factorization Machines (algorithm) (p. 1174)
• Hugging Face (algorithm) (p. 1174)
• IP Insights (algorithm) (p. 1177)
• Image classification (algorithm) (p. 1177)
• Inferentia MXNet (DLC) (p. 1178)
• Inferentia PyTorch (DLC) (p. 1178)
• K-Means (algorithm) (p. 1179)
• KNN (algorithm) (p. 1179)
• LDA (algorithm) (p. 1179)
• Linear Learner (algorithm) (p. 1180)
• MXNet (DLC) (p. 1180)
• MXNet Coach (DLC) (p. 1183)
• Model Monitor (algorithm) (p. 1183)
• NTM (algorithm) (p. 1183)
• Neo Image Classification (algorithm) (p. 1184)
• Neo MXNet (DLC) (p. 1184)
• Neo PyTorch (DLC) (p. 1184)
• Neo Tensorflow (DLC) (p. 1185)
• Neo XGBoost (algorithm) (p. 1186)
• Object Detection (algorithm) (p. 1186)
• Object2Vec (algorithm) (p. 1186)
• PCA (algorithm) (p. 1186)
• PyTorch (DLC) (p. 1187)
• Random Cut Forest (algorithm) (p. 1190)
• Ray PyTorch (DLC) (p. 1190)
• Scikit-learn (algorithm) (p. 1191)
• Semantic Segmentation (algorithm) (p. 1191)
• Seq2Seq (algorithm) (p. 1192)
• Spark (algorithm) (p. 1192)
• SparkML Serving (algorithm) (p. 1192)
• Tensorflow (DLC) (p. 1193)
• Tensorflow Coach (DLC) (p. 1201)
• Tensorflow Inferentia (DLC) (p. 1202)
• Tensorflow Ray (DLC) (p. 1203)
• VW (algorithm) (p. 1203)
• XGBoost (algorithm) (p. 1204)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='us-west-2', image_scope='inference', version='0.4')
```

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='us-west-2')
```
### Use Built-in Algorithms

#### Registry path | Version | Job types (image scope)
--- | --- | ---
433757028032.dkr.ecr.us-west-2.amazonaws.com/semantic-segmentation:<tag> | 1 | inference, training

#### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq', region='us-west-2')
```

#### Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='us-west-2', version='3.0', image_scope='processing')
```

#### SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
Use Built-in Algorithms

```python
image_uris.retrieve(framework='sparkml-serving', region='us-west-2', version='2.4')
```

### Docker Registry Paths and Example Code for Africa (Cape Town) (af-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1206)
- BlazingText (algorithm) (p. 1207)
- Chainer (DLC) (p. 1207)
- Clarify (algorithm) (p. 1208)
- Data Wrangler (algorithm) (p. 1208)
- Debugger (algorithm) (p. 1208)
- DeepAR Forecasting (algorithm) (p. 1209)
- Factorization Machines (algorithm) (p. 1209)
- Hugging Face (algorithm) (p. 1209)
- IP Insights (algorithm) (p. 1213)
- Image classification (algorithm) (p. 1213)
- Inferentia MXNet (DLC) (p. 1213)
- Inferentia PyTorch (DLC) (p. 1213)
- K-Means (algorithm) (p. 1214)
- KNN (algorithm) (p. 1214)
- Linear Learner (algorithm) (p. 1215)
- MXNet (DLC) (p. 1215)
- MXNet Coach (DLC) (p. 1218)
- Model Monitor (algorithm) (p. 1218)
- NTM (algorithm) (p. 1218)
- Neo Image Classification (algorithm) (p. 1219)
- Neo MXNet (DLC) (p. 1219)
- Neo PyTorch (DLC) (p. 1219)
- Neo Tensorflow (DLC) (p. 1220)
- Neo XGBoost (algorithm) (p. 1221)
- Object Detection (algorithm) (p. 1221)
- Object2Vec (algorithm) (p. 1221)
- PCA (algorithm) (p. 1221)
- PyTorch (DLC) (p. 1222)

1205
Use Built-in Algorithms

- Random Cut Forest (algorithm) (p. 1225)
- Scikit-learn (algorithm) (p. 1225)
- Semantic Segmentation (algorithm) (p. 1226)
- Seq2Seq (algorithm) (p. 1226)
- Spark (algorithm) (p. 1226)
- SparkML Serving (algorithm) (p. 1227)
- Tensorflow (DLC) (p. 1227)
- Tensorflow Coach (DLC) (p. 1236)
- Tensorflow Inferentia (DLC) (p. 1237)
- Tensorflow Ray (DLC) (p. 1237)
- XGBoost (algorithm) (p. 1238)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='af-south-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>626614931356.dkr.ecr.af-south-1.amazonaws.com/autogluon-training:&lt;tag&gt;</td>

**Random Cut Forest (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='af-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>randomcutforest:0.2.0</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Scikit-learn (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='af-south-1', version='0.23-1', image_scope='inference')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Package version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sklearn:1.0.2</td>
<td></td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>
## Use Built-in Algorithms

<table>

Docker Registry Paths and Example Code for Asia Pacific (Hong Kong) (ap-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1239)
- BlazingText (algorithm) (p. 1241)
Use Built-in Algorithms

- Chainer (DLC) (p. 1241)
- Clarify (algorithm) (p. 1241)
- Data Wrangler (algorithm) (p. 1242)
- Debugger (algorithm) (p. 1242)
- DeepAR Forecasting (algorithm) (p. 1242)
- Factorization Machines (algorithm) (p. 1243)
- Hugging Face (algorithm) (p. 1243)
- IP Insights (algorithm) (p. 1246)
- Image classification (algorithm) (p. 1246)
- Inferentia MXNet (DLC) (p. 1247)
- Inferentia PyTorch (DLC) (p. 1247)
- K-Means (algorithm) (p. 1248)
- KNN (algorithm) (p. 1248)
- Linear Learner (algorithm) (p. 1248)
- MXNet (DLC) (p. 1248)
- MXNet Coach (DLC) (p. 1251)
- Model Monitor (algorithm) (p. 1252)
- NTM (algorithm) (p. 1252)
- Neo Image Classification (algorithm) (p. 1252)
- Neo MXNet (DLC) (p. 1253)
- Neo PyTorch (DLC) (p. 1253)
- Neo Tensorflow (DLC) (p. 1254)
- Neo XGBoost (algorithm) (p. 1254)
- Object Detection (algorithm) (p. 1255)
- Object2Vec (algorithm) (p. 1255)
- PCA (algorithm) (p. 1255)
- PyTorch (DLC) (p. 1255)
- Random Cut Forest (algorithm) (p. 1259)
- Scikit-learn (algorithm) (p. 1259)
- Semantic Segmentation (algorithm) (p. 1259)
- Seq2Seq (algorithm) (p. 1260)
- Spark (algorithm) (p. 1260)
- SparkML Serving (algorithm) (p. 1260)
- Tensorflow (DLC) (p. 1261)
- Tensorflow Coach (DLC) (p. 1269)
- Tensorflow Inferentia (DLC) (p. 1270)
- Tensorflow Ray (DLC) (p. 1270)
- XGBoost (algorithm) (p. 1271)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-east-1', image_scope='inference', version='0.4')
```

**Docker Registry Paths and Example Code for Asia Pacific (Mumbai) (ap-south-1)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1273)
- BlazingText (algorithm) (p. 1274)
- Chainer (DLC) (p. 1275)
- Clarify (algorithm) (p. 1275)
- Data Wrangler (algorithm) (p. 1276)
- Debugger (algorithm) (p. 1276)
- DeepAR Forecasting (algorithm) (p. 1276)
- Factorization Machines (algorithm) (p. 1276)
- Hugging Face (algorithm) (p. 1277)
- IP Insights (algorithm) (p. 1280)
- Image classification (algorithm) (p. 1280)
- Inferentia MXNet (DLC) (p. 1280)
- Inferentia PyTorch (DLC) (p. 1281)
- K-Means (algorithm) (p. 1281)
- KNN (algorithm) (p. 1282)
- LDA (algorithm) (p. 1282)
- Linear Learner (algorithm) (p. 1282)
- MXNet (DLC) (p. 1283)
Use Built-in Algorithms

- MXNet Coach (DLC) (p. 1285)
- Model Monitor (algorithm) (p. 1286)
- NTM (algorithm) (p. 1286)
- Neo Image Classification (algorithm) (p. 1286)
- Neo MXNet (DLC) (p. 1287)
- Neo PyTorch (DLC) (p. 1287)
- Neo Tensorflow (DLC) (p. 1288)
- Neo XGBoost (algorithm) (p. 1288)
- Object Detection (algorithm) (p. 1289)
- Object2Vec (algorithm) (p. 1289)
- PCA (algorithm) (p. 1289)
- PyTorch (DLC) (p. 1289)
- Random Cut Forest (algorithm) (p. 1293)
- Ray PyTorch (DLC) (p. 1293)
- Scikit-learn (algorithm) (p. 1293)
- Semantic Segmentation (algorithm) (p. 1294)
- Seq2Seq (algorithm) (p. 1294)
- Spark (algorithm) (p. 1295)
- SparkML Serving (algorithm) (p. 1295)
- Tensorflow (DLC) (p. 1295)
- Tensorflow Coach (DLC) (p. 1304)
- Tensorflow Inherentia (DLC) (p. 1305)
- Tensorflow Ray (DLC) (p. 1305)
- VW (algorithm) (p. 1306)
- XGBoost (algorithm) (p. 1306)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

Use Built-in Algorithms

### Random Cut Forest (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='ap-south-1')
```

### Ray PyTorch (DLC)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch', region='ap-south-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='ap-south-1',version='0.23-1',image_scope='inference')

<table>

Docker Registry Paths and Example Code for Asia Pacific (Osaka) (ap-northeast-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1308)
- BlazingText (algorithm) (p. 1309)
- Clarify (algorithm) (p. 1310)
- Debugger (algorithm) (p. 1310)
- DeepAR Forecasting (algorithm) (p. 1310)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='ap-northeast-3',image_scope='inference',version='0.4')
```

<table>

**Docker Registry Paths and Example Code for Asia Pacific (Seoul) (ap-northeast-2)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1334)
- BlazingText (algorithm) (p. 1336)
- Chainer (DLC) (p. 1336)
- Clarify (algorithm) (p. 1336)
- Data Wrangler (algorithm) (p. 1337)
- Debugger (algorithm) (p. 1337)
- DeepAR Forecasting (algorithm) (p. 1337)
• Factorization Machines (algorithm) (p. 1338)
• Hugging Face (algorithm) (p. 1338)
• IP Insights (algorithm) (p. 1341)
• Image classification (algorithm) (p. 1341)
• Inferentia MXNet (DLC) (p. 1342)
• Inferentia PyTorch (DLC) (p. 1342)
• K-Means (algorithm) (p. 1343)
• KNN (algorithm) (p. 1343)
• LDA (algorithm) (p. 1343)
• Linear Learner (algorithm) (p. 1344)
• MXNet (DLC) (p. 1344)
• MXNet Coach (DLC) (p. 1347)
• Model Monitor (algorithm) (p. 1347)
• NTM (algorithm) (p. 1347)
• Neo Image Classification (algorithm) (p. 1348)
• Neo MXNet (DLC) (p. 1348)
• Neo PyTorch (DLC) (p. 1348)
• Neo Tensorflow (DLC) (p. 1349)
• Neo XGBoost (algorithm) (p. 1350)
• Object Detection (algorithm) (p. 1350)
• Object2Vec (algorithm) (p. 1350)
• PCA (algorithm) (p. 1350)
• PyTorch (DLC) (p. 1351)
• Random Cut Forest (algorithm) (p. 1354)
• Ray PyTorch (DLC) (p. 1354)
• Scikit-learn (algorithm) (p. 1355)
• Semantic Segmentation (algorithm) (p. 1355)
• Seq2Seq (algorithm) (p. 1356)
• Spark (algorithm) (p. 1356)
• SparkML Serving (algorithm) (p. 1356)
• Tensorflow (DLC) (p. 1357)
• Tensorflow Coach (DLC) (p. 1365)
• Tensorflow Inferentia (DLC) (p. 1366)
• Tensorflow Ray (DLC) (p. 1367)
• VW (algorithm) (p. 1367)
• XGBoost (algorithm) (p. 1368)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

### Scikit-learn (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='ap-northeast-2', version='0.23-1', image.scope='inference')
```

### Registry path | Version | Package version | Job types (image scope)
--- | --- | --- | ---
366743142698.dkr.ecr.ap-northeast-2.amazonaws.com/sagemaker-scikit-learn | 1.0.2 | inference, training
366743142698.dkr.ecr.ap-northeast-2.amazonaws.com/sagemaker-scikit-learn | 0.23.2 | inference, training
366743142698.dkr.ecr.ap-northeast-2.amazonaws.com/sagemaker-scikit-learn | 0.20.0 | inference, training

### Semantic Segmentation (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='ap-northeast-2')
```
### Use Built-in Algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>306986355934.dkr.ecr.ap-northeast-2.amazonaws.com/semantic-segmentation:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

#### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq', region='ap-northeast-2')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>306986355934.dkr.ecr.ap-northeast-2.amazonaws.com/seq2seq:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

#### Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='ap-northeast-2', version='3.0', image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>860869212795.dkr.ecr.ap-northeast-2.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td>3.1</td>
<td>processing</td>
</tr>
<tr>
<td>860869212795.dkr.ecr.ap-northeast-2.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td>3.0</td>
<td>processing</td>
</tr>
<tr>
<td>860869212795.dkr.ecr.ap-northeast-2.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>
<td>2.4</td>
<td>processing</td>
</tr>
</tbody>
</table>

#### SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```

### SageMaker Developer Guide

1356
image_uris.retrieve(framework='sparkml-serving', region='ap-northeast-2', version='2.4')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>366743142698.dkr.ecr.ap-northeast-2.amazonaws.com/sagemaker-sparkml-serving:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
</tr>
<tr>
<td>366743142698.dkr.ecr.ap-northeast-2.amazonaws.com/sagemaker-sparkml-serving:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
</tr>
</tbody>
</table>

**Tensorflow (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='ap-northeast-2', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>

Docker Registry Paths and Example Code for Asia Pacific (Singapore) (ap-southeast-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1370)
- BlazingText (algorithm) (p. 1371)
- Chainer (DLC) (p. 1371)
- Clarify (algorithm) (p. 1372)
- Data Wrangler (algorithm) (p. 1372)
- Debugger (algorithm) (p. 1372)
- DeepAR Forecasting (algorithm) (p. 1373)
- Factorization Machines (algorithm) (p. 1373)
- Hugging Face (algorithm) (p. 1373)
- IP Insights (algorithm) (p. 1377)
- Image classification (algorithm) (p. 1377)
- Inferentia MXNet (DLC) (p. 1377)
- Inferentia PyTorch (DLC) (p. 1377)
- K-Means (algorithm) (p. 1378)
- KNN (algorithm) (p. 1378)
- LDA (algorithm) (p. 1379)
- Linear Learner (algorithm) (p. 1379)
- MXNet (DLC) (p. 1379)
- MXNet Coach (DLC) (p. 1382)
- Model Monitor (algorithm) (p. 1382)
- NTM (algorithm) (p. 1383)
- Neo Image Classification (algorithm) (p. 1383)
- Neo MXNet (DLC) (p. 1383)
- Neo PyTorch (DLC) (p. 1384)
- Neo Tensorflow (DLC) (p. 1384)
- Neo XGBoost (algorithm) (p. 1385)
- Object Detection (algorithm) (p. 1385)
- Object2Vec (algorithm) (p. 1385)
- PCA (algorithm) (p. 1386)
- PyTorch (DLC) (p. 1386)
- Random Cut Forest (algorithm) (p. 1389)
- Ray PyTorch (DLC) (p. 1390)
- Scikit-learn (algorithm) (p. 1390)
- Semantic Segmentation (algorithm) (p. 1391)
- Seq2Seq (algorithm) (p. 1391)
- Spark (algorithm) (p. 1391)
- SparkML Serving (algorithm) (p. 1392)
- Tensorflow (DLC) (p. 1392)
- Tensorflow Coach (DLC) (p. 1401)
- Tensorflow Inferentia (DLC) (p. 1402)
- Tensorflow Ray (DLC) (p. 1402)
- VW (algorithm) (p. 1403)
- XGBoost (algorithm) (p. 1403)

**AutoGluon (algorithm)**

- **Inference:** 763104351884.dkr.ecr.ap-southeast-1.amazonaws.com/pytorch-inference:1.2.0
- **Training:** 520713654638.dkr.ecr.ap-southeast-1.amazonaws.com/sagemaker-pytorch:1.1.0
- **Inference:** 520713654638.dkr.ecr.ap-southeast-1.amazonaws.com/sagemaker-pytorch:1.0.0
- **Training:** 520713654638.dkr.ecr.ap-southeast-1.amazonaws.com/sagemaker-pytorch:0.4.0

#### Job types (image scope)
- Training
- Inference

#### Processor types
- CPU, GPU

#### Python versions
- py2, py3

---

**Random Cut Forest (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
def_image_uri = image_uris.retrieve(framework='randomcutforest', region='ap-southeast-1')
```
### Amazon SageMaker Developer Guide

**Use Built-in Algorithms**

Docker Registry Paths and Example Code for Asia Pacific (Sydney) (ap-southeast-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1405)
- BlazingText (algorithm) (p. 1407)
- Chainer (DLC) (p. 1407)
- Clarify (algorithm) (p. 1407)
- Data Wrangler (algorithm) (p. 1408)
- Debugger (algorithm) (p. 1408)
- DeepAR Forecasting (algorithm) (p. 1408)
- Factorization Machines (algorithm) (p. 1409)
- Hugging Face (algorithm) (p. 1409)
- IP Insights (algorithm) (p. 1412)
- Image classification (algorithm) (p. 1412)
Use Built-in Algorithms

- Inferentia MXNet (DLC) (p. 1413)
- Inferentia PyTorch (DLC) (p. 1413)
- K-Means (algorithm) (p. 1414)
- KNN (algorithm) (p. 1414)
- LDA (algorithm) (p. 1414)
- Linear Learner (algorithm) (p. 1414)
- MXNet (DLC) (p. 1415)
- MXNet Coach (DLC) (p. 1418)
- Model Monitor (algorithm) (p. 1418)
- NTM (algorithm) (p. 1418)
- Neo Image Classification (algorithm) (p. 1419)
- Neo MXNet (DLC) (p. 1419)
- Neo PyTorch (DLC) (p. 1419)
- Neo Tensorflow (DLC) (p. 1420)
- Neo XGBoost (algorithm) (p. 1420)
- Object Detection (algorithm) (p. 1421)
- Object2Vec (algorithm) (p. 1421)
- PCA (algorithm) (p. 1421)
- PyTorch (DLC) (p. 1422)
- Random Cut Forest (algorithm) (p. 1425)
- Ray PyTorch (DLC) (p. 1425)
- Scikit-learn (algorithm) (p. 1426)
- Semantic Segmentation (algorithm) (p. 1426)
- Seq2Seq (algorithm) (p. 1426)
- Spark (algorithm) (p. 1427)
- SparkML Serving (algorithm) (p. 1427)
- Tensorflow (DLC) (p. 1428)
- Tensorflow Coach (DLC) (p. 1436)
- Tensorflow Inferentia (DLC) (p. 1437)
- Tensorflow Ray (DLC) (p. 1437)
- VW (algorithm) (p. 1438)
- XGBoost (algorithm) (p. 1439)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-southeast-2', image_scope='inference', version='0.4')
```

Docker Registry Paths and Example Code for Asia Pacific (Jakarta) (ap-southeast-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1440)
- BlazingText (algorithm) (p. 1442)
- DeepAR Forecasting (algorithm) (p. 1442)
- Factorization Machines (algorithm) (p. 1442)
- Hugging Face (algorithm) (p. 1443)
- IP Insights (algorithm) (p. 1446)
- Image classification (algorithm) (p. 1446)
- K-Means (algorithm) (p. 1446)
- KNN (algorithm) (p. 1447)
- Linear Learner (algorithm) (p. 1447)
- MXNet (DLC) (p. 1447)
- NTM (algorithm) (p. 1449)
- Object Detection (algorithm) (p. 1449)
- Object2Vec (algorithm) (p. 1449)
- PCA (algorithm) (p. 1450)
- PyTorch (DLC) (p. 1450)
- Random Cut Forest (algorithm) (p. 1453)
- Scikit-learn (algorithm) (p. 1453)
- Semantic Segmentation (algorithm) (p. 1454)
- Seq2Seq (algorithm) (p. 1454)
- Spark (algorithm) (p. 1454)
- Tensorflow (DLC) (p. 1455)
- XGBoost (algorithm) (p. 1461)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

### Docker Registry Paths and Example Code for Asia Pacific (Tokyo) (ap-northeast-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1463)
- BlazingText (algorithm) (p. 1464)
- Chainer (DLC) (p. 1465)
- Clarify (algorithm) (p. 1465)
- Data Wrangler (algorithm) (p. 1465)
- Debugger (algorithm) (p. 1466)
- DeepAR Forecasting (algorithm) (p. 1466)
- Factorization Machines (algorithm) (p. 1466)
- Hugging Face (algorithm) (p. 1467)
- IP Insights (algorithm) (p. 1470)
- Image classification (algorithm) (p. 1470)
- Inferentia MXNet (DLC) (p. 1470)
- Inferentia PyTorch (DLC) (p. 1471)
- K-Means (algorithm) (p. 1471)
- KNN (algorithm) (p. 1472)
- LDA (algorithm) (p. 1472)
- Linear Learner (algorithm) (p. 1472)
- MXNet (DLC) (p. 1473)
- MXNet Coach (DLC) (p. 1475)
- Model Monitor (algorithm) (p. 1476)
- NTM (algorithm) (p. 1476)
- Neo Image Classification (algorithm) (p. 1476)
- Neo MXNet (DLC) (p. 1477)
- Neo PyTorch (DLC) (p. 1477)
- Neo Tensorflow (DLC) (p. 1478)
- Neo XGBoost (algorithm) (p. 1478)
- Object Detection (algorithm) (p. 1479)
- Object2Vec (algorithm) (p. 1479)
- PCA (algorithm) (p. 1479)
- PyTorch (DLC) (p. 1479)
- Random Cut Forest (algorithm) (p. 1483)
- Ray PyTorch (DLC) (p. 1483)
- Scikit-learn (algorithm) (p. 1484)
- Semantic Segmentation (algorithm) (p. 1484)
- Seq2Seq (algorithm) (p. 1484)
- Spark (algorithm) (p. 1485)
- SparkML Serving (algorithm) (p. 1485)
- Tensorflow (DLC) (p. 1485)
- Tensorflow Coach (DLC) (p. 1494)
- Tensorflow Inferentia (DLC) (p. 1495)
- Tensorflow Ray (DLC) (p. 1495)
- VW (algorithm) (p. 1496)
- XGBoost (algorithm) (p. 1496)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-northeast-1', image_scope='inference', version='0.4')
```

<table>

</tr>
</tbody>
</table>

K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='kmeans', region='ap-northeast-1')
### KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='ap-northeast-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>

Docker Registry Paths and Example Code for Canada (Central) (ca-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1498)
- BlazingText (algorithm) (p. 1500)
- Chainer (DLC) (p. 1500)
- Clarify (algorithm) (p. 1500)
- Data Wrangler (algorithm) (p. 1501)
• Debugger (algorithm) (p. 1501)
• DeepAR Forecasting (algorithm) (p. 1501)
• Factorization Machines (algorithm) (p. 1502)
• Hugging Face (algorithm) (p. 1502)
• IP Insights (algorithm) (p. 1505)
• Image classification (algorithm) (p. 1505)
• Inferentia MXNet (DLC) (p. 1506)
• Inferentia PyTorch (DLC) (p. 1506)
• K-Means (algorithm) (p. 1507)
• KNN (algorithm) (p. 1507)
• LDA (algorithm) (p. 1507)
• Linear Learner (algorithm) (p. 1508)
• MXNet (DLC) (p. 1508)
• MXNet Coach (DLC) (p. 1511)
• Model Monitor (algorithm) (p. 1511)
• NTM (algorithm) (p. 1511)
• Neo Image Classification (algorithm) (p. 1512)
• Neo MXNet (DLC) (p. 1512)
• Neo PyTorch (DLC) (p. 1512)
• Neo Tensorflow (DLC) (p. 1513)
• Neo XGBoost (algorithm) (p. 1514)
• Object Detection (algorithm) (p. 1514)
• Object2Vec (algorithm) (p. 1514)
• PCA (algorithm) (p. 1514)
• PyTorch (DLC) (p. 1515)
• Random Cut Forest (algorithm) (p. 1518)
• Ray PyTorch (DLC) (p. 1518)
• Scikit-learn (algorithm) (p. 1519)
• Semantic Segmentation (algorithm) (p. 1519)
• Seq2Seq (algorithm) (p. 1520)
• Spark (algorithm) (p. 1520)
• SparkML Serving (algorithm) (p. 1520)
• Tensorflow (DLC) (p. 1521)
• Tensorflow Coach (DLC) (p. 1529)
• Tensorflow Inferentia (DLC) (p. 1530)
• Tensorflow Ray (DLC) (p. 1531)
• VW (algorithm) (p. 1531)
• XGBoost (algorithm) (p. 1532)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

Below is the image of one page of a document, as well as some raw textual content that was previously extracted for it. Just return the plain text representation of this document as if you were reading it naturally.

### Built-in Algorithms

#### BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='ca-central-1')
```

#### Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='ca-central-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

### Processor types and Python versions

<table>
<thead>
<tr>
<th>Registry path</th>

#### Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='ca-central-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

### Docker Registry Paths and Example Code for China (Beijing) (cn-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1534)
- BlazingText (algorithm) (p. 1534)
- Chainer (DLC) (p. 1535)
- Clarify (algorithm) (p. 1535)
- Data Wrangler (algorithm) (p. 1536)
- Debugger (algorithm) (p. 1536)
- DeepAR Forecasting (algorithm) (p. 1536)
- Factorization Machines (algorithm) (p. 1536)
- Hugging Face (algorithm) (p. 1537)
- IP Insights (algorithm) (p. 1540)
- Image classification (algorithm) (p. 1540)
- Inferentia MXNet (DLC) (p. 1540)
- Inferentia PyTorch (DLC) (p. 1541)
- K-Means (algorithm) (p. 1541)
- KNN (algorithm) (p. 1542)
- Linear Learner (algorithm) (p. 1542)
- MXNet (DLC) (p. 1542)
- MXNet Coach (DLC) (p. 1545)
- Model Monitor (algorithm) (p. 1546)
- NTM (algorithm) (p. 1546)
- Neo Image Classification (algorithm) (p. 1546)
- Neo MXNet (DLC) (p. 1546)
- Neo PyTorch (DLC) (p. 1547)
- Neo Tensorflow (DLC) (p. 1548)
- Neo XGBoost (algorithm) (p. 1548)
- Object Detection (algorithm) (p. 1548)
- Object2Vec (algorithm) (p. 1549)
- PCA (algorithm) (p. 1549)
- PyTorch (DLC) (p. 1549)
- Random Cut Forest (algorithm) (p. 1552)
- Scikit-learn (algorithm) (p. 1553)
• Semantic Segmentation (algorithm) (p. 1553)
• Seq2Seq (algorithm) (p. 1553)
• Spark (algorithm) (p. 1554)
• SparkML Serving (algorithm) (p. 1554)
• Tensorflow (DLC) (p. 1555)
• Tensorflow Coach (DLC) (p. 1563)
• Tensorflow Inference (DLC) (p. 1564)
• Tensorflow Ray (DLC) (p. 1564)
• XGBoost (algorithm) (p. 1565)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='cn-north-1',image_scope='inference',version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>727897471807.dkr.ecr.cn-0.5.2 north-1.amazonaws.com.cn/autogluon-inference:tag</td>

**Tensorflow (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='cn-north-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

TensorFlow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow',region='cn-north-1',version='1.0.0',image_scope='training',instance_type='ml.c5.4xlarge')
```
### Tensorflow Inferentia (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow',region='cn-north-1',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

### Registry path | Version | Job types (image scope) | Processor types | Python versions
--- | --- | --- | --- | ---
`sagemaker-rl-tensorflow:ray0.6-<tag>` | | | | |
422961961927.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-rl-tensorflow:ray0.5.3-<tag> | training | CPU, GPU | py3 |
422961961927.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-rl-tensorflow:ray0.5-<tag> | training | CPU, GPU | py3 |

**XGBoost (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost',region='cn-north-1',version='1.2-1')
```

### Registry path | Version | Package version | Job types (image scope)
--- | --- | --- | ---
450853457545.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-xgboost:1.5-1 | 1.5.2 | inference, training |

390948362332.dkr.ecr.cn-north-1.amazonaws.com.cn/xgboost:1 | 1.5.2 | inference, training |
### Amazon SageMaker Developer Guide

#### Use Built-in Algorithms

Docker Registry Paths and Example Code for China (Ningxia) (cn-northwest-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1567)
- BlazingText (algorithm) (p. 1568)
- Chainer (DLC) (p. 1568)
- Clarify (algorithm) (p. 1568)
- Data Wrangler (algorithm) (p. 1569)
- Debugger (algorithm) (p. 1569)
- DeepAR Forecasting (algorithm) (p. 1569)
- Factorization Machines (algorithm) (p. 1570)
- Hugging Face (algorithm) (p. 1570)
- IP Insights (algorithm) (p. 1573)
- Image classification (algorithm) (p. 1573)
- Inferentia MXNet (DLC) (p. 1574)
- Inferentia PyTorch (DLC) (p. 1574)
- K-Means (algorithm) (p. 1575)
- KNN (algorithm) (p. 1575)
- Linear Learner (algorithm) (p. 1575)
- MXNet (DLC) (p. 1575)
- MXNet Coach (DLC) (p. 1578)
- Model Monitor (algorithm) (p. 1579)
- NTM (algorithm) (p. 1579)
- Neo Image Classification (algorithm) (p. 1579)
- Neo MXNet (DLC) (p. 1580)
- Neo PyTorch (DLC) (p. 1580)
- Neo Tensorflow (DLC) (p. 1581)
- Neo XGBoost (algorithm) (p. 1581)
- Object Detection (algorithm) (p. 1581)
- Object2Vec (algorithm) (p. 1582)
- PCA (algorithm) (p. 1582)
• PyTorch (DLC) (p. 1582)
• Random Cut Forest (algorithm) (p. 1586)
• Scikit-learn (algorithm) (p. 1586)
• Semantic Segmentation (algorithm) (p. 1586)
• Seq2Seq (algorithm) (p. 1587)
• Spark (algorithm) (p. 1587)
• SparkML Serving (algorithm) (p. 1587)
• Tensorflow (DLC) (p. 1588)
• Tensorflow Coach (DLC) (p. 1596)
• Tensorflow Inference (DLC) (p. 1597)
• Tensorflow Ray (DLC) (p. 1597)
• XGBoost (algorithm) (p. 1598)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='cn-northwest-1',image_scope='inference',version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>727897471807.dkr.ecr.cn-0.5.2 northwest-1.amazonaws.com.cn/autogluon-inference:&lt;tag&gt;</td>
<td>inference</td>
<td></td>
</tr>
<tr>
<td>727897471807.dkr.ecr.cn-0.4.3 northwest-1.amazonaws.com.cn/autogluon-inference:&lt;tag&gt;</td>
<td>inference</td>
<td></td>
</tr>
<tr>
<td>727897471807.dkr.ecr.cn-0.4.2 northwest-1.amazonaws.com.cn/autogluon-inference:&lt;tag&gt;</td>
<td>inference</td>
<td></td>
</tr>
<tr>
<td>727897471807.dkr.ecr.cn-0.4.0 northwest-1.amazonaws.com.cn/autogluon-inference:&lt;tag&gt;</td>

<td>inference</td>
<td></td>
</tr>
</tbody>
</table>
**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='cn-northwest-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>

<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>

**Clarify (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='cn-northwest-1', version='1.0', image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>122578899357.dkr.ecr.cn-northwest-1.amazonaws.com.cn/clarify:&lt;tag&gt;</td>
<td></td>
<td>processing</td>

<td>Registry path</td>
<td>Version</td>
<td>Job types (image scope)</td>
</tr>
<tr>
<td>---------------</td>
<td>---------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>sagemaker-clarify-processing:&lt;tag&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Data Wrangler (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
def from_sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='cn-northwest-1')```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>249157047649.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-data-wrangler-container:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

**Debugger (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
def from_sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='cn-northwest-1')```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>658757709296.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-debugger-rules:&lt;tag&gt;</td>
<td></td>
<td>debugger</td>
</tr>
</tbody>
</table>

**DeepAR Forecasting (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
def from_sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='cn-northwest-1')```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/forecasting-deepar:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>
Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

**IP Insights (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-1 north-west-1.amazonaws.com.cn/</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ipinsights:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Image classification (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='cn-northwest-1')
```
### Use Built-in Algorithms

#### Registry path

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/image-classification:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

#### Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='cn-northwest-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

#### Registry path

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
<tr>
<td>474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>

#### Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='cn-northwest-1', version='1.9', py_version='py3')
```

#### Registry path

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-neo-pytorch:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
<td>inf</td>
<td>py3</td>

Docker Registry Paths and Example Code for Europe (Frankfurt) (eu-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1600)
- BlazingText (algorithm) (p. 1601)
- Chainer (DLC) (p. 1602)
- Clarify (algorithm) (p. 1602)
- Data Wrangler (algorithm) (p. 1603)
- Debugger (algorithm) (p. 1603)
- DeepAR Forecasting (algorithm) (p. 1603)
- Factorization Machines (algorithm) (p. 1603)
- Hugging Face (algorithm) (p. 1604)
- IP Insights (algorithm) (p. 1607)
- Image classification (algorithm) (p. 1607)
- Inferentia MXNet (DLC) (p. 1607)
- Inferentia PyTorch (DLC) (p. 1608)
- K-Means (algorithm) (p. 1608)
- KNN (algorithm) (p. 1609)
- LDA (algorithm) (p. 1609)
- Linear Learner (algorithm) (p. 1609)
- MXNet (DLC) (p. 1610)
• MXNet Coach (DLC) (p. 1612)
• Model Monitor (algorithm) (p. 1613)
• NTM (algorithm) (p. 1613)
• Neo Image Classification (algorithm) (p. 1613)
• Neo MXNet (DLC) (p. 1614)
• Neo PyTorch (DLC) (p. 1614)
• Neo Tensorflow (DLC) (p. 1615)
• Neo XGBoost (algorithm) (p. 1615)
• Object Detection (algorithm) (p. 1616)
• Object2Vec (algorithm) (p. 1616)
• PCA (algorithm) (p. 1616)
• PyTorch (DLC) (p. 1616)
• Random Cut Forest (algorithm) (p. 1620)
• Ray PyTorch (DLC) (p. 1620)
• Scikit-learn (algorithm) (p. 1620)
• Semantic Segmentation (algorithm) (p. 1621)
• Seq2Seq (algorithm) (p. 1621)
• Spark (algorithm) (p. 1622)
• SparkML Serving (algorithm) (p. 1622)
• Tensorflow (DLC) (p. 1622)
• Tensorflow Coach (DLC) (p. 1631)
• Tensorflow Inferentia (DLC) (p. 1632)
• Tensorflow Ray (DLC) (p. 1632)
• VW (algorithm) (p. 1633)
• XGBoost (algorithm) (p. 1633)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='eu-central-1', image_scope='inference', version='0.4')
```

**TensorFlow Coach (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow',region='eu-central-1',version='1.0.0',image_scope='training',instance_type='ml.c5.4xlarge')
```
**Tensorflow Inferentia (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow',region='eu-central-1',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

#### XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1635)
- BlazingText (algorithm) (p. 1637)
- Chainer (DLC) (p. 1637)
- Clarify (algorithm) (p. 1637)
- Data Wrangler (algorithm) (p. 1638)
- Debugger (algorithm) (p. 1638)
- DeepAR Forecasting (algorithm) (p. 1638)
- Factorization Machines (algorithm) (p. 1639)
- Hugging Face (algorithm) (p. 1639)
- IP Insights (algorithm) (p. 1642)
- Image classification (algorithm) (p. 1642)
- Inferentia MXNet (DLC) (p. 1643)
- Inferentia PyTorch (DLC) (p. 1643)
- K-Means (algorithm) (p. 1644)
- KNN (algorithm) (p. 1644)
- LDA (algorithm) (p. 1644)
- Linear Learner (algorithm) (p. 1645)
- MXNet (DLC) (p. 1645)
- MXNet Coach (DLC) (p. 1648)
- Model Monitor (algorithm) (p. 1648)
- NTM (algorithm) (p. 1648)
- Neo Image Classification (algorithm) (p. 1649)
- Neo MXNet (DLC) (p. 1649)
- Neo PyTorch (DLC) (p. 1649)
- Neo Tensorflow (DLC) (p. 1650)
- Neo XGBoost (algorithm) (p. 1651)
- Object Detection (algorithm) (p. 1651)
- Object2Vec (algorithm) (p. 1651)
- PCA (algorithm) (p. 1651)
- PyTorch (DLC) (p. 1652)
- Random Cut Forest (algorithm) (p. 1655)
- Ray PyTorch (DLC) (p. 1655)
- Scikit-learn (algorithm) (p. 1656)
- Semantic Segmentation (algorithm) (p. 1656)
- Seq2Seq (algorithm) (p. 1657)
- Spark (algorithm) (p. 1657)
- SparkML Serving (algorithm) (p. 1657)
- Tensorflow (DLC) (p. 1658)
- Tensorflow Coach (DLC) (p. 1666)
- Tensorflow Inferentia (DLC) (p. 1667)
- Tensorflow Ray (DLC) (p. 1668)
- VW (algorithm) (p. 1668)
- XGBoost (algorithm) (p. 1669)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='eu-west-1',image_scope='inference',version='0.4')
```

Docker Registry Paths and Example Code for Europe (London) (eu-west-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1671)
- BlazingText (algorithm) (p. 1672)
- Chainer (DLC) (p. 1672)
- Clarify (algorithm) (p. 1673)
- Data Wrangler (algorithm) (p. 1673)
- Debugger (algorithm) (p. 1673)
- DeepAR Forecasting (algorithm) (p. 1674)
- Factorization Machines (algorithm) (p. 1674)
- Hugging Face (algorithm) (p. 1674)
- IP Insights (algorithm) (p. 1678)
- Image classification (algorithm) (p. 1678)
- Inferentia MXNet (DLC) (p. 1678)
- Inferentia PyTorch (DLC) (p. 1678)
- K-Means (algorithm) (p. 1679)
- KNN (algorithm) (p. 1679)
- LDA (algorithm) (p. 1680)
- Linear Learner (algorithm) (p. 1680)
- MXNet (DLC) (p. 1680)
- MXNet Coach (DLC) (p. 1683)
- Model Monitor (algorithm) (p. 1683)
- NTM (algorithm) (p. 1684)
- Neo Image Classification (algorithm) (p. 1684)
- Neo MXNet (DLC) (p. 1684)
- Neo PyTorch (DLC) (p. 1685)
- Neo Tensorflow (DLC) (p. 1685)
- Neo XGBoost (algorithm) (p. 1686)
- Object Detection (algorithm) (p. 1686)
- Object2Vec (algorithm) (p. 1686)
- PCA (algorithm) (p. 1687)
- PyTorch (DLC) (p. 1687)
- Random Cut Forest (algorithm) (p. 1690)
- Ray PyTorch (DLC) (p. 1691)
- Scikit-learn (algorithm) (p. 1691)
- Semantic Segmentation (algorithm) (p. 1691)
- Seq2Seq (algorithm) (p. 1692)
- Spark (algorithm) (p. 1692)
- SparkML Serving (algorithm) (p. 1692)
- Tensorflow (DLC) (p. 1693)
- Tensorflow Coach (DLC) (p. 1701)
- Tensorflow Inferentia (DLC) (p. 1702)
- Tensorflow Ray (DLC) (p. 1703)
- VW (algorithm) (p. 1703)
- XGBoost (algorithm) (p. 1704)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='eu-west-2',image_scope='inference',version='0.4')
```

<table>
<thead>

Docker Registry Paths and Example Code for Europe (Paris) (eu-west-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1706)
- BlazingText (algorithm) (p. 1707)
- Chainer (DLC) (p. 1707)
- Clarify (algorithm) (p. 1708)
- Data Wrangler (algorithm) (p. 1708)
- Debugger (algorithm) (p. 1708)
- DeepAR Forecasting (algorithm) (p. 1709)
- Factorization Machines (algorithm) (p. 1709)
- Hugging Face (algorithm) (p. 1709)
- IP Insights (algorithm) (p. 1713)
- Image classification (algorithm) (p. 1713)
- Inferentia MXNet (DLC) (p. 1713)
- Inferentia PyTorch (DLC) (p. 1713)
- K-Means (algorithm) (p. 1714)
- KNN (algorithm) (p. 1714)
- Linear Learner (algorithm) (p. 1715)
- MXNet (DLC) (p. 1715)
- MXNet Coach (DLC) (p. 1718)
- Model Monitor (algorithm) (p. 1718)
- NTM (algorithm) (p. 1718)
- Neo Image Classification (algorithm) (p. 1719)
- Neo MXNet (DLC) (p. 1719)
- Neo PyTorch (DLC) (p. 1719)
- Neo Tensorflow (DLC) (p. 1720)
- Neo XGBoost (algorithm) (p. 1721)
- Object Detection (algorithm) (p. 1721)
- Object2Vec (algorithm) (p. 1721)
- PCA (algorithm) (p. 1721)
- PyTorch (DLC) (p. 1722)
• Random Cut Forest (algorithm) (p. 1725)
• Scikit-learn (algorithm) (p. 1725)
• Semantic Segmentation (algorithm) (p. 1726)
• Seq2Seq (algorithm) (p. 1726)
• Spark (algorithm) (p. 1726)
• SparkML Serving (algorithm) (p. 1727)
• Tensorflow (DLC) (p. 1727)
• Tensorflow Coach (DLC) (p. 1736)
• Tensorflow Inference (DLC) (p. 1737)
• Tensorflow Ray (DLC) (p. 1737)
• XGBoost (algorithm) (p. 1738)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python

**Random Cut Forest (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest',region='eu-north-1')
```

### Registry path | Version | Job types (image scope)
---|---|---
669576153137.dkr.ecr.eu-north-1.amazonaws.com/randomcutforest:tag | | inference, training

**Scikit-learn (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='eu-north-1',version='0.23-1',image_scope='inference')
```

### Registry path | Version | Package version | Job types (image scope)
---|---|---|---
662702820516.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-sklearn:tag | 1.0.2 | | inference, training
662702820516.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-sklearn:tag | 0.23.2 | | inference, training
662702820516.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-sklearn:tag | 0.20.0 | | inference, training
**Semantic Segmentation (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='eu-north-1')
```

<table>

**Docker Registry Paths and Example Code for Europe (Milan) (eu-south-1)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1773)
- BlazingText (algorithm) (p. 1774)
- Chainer (DLC) (p. 1775)
- Clarify (algorithm) (p. 1775)
- Data Wrangler (algorithm) (p. 1775)
- Debugger (algorithm) (p. 1776)
- DeepAR Forecasting (algorithm) (p. 1776)
- Factorization Machines (algorithm) (p. 1776)
- Hugging Face (algorithm) (p. 1777)
- IP Insights (algorithm) (p. 1780)
- Image classification (algorithm) (p. 1780)
- Inferentia MXNet (DLC) (p. 1780)
- Inferentia PyTorch (DLC) (p. 1781)
- K-Means (algorithm) (p. 1781)
- KNN (algorithm) (p. 1782)
- Linear Learner (algorithm) (p. 1782)
- MXNet (DLC) (p. 1782)
- MXNet Coach (DLC) (p. 1785)
• Model Monitor (algorithm) (p. 1786)
• NTM (algorithm) (p. 1786)
• Neo Image Classification (algorithm) (p. 1786)
• Neo MXNet (DLC) (p. 1786)
• Neo PyTorch (DLC) (p. 1787)
• Neo Tensorflow (DLC) (p. 1788)
• Neo XGBoost (algorithm) (p. 1788)
• Object Detection (algorithm) (p. 1788)
• Object2Vec (algorithm) (p. 1789)
• PCA (algorithm) (p. 1789)
• PyTorch (DLC) (p. 1789)
• Random Cut Forest (algorithm) (p. 1792)
• Scikit-learn (algorithm) (p. 1793)
• Semantic Segmentation (algorithm) (p. 1793)
• Seq2Seq (algorithm) (p. 1793)
• Spark (algorithm) (p. 1794)
• SparkML Serving (algorithm) (p. 1794)
• Tensorflow (DLC) (p. 1795)
• Tensorflow Coach (DLC) (p. 1803)
• Tensorflow Inferentia (DLC) (p. 1804)
• Tensorflow Ray (DLC) (p. 1804)
• XGBoost (algorithm) (p. 1805)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='eu-south-1', image_scope='inference', version='0.4')
```

### Docker Registry Paths and Example Code for Middle East (Bahrain) (me-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics
- AutoGluon (algorithm) (p. 1807)
- BlazingText (algorithm) (p. 1808)
- Chainer (DLC) (p. 1808)
- Clarify (algorithm) (p. 1809)
- Data Wrangler (algorithm) (p. 1809)
- Debugger (algorithm) (p. 1809)
- DeepAR Forecasting (algorithm) (p. 1810)
- Factorization Machines (algorithm) (p. 1810)
- Hugging Face (algorithm) (p. 1810)
- IP Insights (algorithm) (p. 1814)
- Image classification (algorithm) (p. 1814)
- Inferentia MXNet (DLC) (p. 1814)
- Inferentia PyTorch (DLC) (p. 1814)
- K-Means (algorithm) (p. 1815)
- KNN (algorithm) (p. 1815)
- Linear Learner (algorithm) (p. 1816)
- MXNet (DLC) (p. 1816)
- MXNet Coach (DLC) (p. 1819)
- Model Monitor (algorithm) (p. 1819)
- NTM (algorithm) (p. 1819)
- Neo Image Classification (algorithm) (p. 1820)
- Neo MXNet (DLC) (p. 1820)
- Neo PyTorch (DLC) (p. 1820)
- Neo Tensorflow (DLC) (p. 1821)
- Neo XGBoost (algorithm) (p. 1822)
- Object Detection (algorithm) (p. 1822)
- Object2Vec (algorithm) (p. 1822)
- PCA (algorithm) (p. 1822)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='me-south-1', image_scope='inference', version='0.4')
```

Docker Registry Paths and Example Code for South America (São Paulo) (sa-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1840)
- BlazingText (algorithm) (p. 1842)
• Chainer (DLC) (p. 1842)
• Clarify (algorithm) (p. 1842)
• Data Wrangler (algorithm) (p. 1843)
• Debugger (algorithm) (p. 1843)
• DeepAR Forecasting (algorithm) (p. 1843)
• Factorization Machines (algorithm) (p. 1844)
• Hugging Face (algorithm) (p. 1844)
• IP Insights (algorithm) (p. 1847)
• Image classification (algorithm) (p. 1847)
• Inferentia MXNet (DLC) (p. 1848)
• Inferentia PyTorch (DLC) (p. 1848)
• K-Means (algorithm) (p. 1849)
• KNN (algorithm) (p. 1849)
• Linear Learner (algorithm) (p. 1849)
• MXNet (DLC) (p. 1849)
• MXNet Coach (DLC) (p. 1852)
• Model Monitor (algorithm) (p. 1853)
• NTM (algorithm) (p. 1853)
• Neo Image Classification (algorithm) (p. 1853)
• Neo MXNet (DLC) (p. 1854)
• Neo PyTorch (DLC) (p. 1854)
• Neo Tensorflow (DLC) (p. 1855)
• Neo XGBoost (algorithm) (p. 1855)
• Object Detection (algorithm) (p. 1856)
• Object2Vec (algorithm) (p. 1856)
• PCA (algorithm) (p. 1856)
• PyTorch (DLC) (p. 1856)
• Random Cut Forest (algorithm) (p. 1860)
• Scikit-learn (algorithm) (p. 1860)
• Semantic Segmentation (algorithm) (p. 1860)
• Seq2Seq (algorithm) (p. 1861)
• Spark (algorithm) (p. 1861)
• SparkML Serving (algorithm) (p. 1861)
• Tensorflow (DLC) (p. 1862)
• Tensorflow Coach (DLC) (p. 1870)
• Tensorflow Inferentia (DLC) (p. 1871)
• Tensorflow Ray (DLC) (p. 1871)
• XGBoost (algorithm) (p. 1872)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='sa-east-1',image_scope='inference',version='0.4')
```

Docker Registry Paths and Example Code for AWS GovCloud (US-West) (us-gov-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1874)
- BlazingText (algorithm) (p. 1875)
- Chainer (DLC) (p. 1876)
- Clarify (algorithm) (p. 1876)
- Debugger (algorithm) (p. 1877)
- DeepAR Forecasting (algorithm) (p. 1877)
- Factorization Machines (algorithm) (p. 1877)
- Hugging Face (algorithm) (p. 1878)
- IP Insights (algorithm) (p. 1881)
- Image classification (algorithm) (p. 1882)
- Inferentia MXNet (DLC) (p. 1882)
- Inferentia PyTorch (DLC) (p. 1883)
- K-Means (algorithm) (p. 1883)
- KNN (algorithm) (p. 1883)
- LDA (algorithm) (p. 1884)
- Linear Learner (algorithm) (p. 1884)
- MXNet (DLC) (p. 1884)
- MXNet Coach (DLC) (p. 1888)
- NTM (algorithm) (p. 1888)
• Neo Image Classification (algorithm) (p. 1889)
• Neo MXNet (DLC) (p. 1889)
• Neo PyTorch (DLC) (p. 1889)
• Neo Tensorflow (DLC) (p. 1890)
• Neo XGBoost (algorithm) (p. 1891)
• Object Detection (algorithm) (p. 1891)
• Object2Vec (algorithm) (p. 1891)
• PCA (algorithm) (p. 1891)
• PyTorch (DLC) (p. 1892)
• Random Cut Forest (algorithm) (p. 1896)
• Scikit-learn (algorithm) (p. 1896)
• Semantic Segmentation (algorithm) (p. 1897)
• Seq2Seq (algorithm) (p. 1897)
• Spark (algorithm) (p. 1897)
• SparkML Serving (algorithm) (p. 1898)
• Tensorflow (DLC) (p. 1898)
• Tensorflow Coach (DLC) (p. 1908)
• Tensorflow Inferentia (DLC) (p. 1909)
• Tensorflow Ray (DLC) (p. 1910)
• XGBoost (algorithm) (p. 1910)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='us-gov-west-1', image_scope='inference', version='0.4')
```

### Common Data Formats for Built-in Algorithms
The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

**Topics**
- Common Data Formats for Training (p. 1912)
- Common Data Formats for Inference (p. 1915)
Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data need to go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

Topics

- Content Types Supported by Built-In Algorithms (p. 1912)
- Using Pipe Mode (p. 1913)
- Using CSV Format (p. 1913)
- Using RecordIO Format (p. 1913)
- Trained Model Deserialization (p. 1915)

Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported `ContentType` values and the algorithms that use them:

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Algorithm</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-image</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>application/x-recordio</td>
<td>Object Detection Algorithm</td>
</tr>
</tbody>
</table>
| application/x-recordio-
  protobuf                    | Factorization Machines, K-Means, k-NN, Latent Dirichlet Allocation, Linear
  Learner, NTM, PCA, RCF, Sequence-to-Sequence |
| application/jsonlines        | BlazingText, DeepAR                                                       |
| image/jpeg                   | Object Detection Algorithm, Semantic Segmentation                          |
| image/png                    | Object Detection Algorithm, Semantic Segmentation                          |
| text/libsvm                  | XGBoost                                                                   |

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this table.
Using Pipe Mode

In **Pipe mode**, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to **File mode**, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the AlgorithmSpecification for additional details on the training input mode.

Using CSV Format

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify `text/csv` as the ContentType. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the number of label columns in the content type. For example, in this case `content_type=text/csv;label_size=0`. For a notebook example that uses CSV format, see Breast Cancer Prediction. For more information, see Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms.

Using RecordIO Format

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However, if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

**Note**

For an example that shows how to convert the commonly used numPy array into the protobuf recordIO format, see An Introduction to Factorization Machines with MNIST.

```protobuf
syntax = "proto2";

package aialgs.data;

option java_package = "com.amazonaws.aialgorithms.proto";
option java_outer_classname = "RecordProtos";

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
  repeated float values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 20) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
  repeated float values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 20) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}
```
Repeated double values = 1 [packed = true];

// If this is not empty, the vector is treated as sparse, with
// each key specifying the location of the value in the sparse vector.
repeated uint64 keys = 2 [packed = true];

// An optional shape that allows the vector to represent a matrix.
// For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
// and keys[i] % 20 gives the column.
// This also supports n-dimensional tensors.
// Note: If the tensor is sparse, you must specify this value.
repeated uint64 shape = 3 [packed = true];

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
  repeated int32 values = 1 [packed = true];

  // If this is not empty, the vector is treated as sparse with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
  repeated bytes value = 1;

  // If the content type of the data is known, stores it.
  // This allows for the possibility of using decoders for common formats
  // in the future.
  optional string content_type = 2;
}

message Value {
  oneof value {
    // The numbering assumes the possible use of:
    // - float16, float128
    // - int8, int16, int32
    Float32Tensor float32_tensor = 2;
    Float64Tensor float64_tensor = 3;
    Int32Tensor int32_tensor = 7;
    Bytes bytes = 9;
  }
}

message Record {
  // Map from the name of the feature to the value.
  // For vectors and libsvm-like datasets,
  // a single feature with the name `values`
  // should be specified.
  map<string, Value> features = 1;

  // An optional set of labels for this record.
  // Similar to the features field above, the key used for
  // generic scalar / vector labels should be `values`.
}
map<string, Value> label = 2;

// A unique identifier for this record in the dataset.
//
// Whilst not necessary, this allows better
// debugging where there are data issues.
//
// This is not used by the algorithm directly.
optional string uid = 3;

// Textual metadata describing the record.
//
// This may include JSON-serialized information
// about the source of the record.
//
// This is not used by the algorithm directly.
optional string metadata = 4;

// An optional serialized JSON object that allows per-record
// hyper-parameters/configuration/other information to be set.
//
// The meaning/interpretation of this field is defined by
// the algorithm author and may not be supported.
//
// This is used to pass additional inference configuration
// when batch inference is used (e.g. types of scores to return).
optional string configuration = 5;
}

After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of InputDataConfig in create_training_job.

**Note**
For all Amazon SageMaker algorithms, the ChannelName in InputDataConfig must be set to train. Some algorithms also support a validation or test input channels. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

**Trained Model Deserialization**

Amazon SageMaker models are stored as model.tar.gz in the S3 bucket specified in OutputDataConfig S3OutputPath parameter of the create_training_job call. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When model.tar.gz is untarred, it contains model_algo-1, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```python
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

**Common Data Formats for Inference**

Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various AWS services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)
Convert Data for Inference Request Serialization

Content type options for Amazon SageMaker algorithm inference requests include: text/csv, application/json, and application/x-recordio-protobuf. Algorithms that don’t support all of these types can support other types. XGBoost, for example, only supports text/csv from this list, but also supports text/libsvm.

For text/csv, the value for the Body argument to invoke_endpoint should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like 1.5, 16.0, 14, 23.0. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

application/json is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```javascript
let request = {
  "instances": [
    {
      // Request and algorithm specific inference parameters.
      "configuration": {},
      // Data in the specific format required by the algorithm.
      "data": {
        "<field name>": dataElement
      }
    }
  ]
}
```

You have the following options for specifying the `dataElement`:

**Protocol buffers equivalent**

```javascript
// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
  "keys": [],
  "values": [],
  "shape": []
}
```

**Simple numeric vector**

```javascript
// An array containing numeric values is treated as an instance containing a single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
  "features": {
    "values": dataElement
  }
}
```
For multiple records

```javascript
let request = {
  "instances": [
    // First instance.
    {
      "features": [1.5, 16.0, 14.0, 23.0]
    },
    // Second instance.
    {
      "features": [-2.0, 100.2, 15.2, 9.2]
    }
  ]
}
```

Convert Data for Inference Response Deserialization

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

```javascript
let response = {
  "predictions": [
    // Fields in the response object are defined on a per algorithm-basis.
  ]
}
```

The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

Single-record inference

```javascript
let response = {
  "predictions": [
    // Fields in the response object are defined on a per algorithm-basis.
    {
      "closest_cluster": 5,
      "distance_to_cluster": 36.5
    }
  ]
}
```

Multi-record inference

```javascript
let response = {
  "predictions": [
    // First instance prediction.
    {
      "closest_cluster": 5,
      "distance_to_cluster": 36.5
    },
    // Second instance prediction.
    {
      "closest_cluster": 2,
      "distance_to_cluster": 90.3
    }
  ]
}
```

Multi-record inference with protobuf input

```javascript
{
  "features": [],
  "label": {
    "closest_cluster": {
```
SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```
{"distance_to_cluster": 23.40593910217285, "closest_cluster": 0.0}
{"distance_to_cluster": 27.250282287597656, "closest_cluster": 0.0}
```

While running batch transform, we recommended using the jsonlines response type by setting the `Accept` field in the `CreateTransformJobRequest` to application/jsonlines.

**Common Request Formats for All Algorithms**

Most algorithms use several of the following inference request formats.

**JSON Request Format**

**Content type:** application/JSON

**Dense format**

```
let request = {
  "instances": [
    {
      "features": [1.5, 16.0, 14.0, 23.0]
    }
  ]
}
```

```
let request = {
  "instances": [
    {
      "data": {
        "features": {
          "values": [ 1.5, 16.0, 14.0, 23.0]
        }
      }
    }
  ]
}
```

**Sparse format**

```
{"instances": [
{"data": {"features": {
  "keys": [26, 182, 232, 243, 431],
  "shape": [2000],
  "values": [1, 1, 1, 4, 1]}
}
```
JSONLINES Request Format

Content type: application/JSONLINES

Dense format

A single record in dense format can be represented as either:

```json
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```json
{ "data": { "features": { "values": [1.5, 16.0, 14.0, 23.0] } }
```

Sparse Format

A single record in sparse format is represented as:

```json
{"data": { "features": { "keys": [26, 182, 232, 243, 431], "shape": [2000], "values": [1, 1, 1, 4, 1] } }}
```

Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```json
{"data": { "features": { "keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } }}
{"data": { "features": { "values": [1.5, 16.0, 14.0, 23.0] } }}
{"features": [1.5, 16.0, 14.0, 23.0] }
```

CSV Request Format

Content type: text/CSV; label_size=0

Note: CSV support is not available for factorization machines.

RECORDIO Request Format

Content type: application/x-recordio-protobuf

Use Batch Transform with Built-in Algorithms

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the Accept field in the CreateTransformJobRequest to application/jsonlines.

When you create a transform job, the SplitType must be set according to the ContentType of the input data. Similarly, depending on the Accept field in the CreateTransformJobRequest,
AssembleWith must be set accordingly. Please use the following table to help appropriately set these fields:

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Recommended SplitType</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>RecordIO</td>
<td></td>
</tr>
<tr>
<td>text/csv</td>
<td>Line</td>
<td></td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>Line</td>
<td></td>
</tr>
<tr>
<td>application/json</td>
<td>None</td>
<td></td>
</tr>
<tr>
<td>application/x-image</td>
<td>None</td>
<td></td>
</tr>
<tr>
<td>image/*</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

For more information on response formats for specific algorithms, see the following:

- DeepAR Inference Formats (p. 2079)
- Factorization Machines Response Formats (p. 1947)
- IP Insights Inference Data Formats (p. 2090)
- K-Means Response Formats (p. 2099)
- k-NN Request and Response Formats (p. 1954)
- Linear learner response formats (p. 1981)
- NTM Response Formats (p. 2038)
- Data Formats for Object2Vec Inference (p. 2052)
- Encoder Embeddings for Object2Vec (p. 2054)
- PCA Response Formats (p. 2103)
- RCF Response Formats (p. 2110)

**Instance Types for Built-in Algorithms**

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.12xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types
can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution.

For more information on SageMaker hardware specifications, see Amazon SageMaker ML Instance Types.

Logs for Built-in Algorithms

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose CloudWatch, choose Logs, and then choose the /aws/sagemaker/TrainingJobs log group. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the TrainingJobName parameter when the job was created.

**Note**

If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm

Common Errors

If a training job fails, some details about the failure are provided by the FailureReason return value in the training job description, as follows:

```python
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

   **From the CloudWatch Log**

   ```
   [10/16/2017 23:45:17 ERROR 139623806805824 train.py:48]
   Additional properties are not allowed (u'mini_batch_siz' was unexpected)
   ```

2. Specifying an invalid value for a hyperparameter.

   **FailureReason**

   ```
   AlgorithmError: u'abc' is not valid under any of the given schemas\n\n   {u'oneOf': [{u'pattern': u'^([1-9][0-9]*)$', u'type': u'string'},
   {u'minimum': 1, u'type': u'integer'}]}
   ```

   **FailureReason**

   ```
   [10/16/2017 23:57:17 ERROR 140373086025536 train.py:48] u'abc' is not valid under any of the given schemas
   ```
3. Inaccurate protobuf file format.

From the CloudWatch log

```
[10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot copy sequence with size 785 to array axis with dimension 784
```

**Built-in SageMaker Algorithms for Tabular Data**

Amazon SageMaker provides built-in algorithms that are tailored to the analysis of tabular data. The built-in SageMaker algorithms for tabular data can be used for either classification or regression problems.

- **AutoGluon-Tabular (p. 1923)**—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- **CatBoost (p. 1930)**—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- **Factorization Machines Algorithm (p. 1938)**—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- **K-Nearest Neighbors (k-NN) Algorithm (p. 1948)**—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.

**AutoGluon-Tabular**

**AutoGluon-Tabular** is a popular open-source AutoML framework that trains highly accurate machine learning models on an unprocessed tabular dataset. Unlike existing AutoML frameworks that primarily focus on model and hyperparameter selection, AutoGluon-Tabular succeeds by ensembling multiple models and stacking them in multiple layers.

**How to use SageMaker AutoGluon-Tabular**

You can use AutoGluon-Tabular as an Amazon SageMaker built-in algorithm. The following section describes how to use AutoGluon-Tabular with the SageMaker Python SDK. For information on how to use AutoGluon-Tabular from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

- **Use AutoGluon-Tabular as a built-in algorithm**

  Use the AutoGluon-Tabular built-in algorithm to build an AutoGluon-Tabular training container as shown in the following code example. You can automatically spot the AutoGluon-Tabular built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 2).

  After specifying the AutoGluon-Tabular image URI, you can use the AutoGluon-Tabular container to construct an estimator using the SageMaker Estimator API and initiate a training job. The AutoGluon-Tabular built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own AutoGluon-Tabular training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "autogluon-regression-ensemble", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    pipeline_name=train_model_id,
    version=train_model_version,
    container_image=train_image_uri,
    instance_type=training_instance_type,
    training_scope=train_scope)
```

1923
framework=None,
model_id=train_model_id,
model_version=train_model_version,
image_scope=train_scope,
instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"
output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["auto_stack"] = "True"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {'training': training_dataset_s3_path}, logs=True, job_name=training_job_name
)
For more information about how to set up the AutoGluon-Tabular as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm
- Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm

Input and Output interface for the AutoGluon-Tabular algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of AutoGluon-Tabular supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be `text/csv`.
- For **Inference ContentType**, valid inputs must be `text/csv`.

**Note**
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the AutoGluon-Tabular model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.
- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then a fraction of your training data is randomly sampled to serve as the validation data. This fraction is selected based on the number of rows in your training data. For more information see Tabular Prediction in the AutoGluon documentation.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker AutoGluon-Tabular uses the `autogluon.tabular.TabularPredictor` module to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker AutoGluon-Tabular with the AutoGluon framework**

- Use the following Python code:

```python
import tarfile
from autogluon.tabular import TabularPredictor
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = TabularPredictor.load(model_file_path)
# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
```
Amazon EC2 instance recommendation for the AutoGluon-Tabular algorithm

SageMaker AutoGluon-Tabular supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker AutoGluon-Tabular currently does not support multi-GPU training.

AutoGluon-Tabular sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AutoGluon-Tabular algorithm.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How AutoGluon-Tabular works

AutoGluon-Tabular performs advanced data processing, deep learning, and multi-layer model ensemble methods. It automatically recognizes the data type in each column for robust data preprocessing, including special handling of text fields.

AutoGluon fits various models ranging from off-the-shelf boosted trees to customized neural networks. These models are ensembled in a novel way: models are stacked in multiple layers and trained in a layer-wise manner that guarantees raw data can be translated into high-quality predictions within a given time constraint. This process mitigates overfitting by splitting the data in various ways with careful tracking of out-of-fold examples.

The AutoGluon-Tabular algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, and distributions. You can use AutoGluon-Tabular for regression, classification (binary and multiclass), and ranking problems.

Refer to the following diagram illustrating how the multi-layer stacking strategy works.
For more information, see *AutoGluon-Tabular: Robust and Accurate AutoML for Structured Data*.

**AutoGluon-Tabular hyperparameters**

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AutoGluon-Tabular algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AutoGluon-Tabular algorithm is an implementation of the open-source AutoGluon-Tabular package.

**Note**

The default hyperparameters are based on example datasets in the AutoGluon-Tabular sample notebooks (p. 1926).

By default, the SageMaker AutoGluon-Tabular algorithm automatically chooses an evaluation metric based on the type of classification problem. The algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error. For binary classification problems, the evaluation metric is area under the receiver operating characteristic curve (AUC). For multiclass classification problems, the evaluation metric is accuracy. You can use the `eval_metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `eval_metric` | The evaluation metric for validation data. If `eval_metric` is set to the default "auto" value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem:  
  - "root_mean_squared_error" for regression  
  - "roc_auc" for binary classification  
  - "accuracy" for multi-class classification |
## Use Built-in Algorithms

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **preset**     | List of preset configurations for various arguments in `fit()`.
|                | - "best_quality": high predictive accuracy, slower inference times and higher disk usage
|                | - "high_quality": high predictive accuracy and fast inference
|                | - "good_quality": good predictive accuracy and very fast inference
|                | - "medium_quality": medium predictive accuracy, very fast inference and training time
|                | - "optimize_for_deployment": delete unused models and remove training artifacts
|                | - "interpretable": fits only interpretable rule-based models from the `imodels` package
|                | For more details, see AutoGluon Predictors.
|                | Valid values: string, any of the following: ("best_quality", "high_quality", "good_quality", "medium_quality", "optimize_for_deployment", or "interpretable").
|                | Default value: "medium_quality". |
| **auto_stack** | Whether AutoGluon should automatically utilize bagging and multi-layer stack ensembling to boost predictive accuracy. Set `auto_stack` to "True" if you are willing to tolerate longer training times in order to maximize predictive accuracy. This automatically sets the `num_bag_folds` and `num_stack_levels` arguments based on dataset properties.
|                | Valid values: string, "True" or "False".
|                | Default value: "False". |
| **num_bag_folds** | Number of folds used for bagging of models. When `num_bag_folds` is equal to `k`, training time is roughly increased by a factor of `k`. Set `num_bag_folds` to 0 to deactivate bagging. This is disabled by default, but we recommend using values between 5 and 10 to maximize predictive performance. Increasing `num_bag_folds` results in models with lower bias, but that are more prone to overfitting. One is an invalid value for this parameter, and will raise a `ValueError`. Values greater than 10 may produce diminishing returns and can even harm overall results due to overfitting. To further improve predictions, avoid increasing `num_bag_folds` and instead increase `num_bag_sets`.
|                | Valid values: string, any integer between (and including) "0" and "10".
<p>|                | Default value: &quot;0&quot;. |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_bag_sets</td>
<td>Number of repeats of kfold bagging to perform (values must be greater than or equal to 1). The total number of models trained during bagging is equal to num_bag_folds * num_bag_sets. This parameter defaults to one if time_limit is not specified. This parameter is disabled if num_bag_folds is not specified. Values greater than one result in superior predictive performance, especially on smaller problems and with stacking enabled. Valid values: integer, range: [1, 20]. Default value: 1.</td>
</tr>
<tr>
<td>num_stack_levels</td>
<td>Number of stacking levels to use in stack ensemble. Roughly increases model training time by factor of num_stack_levels + 1. Set this parameter to 0 to deactivate stack ensembling. This parameter is deactivated by default, but we recommend using values between 1 and 3 to maximize predictive performance. To prevent overfitting and a ValueError, num_bag_folds must be greater than or equal to 2. Valid values: float, range: [0, 3]. Default value: 0.</td>
</tr>
<tr>
<td>refit_full</td>
<td>Whether or not to retrain all models on all of the data (training and validation) after the normal training procedure. For more details, see AutoGluon Predictors.                                                                                                                       Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>set_best_to_refit_full</td>
<td>Whether or not to change the default model that the predictor uses for prediction. If set_best_to_refit_full is set to &quot;True&quot;, the default model changes to the model that exhibited the highest validation score as a result of refitting (activated by refit_full). Only valid if refit_full is set. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>save_space</td>
<td>Whether or not to reduce the memory and disk size of predictor by deleting auxiliary model files that aren't needed for prediction on new data. This has no impact on inference accuracy. We recommend setting save_space to &quot;True&quot; if the only goal is to use the trained model for prediction. Certain advanced functionality may no longer be available if save_space is set to &quot;True&quot;. Refer to the predictor.save_space() documentation for more details. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
</tbody>
</table>
### Parameter Name | Description
--- | ---
verbosity | The verbosity of print messages. *verbosity* levels range from 0 to 4, with higher levels corresponding to more detailed print statements. A *verbosity* of 0 suppresses warnings.

Valid values: integer, any of the following: (0, 1, 2, 3, or 4).

Default value: 2.

---

**Tuning an AutoGluon-Tabular model**

Although AutoGluon-Tabular can be used with model tuning, its design can deliver good performance using stacking and ensemble methods, meaning hyperparameter optimization is not necessary. Rather than focusing on model tuning, AutoGluon-Tabular succeeds by stacking models in multiple layers and training in a layer-wise manner.

For more information about AutoGluon-Tabular hyperparameters, see AutoGluon-Tabular hyperparameters (p. 1927).

**CatBoost**

*CatBoost* is a popular and high-performance open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.

CatBoost introduces two critical algorithmic advances to GBDT:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

**How to use SageMaker CatBoost**

You can use CatBoost as an Amazon SageMaker built-in algorithm. The following section describes how to use CatBoost with the SageMaker Python SDK. For information on how to use CatBoost from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

- **Use CatBoost as a built-in algorithm**

  Use the CatBoost built-in algorithm to build a CatBoost training container as shown in the following code example. You can automatically spot the CatBoost built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the CatBoost image URI, you can use the CatBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. The CatBoost built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own CatBoost training scripts.

  ```python
  from sagemaker import image_uris, model_uris, script_uris

  train_model_id, train_model_version, train_scope = "catboost-classification-model", "+", "training"
  ```

---

1930
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["iterations"] = "500"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
For more information about how to set up CatBoost as a built-in algorithm, see the following notebook examples:

- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

Input and Output interface for the CatBoost algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of CatBoost supports CSV for training and inference:

- For Training ContentType, valid inputs must be text/csv.
- For Inference ContentType, valid inputs must be text/csv.

Note

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the CatBoost model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- **Training data input format:** Your training data should be in a subdirectory named train/ that contains a data.csv file. The target variables should be in the first column of data.csv. The predictor variables (features) should be in the remaining columns.

- **Validation data input format:** You can optionally include another directory called validation/ that also has a data.csv file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.

- **Categorical features input format:** If your predictors include categorical features, you can provide a JSON file named categorical_index.json in the same location as your data directories. This file should contain a Python dictionary where the key is the string "cat_index_list" and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the Int32.MaxValue (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the InstanceType) must be able to hold the training dataset.

SageMaker CatBoost uses the catboost.CatBoostClassifier and catboost.CatBoostRegressor modules to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker CatBoost with catboost**

- Use the following Python code:

```python
import tarfile
```
from catboost import CatBoostClassifier

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

file_path = os.path.join(model_file_path, "model")
model = CatBoostClassifier()
model.load_model(file_path)

# prediction with test data
# dtest should be a pandas DataFrame with columns feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)

Amazon EC2 instance recommendation for the CatBoost algorithm

SageMaker CatBoost currently only trains using CPUs. CatBoost is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, CS). Further, we recommend that you have enough total memory in selected instances to hold the training data.

CatBoost sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker CatBoost algorithm.

<table>
<thead>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How CatBoost Works

CatBoost implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two critical algorithmic advances:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

The CatBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use CatBoost for regression, classification (binary and multiclass), and ranking problems.
For more information on gradient boosting, see How XGBoost Works (p. 1995). For in-depth details about the additional GOSS and EFB techniques used in the CatBoost method, see CatBoost: unbiased boosting with categorical features.

CatBoost hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker CatBoost algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker CatBoost algorithm is an implementation of the open-source CatBoost package.

*Note*
The default hyperparameters are based on example datasets in the CatBoost sample notebooks (p. 1933).

By default, the SageMaker CatBoost algorithm automatically chooses an evaluation metric and loss function based on the type of classification problem. The CatBoost algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric and loss functions are both root mean squared error. For binary classification problems, the evaluation metric is Area Under the Curve (AUC) and the loss function is log loss. For multiclass classification problems, the evaluation metric and loss functions are multiclass cross entropy. You can use the eval_metric hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

<table>
<thead>

verbose | The verbosity of print messages, with higher levels corresponding to more detailed print statements. Valid values: integer, range: Positive integer. Default value: 1.

Tune a CatBoost model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

**Note**
The learning loss function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see CatBoost hyperparameters (p. 1934).

- A learning loss function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**
Automatic model tuning for CatBoost is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

Evaluation metrics computed by the CatBoost algorithm

The SageMaker CatBoost algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For a

Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.
Note
The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

Topics
- Input/Output Interface for the Factorization Machines Algorithm (p. 1939)
- EC2 Instance Recommendation for the Factorization Machines Algorithm (p. 1939)
- Factorization Machines Sample Notebooks (p. 1939)
- How Factorization Machines Work (p. 1940)
- Factorization Machines Hyperparameters (p. 1940)
- Tune a Factorization Machines Model (p. 1945)
- Factorization Machines Response Formats (p. 1947)

Input/Output Interface for the Factorization Machines Algorithm

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the test channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For training, the Factorization Machines algorithm currently supports only the recordIO-protobuf format with Float32 tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For inference, the Factorization Machines algorithm supports the application/json and x-recordio-protobuf formats.

- For the binary classification problem, the algorithm predicts a score and a label. The label is a number and can be either 0 or 1. The score is a number that indicates how strongly the algorithm believes that the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.
- For the regression problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.

Please see Factorization Machines Sample Notebooks (p. 1939) for more details on training and inference file formats.

EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data. The Factorization Machines algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.
How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function \( \hat{y} \) from a feature set \( x_i \) to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset \((x_i,y_j)\) available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

\[
\hat{y} = w_0 + \sum_i w_i x_i + \sum_{i<j} <v_i,v_j> x_i x_j
\]

The three terms in this equation correspond respectively to the three components of the model:

- The \( w_0 \) term represents the global bias.
- The \( w_i \) linear terms model the strength of the \( i^{th} \) variable.
- The \(<v_i,v_j>\) factorization terms model the pairwise interaction between the \( i^{th} \) and \( j^{th} \) variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see Factorization Machines.

For regression tasks, the model is trained by minimizing the squared error between the model prediction \( \hat{y}_n \) and the target value \( y_n \). This is known as the square loss:

\[
L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2
\]

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

\[
L = \frac{1}{N} \sum_n [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)]
\]

where:

\[
\hat{p}_n = \frac{1}{1 + e^{-\hat{y}_n}}
\]

For more information about loss functions for classification, see Loss functions for classification.

Factorization Machines Hyperparameters

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>feature_dim</td>
<td>The dimension of the input feature space. This could be very high with sparse input.</td>
</tr>

<td>Range for initialization of the bias term. Takes effect if bias_init_method is set to uniform.</td>
</tr>
<tr>
<td>bias_init_sigma</td>
<td>The standard deviation for initialization of the bias term. Takes effect if bias_init_method is set to normal.</td>
</tr>
</tbody>
</table>

**Parameter Name**
- **num_factors**: The dimensionality of factorization.

**Description**
- **num_factors**: Valid values: Positive integer. Suggested value range: [10000, 10000000]

**predictor_type**
- The type of predictor.

**Description**
- **predictor_type**: Valid values: String: binary_classifier or regressor

**bias_init_method**
- The initialization method for the bias term:

**Description**
- **bias_init_method**: Valid values: uniform, normal, or constant

**bias_init_scale**
- Range for initialization of the bias term. Takes effect if bias_init_method is set to uniform.

**Description**
- **bias_init_scale**: Valid values: Non-negative float. Suggested value range: [1e-8, 512].

**bias_init_sigma**
- The standard deviation for initialization of the bias term. Takes effect if bias_init_method is set to normal.

**Description**
- **bias_init_sigma**: Valid values: Non-negative float. Suggested value range: [1e-8, 512].

### Tune a Factorization Machines Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2360).

### Metrics Computed by the Factorization Machines Algorithm

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a test:rmse regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

<table>

Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: uniform, normal, and constant. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is uniform, then only the scale parameters are tunable. Specifically, if bias_init_method==uniform, then bias_init_scale, linear_init_scale, and factors_init_scale are tunable. Similarly, if the initialization method is normal, then only sigma parameters are tunable. If the initialization method is constant, then only value parameters are tunable. These dependencies are listed in the following table.

**Factorization Machines Response Formats**

**JSON Response Format**

Binary classification

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

Regression

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

**JSONLINES Response Format**

Binary classification

```javascript
{"score": 0.4, "predicted_label": 0}
```

Regression

```javascript
{"score": 0.4}
```
RECORDIO Response Format

Binary classification

```
[  
  Record = {
    features = {},
    label = {
      'score': {
        keys: [],
        values: [0.4]  # float32
      },
      'predicted_label': {
        keys: [],
        values: [0.0]  # float32
      }
    }
  }
]
```

Regression

```

  Record = {
    features = {},
    label = {
      'score': {
        keys: [],
        values: [0.4]  # float32
      }
    }
  }
]
```

K-Nearest Neighbors (k-NN) Algorithm

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the $k$ points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the $k$ closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional ($d >1000$) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN's training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the $k$ nearest points to use for inference.

Input/Output Interface for the k-NN Algorithm

SageMaker k-NN supports train and test data channels.

• Use a **train channel** for data that you want to sample and construct into the k-NN index.
• Use a **test channel** to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for classifier, mean-squared error (mse) for regressor for score.

For training inputs, k-NN supports **text/csv** and **application/x-recordio-protobuf** data formats. For input type **text/csv**, the first **label_size** columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference inputs, k-NN supports the **application/json**, **application/x-recordio-protobuf**, and **text/csv** data formats. The **text/csv** format accepts a **label_size** and encoding parameter. It assumes a **label_size** of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the **application/json** and **application/x-recordio-protobuf** data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.

For batch transform, k-NN supports the **application/jsonlines** data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines
{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

An example output is as follows:

```
accept: application/jsonlines
{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see Data Formats for k-NN Training Input (p. 1953) for training, k-NN Request and Response Formats (p. 1954) for inference, and the k-NN Sample Notebooks (p. 1949).

k-NN Sample Notebooks

For a sample notebook that uses the SageMaker k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the K-Nearest Neighbor Covertype.

Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the Introduction to Amazon algorithms section. To open a notebook, click on its **Use** tab and select **Create copy**.
How the k-NN Algorithm Works

Step 1: Sample

To specify the total number of data points to be sampled from the training dataset, use the `sample_size` parameter. For example, if the initial dataset has 1,000 data points and the `sample_size` is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

Step 2: Perform Dimension Reduction

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the `dimension_reduction_type` hyperparameter. The `sign` method specifies a random projection, which uses a linear projection using a matrix of random signs, and the `fjlt` method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The `fjlt` method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The `sign` method requires $O(ndk)$ time to reduce the dimension of a batch of $n$ points of dimension $d$ into a target dimension $k$. The `fjlt` method requires $O(nd \log(d))$ time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

Step 3: Build an Index

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the `index_type` parameter.

Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- `model_algo-1`: Contains the serialized index for computing the nearest neighbors.
- `model_algo-1.labels`: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
- `model_algo-1.json`: Contains the JSON-formatted model metadata which stores the $k$ and `predictor_type` hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change $k$ to 10 or change `predictor_type` to `regressor`.

```json
{
    "k": 5,
    "predictor_type": "classifier",
    "dimension_reduction": {
        "type": "sign",
        "seed": 3,
        "target_dim": 10,
        "input_dim": 20
    },
    "normalize": false,
    "version": "1.0"
}
```

EC2 Instance Recommendation for the k-NN Algorithm

We recommend training on a CPU instance (such as ml.m5.2xlarge) or on a GPU instance. The k-NN algorithm supports P2, P3, G4dn, and G5 GPU instance families for training and inference.
Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

### k-NN Hyperparameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>feature_dim</td>
<td>The number of features in the input data. Required Valid values: positive integer.</td>
</tr>
<tr>
<td>k</td>
<td>The number of nearest neighbors. Required Valid values: positive integer.</td>
</tr>
<tr>
<td>predictor_type</td>
<td>The type of inference to use on the data labels. Required Valid values: classifier for classification or regressor for regression.</td>
</tr>
<tr>
<td>sample_size</td>
<td>The number of data points to be sampled from the training data set. Required Valid values: positive integer</td>
</tr>
<tr>
<td>dimension_reduction_target</td>
<td>The target dimension to reduce to. Required when you specify the dimension_reduction_type parameter. Valid values: positive integer greater than 0 and less than feature_dim.</td>
</tr>
<tr>
<td>dimension_reduction_type</td>
<td>The type of dimension reduction method. Optional Valid values: sign for random projection or fjlt for the fast Johnson-Lindenstrauss transform. Default value: No dimension reduction</td>
</tr>
<tr>
<td>faiss_index_ivf_nlists</td>
<td>The number of centroids to construct in the index when index_type is faiss.IVFFlat or faiss.IVFPQ. Optional Valid values: positive integer Default value: auto, which resolves to sqrt(sample_size).</td>
</tr>
<tr>
<td>faiss_index_pq_m</td>
<td>The number of vector sub-components to construct in the index when index_type is set to faiss.IVFPQ.</td>
</tr>
</tbody>
</table>
Parameter Name | Description
--- | ---
The FaceBook AI Similarity Search (FAISS) library requires that the value of `faiss_index_pq_m` is a divisor of the data dimension. If `faiss_index_pq_m` is not a divisor of the data dimension, we increase the data dimension to smallest integer divisible by `faiss_index_pq_m`. If no dimension reduction is applied, the algorithm adds a padding of zeros. If dimension reduction is applied, the algorithm increase the value of the `dimension_reduction_target` hyper-parameter.

Optional
Valid values: One of the following positive integers: 1, 2, 3, 4, 8, 12, 16, 20, 24, 28, 32, 40, 48, 56, 64, 96

index_metric | The metric to measure the distance between points when finding nearest neighbors. When training with `index_type` set to `faiss.IVFPQ`, the `INNER_PRODUCT` distance and `COSINE` similarity are not supported.

Optional
Valid values: `L2` for Euclidean-distance, `INNER_PRODUCT` for inner-product distance, `COSINE` for cosine similarity.
Default value: `L2`

index_type | The type of index.

Optional
Valid values: `faiss.Flat`, `faiss.IVFFlat`, `faiss.IVFPQ`.
Default values: `faiss.Flat`

mini_batch_size | The number of observations per mini-batch for the data iterator.

Optional
Valid values: positive integer
Default value: 5000

### Tune a k-NN Model

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.
For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

**Metrics Computed by the k-NN Algorithm**

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the `predictor_type` hyper-parameter.

- **classifier** specifies a classification task and computes `test:accuracy`
- **regressor** specifies a regression task and computes `test:mse`.

Choose the `predictor_type` value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:accuracy</td>
<td>When <code>predictor_type</code> is set to <code>classifier</code>, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The accuracy reported ranges from 0.0 (0%) to 1.0 (100%).</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:mse</td>
<td>When <code>predictor_type</code> is set to <code>regressor</code>, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The mean squared error is computed by comparing the two labels.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

**Tunable k-NN Hyperparameters**

Tune the Amazon SageMaker k-nearest neighbor model with the following hyperparameters.

<table>

**Data Formats for k-NN Training Input**

All Amazon SageMaker built-in algorithms adhere to the common input training formats described in Common Data Formats - Training. This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

**CSV Data Format**

```
content-type: text/csv; label_size=1
```

```
4,1.2,1.3,9.6,20.3
```

The first `label_size` columns are interpreted as the label vector for that row.
RECORDIO Data Format
content-type: application/x-recordio-protobuf

```
[  
  Record = {  
    features = {  
      'values': {  
        values: [1.2, 1.3, 9.6, 20.3]  # float32  
      }  
    },  
    label = {  
      'values': {  
        values: [4]  # float32  
      }  
    }  
  }  
]
```

k-NN Request and Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

INPUT: CSV Request Format
content-type: text/csv

```
1.2,1.3,9.6,20.3
```

This accepts a label_size or encoding parameter. It assumes a label_size of 0 and a utf-8 encoding.

INPUT: JSON Request Format
content-type: application/json

```
{
  "instances": [
    {"data": {"features": {"values": [-3, -1, -4, 2]}},
    {"features": [3.0, 0.1, 0.04, 0.002]}}
  ]
}
```

INPUT: JSONLINES Request Format
content-type: application/jsonlines

```
{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

INPUT: RECORDIO Request Format
content-type: application/x-recordio-protobuf

```
[  
  Record = {  
    features = {
```
'values': {
    'values': [-3, -1, -4, 2]  # float32
},
'features': {
    'values': {
        'values': [3.0, 0.1, 0.04, 0.002]  # float32
    },
    'label': {}
},
'Record': {
    'features': {
        'values': {
            'values': [3.0, 0.1, 0.04, 0.002]  # float32
        },
        'label': {}
    }
}

OUTPUT: JSON Response Format

accept: application/json

{
    "predictions": [
        {"predicted_label": 0.0},
        {"predicted_label": 2.0}
    ]
}

OUTPUT: JSONLINES Response Format

accept: application/jsonlines

{"predicted_label": 0.0}
{"predicted_label": 2.0}

OUTPUT: VERBOSE JSON Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/json; verbose=true

{
    "predictions": [
        {
            "predicted_label": 0.0,
            "distances": [3.11792408, 3.89746071, 6.32548437],
            "labels": [0.0, 1.0, 0.0]
        },
        {
            "predicted_label": 2.0,
            "distances": [1.08470316, 3.04917915, 5.25393973],
            "labels": [2.0, 2.0, 0.0]
        }
    ]
}

OUTPUT: RECORDIO-PROTOBUF Response Format

content-type: application/x-recordio-protobuf

[ 1955]
Record = {
    features = {},
    label = {
        'predicted_label': {
            values: [0.0] # float32
        }
    }
},
Record = {
    features = {},
    label = {
        'predicted_label': {
            values: [2.0] # float32
        }
    }
},
]

OUTPUT: VERBOSE RECORDIO-PROTOBUF Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/x-recordio-protobuf; verbose=true

[
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [0.0] # float32
            },
            'distances': {
                values: [3.11792408, 3.89746071, 6.32548437] # float32
            },
            'labels': {
                values: [0.0, 1.0, 0.0] # float32
            }
        }
    },
    Record = {
        features = {},
        label = {
            'predicted_label': {
                values: [0.0] # float32
            },
            'distances': {
                values: [1.08470316, 3.04917915, 5.25393973] # float32
            },
            'labels': {
                values: [2.0, 2.0, 0.0] # float32
            }
        }
    }
]

SAMPLE OUTPUT for the k-NN Algorithm

For regressor tasks:

[06/08/2018 20:15:33 INFO 140026520049408] #test_score (algo-1) : ('mse', 0.01333333333333334)
For classifier tasks:

```
[06/08/2018 20:15:46 INFO 140285487171328] #test_score (algo-1) : ('accuracy', 0.98666666666666669)
```

**LightGBM**

LightGBM is a popular and efficient open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. LightGBM uses additional techniques to significantly improve the efficiency and scalability of conventional GBDT.

**How to use SageMaker LightGBM**

You can use LightGBM as an Amazon SageMaker built-in algorithm. The following section describes how to use LightGBM with the SageMaker Python SDK. For information on how to use LightGBM from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

- **Use LightGBM as a built-in algorithm**

  Use the LightGBM built-in algorithm to build a LightGBM training container as shown in the following code example. You can automatically spot the LightGBM built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the LightGBM image URI, you can use the LightGBM container to construct an estimator using the SageMaker Estimator API and initiate a training job. The LightGBM built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own LightGBM training scripts.

    ```python
    from sagemaker import image_uris, model_uris, script_uris

    train_model_id, train_model_version, train_scope = "lightgbm-classification-model", ",", ",training"
    training_instance_type = "ml.m5.xlarge"

    # Retrieve the docker image
    train_image_uri = image_uris.retrieve(  
        region=None,  
        framework=None,  
        model_id=train_model_id,  
        model_version=train_model_version,  
        image_scope=train_scope,  
        instance_type=training_instance_type
    )

    # Retrieve the training script
    train_source_uri = script_uris.retrieve(  
        model_id=train_model_id,  
        model_version=train_model_version,  
        script_scope=train_scope
    )

    train_model_uri = model_uris.retrieve(  
        model_id=train_model_id,  
        model_version=train_model_version,  
        model_scope=train_scope
    )

    # Sample training data is available in this bucket
    training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
    training_data_prefix = "training-datasets/tabular_multiclass/"

    training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"
    ```
output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["num_boost_round"] = "500"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data

# Create SageMaker Estimator instance

# Launch a SageMaker Training job by passing the S3 path of the training data

For more information about how to set up the LightGBM as a built-in algorithm, see the following notebook examples.
- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

Input and Output interface for the LightGBM algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of LightGBM supports CSV for training and inference:
- For **Training ContentType**, valid inputs must be text/csv.
- For **Inference ContentType**, valid inputs must be text/csv.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

Be mindful of how to format your training data for input to the LightGBM model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.

- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.

- **Categorical features input format**: If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data directories. This file should contain a Python dictionary where the key is the string "cat_index_list" and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker LightGBM uses the Python Joblib module to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker LightGBM with the JobLib module**

- Use the following Python code:

```python
import joblib
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = joblib.load(model_file_path)
# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)
```

**Amazon EC2 instance recommendation for the LightGBM algorithm**

SageMaker LightGBM currently only trains using CPUs. LightGBM is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

**LightGBM sample notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker LightGBM algorithm.
Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm

This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular classification model.

Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular regression model.

How LightGBM works

LightGBM implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two novel techniques: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB). These techniques are designed to significantly improve the efficiency and scalability of GBDT.

The LightGBM algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use LightGBM for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How XGBoost Works (p. 1995). For in-depth details about the additional GOSS and EFB techniques used in the LightGBM method, see LightGBM: A Highly Efficient Gradient Boosting Decision Tree.

LightGBM hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker LightGBM algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker LightGBM algorithm is an implementation of the open-source LightGBM package.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_boost_round</td>
<td>The maximum number of boosting iterations. <strong>Note:</strong> Internally, LightGBM constructs num_class * num_boost_round trees for multi-class classification problems.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>early_stopping_rounds</td>
<td>The training will stop if one metric of one validation data point does not improve in the last early_stopping_rounds round. If early_stopping_rounds is less than or equal to zero, this hyperparameter is ignored. Valid values: integer. Default value: 10.</td>
</tr>
</tbody>
</table>
| metric              | The evaluation metric for validation data. If metric is set to the default "auto" value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem:  
  - rmse for regression  
  - binary_logloss for binary classification  
  - multi_logloss for multi-class classification  
  Valid values: string, any of the following: ("auto", "rmse", "l1", "l2", "huber", "fair", "binary_logloss", "binary_error", "auc", "average_precision", "multi_logloss", "multi_error", "auc_mu", or "cross_entropy"). Default value: "auto". |
<p>| learning_rate       | The rate at which the model weights are updated after working through each batch of training examples. Valid values: float, range: (0.0, 1.0). Default value: 0.1. |
| num_leaves          | The maximum number of leaves in one tree. Valid values: integer, range: (1, 131072). Default value: 64. |
| feature_fraction    | A subset of features to be selected on each iteration (tree). Must be less than 1.0. Valid values: float, range: (0.0, 1.0). Default value: 0.9. |
| bagging_fraction    | A subset of features similar to feature_fraction, but bagging_fraction randomly selects part of the data without resampling. Valid values: float, range: (0.0, 1.0]. Default value: 0.9. |</p>

</tbody>
</table>
Parameter Name | Description
--- | ---
verbosity | The verbosity of print messages. If the verbosity is less than 0, then print messages only show fatal errors. If verbosity is set to 0, then print messages include errors and warnings. If verbosity is 1, then print messages show more information. A verbosity greater than 1 shows the most information in print messages and can be used for debugging.

Valid values: integer.
Default value: 1.

Tune a LightGBM model

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

**Note**
The learning objective function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see LightGBM hyperparameters (p. 1960).

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your specified hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**
Automatic model tuning for LightGBM is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

**Evaluation metrics computed by the LightGBM algorithm**

The SageMaker LightGBM algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

<table>
<thead>
<tr>

**Tunable LightGBM hyperparameters**

Tune the LightGBM model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the LightGBM evaluation metrics are: learning_rate, num_leaves, feature_fraction, bagging_fraction, bagging_freq, max_depth and min_data_in_leaf. For a list of all the LightGBM hyperparameters, see LightGBM hyperparameters (p. 1960).

Linear Learner Algorithm

*Linear models* are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples \((x, y)\). \(x\) is a high-dimensional vector and \(y\) is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to \(num\_classes - 1\). For regression problems, \(y\) is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector \(x\) to an approximation of the label \(y\).

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see [CreateTrainingJob](#). You can specify additional parameters in the `HyperParameters` string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you're using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

**Topics**

- Input/Output interface for the linear learner algorithm (p. 1966)
- EC2 instance recommendation for the linear learner algorithm (p. 1967)
- Linear learner sample notebooks (p. 1967)
- How linear learner works (p. 1968)
- Linear learner hyperparameters (p. 1968)
- Tune a linear learner model (p. 1977)
- Linear learner response formats (p. 1981)

**Input/Output interface for the linear learner algorithm**

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the `S3DataDistributionType` should be `FullyReplicated`. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

For training, the linear learner algorithm supports both `recordIO-wrapped protobuf` and `CSV` formats. For the `application/x-recordio-protobuf` input type, only `Float32` tensors are supported. For the `text/csv` input type, the first column is assumed to be the label, which is the target.
variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, the linear learner algorithm supports the application/json, application/x-recordio-protobuf, and text/csv formats. When you make predictions on new data, the format of the response depends on the type of model. For regression (`predictor_type='regressor'`), the score is the prediction produced by the model. For classification (`predictor_type='binary_classifier'` or `predictor_type='multiclass_classifier'`), the model returns a score and also a predicted_label. The `predicted_label` is the class predicted by the model and the score measures the strength of that prediction.

- For binary classification, `predicted_label` is 0 or 1, and `score` is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- For multiclass classification, the `predicted_class` will be an integer from 0 to `num_classes-1`, and `score` will be a list of one floating point number per class.

To interpret the `score` in classification problems, you have to consider the loss function used. If the `loss` hyperparameter value is `logistic` for binary classification or `softmax_loss` for multiclass classification, then the score can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the `loss` value is auto default value. But if the loss is set to `hinge_loss`, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats (p. 1981). For more information on inference formats, and the Linear learner sample notebooks (p. 1967).

**EC2 instance recommendation for the linear learner algorithm**

The linear learner algorithm supports both CPU and GPU instances for training and inference. For GPU, the linear learner algorithm supports P2, P3, G4dn, and G5 GPU families.

During testing, we have not found substantial evidence that multi-GPU instances are faster than single-GPU instances. Results can vary, depending on your specific use case.

**Linear learner sample notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

<table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the
SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the *Introduction to Amazon algorithms* section. To open a notebook, choose its **Use** tab and choose **Create copy**.

**How linear learner works**

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate.

**Step 1: Preprocess**

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

**Note**

For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the `normalize_data` and `normalize_label` hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

**Step 2: Train**

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

**Step 3: Validate and set the threshold**

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.

**Note**

If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

**Linear learner hyperparameters**

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to `auto`, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>The number of classes for the response variable. The algorithm assumes that classes are labeled 0, ..., num_classes - 1. Required when predictor_type is multiclass_classifier. Otherwise, the algorithm ignores it. Valid values: Integers from 3 to 1,000,000</td>
</tr>
<tr>
<td>predictor_type</td>
<td>Specifies the type of target variable as a binary classification, multiclass classification, or regression. Required Valid values: binary_classifier, multiclass_classifier, or regressor</td>
</tr>
<tr>
<td>accuracy_top_k</td>
<td>When computing the top-k accuracy metric for multiclass classification, the value of k. If the model assigns one of the top-k scores to the true label, an example is scored as correct. Optional Valid values: Positive integers Default value: 3</td>
</tr>
<tr>
<td>balance_multiclass_weights</td>
<td>Specifies whether to use class weights, which give each class equal importance in the loss function. Used only when the predictor_type is multiclass_classifier. Optional Valid values: true, false Default value: false</td>
</tr>
<tr>
<td>beta_1</td>
<td>The exponential decay rate for first-moment estimates. Applies only when the optimizer value is adam. Optional Valid values: auto or floating-point value between 0 and 1.0 Default value: auto</td>
</tr>
<tr>
<td>beta_2</td>
<td>The exponential decay rate for second-moment estimates. Applies only when the optimizer value is adam. Optional Valid values: auto or floating-point integer between 0 and 1.0 Default value: auto</td>
</tr>
<tr>
<td>bias_lr_mult</td>
<td>Allows a different learning rate for the bias term. The actual learning rate for the bias is learning_rate * bias_lr_mult. Optional</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>bias_wd_mult</td>
<td>Allows different regularization for the bias term. The actual L2 regularization weight for the bias is $\text{wd} \times \text{bias_wd_mult}$. By default, there is no regularization on the bias term. <strong>Optional</strong> Valid values: auto or non-negative floating-point integer Default value: auto</td>
</tr>
<tr>
<td>binary_classifier_model_selection_criteria</td>
<td>When <code>predictor_type</code> is set to <code>binary_classifier</code>, the model evaluation criteria for the validation dataset (or for the training dataset if you don’t provide a validation dataset). Criteria include: • accuracy—The model with the highest accuracy. • f_beta—The model with the highest F1 score. The default is F1. • precision_at_target_recall—The model with the highest precision at a given recall target. • recall_at_target_precision—The model with the highest recall at a given precision target. • loss_function—The model with the lowest value of the loss function used in training. <strong>Optional</strong> Valid values: accuracy, f_beta, precision_at_target_recall, recall_at_target_precision, or loss_function Default value: accuracy</td>
</tr>
<tr>
<td>early_stopping_patience</td>
<td>If no improvement is made in the relevant metric, the number of epochs to wait before ending training. If you have provided a value for <code>binary_classifier_model_selection_criteria</code>, the metric is that value. Otherwise, the metric is the same as the value specified for the loss hyperparameter. The metric is evaluated on the validation data. If you haven’t provided validation data, the metric is always the same as the value specified for the loss hyperparameter and is evaluated on the training data. To disable early stopping, set <code>early_stopping_patience</code> to a value greater than the value specified for <code>epochs</code>. <strong>Optional</strong> Valid values: Positive integer Default value: 3</td>
</tr>
<tr>

</table>
| init_method    | Sets the initial distribution function used for model weights. Functions include:  
• uniform—Uniformly distributed between (-scale, +scale)  
• normal—Normal distribution, with mean 0 and sigma  
Optional  
Valid values: uniform or normal  
Default value: uniform |
| init_scale     | Scales an initial uniform distribution for model weights. Applies only when the init_method hyperparameter is set to uniform.  
Optional  
Valid values: Positive floating-point integer  
Default value: 0.07 |
| init_sigma     | The initial standard deviation for the normal distribution. Applies only when the init_method hyperparameter is set to normal.  
Optional  
Valid values: Positive floating-point integer  
Default value: 0.01 |
| l1             | The L1 regularization parameter. If you don't want to use L1 regularization, set the value to 0.  
Optional  
Valid values: auto or non-negative float  
Default value: auto |
| learning_rate  | The step size used by the optimizer for parameter updates.  
Optional  
Valid values: auto or positive floating-point integer  
Default value: auto, whose value depends on the optimizer chosen. |
**Parameter Name** | **Description**
--- | ---
**loss** | Specifies the loss function. The available loss functions and their default values depend on the value of `predictor_type`:
- If the `predictor_type` is set to `regressor`, the available options are `auto`, `squared_loss`, `absolute_loss`, `eps_insensitive_squared_loss`, `eps_insensitive_absolute_loss`, `quantile_loss`, and `huber_loss`. The default value for `auto` is `squared_loss`.
- If the `predictor_type` is set to `binary_classifier`, the available options are `auto`, `logistic`, and `hinge_loss`. The default value for `auto` is `logistic`.
- If the `predictor_type` is set to `multiclass_classifier`, the available options are `auto` and `softmax_loss`. The default value for `auto` is `softmax_loss`.

Valid values: `auto`, `logistic`, `squared_loss`, `absolute_loss`, `hinge_loss`, `eps_insensitive_squared_loss`, `eps_insensitive_absolute_loss`, `quantile_loss`, or `huber_loss`  
Optional  
Default value: `auto`

**loss_insensitivity** | The parameter for the epsilon-insensitive loss type. During training and metric evaluation, any error smaller than this value is considered to be zero.  
Optional  
Valid values: Positive floating-point integer  
Default value: 0.01

**lr_scheduler_factor** | For every `lr_scheduler_step` hyperparameter, the learning rate decreases by this quantity. Applies only when the `use_lr_scheduler` hyperparameter is set to `true`.  
Optional  
Valid values: `auto` or positive floating-point integer between 0 and 1  
Default value: `auto`

**lr_scheduler_minimum_lr** | The learning rate never decreases to a value lower than the value set for `lr_scheduler_minimum_lr`. Applies only when the `use_lr_scheduler` hyperparameter is set to `true`.  
Optional  
Valid values: `auto` or positive floating-point integer  
Default values: `auto`

**Tune a linear learner model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, `num_models`, to 1. The algorithm ignores any value that you set for `num_models`.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2360).

### Metrics computed by the linear learner algorithm

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.

| Metric Name | Description | Optimization Direction |
--- | --- | ---
**test:absolute_loss** | The absolute loss of the final model on the test dataset. This objective metric is only valid for regression. | Minimize |
**test:binary_classification_accuracy** | The accuracy of the final model on the test dataset. This objective metric is only valid for binary classification. | Maximize |
**test:binary_f_beta** | The F-beta score of the final model on the test dataset. By default, it is the F1 score, which is the harmonic mean of precision and recall. This objective metric is only valid for binary classification. | Maximize |
<table>

### Linear learner response formats

#### JSON response formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. The following are the available output formats for the SageMaker linear learner algorithm.

#### Binary Classification

```json
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

#### Multiclass Classification

```json
let response = {
  "predictions": [
    {
      "score": [0.1, 0.2, 0.4, 0.3],
      "predicted_label": 2
    }
  ]
}
```

#### Regression

```json
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

#### JSONLINES response formats

#### Binary Classification

```json
{"score": 0.4, "predicted_label": 0}
```

#### Multiclass Classification
Regression

["score": 0.4]

RECORDIO response formats

Binary Classification

[ Record = {
    features = {},
    label = {
        'score': {
            keys: [],
            values: [0.4]  # float32
        },
        'predicted_label': {
            keys: [],
            values: [0.0]  # float32
        }
    }
} ]

Multiclass Classification

[ Record = {
    "features": [],
    "label": {
        "score": {
            "values": [0.1, 0.2, 0.3, 0.4]
        },
        "predicted_label": {
            "values": [3]
        }
    },
    "uid": "abc123",
    "metadata": "{created_at: '2017-06-03'}"
} ]

Regression

[ Record = {
    features = {},
    label = {
        'score': {
            keys: [],
            values: [0.4]  # float32
        }
    }
} ]
TabTransformer

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer architecture is built on self-attention-based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

How to use SageMaker TabTransformer

You can use TabTransformer as an Amazon SageMaker built-in algorithm. The following section describes how to use TabTransformer with the SageMaker Python SDK. For information on how to use TabTransformer from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

• Use TabTransformer as a built-in algorithm

Use the TabTransformer built-in algorithm to build a TabTransformer training container as shown in the following code example. You can automatically spot the TabTransformer built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 2).

After specifying the TabTransformer image URI, you can use the TabTransformer container to construct an estimator using the SageMaker Estimator API and initiate a training job. The TabTransformer built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own TabTransformer training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "pytorch-tabtransformerclassification-model", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"

s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"
```
from sagemaker import hyperparameters

# Retrieve the default hyper-parameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "n_epochs"
] = "50"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {"training": training_dataset_s3_path}, logs=True, job_name=training_job_name
)

For more information about how to set up the TabTransformer as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker TabTransformer algorithm
- Tabular regression with Amazon SageMaker TabTransformer algorithm

Input and Output interface for the TabTransformer algorithm

TabTransformer operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of TabTransformer supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be text/csv.
- For **Inference ContentType**, valid inputs must be text/csv.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.
Be mindful of how to format your training data for input to the TabTransformer model. You must provide the path to an Amazon S3 bucket containing subdirectories for your training and optional validation data. You can also include a list of categorical features.

- **Training data input format**: Your training data should be in a subdirectory named `train/` that contains a `data.csv` file. The target variables should be in the first column of `data.csv`. The predictor variables (features) should be in the remaining columns.

- **Validation data input format**: You can optionally include another directory called `validation/` that also has a `data.csv` file. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data.

- **Categorical features input format**: If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data directories. This file should contain a Python dictionary where the key is the string `"cat_index_list"` and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

**Amazon EC2 instance recommendation for the TabTransformer algorithm**

SageMaker TabTransformer supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker TabTransformer currently does not support multi-GPU training.

**TabTransformer sample notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker TabTransformer algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tabular classification with Amazon SageMaker TabTransformer algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker TabTransformer algorithm to train and host a tabular classification model.</td>

<td>This notebook demonstrates the use of the Amazon SageMaker TabTransformer algorithm to train and host a tabular regression model.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

**How TabTransformer works**

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer is built upon self-attention based Transformers. The Transformer layers transform the
embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

TabTransformer performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use TabTransformer for regression, classification (binary and multiclass), and ranking problems.

The following diagram illustrates the TabTransformer architecture.
For more information, see *TabTransformer: Tabular Data Modeling Using Contextual Embeddings*. 

Figure 1: The architecture of TabTransformer.
TabTransformer hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker TabTransformer algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker TabTransformer algorithm is an implementation of the open-source TabTransformer package.

Note
The default hyperparameters are based on example datasets in the TabTransformer sample notebooks (p. 1985).

The SageMaker TabTransformer algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The TabTransformer algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is r square and the objective function is mean square error. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric and objective function are both multiclass cross entropy.

Note
The TabTransformer evaluation metric and objective functions are not currently available as hyperparameters. Instead, the SageMaker TabTransformer built-in algorithm automatically detects the type of classification task (regression, binary, or multiclass) based on the number of unique integers in the label column and assigns an evaluation metric and objective function.

<table>

**Tune a TabTransformer model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

  **Note**
  The learning objective function and evaluation metric are both automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see [TabTransformer hyperparameters](p. 1988).

  - A learning objective function to optimize during model training
  - An evaluation metric that is used to evaluate model performance during validation
  - A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

  **Note**
  Automatic model tuning for TabTransformer is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2360).

**Evaluation metrics computed by the TabTransformer algorithm**

The SageMaker TabTransformer algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

#### XGBoost Algorithm

The XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as an Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost estimator that executes a training script in a managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 1.0, 1.2, 1.3, and 1.5.
Supported versions

- Framework (open source) mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1
- Algorithm mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1

Important
When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 1991) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

Warning
The XGBoost 0.90 versions are deprecated. Supports for security updates or bug fixes for XGBoost 0.90 is discontinued. It is highly recommended to upgrade the XGBoost version to one of the newer versions.

Note
XGBoost v1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost v1.2. Consider using SageMaker XGBoost 1.2-2 or later.

How to Use SageMaker XGBoost

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts. The following sections describe how to use XGBoost with the SageMaker Python SDK. For information on how to use XGBoost from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

• Use XGBoost as a framework

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth":"5",
    "eta":0.2",
    "gamma":"4",
    "min_child_weight":"6",
    "subsample":0.7",
    "verbosity":1",
    "objective":"reg:squarederror",
    "num_round":50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}//{}//{}//output'.format(bucket, prefix, 'abalone-xgb-framework')
```
# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
    framework_version='1.5-1',
    hyperparameters=hyperparameters,
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.m5.2xlarge',
    output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
    content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'validation'),
    content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

For an end-to-end example of using SageMaker XGBoost as a framework, see Regression with Amazon SageMaker XGBoost

- Use XGBoost as a built-in algorithm

Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the image_uris.retrieve API finds the correct URI, see Common parameters for built-in algorithms and look up xgboost from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

**Important**
When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 1991) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

```python
import sagemaker
import boto3
from sagemaker import image_uris
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth":5,
    "eta":0.2,
    "gamma":4,
    "min_child_weight":6,
    "subsample":0.7,
    "objective":"reg:squarederror",
    "num_round":50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
```
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           volume_size=5, # 5 GB
                                           output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'train'),
                            content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}/".format(bucket, prefix, 'validation'),
                                content_type=content_type)

# execute the XGBoost training job
estimator.fit({"train": train_input, "validation": validation_input})

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.
- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker XGBoost (Parquet input)

Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm (default) or text/csv.

Note
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.
For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: <label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm might not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.
SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

**To use a model trained with SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
pred = model.predict(dtest)
```

**To differentiate the importance of labelled data points use Instance Weight Supports**

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For `text/libsvm` input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For `text/csv` input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

**EC2 Instance Recommendation for the XGBoost Algorithm**

SageMaker XGBoost 1.0-1 or earlier only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

SageMaker XGBoost version 1.2 or later supports single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. SageMaker XGBoost version 1.2 or later supports P2 and P3 instances.

SageMaker XGBoost version 1.2-2 or later supports P2, P3, G4dn, and G5 GPU instance families.

To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script. SageMaker XGBoost currently does not support multi-GPU training.

SageMaker XGBoost supports CPU and GPU instances for inference. For information about the instance types for inference, see Amazon SageMaker ML Instance Types.

**XGBoost Sample Notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.
### How to Create a Custom XGBoost container?
This notebook shows you how to build a custom XGBoost Container with Amazon SageMaker Batch Transform.

### Regression with XGBoost using Parquet
This notebook shows you how to use the Abalone dataset in Parquet to train a XGBoost model.

### How to Train and Host a Multiclass Classification Model?
This notebook shows how to use the MNIST dataset to train and host a multiclass classification model.

### How to train a Model for Customer Churn Prediction?
This notebook shows you how to train a model to Predict Mobile Customer Departure in an effort to identify unhappy customers.

### An Introduction to Amazon SageMaker Managed Spot infrastructure for XGBoost Training
This notebook shows you how to use Spot Instances for training with a XGBoost Container.

### How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs?
This notebook shows you how to use Amazon SageMaker Debugger to monitor training jobs to detect inconsistencies.

### How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs in Real-Time?
This notebook shows you how to use the MNIST dataset and Amazon SageMaker Debugger to perform real-time analysis of XGBoost training jobs while training jobs are running.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

**How XGBoost Works**

XGBoost is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using gradient boosting for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leafs that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It’s called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.
For more detail on XGBoost, see:

- XGBoost: A Scalable Tree Boosting System
- Gradient Tree Boosting
- Introduction to Boosted Trees

### XGBoost Hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. Currently SageMaker supports version 1.2-2. For details about full set of hyperparameter that can be configured for this version of XGBoost, see XGBoost Parameters.

| csv_weights | When this flag is enabled, XGBoost differentiates the importance of instances for csv input by taking the second column (the column after labels) in training data as the instance weights.  
  **Optional**  
  Valid values: 0 or 1  
  Default value: 0 |
| deterministic_histogram | When this flag is enabled, XGBoost builds histogram on GPU deterministically. Used only if tree_method is set to gpu_hist.  
  For a full list of valid inputs, please refer to XGBoost Parameters.  
  **Optional**  
  Valid values: String. Range: true or false  
  Default value: true |
| early_stopping_rounds | The model trains until the validation score stops improving. Validation error needs to decrease at least every early_stopping_rounds to continue training. SageMaker hosting uses the best model for inference.  
  **Optional**  
  Valid values: integer  
  Default value: - |
| eta | Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The eta parameter actually shrinks the feature weights to make the boosting process more conservative.  
  **Optional**  
  Valid values: Float. Range: [0,1].  
  Default value: 0.3 |
| eval_metric | Evaluation metrics for validation data. A default metric is assigned according to the objective:  
  - rmse: for regression  
  - error: for classification  
  - map: for ranking  
  For a list of valid inputs, see XGBoost Learning Task Parameters.  
  **Optional**  
  Valid values: string  
  Default value: Default according to objective. |

Tune an XGBoost Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

**Note**
Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

Evaluation Metrics Computed by the XGBoost Algorithm

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to XGBoost Learning Task Parameters.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:accuracy</td>
<td>Classification rate, calculated as #(right)/#(all cases).</td>
<td>Maximize</td>
</tr>

Deprecated Versions of XGBoost and their Upgrades

This topic contains documentation for previous versions of Amazon SageMaker XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.

Topics
- Upgrade XGBoost Version 0.90 to Version 1.5 (p. 2005)
- XGBoost Version 0.72 (p. 2007)

Upgrade XGBoost Version 0.90 to Version 1.5

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.5, you must have version 2.x of the SDK installed and change the XGBoost version and framework_version parameters to 1.5-1. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.
Upgrade SageMaker Python SDK Version 1.x to Version 2.x

If you are still using Version 1.x of the SageMaker Python SDK, you must upgrade to Version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see Use Version 2.x of the SageMaker Python SDK. To install the latest version, run:

```
python -m pip install --upgrade sagemaker
```

Change the image tag to 1.5-1

If you are using the SageMaker Python SDK and using the XGBoost build-in algorithm, change the version parameter in `image_uris.retrieve`.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           volume_size=5, # 5 GB
                                           output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```python
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                   framework_version='1.5-1',
                   hyperparameters=hyperparameters,
                   role=sagemaker.get_execution_role(),
                   instance_count=1,
                   instance_type='ml.m5.2xlarge',
                   output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.

```python
content_type = "libsvm"
train_input = TrainingInput("s3://{{bucket}}/{{prefix}}/train",
                           content_type=content_type)
validation_input = TrainingInput("s3://{{bucket}}/{{prefix}}/validation",
                                content_type=content_type)
```

For the full list of SageMaker Python SDK version 2.x changes, see Use Version 2.x of the SageMaker Python SDK.

Change Docker Image for Boto3

If you are using Boto3 to train or deploy your model, change the docker image tag (1, 0.72, 0.90-1 or 0.90-2) to 1.5-1.
Use Built-in Algorithms

If you're using the SageMaker Python SDK to retrieve the registry path, change the `version` parameter in `image_uris.retrieve`.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")
```

**Update Hyperparameters and Learning Objectives**

The `silent` parameter has been deprecated and is no longer available in XGBoost 1.5 and later versions. Use `verbosity` instead. If you were using the `reg:linear` learning objective, it has been deprecated as well in favor of `reg:squarederror`. Use `reg:squarederror` instead.

```python
hyperparameters = {
    "verbosity": "2",
    "objective": "reg:squarederror",
    "num_round": "50",
    ...
}
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          ...)
```

**XGBoost Version 0.72**

**Important**

The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with :1 is for the old version.

**SageMaker Python SDK v1**

```python
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri

xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",
                            repo_version="1")
```

**SageMaker Python SDK v2**

```python
import boto3
from sagemaker import image_uris

xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name, "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see Supported versions (p. 1991)).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. **XGBoost** (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of
the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost Algorithm (p. 1990). They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

Input/Output Interface for the XGBoost Release 0.72

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm or (the default) text/csv.

Note

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: <label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

To use a model trained with SageMaker XGBoost in open source XGBoost

- Use the following Python code:

```python
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
```
pred = model.predict(dtest)

To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, label:weight idx_0:val_0 idx_1:val_1... For text/csv input, customers need to turn on the csv_weights flag in the parameters and attach weight values in the column after labels. For example: label,weight,val_0,val_1,...).

EC2 Instance Recommendation for the XGBoost Release 0.72

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

XGBoost Release 0.72 Sample Notebooks

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see Regression with Amazon SageMaker XGBoost algorithm. To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

XGBoost Release 0.72 Hyperparameters

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see XGBoost Parameters.

| **gamma**     | Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is.        |
|               | **Optional**                                                                                                                                 |
|               | Valid values: Float. Range: [0,∞).                                                                                                           |
|               | Default value: 0                                                                                                                             |
| **grow_policy** | Controls the way that new nodes are added to the tree. Currently supported only if tree_method is set to hist.  
 **Optional**                                                                                                                                 |
<p>|               | Valid values: String. Either <em>depthwise</em> or <em>lossguide</em>.                                                                                     |
|               | Default value: <em>depthwise</em>                                                                                                                   |
| <strong>lambda</strong>    | L2 regularization term on weights. Increasing this value makes models more conservative.                                                      |
|               | <strong>Optional</strong>                                                                                                                                 |
|               | Valid values: float                                                                                                                           |
|               | Default value: 1                                                                                                                             |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| lambda_bias      | L2 regularization term on bias.  
Optional  
Valid values: Float. Range: [0.0, 1.0].  
Default value: 0 |
| max_bin          | Maximum number of discrete bins to bucket continuous features.  
Used only if `tree_method` is set to hist.  
Optional  
Valid values: integer  
Default value: 256 |
| max_delta_step   | Maximum delta step allowed for each tree's weight estimation.  
When a positive integer is used, it helps make the update more  
conservative. The preferred option is to use it in logistic regression.  
Set it to 1-10 to help control the update.  
Optional  
Valid values: Integer. Range: [0,∞).  
Default value: 0 |
| max_depth        | Maximum depth of a tree. Increasing this value makes the model more complex and likely to be overfit.  
0 indicates no limit. A limit is required when `grow_policy`=depth-wise.  
Optional  
Valid values: Integer. Range: [0,∞)  
Default value: 6 |
| max_leaves       | Maximum number of nodes to be added. Relevant only if `grow_policy` is set to lossguide.  
Optional  
Valid values: integer  
Default value: 0 |
| min_child_weight | Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than `min_child_weight`, the building process gives up further partitioning. In linear regression models, this simply corresponds to a minimum number of instances needed in each node. The larger the algorithm, the more conservative it is.  
Optional  
Valid values: Float. Range: [0,∞).  
Default value: 1 |
<table>
<thead>

| normalize_type | Type of normalization algorithm.  
Optional  
Valid values: Either `tree` or `forest`.  
Default value: `tree`
| nthread | Number of parallel threads used to run `xgboost`.  
Optional  
Valid values: integer  
Default value: Maximum number of threads.
| objective | Specifies the learning task and the corresponding learning objective. Examples: `reg:logistic`, `reg:softmax`, `multi:squarederror`. For a full list of valid inputs, refer to XGBoost Parameters.  
Optional  
Valid values: string  
Default value: `reg:squarederror`
| one_drop | When this flag is enabled, at least one tree is always dropped during the dropout.  
Optional  
Valid values: 0 or 1  
Default value: 0
| process_type | The type of boosting process to run.  
Optional  
Valid values: String. Either `default` or `update`.  
Default value: `default`
| rate_drop | The dropout rate that specifies the fraction of previous trees to drop during the dropout.  
Optional  
Valid values: Float. Range: [0.0, 1.0].  
Default value: 0.0

### Tune an XGBoost Release 0.72 Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning **objective function** to optimize during model training
- an **eval_metric** to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically
You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

**Metrics Computed by the XGBoost Release 0.72 Algorithm**

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to XGBoost Learning Task Parameters

<table>
<thead>
<tr>

Built-in SageMaker Algorithms for Text Data

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- **BlazingText algorithm (p. 2018)**—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- **Latent Dirichlet Allocation (LDA) Algorithm (p. 2028)**—an algorithm suitable for determining topics in a set of documents. It is an unsupervised algorithm, which means that it doesn't use example data with answers during training.
- **Neural Topic Model (NTM) Algorithm (p. 2033)**—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- **Object2Vec Algorithm (p. 2039)**—a general-purpose neural embedding algorithm that can be used for recommendation systems, document classification, and sentence embeddings.
- **Sequence-to-Sequence Algorithm (p. 2055)**—a supervised algorithm commonly used for neural machine translation.

**BlazingText algorithm**

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a word embedding. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see [Docker Registry Paths for SageMaker Built-in Algorithms](#).

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see [BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs](#).

- **Enriched Word Vectors with Subword Information** by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.

- A batch_skipgram mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The batch_skipgram mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see [Parallelizing Word2Vec in Shared and Distributed Memory](#).

To summarize, the following modes are supported by BlazingText on different types instances:

For more information about the mathematics behind BlazingText, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.

**Topics**

- Input/Output Interface for the BlazingText Algorithm (p. 2019)
- EC2 Instance Recommendation for the BlazingText Algorithm (p. 2022)
- BlazingText Sample Notebooks (p. 2022)
- BlazingText Hyperparameters (p. 2022)
- Tune a BlazingText Model (p. 2026)

**Input/Output Interface for the BlazingText Algorithm**

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.

**Training and Validation Data Format**

**Training and Validation Data Format for the Word2Vec Algorithm**

For Word2Vec training, upload the file under the `train` channel. No other channels are supported. The file should contain a training sentence per line.

**Training and Validation Data Format for the Text Classification Algorithm**

For supervised mode, you can train with file mode or with the augmented manifest text format.

**Train with File Mode**

For supervised mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string `__label__`. Here is an example of a training/validation file:

```
__label__4  linux ready for prime time , intel says , despite all the linux hype , the open-source movement has yet to make a huge splash in the desktop market . that may be about to change , thanks to chipmaking giant intel corp .
```
Amazon SageMaker Developer Guide
Use Built-in Algorithms
__label__2 bowled by the slower one again , kolkata , november 14 the past caught up with
sourav ganguly as the indian skippers return to international cricket was short lived .

Note

The order of labels within the sentence doesn't matter.
Upload the training ﬁle under the train channel, and optionally upload the validation ﬁle under the
validation channel.

Train with Augmented Manifest Text Format
The supervised mode also supports the augmented manifest format, which enables you to do training in
pipe mode without needing to create RecordIO ﬁles. While using the format, an S3 manifest ﬁle needs to
be generated that contains the list of sentences and their corresponding labels. The manifest ﬁle format
should be in JSON Lines format in which each line represents one sample. The sentences are speciﬁed
using the source tag and the label can be speciﬁed using the label tag. Both source and label tags
should be provided under the AttributeNames parameter value as speciﬁed in the request.
{"source":"linux ready for prime time , intel says , despite all the linux hype",
"label":1}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up with
sourav ganguly", "label":2}

Multi-label training is also supported by specifying a JSON array of labels.
{"source":"linux ready for prime time , intel says , despite all the linux hype", "label":
[1, 3]}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up with
sourav ganguly", "label": [2, 4, 5]}

For more information on augmented manifest ﬁles, see Provide Dataset Metadata to Training Jobs with
an Augmented Manifest File (p. 2608).

Model Artifacts and Inference
Model Artifacts for the Word2Vec Algorithm
For Word2Vec training, the model artifacts consist of vectors.txt, which contains words-to-vectors
mapping, and vectors.bin, a binary used by BlazingText for hosting, inference, or both. vectors.txt stores
the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim
user can run the following commands to load the vectors.txt ﬁle:
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesnt_match("breakfast cereal dinner lunch".split())

If the evaluation parameter is set to True, an additional ﬁle, eval.json, is created. This ﬁle contains the
similarity evaluation results (using Spearman’s rank correlation coeﬃcients) on WS-353 dataset. The
number of words from the WS-353 dataset that aren't there in the training corpus are reported.
For inference requests, the model accepts a JSON ﬁle containing a list of strings and returns a list of
vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to
True during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

Sample JSON Request
Mime-type: application/json

2020


Model Artifacts for the Text Classification Algorithm

Training with supervised outputs creates a `model.bin` file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

Sample JSON Request

Mime-type: `application/json`

```json
{
    "instances": ["the movie was excellent", "i did not like the plot ."],
    "configuration": {"k": 2}
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top $k$ predictions, you can set $k$ in the configuration, as follows:

```json
{
    "instances": ["the movie was excellent", "i did not like the plot ."],
    "configuration": {"k": 2}
}
```

For BlazingText, the `content-type` and `accept` parameters must be equal. For batch transform, they both need to be `application/jsonlines`. If they differ, the `Accept` field is ignored. The format for input follows:

```
content-type: application/jsonlines

{"source": "source_0"}
{"source": "source_1"}
```

If you need to pass the value of $k$ for top-$k$, then you can do it in the following way:

```
{"source": "source_0", "k": 2}
{"source": "source_1", "k": 3}
```

The format for output follows:

```
accept: application/jsonlines

{"prob": [prob_1], "label": ["__label__1"]}
{"prob": [prob_1], "label": ["__label__1"]}
```

If you have passed the value of $k$ to be more than 1, then response will be in this format:

```
{"prob": [prob_1, prob_2], "label": ["__label__1", __label__2"]}
{"prob": [prob_1, prob_2], "label": ["__label__1", __label__2"]}
```

For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (*\.bin*) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries
produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```bash
#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz

#Unzip the model archive
tar -xzf model.tar.gz

#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

For more details on dataset formats and model hosting, see the example notebooks Text Classification with the BlazingText Algorithm, FastText Models, and Generating Subword Embeddings with the Word2Vec Algorithm.

EC2 Instance Recommendation for the BlazingText Algorithm

For cbow and skipgram modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of subwords embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.

For batch_skipgram mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the S3DataDistributionType field of the S3DataSource object that you pass to CreateTrainingJob to FullyReplicated. BlazingText takes care of distributing data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less than 2 GB. For larger datasets, use an instance with a single GPU. BlazingText supports P2, P3, G4dn, and G5 instances for training and inference.

BlazingText Sample Notebooks

For a sample notebook that uses the SageMaker BlazingText algorithm to train and deploy supervised binary and multiclass classification models, see Blazing Text classification on the DBPedia dataset. For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the Blazing Text are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab, then choose Create copy.

BlazingText Hyperparameters

When you start a training job with a CreateTrainingJob request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

Word2Vec Hyperparameters

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker.
## Use Built-in Algorithms

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **mode**       | The Word2vec architecture used for training.  
  **Required**  
  Valid values: batch_skipgram, skipgram, or cbow |
| **batch_size** | The size of each batch when mode is set to batch_skipgram. Set to a number between 10 and 20.  
  **Optional**  
  Valid values: Positive integer  
  Default value: 11 |
| **buckets**    | The number of hash buckets to use for subwords.  
  **Optional**  
  Valid values: positive integer  
  Default value: 2000000 |
| **epochs**     | The number of complete passes through the training data.  
  **Optional**  
  Valid values: Positive integer  
  Default value: 5 |
| **evaluation** | Whether the trained model is evaluated using the WordSimilarity-353 Test.  
  **Optional**  
  Valid values: (Boolean) True or False  
  Default value: True |
| **learning_rate** | The step size used for parameter updates.  
  **Optional**  
  Valid values: Positive float  
  Default value: 0.05 |
| **min_char**   | The minimum number of characters to use for subwords/character n-grams.  
  **Optional**  
  Valid values: positive integer  
  Default value: 3 |
<p>| <strong>min_count</strong>  | Words that appear less than min_count times are discarded. |</p>

### Tune a BlazingText Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

### Metrics Computed by the BlazingText Algorithm

The BlazingText Word2Vec algorithm (skipgram, cbow, and batch_skipgram modes) reports on a single metric during training: `train:mean_rho`. This metric is computed on WS-353 word similarity datasets. When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (supervised mode), also reports on a single metric during training: the `validation:accuracy`. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.
<table>
<thead>
<tr>

Latent Dirichlet Allocation (LDA) Algorithm

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: *eat*, *sleep*, *play*, *meow*, and *bark*, LDA might produce topics like the following:

<table>
<thead>
<tr>
<th>Topic</th>
<th><em>eat</em></th>
<th><em>sleep</em></th>
<th><em>play</em></th>
<th><em>meow</em></th>
<th><em>bark</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic 1</td>
<td>0.1</td>
<td>0.3</td>
<td>0.2</td>
<td>0.4</td>
<td>0.0</td>
</tr>
<tr>
<td>Topic 2</td>
<td>0.2</td>
<td>0.1</td>
<td>0.4</td>
<td>0.0</td>
<td>0.3</td>
</tr>
</tbody>
</table>

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to *meow* and *sleep*), and documents that fall into Topic 2 are about dogs (who prefer to *play* and *bark*). These topics can be found even though the words dog and cat never appear in any of the texts.

Topics

- Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM) (p. 2028)
- Input/Output Interface for the LDA Algorithm (p. 2029)
- EC2 Instance Recommendation for the LDA Algorithm (p. 2029)
- LDA Sample Notebooks (p. 2029)
- How LDA Works (p. 2029)
- LDA Hyperparameters (p. 2031)
- Tune an LDA Model (p. 2032)

Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to
the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.

Topics
- Input/Output Interface for the LDA Algorithm (p. 2029)
- EC2 Instance Recommendation for the LDA Algorithm (p. 2029)
- LDA Sample Notebooks (p. 2029)
- How LDA Works (p. 2029)
- LDA Hyperparameters (p. 2031)
- Tune an LDA Model (p. 2032)

Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to number of records * vocabulary size. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, text/csv, application/json, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. LDA inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_mixture vector for each observation.

Please see the LDA Sample Notebooks (p. 2029) for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.

LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the An Introduction to SageMaker LDA. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How LDA Works

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to
provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to
discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to
automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in
text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A
feature is referred to as a word. And the resulting categories are referred to as topics.

**Note**
Lemmatization significantly increases algorithm performance and accuracy. Consider pre-
processing any input text data.

An LDA model is defined by two parameters:

- **α**—A prior estimate on topic probability (in other words, the average frequency that each topic within
  a given document occurs).
- **β**—a collection of k topics where each topic is given a probability distribution over the vocabulary used
  in a document corpus, also called a “topic-word distribution.”

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a
generative model where each document is generated word-by-word by choosing a topic mixture \( \theta \sim \text{Dirichlet}(\alpha) \).

For each word in the document:

- Choose a topic \( z \sim \text{Multinomial}(\theta) \)
- Choose the corresponding topic-word distribution \( \beta_z \).
- Draw a word \( w \sim \text{Multinomial}(\beta_z) \).

When training the model, the goal is to find parameters \( \alpha \) and \( \beta \), which maximize the probability that the
text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation
Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This
provides several advantages:

- **Theoretical guarantees on results.** The standard EM-method is guaranteed to converge only to local
  optima, which are often of poor quality.
- **Embarrassingly parallelizable.** The work can be trivially divided over input documents in both training
  and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
- **Fast.** Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs
  Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a \( V \times V \times V \) tensor, which summarizes the
   moments of the documents in our corpus. \( V \) is vocabulary size (in other words, the number of distinct
   words in all of the documents). The spectral components of this tensor are the LDA parameters \( \alpha \) and
   \( \beta \), which maximize the overall likelihood of the document corpus. However, because vocabulary size
   tends to be large, this \( V \times V \times V \) tensor is prohibitively large to store in memory.
2. Instead, it uses a \( V \times V \) moment matrix, which is the two-dimensional analog of the tensor from step
   1, to find a whitening matrix of dimension \( V \times k \). This matrix can be used to convert the \( V \times V \) moment
   matrix into a \( k \times k \) identity matrix. \( k \) is the number of topics in the model.
3. This same whitening matrix can then be used to find a smaller \( k \times k \times k \) tensor. When spectrally
   decomposed, this tensor has components that have a simple relationship with the components of the
   \( V \times V \times V \) tensor.
4. *Alternating Least Squares* is used to decompose the smaller $k \times k \times k$ tensor. This provides a substantial improvement in memory consumption and speed. The parameters $\alpha$ and $\beta$ can be found by “unwhitening” these outputs in the spectral decomposition.

After the LDA model’s parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

For more information about algorithms for LDA and the SageMaker implementation, see the following:

**LDA Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see *How LDA Works* (p. 2029).

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

**Tune an LDA Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood” (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.
For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

**Metrics Computed by the LDA Algorithm**

The LDA algorithm reports on a single metric during training: `test:pwll`. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>test:pwll</code></td>
<td>Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

**Tunable LDA Hyperparameters**

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, `alpha0` and `num_topics`, can affect the LDA objective metric (`test:pwll`). If you don't already know the optimal values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

**Neural Topic Model (NTM) Algorithm**

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into *topics* that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on topic similarities. The topics from documents that NTM learns are characterized as a *latent representation* because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.

Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see Neural Variational Inference for Text Processing.

Input/Output Interface for the NTM Algorithm

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the S3DataDistributionType parameter for them to FullyReplicated. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to: (number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The ContentType for the auxiliary channel is text/plain, with each line containing a single word, in the order corresponding to the integer IDs provided in the data. The vocabulary file must be named vocab.txt and currently only UTF-8 encoding is supported.

For inference, text/csv, application/json, application/jsonlines, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. NTM inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_weights vector for each observation.

See the blog post and the companion notebook for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker Neural Topic Model.

For more information on input and output file formats, see NTM Response Formats (p. 2038) for inference and the NTM Sample Notebooks (p. 2034).

EC2 Instance Recommendation for the NTM Algorithm

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference. NTM training supports P2, P3, and G4dn GPU instance families for training and inference.

NTM Sample Notebooks

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality of NTM. For instructions how to create and access Jupyter notebook instances that you can use to run
the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

#### Tune an NTM Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. Training loss measures how well the model fits the training data. Validation loss measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which it has not been trained. Usually, it's preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).
Metrics Computed by the NTM Algorithm

The NTM algorithm reports a single metric that is computed during training: validation:total_loss. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:total_loss</td>
<td>Total Loss on validation set</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

Tunable NTM Hyperparameters

You can tune the following hyperparameters for the NTM algorithm. Usually setting low mini_batch_size and small learning_rate values results in lower validation losses, although it might take longer to train. Low validation losses don’t necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see NTM Hyperparameters (p. 2035).

NTM Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker NTM algorithm.

**JSON Response Format**

```json
{
    "predictions": [
        {
            "topic_weights": [0.02, 0.1, 0,...],
            "topic_weights": [0.25, 0.067, 0,...]
        }
    ]
}
```

**JSONLINES Response Format**

```json
{"topic_weights": [0.02, 0.1, 0,...]}
{"topic_weights": [0.25, 0.067, 0,...]}
```
RECORDIO Response Format

```json
[
  Record = {
    features = {},
    label = {
      'topic_weights': {
        keys: [],
        values: [0.25, 0.067, 0, ...] # float32
      }
    }
  },
  Record = {
    features = {},
    label = {
      'topic_weights': {
        keys: [],
        values: [0.25, 0.067, 0, ...] # float32
      }
    }
  }
]
```

Object2Vec Algorithm

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker BlazingText algorithm (p. 2018). For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker Object2Vec.

I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

<table>
<thead>
<tr>
<th>Input Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentence-sentence pairs</td>
<td>&quot;A soccer game with multiple males playing.&quot; and &quot;Some men are playing a sport.&quot;</td>
</tr>
<tr>
<td>Input Data Type</td>
<td>Example</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Labels-sequence pairs</td>
<td>The genre tags of the movie &quot;Titanic&quot;, such as &quot;Romance&quot; and &quot;Drama&quot;, and its short description: &quot;James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912.&quot;</td>
</tr>
<tr>
<td>Customer-customer pairs</td>
<td>The customer ID of Jane and customer ID of Jackie.</td>
</tr>
<tr>
<td>Product-product pairs</td>
<td>The product ID of football and product ID of basketball.</td>
</tr>
<tr>
<td>Item review user-item pairs</td>
<td>A user's ID and the items she has bought, such as apple, pear, and orange.</td>
</tr>
</tbody>
</table>

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single integer-id. For example, [10].
- A sequences of discrete tokens, which is represented as a list of integer-ids. For example, [0, 12, 10, 13].

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss function. Specify these loss functions with the `output_layer` hyperparameter when you create the model training job.

**EC2 Instance Recommendation for the Object2Vec Algorithm**

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inference.

When training a model using the Object2Vec algorithm on a CPU, start with an ml.m5.2xlarge instance. For training on a GPU, start with an ml.p2.xlarge instance. If the training takes too long on this instance, you can use a larger instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs. Object2Vec supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

For inference with a trained Object2Vec model that has a deep neural network, we recommend using ml.p3.2xlarge GPU instance. Due to GPU memory scarcity, the `INFEERENCE_PREFERRED_MODE`
A environment variable can be specified to optimize on whether the section called "GPU optimization: Classification or Regression" (p. 2052) or the section called "GPU optimization: Encoder Embeddings" (p. 2054) inference network is loaded into GPU.

Object2Vec Sample Notebooks

- Using Object2Vec to Encode Sentences into Fixed Length Embeddings
- Using Object2Vec to learn document embeddings

Note
To run the notebooks on a notebook instance, see Example Notebooks (p. 298). To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 132).

How Object2Vec Works

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

Topics
• Step 1: Process Data (p. 2041)
• Step 2: Train a Model (p. 2041)
• Step 3: Produce Inferences (p. 2042)

Step 1: Process Data

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training (p. 2052). To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For Python, you could use np.random.shuffle; for Unix, shuf.

Step 2: Train a Model

The SageMaker Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.
- **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.
- **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.

During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the tied_token_embedding_weight hyperparameter to True when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the negative_sampling_rate hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which
assembles the vectors into a single vector using the value specified in the `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.

**Architecture of the Object2Vec Algorithm from Data Inputs to Scores**

**Step 3: Produce Inferences**

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

- To convert singleton input objects into fixed-length embeddings using the corresponding encoder
- To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.

**Object2Vec Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enc0_max_seq_len</code></td>
<td>The maximum sequence length for the <code>enc0</code> encoder. Required</td>
</tr>
<tr>
<td><code>enc0_vocab_size</code></td>
<td>The vocabulary size of <code>enc0</code> tokens. Valid values: $1 \leq \text{integer} \leq 5000$</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>bucket_width</strong></td>
<td>The allowed difference between data sequence length when bucketing is enabled. To enable bucketing, specify a non-zero value for this parameter.</td>
</tr>
<tr>
<td><strong>comparator_list</strong></td>
<td>A list used to customize the way in which two embeddings are compared. The Object2Vec comparator operator layer takes the encodings from both encoders as inputs and outputs a single vector. This vector is a concatenation of subvectors. The string values passed to the comparator_list and the order in which they are passed determine how these subvectors are assembled. For example, if comparator_list=&quot;hadamard, concat&quot;, then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two encodings. If, on the other hand, comparator_list=&quot;hadamard&quot;, then the comparator operator constructs the vector as the hadamard product of only two encodings.</td>
</tr>
<tr>
<td><strong>dropout</strong></td>
<td>The dropout probability for network layers. Dropout is a form of regularization used in neural networks that reduces overfitting by trimming codependent neurons.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>

</table>
| enc1_network      | The network model for the enc1 encoder. If you want the enc1 encoder to use the same network model as enc0, including the hyperparameter values, set the value to enc0. **Note**  
* Even when the enc0 and enc1 encoder networks have symmetric architectures, you can’t share parameter values for these networks.  
**Optional**  
Valid values: enc0, hcnn, bilstm, or pooled_embedding  
* enc0: The network model for the enc0 encoder.  
* hcnn: A hierarchical convolutional neural network.  
* bilstm: A bidirectional LSTM, in which the signal propagates backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks.  
* pooled_embedding: The averages of the embeddings of all of the tokens in the input.  
Default value: enc0 |
| enc1_cnn_filter_width | The filter width of the CNN enc1 encoder. **Conditional**  
Valid values: 1 ≤ integer ≤ 9  
Default value: 3 |
| enc1_freeze_pretrained_embedding | Whether to freeze enc1 pretrained embedding weights. **Conditional**  
Valid values: True or False  
Default value: True |
| enc1_layers       | The number of layers in the enc1 encoder. **Conditional**  
Valid values: auto or 1 ≤ integer ≤ 4  
* For hcnn, auto means 4.  
* For bilstm, auto means 1.  
* For pooled_embedding, auto ignores the number of layers.  
Default value: auto |
| enc1_max_seq_len  | The maximum sequence length for the enc1 encoder. **Conditional**  
Valid values: 1 ≤ integer ≤ 5000 |

#### Optional

- Valid values: dense or row_sparse
- Default value: dense

---

Tune an Object2Vec Model

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2360).

**Metrics Computed by the Object2Vec Algorithm**

The Object2Vec algorithm has both classification and regression metrics. The output_layer type determines which metric you can use for automatic model tuning.

**Regressor Metrics Computed by the Object2Vec Algorithm**

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.
Use Built-in Algorithms

Data Formats for Object2Vec Training

Input: JSON Lines Request Format

Content-type: application/jsonlines

```
{"label": 0, "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"label": 1, "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [32, 32, 13, 25, 1016, 573, 3252, 4]}
{"label": 1, "in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

The “in0” and “in1” are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field “label” can accept real valued inputs.

Data Formats for Object2Vec Inference

GPU optimization: Classification or Regression

Due to GPU memory scarcity, the `INFERNECE_PREFERRED_MODE` environment variable can be specified to optimize on whether the classification/regression or the section called “Output: Encoder Embeddings” (p. 2054) inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify `INFERNECE_PREFERRED_MODE=classification`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for classification/regression inference:

```
transformer = o2v.transformer(instance_count=4,
```
Use Built-in Algorithms

instance_type="ml.p2.xlarge",
max_concurrent_transforms=2,
max_payload=1, # 1MB
strategy='MultiRecord',
env={'INFERENCE_PREFERRED_MODE': 'classification'}, # only useful with GPU
output_path=output_s3_path)

Input: Classification or Regression Request Format

Content-type: application/json

```json
{
"instances" : [
  {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]},
  {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]},
  {"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}]
}
```

Content-type: application/json

```json
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

For classification problems, the length of the scores vector corresponds to `num_classes`. For regression problems, the length is 1.

Output: Classification or Regression Response Format

Accept: application/json

```json
{
 "predictions": [  
  {
 "scores": [  
  0.653935070037842,
  0.07582679390907288,
  0.2707797586917877
  ]
  },
  {
 "scores": [  
  0.026291321963071823,
  0.6577019095420837,
  0.31600672006607056
  ]
  }
  ]
}
```

Accept: application/json

```json
{"scores":[0.195667684078216,0.395351558923721,0.408980727195739]}
{"scores":[0.251988261938095,0.258233487606048,0.489778398628231]}
{"scores":[0.280087798833847,0.368331134319305,0.351581096649169]}
```
In both the classification and regression formats, the scores apply to individual labels.

**Encoder Embeddings for Object2Vec**

**GPU optimization: Encoder Embeddings**

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the `INFORMATION_PREFERRED_MODE` environment variable can be specified to optimize on whether the the section called “Inference Formats: Scoring” (p. 2052) or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify `INFORMATION_PREFERRED_MODE=embedding`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```python
transformer = o2v.transformer(instance_count=4,
                             instance_type="ml.p2.xlarge",
                             max_concurrent_transforms=2,
                             max_payload=1,  # 1MB
                             strategy='MultiRecord',
                             env={'INFORMATION_PREFERRED_MODE': 'embedding'},  # only useful
                             output_path=output_s3_path)
```

**Input: Encoder Embeddings**

Content-type: application/json; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where `<FWD-LENGTH>` and `<BCK-LENGTH>` are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```json
{
  "instances": [
    {
      "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
      "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]},
    {
      "in0": [774, 14, 21, 206]
    }
  ]
}
```

Content-type: application/jsonlines; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where `<FWD-LENGTH>` and `<BCK-LENGTH>` are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```json
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]}
{"in0": [774, 14, 21, 206]}
```

In both of these formats, you specify only one input type: “in0” or “in1.” The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

**Output: Encoder Embeddings**

Content-type: application/json

```json
{
  "predictions": [
    {"embeddings": [0.057368703186511,0.030703511089086,0.099890425801277,0.063688032329082,0.026327300816774,0.003637571120634,0.021305780857801,0.004316598642617,0.0,0.003397724591195,0.0,0.000378780066967,0.0,0.0,0.0,0.007419463712722]},
    {"embeddings": [0.150190666317939,0.05145975202322,0.098204270005226,0.064249359071254,0.056249320507049,0.01513972133398,0.047553978860378,0.0,0.0,0.011533712036907,0.011472506448626,0.010696629062294,0.0,0.0,0.0,0.008508535102009]}
  ]
}
```

2054
The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: enc0_token_embedding_dim, enc1_token_embedding_dim, or enc_dim.

**Sequence-to-Sequence Algorithm**

Amazon SageMaker Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

**Topics**

- Input/Output Interface for the Sequence-to-Sequence Algorithm (p. 2055)
- EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm (p. 2056)
- Sequence-to-Sequence Sample Notebooks (p. 2056)
- How Sequence-to-Sequence Works (p. 2056)
- Sequence-to-Sequence Hyperparameters (p. 2057)
- Tune a Sequence-to-Sequence Model (p. 2065)

**Input/Output Interface for the Sequence-to-Sequence Algorithm**

**Training**

SageMaker seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in the seq2seq example notebook. In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:

- **train**: It should contain the training data (for example, the train.rec file generated by the preprocessing script).
- **validation**: It should contain the validation data (for example, the val.rec file generated by the preprocessing script).
- **vocab**: It should contain two vocabulary files (vocab.src.json and vocab.trg.json)

If the algorithm doesn't find data in any of these three channels, training results in an error.
Inference

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the application/json format. Otherwise, use the recordio-protobuf format to work with the integer encoded data. Both modes support batching of input data. application/json format also allows you to visualize the attention matrix.

- application/json: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be application/json. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:
  
  configuration: {attention_matrix: true}: Returns the attention matrix for the particular input sequence.

- application/x-recordio-protobuf: Expects the input in recordio-protobuf format and returns the output in recordio-protobuf format. Both content and accept types should be applications/x-recordio-protobuf. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be application/jsonlines. The format for input is as follows:

```
content-type: application/jsonlines

{"source": "source_sequence_0"}
{"source": "source_sequence_1"}
```

The format for response is as follows:

```
accept: application/jsonlines

{"target": "predicted_sequence_0"}
{"target": "predicted_sequence_1"}
```

For additional details on how to serialize and deserialize the inputs and outputs to specific formats for inference, see the Sequence-to-Sequence Sample Notebooks (p. 2056).

EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm

The Amazon SageMaker seq2seq algorithm only supports on GPU instance types and can only train on a single machine. However, you can use instances with multiple GPUs. The seq2seq algorithm supports P2, P3, G4dn, and G5 GPU instance families.

Sequence-to-Sequence Sample Notebooks

For a sample notebook that shows how to use the SageMaker Sequence to Sequence algorithm to train a English–German translation model, see Machine Translation English–German Example Using SageMaker Seq2Seq. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Sequence-to-Sequence Works

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:
• An **embedding layer**. In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like FastText or Glove or to initialize it randomly and learn the parameters during training.

• An **encoder layer**. After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). (Colah’s blog explains LSTM in a great detail.)

• A **decoder layer**. The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by Sutskever et al. in 2014.

**Attention mechanism.** The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the attention mechanism. In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.

For more in details, see the whitepaper Effective Approaches to Attention-based Neural Machine Translation by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper Google’s Neural Machine Translation System: Bridging the Gap between Human and Machine Translation by Wu, et al. describes Google’s architecture for machine translation, which uses skip connections between encoder and decoder layers.

**Tune a Sequence-to-Sequence Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.
For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

**Metrics Computed by the Sequence-to-Sequence Algorithm**

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.

fixed_rate_lr_half_life | IntegerParameterRange | [10-30]

### Built-in SageMaker Algorithms for Time-Series Data
SageMaker provides algorithms that are tailored to the analysis of time-series data for forecasting product demand, server loads, webpage requests, and more.

- **DeepAR Forecasting Algorithm** (p. 2068)—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).
DeepAR Forecasting Algorithm

The Amazon SageMaker DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.

In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more target time series that have been generated by the same process or similar processes. Based on this input dataset, the algorithm trains a model that learns an approximation of this process/processes and uses it to predict how the target time series evolves. Each target time series can be optionally associated with a vector of static (time-independent) categorical features provided by the cat field and a vector of dynamic (time-dependent) time series provided by the dynamic_feat field. SageMaker trains the DeepAR model by randomly sampling training examples from each target time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To control how far in the past the network can see, use the context_length hyperparameter. To control how far in the future predictions can be made, use the prediction_length hyperparameter. For more information, see How the DeepAR Algorithm Works (p. 2072).

Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required train channel describes the training dataset. The optional test channel describes a dataset that the algorithm uses to evaluate model accuracy after training. You can provide training and test datasets in JSON Lines format. Files can be in gzip or Parquet file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all files in the directory as inputs for the corresponding channel, except those that start with a period (.) and...
those named \_SUCCESS. This ensures that you can directly use output folders produced by Spark jobs as input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (.json, .json.gz, or .parquet) in the specified input path. If the path does not end in one of these extensions, you must explicitly specify the format in the SDK for Python. Use the content_type parameter of the s3_input class.

The records in your input files should contain the following fields:

- **start**—A string with the format YYYY-MM-DD HH:MM:SS. The start timestamp can't contain time zone information.
- **target**—An array of floating-point values or integers that represent the time series. You can encode missing values as null literals, or as "NaN" strings in JSON, or as nan floating-point values in Parquet.
- **dynamic_feat** (optional)—An array of arrays of floating-point values or integers that represents the vector of custom feature time series (dynamic features). If you set this field, all records must have the same number of inner arrays (the same number of feature time series). In addition, each inner array must be the same length as the associated target value plus prediction_length. Missing values are not supported in the features. For example, if target time series represents the demand of different products, an associated dynamic_feat might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

```
{
    "start": ..., "target": [1, 5, 10, 2], "dynamic_feat": [[0, 1, 1, 0]]
}
```

- **cat** (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain {R, G, B} can be encoded as {0, 1, 2}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the embedding_dimension hyperparameter. For more information, see DeepAR Hyperparameters (p. 2074).

If you use a JSON file, it must be in JSON Lines format. For example:

```
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
    "dynamic_feat": [[1.1, 1.2, 0.5, ...]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat":
    [[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
    [[1.3, 0.4]]}
```

In this example, each time series has two associated categorical features and one time series features.

For Parquet, you use the same three fields as columns. In addition, "start" can be the datetime type. You can compress Parquet files using gzip (gzip) or the Snappy compression library (snappy).

If the algorithm is trained without cat and dynamic_feat fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the cat and dynamic_feat feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding cat features. For example, if the target time series represents the demand of clothing items, you can associate a two-dimensional cat vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:
At inference time, you can request predictions for targets with \texttt{cat} values that are combinations of the \texttt{cat} values observed in the training data, for example:

\begin{verbatim}
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
\end{verbatim}

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
- Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
- Make sure to set the \texttt{start} field correctly. The algorithm uses the \texttt{start} timestamp to derive the internal features.
- If you use categorical features (\texttt{cat}), all time series must have the same number of categorical features. If the dataset contains the \texttt{cat} field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, cardinality is "auto". If the dataset contains the \texttt{cat} field, but you don't want to use it, you can disable it by setting \texttt{cardinality} to "". If a model was trained using a \texttt{cat} feature, you must include it for inference.
- If your dataset contains the \texttt{dynamic_feat} field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the \texttt{dynamic_feat} field should have the same length as the target. If the dataset contains the \texttt{dynamic_feat} field, but you don't want to use it, disable it by setting \texttt{num_dynamic_feat} to "". If the model was trained with the \texttt{dynamic_feat} field, you must provide this field for inference. In addition, each of the features has to have the length of the provided target plus the \texttt{prediction_length}. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:

$$\text{RMSE} = \sqrt{\frac{1}{nT} \sum_{i,t} (\hat{y}_{i,t} - y_{i,t})^2}$$

\(y_{i,t}\) is the true value of time series \(i\) at the time \(t\), \(\hat{y}_{i,t}\) is the mean prediction. The sum is over all \(n\) time series in the test set and over the last \(T\) time points for each time series, where \(T\) corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the \texttt{prediction_length} hyperparameter. For more information, see DeepAR Hyperparameters (p. 2074).

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range [0, 1], the weighted quantile loss is defined as follows:

$$w\text{QuantileLoss}[\tau] = 2 \frac{\sum_{i,t} Q^{(\tau)}_{i,t}}{\sum_{i,t} |y_{i,t}|}, \quad \text{with} \quad Q^{(\tau)}_{i,t} = \begin{cases} (1 - \tau) |\hat{y}_{i,t}^{(\tau)} - y_{i,t}| & \text{if } \hat{y}_{i,t}^{(\tau)} > y_{i,t} \\ \tau |\hat{y}_{i,t}^{(\tau)} - y_{i,t}| & \text{otherwise} \end{cases}$$

\(q_{i,t}^{(\tau)}\) is the \(\tau\)-quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the \texttt{test_quantiles} hyperparameter. In addition to these, the average of
the prescribed quantile losses is reported as part of the training logs. For information, see DeepAR Hyperparameters (p. 2074).

For inference, DeepAR accepts JSON format and the following fields:

- "instances", which includes one or more time series in JSON Lines format
- A name of "configuration", which includes parameters for generating the forecast

For more information, see DeepAR Inference Formats (p. 2079).

Best Practices for Using the DeepAR Algorithm

When preparing your time series data, follow these best practices to achieve the best results:

- Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set context_length, don't break up the time series or provide only a part of it. The model uses data points further back than the value set in context_length for the lagged values feature.

- When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but on the future prediction_length time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last prediction_length points from each time series for training. During training, the model doesn't see the target values for time points on which it is evaluated during testing. During testing, the algorithm withhold the last prediction_length points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see Tune a DeepAR Model (p. 2078).

- Avoid using very large values (>400) for the prediction_length because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use 5min instead of 1min.

- Because lags are used, a model can look further back in the time series than the value specified for context_length. Therefore, you don't need to set this parameter to a large value. We recommend starting with the value that you used for prediction_length.

- We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.

EC2 Instance Recommendations for the DeepAR Algorithm

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, ml.c4.2xlarge or ml.c4.4xlarge), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for context_length, prediction_length, num_cells, num_layers, or mini_batch_size can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when
running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

**DeepAR Sample Notebooks**

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker DeepAR algorithm and how to deploy the trained model for performing inferences, see Time series forecasting with DeepAR - Synthetic data as well as DeepAR demo on electricity dataset, which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all of the SageMaker examples. To open a notebook, choose its Use tab, and choose Create copy.

**How the DeepAR Algorithm Works**

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector of feature time series and a vector of categorical features. For more information, see Input/Output Interface for the DeepAR Algorithm (p. 2068).

For example, the following is an element of a training set indexed by \( i \) which consists of a target time series, \( Z_{i,t} \), and two associated feature time series, \( X_{i,1,t} \) and \( X_{i,2,t} \):

\[
Z_{i,t}
\]

\[
X_{i,1,t}
\]

\[
X_{i,2,t}
\]

The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run "what if?" scenarios. What happens, for example, if I change the price of a product in some way?

Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

**How Feature Time Series Work in the DeepAR Algorithm**

To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features: \( u_{i,1,t} \) represents the hour of the day and \( u_{i,2,t} \) the day of the week.
The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.

<table>
<thead>
<tr>
<th>Frequency of the Time Series</th>
<th>Derived Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minute</td>
<td>minute-of-hour, hour-of-day, day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Hour</td>
<td>hour-of-day, day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Day</td>
<td>day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Week</td>
<td>day-of-month, week-of-year</td>
</tr>
<tr>
<td>Month</td>
<td>month-of-year</td>
</tr>
</tbody>
</table>

DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The context_length hyperparameter controls how far in the past the network can see, and the prediction_length hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element $i$. For brevity, we've omitted the feature time series $x_{i,1,t}$ and $u_{i,2,t}$.  

\[ z_{i,t} \]

\[ u_{i,1,t} \]

\[ u_{i,2,t} \]
To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index, $t = T$, the model exposes the $z_{i,t}$ values, which occurred approximately one, two, and three days in the past.

For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next $\text{prediction_length}$ values. Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks.

**DeepAR Hyperparameters**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context_length</td>
<td>The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the $\text{prediction_length}$. The model also receives lagged inputs from the target, so $\text{context_length}$ can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the time series. For example, lag values for daily frequency are previous week, 2 weeks, 3 weeks, 4 weeks, and year. Required Valid values: Positive integer</td>
</tr>
<tr>

<td>prediction_length is fixed when a model is trained and it cannot be changed later. <strong>Required</strong> Valid values: Positive integer</td>
</tr>
<tr>
<td>time_freq</td>
<td>The granularity of the time series in the dataset. Use time_freq to select appropriate date features and lags. The model supports the following basic frequencies. It also supports multiples of these basic frequencies. For example, 5min specifies a frequency of 5 minutes. <strong>Required</strong> Valid values: An integer followed by M, W, D, H, or min. For example, 5min.</td>
</tr>
<tr>
<td>cardinality</td>
<td>When using the categorical features (cat), cardinality is an array specifying the number of categories (groups) per categorical feature. Set this to auto to infer the cardinality from the data. The auto mode also works when no categorical features are used in the dataset. This is the recommended setting for the parameter. Set cardinality to ignore to force DeepAR to not use categorical features, even if they are present in the data. To perform additional data validation, it is possible to explicitly set this parameter to the actual value. For example, if two categorical features are provided where the first has 2 and the other has 3 possible values, set this to [2, 3]. For more information on how to use categorical feature, see the data-section on the main documentation page of DeepAR. <strong>Optional</strong> Valid values: auto, ignore, array of positive integers, empty string, or</td>
</tr>
<tr>
<td>dropout_rate</td>
<td>The dropout rate to use during training. The model uses zoneout regularization. For each iteration, a random subset of hidden neurons are not updated. Typical values are less than 0.2. <strong>Optional</strong> Valid values: float Default value: 0.1</td>

</table>
| likelihood              | The model generates a probabilistic forecast, and can provide quantiles of the distribution and return samples. Depending on your data, select an appropriate likelihood (noise model) that is used for uncertainty estimates. The following likelihoods can be selected:  
  - `gaussian`: Use for real-valued data.  
  - `beta`: Use for real-valued targets between 0 and 1 inclusive.  
  - `negative-binomial`: Use for count data (non-negative integers).  
  - `student-T`: An alternative for real-valued data that works well for bursty data.  
  - `deterministic-L1`: A loss function that does not estimate uncertainty and only learns a point forecast.  |
|                         | **Optional**  
|                         | Valid values: One of `gaussian`, `beta`, `negative-binomial`, `student-T`, or `deterministic-L1`.  
|                         | Default value: `student-T`                                                                                                                   |
| mini_batch_size         | The size of mini-batches used during training. Typical values range from 32 to 512.                                                            |
|                         | **Optional**  
|                         | Valid values: positive integer                                                                                                                  |
|                         | Default value: 128                                                                                                                             |
| num_cells               | The number of cells to use in each hidden layer of the RNN. Typical values range from 30 to 100.                                                 |
|                         | **Optional**  
|                         | Valid values: positive integer                                                                                                                  |
|                         | Default value: 40                                                                                                                             |
| num_dynamic_feat        | The number of `dynamic_feat` provided in the data. Set this to `auto` to infer the number of dynamic features from the data. The `auto` mode also works when no dynamic features are used in the dataset. This is the recommended setting for the parameter.  
|                         | To force DeepAR to not use dynamic features, even if they are present in the data, set `num_dynamic_feat` to `ignore`.  
|                         | To perform additional data validation, it is possible to explicitly set this parameter to the actual integer value. For example, if two dynamic features are provided, set this to 2.  |
|                         | **Optional**  
|                         | Valid values: `auto`, `ignore`, positive integer, or empty string  
|                         | Default value: `auto`                                                                                                                           |
Tune a DeepAR Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

Metrics Computed by the DeepAR Algorithm

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see Best Practices for Using the DeepAR Algorithm (p. 2071).

**DeepAR Inference Formats**

**DeepAR JSON Request Formats**

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the instances field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a **cat** for each instance. If the model was trained without the **cat** field, it should be omitted.

If the model was trained with a custom feature time series (**dynamic_feat**), you have to provide the same number of **dynamic_feat** values for each instance. Each of them should have a length given by length(target) + prediction_length, where the last prediction_length values correspond to
the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```
{
  "instances": [
    {
      "start": "2009-11-01 00:00:00",
      "target": [4.0, 10.0, "NaN", 100.0, 113.0],
      "cat": [0, 1],
      "dynamic_feat": [[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
    },
    {
      "start": "2012-01-30",
      "target": [1.0],
      "cat": [2, 1],
      "dynamic_feat": [[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
    },
    {
      "start": "1999-01-30",
      "target": [2.0, 1.0],
      "cat": [1, 3],
      "dynamic_feat": [[1.0, 0.1, -2.5, 0.3, 2.0, -1.2, -0.1, -3.0, ...]]
    }
  ],
  "configuration": {
    "num_samples": 50,
    "output_types": ["mean", "quantiles", "samples"],
    "quantiles": ["0.5", "0.9"]
  }
}
```

The configuration field is optional. `configuration.num_samples` sets the number of sample paths that the model generates to estimate the mean and quantiles. `configuration.output_types` describes the information that will be returned in the request. Valid values are "mean", "quantiles" and "samples". If you specify "quantiles", each of the quantile values in `configuration.quantiles` is returned as a time series. If you specify "samples", the model also returns the raw samples used to calculate the other outputs.

**DeepAR JSON Response Formats**

The following is the format of a response, where [...] are arrays of numbers:

```
{
  "predictions": [
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    }
  ]
}
```
Amazon SageMaker Developer Guide
Use Built-in Algorithms

}

]

}

"0.5": [...]
},
"samples": [...],
"mean": [...]

DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request,
the forecasts are generated sequentially. Because the forecast for each time series typically takes about
300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a
single request can cause time outs. It's better to send fewer time series per request and send more
requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much
higher throughput by sending multiple requests in parallel.
By default, DeepAR uses one worker per CPU for inference, if there is suﬃcient memory per CPU. If the
model is large and there isn't enough memory to run a model on each CPU, the number of workers is
reduced. The number of workers used for inference can be overwritten using the environment variable
MODEL_SERVER_WORKERS For example, by setting MODEL_SERVER_WORKERS=1) when calling the
SageMaker CreateModel API.

Batch Transform with the DeepAR Algorithm
DeepAR forecasting supports getting inferences by using batch transform from data using the JSON
Lines format. In this format, each record is represented on a single line as a JSON object, and lines
are separated by newline characters. The format is identical to the JSON Lines format used for model
training. For information, see Input/Output Interface for the DeepAR Algorithm (p. 2068). For example:
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
"dynamic_feat": [[1.1, 1.2, 0.5, ..]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat":
[[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
[[1.3, 0.4]]}

Note

When creating the transformation job with CreateTransformJob, set the BatchStrategy
value to SingleRecord and set the SplitType value in the TransformInput conﬁguration
to Line, as the default values currently cause runtime failures.
Similar to the hosted endpoint inference request format, the cat and the dynamic_feat ﬁelds for each
instance are required if both of the following are true:
• The model is trained on a dataset that contained both the cat and the dynamic_feat ﬁelds.
• The corresponding cardinality and num_dynamic_feat values used in the training job are not set
to "".
Unlike hosted endpoint inference, the conﬁguration ﬁeld is set once for the entire batch
inference job using an environment variable named DEEPAR_INFERENCE_CONFIG. The
value of DEEPAR_INFERENCE_CONFIG can be passed when the model is created by calling
CreateTransformJob API. If DEEPAR_INFERENCE_CONFIG is missing in the container environment,
the inference container uses the following default:
{

}

"num_samples": 100,
"output_types": ["mean", "quantiles"],
"quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]

2081


The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance order in the corresponding input file. Predictions are encoded as objects identical to the ones returned by responses in online inference mode. For example:

```
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }
```

Note that in the TransformInput configuration of the SageMaker CreateTransformJob request clients must explicitly set the AssembleWith value to Line, as the default value None concatenates all JSON objects on the same line.

For example, here is a SageMaker CreateTransformJob request for a DeepAR job with a custom DEEPAR_INFERENCE_CONFIG:

```
{
  "BatchStrategy": "SingleRecord",
  "Environment": {
    "DEEPAR_INFERENCE_CONFIG" : ": \"num_samples\": 200, \"output_types\": [\"mean\"] \",
  },
  "TransformInput": {
    "SplitType": "Line",
  },
  "TransformOutput": {
    "AssembleWith": "Line",
  }
}
```

Unsupervised Built-in SageMaker Algorithms

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.

- **IP Insights (p. 2083)**—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
- **K-Means Algorithm (p. 2092)**—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
- **Principal Component Analysis (PCA) Algorithm (p. 2100)**—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
- **Random Cut Forest (RCF) Algorithm (p. 2104)**—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

### IP Insights

Amazon SageMaker IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from Amazon GuardDuty.

The SageMaker IP Insights algorithm can also learn vector representations of IP addresses, known as *embeddings*. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.

### Input/Output Interface for the IP Insights Algorithm

**Training and Validation**

The SageMaker IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in text/csv format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column
is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see IP Insights Training Data Formats (p. 2090).

Inference

For inference, IP Insights supports text/csv, application/json, and application/jsonlines data content types. For more information about the common data formats for inference provided by SageMaker, see Common Data Formats for Inference (p. 1915). IP Insights inference returns output formatted as either application/json or application/jsonlines. Each record in the output data contains the corresponding dot_product (or compatibility score) for each input data point. For more information and some examples, see IP Insights Inference Data Formats (p. 2090).

EC2 Instance Recommendation for the IP Insights Algorithm

The SageMaker IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances. IP Insights supports P2, P3, G4dn, and G5 GPU families.

GPU Instances for the IP Insights Algorithm

IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as ml.p3.2xlarge, and then moving to a multi-GPU environment, such as ml.p3.8xlarge and ml.p3.16xlarge. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the mini_batch_size is divided equally into the number of GPUs used. You may want to increase the value of the mini_batch_size to compensate for this.

CPU Instances for the IP Insights Algorithm

The type of CPU instance that we recommend depends largely on the instance's available memory and the model size. The model size is determined by two hyperparameters: vector_dim and num_entity_vectors. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for vector_dim in the first column range from 32 to 2048 and the values for num_entity_vectors in the first row range from 10,000 to 50,000,000.

<table>

</tbody>
</table>

The values for the mini_batch_size, num_ip_encoder_layers, random_negative_sampling_rate, and shuffled_negative_sampling_rate hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.
IP Insights Sample Notebooks

For a sample notebook that shows how to train the SageMaker IP Insights algorithm and perform inferences with it, see An Introduction to the SageMaker IP Insights Algorithm. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After creating a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. To open a notebook, choose its Use tab and choose Create copy.

How IP Insights Works

Amazon SageMaker IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to ensure that the number of collisions, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see Feature Hashing for Large Scale Multitask Learning. For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the cross entropy, also known as the log loss, defined as follows:

$$L = \frac{1}{N} \sum_{n} [y_n \log p_n + (1 - y_n) \log (1 - p_n)]$$

$y_n$ is the label that indicates whether the sample is from the real distribution governing observed data ($y_n=1$) or from the distribution generating negative samples ($y_n=0$). $p_n$ is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the random_negative_sampling_rate and shuffled_negative_sampling_rate hyperparameters.

Given an nth (entity, IP address pair), the IP Insights model outputs a score, $S_n$, that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given (entity, IP address) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

$$S_n = \log \left( \frac{P_{\text{real}}(n)}{P_{\text{neg}}(n)} \right)$$

The score is essentially a measure of the similarity between the vector representations of the nth entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality.
than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution, $p_n$, to use in the cross entropy minimization, where:

$$p_n = \frac{1}{1 + e^{-s_n}}$$

**IP Insights Hyperparameters**

In the `CreateTransformJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker IP Insights algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `num_entity_vectors`        | The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers. Required  
Valid values: $1 \leq$ positive integer $\leq 250,000,000 |
| `vector_dim`                | The size of embedding vectors to represent entities and IP addresses. The larger the value, the more information that can be encoded using these representations. In practice, model size scales linearly with this parameter and limits how large the dimension can be. In addition, using vector representations that are too large can cause the model to overfit, especially for small training datasets. Overfitting occurs when a model doesn't learn any pattern in the data but effectively memorizes the training data and, therefore, cannot generalize well and performs poorly during inference. The recommended value is 128. Required  
Valid values: $4 \leq$ positive integer $\leq 4096 |
| `batch_metrics_publish_interval` | The interval (every X batches) at which the Apache MXNet Speedometer function prints the training speed of the network (samples/second). Optional  
Valid values: positive integer $\geq 1  
Default value: 1,000 |

Tune an IP Insights Model

*Automatic model tuning*, also called hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker (p. 2360)](https://docs.aws.amazon.com/sagemaker/latest/dg/).
Metrics Computed by the IP Insights Algorithm

The Amazon SageMaker IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model, which learns to separate observed data points (positive samples) from randomly generated data points (negative samples). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This validation:discriminator_auc metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a validation:discriminator_auc metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.

IP Insights Data Formats

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

Topics

- IP Insights Training Data Formats (p. 2090)
- IP Insights Inference Data Formats (p. 2090)

IP Insights Training Data Formats

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input training format described in Common Data Formats for Training (p. 1912). However, the SageMaker IP Insights algorithm currently supports only the CSV data input format.

IP Insights Training Data Input Formats

INPUT: CSV

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

<table>
<thead>
<tr>
<th>entity_id_1, 192.168.1.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>entity_id_2, 10.10.1.2</td>
</tr>
</tbody>
</table>

IP Insights Inference Data Formats

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats for Inference (p. 1915). However, the SageMaker IP Insights algorithm does not currently support RecordIO format.

IP Insights Input Request Formats

INPUT: CSV Format

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

<table>
<thead>
<tr>
<th>entity_id_1, 192.168.1.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>entity_id_2, 10.10.1.2</td>
</tr>
</tbody>
</table>

INPUT: JSON Format

JSON data can be provided in different formats. IP Insights follows the common SageMaker formats. For more information about inference formats, see Common Data Formats for Inference (p. 1915).

content-type: application/json
Use Built-in Algorithms

{  "instances": [  {"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}},  {"features": ["entity_id_2", "10.10.1.2"]}}]}

INPUT: JSONLINES Format

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker inference formats, see Common Data Formats for Inference (p. 1915). For more information on running batch transform jobs, see Use Batch Transform (p. 2807).

content-type: application/jsonlines

{"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}},  {"features": ["entity_id_2", "10.10.1.2"]}}

IP Insights Output Response Formats

OUTPUT: JSON Response Format

The default output of the SageMaker IP Insights algorithm is the dot_product between the input entity and IP address. The dot_product signifies how compatible the model considers the entity and IP address. The dot_product is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the dot_product for anomaly detection, see the An Introduction to the SageMaker IP Insights Algorithm.

accept: application/json

{  "predictions": [  {"dot_product": 0.0},  {"dot_product": 2.0}  ]}

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter verbose=True to the Accept heading. You can use the entity_embedding and ip_embedding for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

accept: application/json;verbose=True

{  "predictions": [  {  "dot_product": 0.0,  "entity_embedding": [1.0, 0.0, 0.0],  "ip_embedding": [0.0, 1.0, 0.0]  },  {  "dot_product": 2.0,  "entity_embedding": [1.0, 0.0, 1.0],  "ip_embedding": [1.0, 0.0, 1.0]  }  ]}
K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see Web-scale k-means Clustering.

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The \( n \) attributes in each row represent a point in \( n \)-dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker, see How K-Means Clustering Works (p. 2093).

**Topics**
- Input/Output Interface for the K-Means Algorithm (p. 2092)
- EC2 Instance Recommendation for the K-Means Algorithm (p. 2093)
- K-Means Sample Notebooks (p. 2093)
- How K-Means Clustering Works (p. 2093)
- K-Means Hyperparameters (p. 2096)
- Tune a K-Means Model (p. 2098)
- K-Means Response Formats (p. 2099)

**Input/Output Interface for the K-Means Algorithm**

For training, the k-means algorithm expects data to be provided in the train channel (recommended S3DataDistributionType=ShardedByS3Key), with an optional test channel (recommended S3DataDistributionType=FullyReplicated) to score the data on. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, text/csv, application/json, and application/x-recordio-protobuf are supported. k-means returns a closest_cluster label and the distance_to_cluster for each observation.

For more information on input and output file formats, see K-Means Response Formats (p. 2099) for inference and the K-Means Sample Notebooks (p. 2093). The k-means algorithm does not support
multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

**EC2 Instance Recommendation for the K-Means Algorithm**

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to single-GPU instances (such as ml.g4dn.xlarge) because only one GPU is used per instance. The k-means algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

**K-Means Sample Notebooks**

For a sample notebook that uses the SageMaker K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see Analyze US census data for population segmentation using Amazon SageMaker. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

**How K-Means Clustering Works**

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the \( n \)-dimensional space (where \( n \) is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points \((t, h)\) in 2-dimensional space.

**Note**

Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren’t used.

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters \((k)\) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit \((0, 1, ..., 9)\). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space \((x, y)\). To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

**Note**

Amazon SageMaker uses a customized version of the algorithm where, instead of specifying that the algorithm create \(k\) clusters, you might choose to improve model accuracy by specifying extra cluster centers \((K = k*\gamma)\). However, the algorithm ultimately reduces these to \(k\) clusters.

In SageMaker, you specify the number of clusters when creating a training job. For more information, see CreateTrainingJob. In the request body, you add the HyperParameters string map to specify the \(k\) and extra_center_factor strings.

The following is a summary of how k-means works for model training in SageMaker:

1. It determines the initial \(K\) cluster centers.
Use Built-in Algorithms

Note
In the following topics, K clusters refer to k * x, where you specify k and x when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.
3. It reduces resulting clusters to k (if the data scientist specified the creation of k*x clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the HyperParameters string map.

Topics
• Step 1: Determine the Initial Cluster Centers (p. 2094)
• Step 2: Iterate over the Training Dataset and Calculate Cluster Centers (p. 2095)
• Step 3: Reduce the Clusters from K to k (p. 2095)

Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

• The random approach—Randomly choose K observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.

• The k-means++ approach, which works as follows:
  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.
  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:
    • For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
    • Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.
  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.
  4. Repeat the process until you have the K cluster centers.

To train a model in SageMaker, you create a training job. In the request, you provide configuration information by specifying the following HyperParameters string maps:

• To specify the number of clusters to create, add the k string.
• For greater accuracy, add the optional extra_center_factor string.
• To specify the strategy that you want to use to determine the initial cluster centers, add the init_method string and set its value to random or k-means++.
For more information about the SageMaker k-means estimator, see K-means in the Amazon SageMaker Python SDK documentation.

You now have an initial set of cluster centers.

**Step 2: Iterate over the Training Dataset and Calculate Cluster Centers**

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the $K$ cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

   **Note**
   When creating a model training job, you specify the batch size in the `mini_batch_size` string in the `HyperParameters` string map.

   a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.

   b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

   For example, consider the following clusters:

   Cluster $c_1 = 100$ previously assigned points. You added 25 points from the mini-batch in this step.

   Cluster $c_2 = 150$ previously assigned points. You added 40 points from the mini-batch in this step.

   Cluster $c_3 = 450$ previously assigned points. You added 5 points from the mini-batch in this step.

   Calculate the proportion of new points assigned to each of clusters as follows:

   $p_1 = \text{proportion of points assigned to } c_1 = \frac{25}{100+25}$

   $p_2 = \text{proportion of points assigned to } c_2 = \frac{40}{150+40}$

   $p_3 = \text{proportion of points assigned to } c_3 = \frac{5}{450+5}$

   c. Compute the center of the new points added to each cluster:

      $d_1 = \text{center of the new points added to cluster } 1$
      $d_2 = \text{center of the new points added to cluster } 2$
      $d_3 = \text{center of the new points added to cluster } 3$

   d. Compute the weighted average to find the updated cluster centers as follows:

      Center of cluster $1 = ((1 - p_1) \times \text{center of cluster } 1) + (p_1 \times d_1)$
      Center of cluster $2 = ((1 - p_2) \times \text{center of cluster } 2) + (p_2 \times d_2)$
      Center of cluster $3 = ((1 - p_3) \times \text{center of cluster } 3) + (p_3 \times d_3)$

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.

3. For more information about mini-batch k-means, see Web-Scale k-means Clustering).

**Step 3: Reduce the Clusters from $K$ to $k$**

If the algorithm created $K$ clusters—($K = k \times x$) where $x$ is greater than 1—then it reduces the $K$ clusters to $k$ clusters. (For more information, see `extra_center_factor` in the preceding discussion.) It does this
by applying Lloyd’s method with kmeans++ initialization to the K cluster centers. For more information about Lloyd’s method, see k-means clustering.

**K-Means Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker. For more information about how k-means clustering works, see How K-Means Clustering Works (p. 2093).

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
