**Tune a K-Means Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn’t use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2360).

---

**Metrics Computed by the K-Means Algorithm**

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:msd</td>
<td>Mean squared distances between each record in the test set and the closest center of the model.</td>

`init_method` | CategoricalParameterRanges | ['kmeans++', 'random']
`mini_batch_size` | IntegerParameterRanges | MinValue: 3000, MaxValue: 15000

## K-Means Response Formats

All SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-means algorithm.

### JSON Response Format

```json
{
   "predictions": [
      {
         "closest_cluster": 1.0,
         "distance_to_cluster": 3.0,
      },
      {
         "closest_cluster": 2.0,
         "distance_to_cluster": 5.0,
      },
      ...
   ]
}
```

### JSONLINES Response Format

```json
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

### RECORDIO Response Format

```json
[
   Record = {
      features = {},
      label = {
         'closest_cluster': {
            keys: [],
            values: [1.0, 2.0] # float32
         },
         'distance_to_cluster': {
            keys: [],
            values: [3.0, 5.0] # float32
         }
      }
   }
]
```

### CSV Response Format

The first value in each line corresponds to `closest_cluster`. 
The second value in each line corresponds to distance_to_cluster.

1.0, 3.0
2.0, 5.0

**Principal Component Analysis (PCA) Algorithm**

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by finding a new set of features called *components*, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker, PCA operates in two modes, depending on the scenario:

- **regular**: For datasets with sparse data and a moderate number of observations and features.
- **randomized**: For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data.

The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

**Topics**

- EC2 Instance Recommendation for the PCA Algorithm (p. 2100)
- PCA Sample Notebooks (p. 2101)
- How PCA Works (p. 2101)
- PCA Hyperparameters (p. 2102)
- PCA Response Formats (p. 2103)

**Input/Output Interface for the PCA Algorithm**

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, PCA supports text/csv, application/json, and application/x-recordio-protobuf. Results are returned in either application/json or application/x-recordio-protobuf format with a vector of "projections."

For more information on input and output file formats, see PCA Response Formats (p. 2103) for inference and the PCA Sample Notebooks (p. 2101).

**EC2 Instance Recommendation for the PCA Algorithm**

PCA supports CPU and GPU instances for training and inference. Which instance type is most performant depends heavily on the specifics of the input data. For GPU instances, PCA supports P2, P3, G4dn, and G5.
PCA Sample Notebooks

For a sample notebook that shows how to use the SageMaker Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to PCA with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How PCA Works

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called components, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren’t used.

Given the input of a matrix with rows $x_1, \ldots, x_n$ each of dimension $1 \times d$, the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.

Modes

The Amazon SageMaker PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm’s last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

Mode 1: Regular

The workers jointly compute both $\sum x_i^T x_i$ and $\sum x_i$.  

**Note**

Because $x_i$ are $1 \times d$ row vectors, $x_i^T x_i$ is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.

The covariance matrix is computed as $\sum x_i^T x_i - (1/n)(\sum x_i)^T \sum x_i$, and its top `num_components` singular vectors form the model.

**Note**

If `subtract_mean` is False, we avoid computing and subtracting $\sum x_i$.

Use this algorithm when the dimension $d$ of the vectors is small enough so that $d^2$ can fit in memory.

Mode 2: Randomized

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch $X_i$ of dimension $b \times d$, we randomly initialize a
(num_components + extra_components) * b matrix that we multiply by each mini-batch, to create a (num_components + extra_components) * d matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final (num_components + extra_components) * d matrix. The top right num_components singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let \( \ell = \text{num_components} + \text{extra_components} \). Given a mini-batch of dimension \( b \times d \), the worker draws a random matrix \( H_i \) of dimension \( \ell \times b \). Depending on whether the environment uses a GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is \( +1 \) or \( -1 \) or a FJLT (fast Johnson Lindenstrauss transform; for information, see FJLT Transforms and the follow-up papers). The worker then computes \( H_iX_i \), and maintains \( B = \sum H_iX_i \). The worker also maintains \( h^T \), the sum of columns of \( H_1, \ldots, H_T \) (\( T \) being the total number of mini-batches), and \( s \), the sum of all input rows. After processing the entire shard of data, the worker sends the server \( B, h, s, \) and \( n \) (the number of input rows).

Denote the different inputs to the server as \( B^1, h^1, s^1, n^1 \). The server computes \( B, h, s, n \) the sums of the respective inputs. It then computes \( C = B - (1/n)h^T s \), and finds its singular value decomposition. The top-right singular vectors and singular values of \( C \) are used as the approximate solution to the problem.

### PCA Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker. For more information about how PCA works, see [How PCA Works](p. 2101).

            keys: [],
            values: [1.0, 2.0, 3.0, 4.0, 5.0]
            }
        }
    }
```
Random Cut Forest (RCF) Algorithm

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-dimensional input. Amazon SageMaker RCF scales well with respect to number of features, data set size, and number of instances.

Input/Output Interface for the RCF Algorithm

Amazon SageMaker Random Cut Forest supports the train and test data channels. The optional test channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and test data content types can be either application/x-recordio-protobuf or text/csv formats. For the test data, when using text/csv format, the content must be specified as text/csv;label_size=1 where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as recordIO-wrapped-protobuf or CSV.

The train channel only supports S3DataDistributionType=ShardedByS3Key and the test channel only supports S3DataDistributionType=FullyReplicated. The following example specifies the S3 distribution type for the train channel using the Amazon SageMaker Python SDK.
Note

The `sagemaker.inputs.s3_input` method was renamed to `sagemaker.inputs.TrainingInput` in SageMaker Python SDK v2.

```python
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
cfr = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.TrainingInput(
    s3_data=s3_training_data_location,
    content_type='text/csv;label_size=0',
    distribution='ShardedByS3Key')

# run the training job on input data stored in S3
cfr.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, `AmazonSageMakerFullAccess` and `AmazonEC2ContainerRegistryFullAccess`. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger than the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different AWS account's Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the ECR repository permissions for more information on setting a repository policy statement.

See the `S3DataSource` for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports `application/x-recordio-protobuf`, `text/csv` and `application/json` input data content types. See the Common Data Formats for Built-in Algorithms (p. 1911) documentation for more information. RCF inference returns `application/x-recordio-protobuf` or `application/json` formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See Common Data Formats--Inference for more information.

For more information on input and output file formats, see RCF Response Formats (p. 2110) for inference and the RCF Sample Notebooks (p. 2105).

Instance Recommendations for the RCF Algorithm

For training, we recommend the `ml.m4`, `ml.c4`, and `ml.c5` instance families. For inference we recommend using a `ml.c5.xl` instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

RCF Sample Notebooks

For an example of how to train an RCF model and perform inferences with it, see the An Introduction to SageMaker Random Cut Forests notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

How RCF Works

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or
patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

Sample Data Randomly

The first step in the RCF algorithm is to obtain a random sample of the training data. In particular, suppose we want a sample of size \( K \) from \( N \) total data points. If the training data is small enough, the entire dataset can be used, and we could randomly draw \( K \) elements from this set. However, frequently the training data is too large to fit all at once, and this approach isn't feasible. Instead, we use a technique called reservoir sampling.

Reservoir sampling is an algorithm for efficiently drawing random samples from a dataset \( S = \{S_1, \ldots, S_N\} \) where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when \( N \) is not known a priori. If only one sample is requested, such as when \( K = 1 \), the algorithm is like this:

Algorithm: Reservoir Sampling

- Input: dataset or data stream \( S = \{S_1, \ldots, S_N\} \)
- Initialize the random sample \( X = S_1 \)
- For each observed sample \( S_n, n = 2, \ldots, N \):
  - Pick a uniform random number \( \xi \in [0, 1] \)
  - If \( \xi < 1/n \)
    - Set \( X = S_n \)
  - Return \( X \)

This algorithm selects a random sample such that \( P(X = S_n) = 1/N \) for all \( n = 1, \ldots, N \). When \( K > 1 \) the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

Train a RCF Model and Produce Inferences

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest. Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:
A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher "variance"), and then randomly determining the position of a hyperplane "cut" through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.

A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point
is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

Choose Hyperparameters

The primary hyperparameters used to tune the RCF model are num_trees and num_samples_per_tree. Increasing num_trees has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm describe above.

The parameter num_samples_per_tree is related to the expected density of anomalies in the dataset. In particular, num_samples_per_tree should be chosen such that 1/num_samples_per_tree approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies 1/256 or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

### Tune an RCF Model

_Automatic model tuning_, also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test data points and then labels the data points as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

### Metrics Computed by the RCF Algorithm

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:f1</td>
<td>F1-score on the test dataset, based on the difference between calculated labels and actual labels.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

**Tunable RCF Hyperparameters**

You can tune a RCF model with the following hyperparameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Recommended Ranges</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_samples_per_tree</td>
<td>IntegerParameterRanges</td>
<td>MinValue: 1, MaxValue:2048</td>
</tr>
<tr>
<td>num_trees</td>
<td>IntegerParameterRanges</td>
<td>MinValue: 50, MaxValue:1000</td>
</tr>
</tbody>
</table>

**RCF Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). Note that SageMaker Random Cut Forest supports both dense and sparse JSON and RecordIO formats. This topic contains a list of the available output formats for the SageMaker RCF algorithm.

**JSON Response Format**

ACCEPT: application/json.

```json
{
    "scores": [
        {
            "score": 0.02,
        },
        {
            "score": 0.25,
        }
    ]
}
```

**JSONLINES Response Format**

ACCEPT: application/jsonlines.

```json
{"score": 0.02},
```
RECORDIO Response Format

ACCEPT: application/x-recordio-protobuf.

```
[  
    Record = {  
      features = {},  
      label = {  
        'score': {  
          keys: [],  
          values: [0.25] # float32  
        }  
      }  
    },  
    Record = {  
      features = {},  
      label = {  
        'score': {  
          keys: [],  
          values: [0.25] # float32  
        }  
      }  
    }  
  ],
```
Built-in SageMaker Algorithms for Computer Vision

SageMaker provides image processing algorithms that are used for image classification, object detection, and computer vision.

- **Image Classification - MXNet (p. 2113)**—uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- **Image Classification - TensorFlow (p. 2124)**—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.
- **Object Detection (p. 2137)**—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- **Semantic Segmentation Algorithm (p. 2147)**—provides a fine-grained, pixel-level approach to developing computer vision applications.

### Image Classification - MXNet

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network that can be trained from scratch or trained using transfer learning when a large number of training images are not available.

The recommended input format for the Amazon SageMaker image classification algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. Refer to this discussion for a broad overview of efficient data preparation and loading for machine learning systems.

**Note**

To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

For more information on convolutional networks, see:

- ImageNet image database
- Image classification with Gluon-CV and MXNet

**Topics**

### Input/Output Interface for the Image Classification Algorithm

The SageMaker Image Classification algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode, and supports the RecordIO (application/x-recordio) content type for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format.
Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the `S3DataDistributionType` of the `S3DataSource` to `FullyReplicated`. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports `image/png`, `image/jpeg`, and `application/x-image` for inference.

**Train with RecordIO Format**

If you use the RecordIO format for training, specify both `train` and `validation` channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify one RecordIO (.rec) file in the `train` channel and one RecordIO file in the `validation` channel. Set the content type for both channels to `application/x-recordio`.

**Train with Image Format**

If you use the Image format for training, specify `train`, `validation`, `train_lst`, and `validation_lst` channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify the individual image data (.jpg or .png files) for the `train` and `validation` channels. Specify one .lst file in each of the `train_lst` and `validation_lst` channels. Set the content type for all four channels to `application/x-image`.

**Note**

SageMaker reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A .lst file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a .lst file:

```
5   1   your_image_directory/train_img_dog1.jpg
1000   0   your_image_directory/train_img_cat1.jpg
22   1   your_image_directory/train_img_dog2.jpg
```

For example, if your training images are stored in `s3://<your_bucket>/train/class_dog, s3://<your_bucket>/train/class_cat, and so on`, specify the path for your `train` channel as `s3://<your_bucket>/train`, which is the top-level directory for your data. In the .lst file, specify the relative path for an individual file named `train_image_dog1.jpg` in the `class_dog` class directory as `class_dog/train_image_dog1.jpg`. You can also store all your image files under one subdirectory inside the `train` directory. In that case, use that subdirectory for the relative path. For example, `s3://<your_bucket>/train/your_image_directory`.

**Train with Augmented Manifest Image Format**

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both `train` and `validation` channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the `source-ref` tag that points to the S3 location of the image. The annotations are provided under the `AttributeNames` parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the `metadata` tag, but these are ignored by the algorithm. In the following example, the `AttributeNames` are contained in the list of image and annotation references `"source-ref", "class"`. The corresponding label value is "0" for the first image and "1" for the second image:

```
{"source-ref":"s3://image/filename1.jpg", "class":"0"}
```
The order of "AttributeNames" in the input files matters when training the ImageClassification algorithm. It accepts piped data in a specific order, with image first, followed by label. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "class". When using the ImageClassification algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO".

Multi-label training is also supported by specifying a JSON array of values. The num_classes hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:

{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": ":[1, 0, 1]"}  
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[0, 0, 1]"}

In the class-id format, each label is a list of the class ids, from [0, num_classes), which apply to the data point. The previous example would instead look like this:

{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": ":[0, 2]"}  
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[2]"}

The multi-hot format is the default, but can be explicitly set in the content type with the label-format parameter: "application/x-recordio; label-format=multi-hot". The class-id format, which is the format outputted by GroundTruth, must be set explicitly: "application/x-recordio; label-format=class-id".

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2608).

Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker image classification models can be seeded only with another built-in image classification model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the num_layers, image_shape and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For a sample notebook that shows how to use incremental training with the SageMaker image classification algorithm, see the End-to-End Incremental Training Image Classification Example. For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 2587).

Inference with the Image Classification Algorithm

The generated models can be hosted for inference and support encoded .jpg and .png image formats as image/png, image/jpeg, and application/x-image content-type. The input image is resized
automatically. The output is the probability values for all classes encoded in JSON format, or in JSON
Lines text format for batch transform. The image classification model processes a single image per
request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a
response in JSON Lines format:

```
accept: application/jsonlines
{"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}
```

For more details on training and inference, see the image classification sample notebook instances
referenced in the introduction.

**EC2 Instance Recommendation for the Image Classification Algorithm**

For image classification, we support P2, P3, G4dn, and G5 instances. We recommend using GPU instances
with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and
multi-machine settings for distributed training. Both CPU (such as C4) and GPU (P2, P3, G4dn, or G5)
instances can be used for inference.

**Image Classification Sample Notebooks**

For a sample notebook that uses the SageMaker image classification algorithm to train a model on the
caltech-256 dataset and then to deploy it to perform inferences, see the End-to-End Multiclass Image
Classification Example. For instructions how to create and access Jupyter notebook instances that you
can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once
you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of
all the SageMaker samples. The example image classification notebooks are located in the Introduction
to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**How Image Classification Works**

The image classification algorithm takes an image as input and classifies it into one of the output
categories. Deep learning has revolutionized the image classification domain and has achieved great
performance. Various deep learning networks such as ResNet [1], DenseNet, inception, and so on, have
been developed to be highly accurate for image classification. At the same time, there have been efforts
to collect labeled image data that are essential for training these networks. ImageNet[2] is one such
large dataset that has more than 11 million images with about 11,000 categories. Once a network is
trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-
adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in
this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a
different dataset.

Image classification in Amazon SageMaker can be run in two modes: full training and transfer learning.
In full training mode, the network is initialized with random weights and trained on user data from
scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top
fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new
data. In this mode, training can be achieved even with a smaller dataset. This is because the network is
already trained and therefore can be used in cases without sufficient training data.

**Image Classification Hyperparameters**

Hyperparameters are parameters that are set before a machine learning model begins learning. The
following hyperparameters are supported by the Amazon SageMaker built-in Image Classification
algorithm. See Tune an Image Classification Model (p. 2123) for information on image classification
hyperparameter tuning.
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>Number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. Besides multi-class classification, multi-label classification is supported too. Please refer to Input/Output Interface for the Image Classification Algorithm (p. 2113) for details on how to work with multi-label classification with augmented manifest files. Required Valid values: positive integer</td>
</tr>
<tr>
<td>num_training_samples</td>
<td>Number of training examples in the input dataset. If there is a mismatch between this value and the number of samples in the training set, then the behavior of the lr_scheduler_step parameter is undefined and distributed training accuracy might be affected. Required Valid values: positive integer</td>
</tr>
<tr>
<td>augmentation_type</td>
<td>Data augmentation type. The input images can be augmented in multiple ways as specified below.</td>
</tr>
<tr>
<td></td>
<td>• crop: Randomly crop the image and flip the image horizontally • crop_color: In addition to ‘crop’, three random values in the range [-36, 36], [-50, 50], and [-50, 50] are added to the corresponding Hue-Saturation-Lightness channels respectively • crop_color_transform: In addition to crop_color, random transformations, including rotation, shear, and aspect ratio variations are applied to the image. The maximum angle of rotation is 10 degrees, the maximum shear ratio is 0.1, and the maximum aspect changing ratio is 0.25. Optional Valid values: crop, crop_color, or crop_color_transform. Default value: no default value</td>
</tr>
<tr>
<td>beta_1</td>
<td>The beta1 for adam, that is the exponential decay rate for the first moment estimates. Optional Valid values: float. Range in [0, 1]. Default value: 0.9</td>
</tr>
<tr>
<td>beta_2</td>
<td>The beta2 for adam, that is the exponential decay rate for the second moment estimates. Optional</td>
</tr>

<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 or 1</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>num_layers</td>
<td>Number of layers for the network. For data with large image size (for example, 224x224 - like ImageNet), we suggest selecting the number of layers from the set [18, 34, 50, 101, 152, 200]. For data with small image size (for example, 28x28 - like CIFAR), we suggest selecting the number of layers from the set [20, 32, 44, 56, 110]. The number of layers in each set is based on the ResNet paper. For transfer learning, the number of layers defines the architecture of base network and hence can only be selected from the set [18, 34, 50, 101, 152, 200].</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>

<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| optimizer | The optimizer type. For more details of the parameters for the optimizers, please refer to MXNet's API.  
  
  **Optional**  
  
  Valid values: One of sgd, adam, rmsprop, or nag.  
  
  - sgd: Stochastic gradient descent  
  - adam: Adaptive momentum estimation  
  - rmsprop: Root mean square propagation  
  - nag: Nesterov accelerated gradient  
  
  Default value: sgd |
| precision_dtype | The precision of the weights used for training. The algorithm can use either single precision (float32) or half precision (float16) for the weights. Using half-precision for weights results in reduced memory consumption.  
  
  **Optional**  
  
  Valid values: float32 or float16  
  
  Default value: float32 |
| resize | The number of pixels in the shortest side of an image after resizing it for training. If the parameter is not set, then the training data is used without resizing. The parameter should be larger than both the width and height components of `image_shape` to prevent training failure.  
  
  **Required** when using image content types  
  
  **Optional** when using the RecordIO content type  
  
  Valid values: positive integer  
  
  Default value: no default value |
| top_k | Reports the top-k accuracy during training. This parameter has to be greater than 1, since the top-1 training accuracy is the same as the regular training accuracy that has already been reported.  
  
  **Optional**  
  
  Valid values: positive integer larger than 1.  
  
  Default value: no default value |
<table>
<thead>
<tr>

**Tune an Image Classification Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2360).

**Metrics Computed by the Image Classification Algorithm**

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

<table>

**Tunable Image Classification Hyperparameters**

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: mini_batch_size, learning_rate,
and optimizer. Tune the optimizer-related hyperparameters, such as momentum, weight_decay, beta_1, beta_2, eps, and gamma, based on the selected optimizer. For example, use beta_1 and beta_2 only when adam is the optimizer.

For more information about which hyperparameters are used in each optimizer, see Image Classification Hyperparameters (p. 2116).

**Image Classification - TensorFlow**

The Amazon SageMaker TensorFlow image classification algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The image classification algorithm takes an image as input and outputs a probability for each provided class label. Training datasets must consist of images in .jpg, .jpeg, or .png format.

**Topics**

- How to use the SageMaker TensorFlow Image Classification algorithm (p. 2125)
- Input and Output interface for the TensorFlow Image Classification algorithm (p. 2126)
- Amazon EC2 instance recommendation for the TensorFlow Image Classification algorithm (p. 2127)
- TensorFlow Image Classification sample notebooks (p. 2127)
- How TensorFlow Image Classification Works (p. 2127)
- TensorFlow Hub Models (p. 2128)
- TensorFlow Image Classification Hyperparameters (p. 2132)
- Tune a TensorFlow Image Classification Model (p. 2136)
How to use the SageMaker TensorFlow Image Classification algorithm

You can use TensorFlow Image Classification as an Amazon SageMaker built-in algorithm. The following section describes how to use TensorFlow Image Classification with the SageMaker Python SDK. For information on how to use TensorFlow Image Classification from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 45).

The TensorFlow Image Classification algorithm supports transfer learning using any of the compatible pretrained TensorFlow Hub models. For a list of all available pretrained models, see TensorFlow Hub Models (p. 2128). Every pretrained model has a unique model_id. The following example uses MobileNet V2 1.00 224 (model_id: tensorflow-ic-imagenet-mobilenet-v2-100-224-classification-4) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with hyperparameters.retrieve_default. For more information, see TensorFlow Image Classification Hyperparameters (p. 2132). Use these values to construct a SageMaker Estimator.

**Note**
Default hyperparameter values are different for different models. For larger models, the default batch size is smaller and the train_only_on_top hyperparameter is set to "True".

This example uses the tf_flowers dataset, which contains five classes of flower images. We pre-downloaded the dataset from TensorFlow under the Apache 2.0 license and made it available with Amazon S3. To fine-tune your model, call .fit using the Amazon S3 location of your training dataset.

```python
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-ic-imagenet-mobilenet-v2-100-224-classification-4", "*
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri = image_uris.retrieve(model_id=model_id,model_version=model_version, image_scope="training", instance_type=training_instance_type, region=None, framework=None)

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version, script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version, model_scope="training")

# Retrieve the default hyper-parameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id, model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# The sample training data is available in the following S3 bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tf_flowers/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"
output_bucket = sess.default_bucket()
```
```
output_prefix = "jumpstart-example-ic-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create SageMaker Estimator instance
tf_ic_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Use S3 path of the training data to launch SageMaker TrainingJob
tf_ic_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

For more information about the TensorFlow Image Classification algorithm, including transfer-learning, fine-tuning, inference, and deployment, see the following notebook example:

- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm

### Input and Output interface for the TensorFlow Image Classification algorithm

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the TensorFlow Image Classification model.

- **Training data input format:** Your training data should be a directory with as many sub-directories as the number of classes. Each sub-directory should contain images belonging to that class in .jpg, .jpeg or .png format.

The following is an example of an input directory structure. This example dataset has two classes: roses and dandelion. The image files in each class folder can have any name. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: `s3://bucket_name/input_directory/`. Note that the trailing `/` is required.

```
input_directory
|-- roses
    |-- abc.jpg
    |-- def.jpg
|-- dandelion
    |-- ghi.jpg
    |-- jkl.jpg
```

Trained models output label mapping files that map class folder names to the indices in the list of output class probabilities. This mapping is in alphabetical order. For example, in the folder structure above, the dandelion class is index 0 and the roses class is index 1.

After training, you will have a fine-tuned model that you can further train using incremental training or deploy for inference. The TensorFlow Image Classification algorithm automatically adds a pre-processing and post-processing signature to the fine-tuned model so that it can take in images as input and return class probabilities. The file mapping class indices to class labels is saved along with the models.
Incremental training

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

**Note**

You can only seed a SageMaker TensorFlow Image Classification model with another TensorFlow Image Classification model trained in SageMaker.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For an example of incremental training with the SageMaker TensorFlow Image Classification algorithm, see the Introduction to SageMaker TensorFlow - Image Classification sample notebook.

### Inference with the TensorFlow Image Classification algorithm

You can host the fine-tuned model that results from your TensorFlow Image Classification training for inference. Any input image for inference must be in .jpg, .jpeg, or .png format and be content type application/x-image. The TensorFlow Image Classification resizes input images automatically.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The TensorFlow Image Classification model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```json
accept: application/json;verbose

{"probabilities": [prob_0, prob_1, prob_2, ...],
"labels": [label_0, label_1, label_2, ...],
"predicted_label": predicted_label}
```

If `accept` is set to application/json, then the model only outputs probabilities. For more information on training and inference with the TensorFlow Image Classification algorithm, see the Introduction to SageMaker TensorFlow - Image Classification sample notebook.

### Amazon EC2 instance recommendation for the TensorFlow Image Classification algorithm

The TensorFlow image classification algorithm supports all CPU and GPU instances for training, including ml.p2.xlarge, ml.p2.16xlarge, ml.p3.2xlarge, ml.p3.16xlarge, ml.g4dn.xlarge, ml.g4dn.16xlarge, ml.g5.xlarge, and ml.g5.48xlarge. We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.

### TensorFlow Image Classification sample notebooks

For more information about how to use the SageMaker TensorFlow Image Classification algorithm for transfer learning on custom dataset, see the following example notebook:

- [Introduction to SageMaker TensorFlow - Image Classification](#)

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

### How TensorFlow Image Classification Works

The TensorFlow Image Classification algorithm takes an image as input and classifies it into one of the output class labels. Various deep learning networks such as MobileNet, ResNet, Inception, and
EfficientNet are highly accurate for image classification. There are also deep learning networks that are trained on large image datasets, such as ImageNet, which has over 11 million images and close to 11,000 classes. After a network is trained with ImageNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific classification tasks. The Amazon SageMaker TensorFlow Image Classification algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a classification layer is attached to the pretrained Transfer Family Hub model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully-connected layer with 2-norm regularizer that is initialized with random weights. The model has hyperparameters for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer. You can then fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

**TensorFlow Hub Models**

The following pretrained models are available to use for transfer learning with the TensorFlow Image Classification algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

**TensorFlow Image Classification Hyperparameters**

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification - TensorFlow algorithm. See [Tune a TensorFlow Image Classification Model (p. 2136)](https://docs.aws.amazon.com/sagemaker/latest/dg/classification-tuning.html) for information on hyperparameter tuning.

<table>
<thead>

<tr>
<td>label_smoothing</td>
<td>Indicates how much to relax the confidence on label values. For example, if label_smoothing is 0.1, then non-target labels are 0.1/num_classes and target labels are 0.9+0.1/num_classes. Valid values: float, range: [0.0, 1.0]. Default value: 0.1.</td>
</tr>
<tr>
<td>learning_rate</td>
<td>The optimizer learning rate. Valid values: float, range: [0.0, 1.0]. Default value: 0.001.</td>
</tr>
<tr>
<td>momentum</td>
<td>The momentum for &quot;sgd&quot;, &quot;nesterov&quot;, and &quot;rmsprop&quot; optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.9.</td>
</tr>
<tr>
<td>optimizer</td>
<td>The optimizer type. For more information, see Optimizers in the TensorFlow documentation. Valid values: string, any of the following: (&quot;adam&quot;, &quot;sgd&quot;, &quot;nesterov&quot;, &quot;rmsprop&quot;, &quot;adagrad&quot;, &quot;adadelta&quot;). Default value: &quot;adam&quot;.</td>
</tr>
<tr>
<td>regularizers_l2</td>
<td>The L2 regularization factor for the dense layer in the classification layer. Valid values: float, range: [0.0, 1.0]. Default value: .0001.</td>
</tr>
<tr>
<td>reinitialize_top_layer</td>
<td>If set to &quot;Auto&quot;, the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to &quot;True&quot;. Valid values: string, any of the following: (&quot;Auto&quot;, &quot;True&quot; or &quot;False&quot;). Default value: &quot;Auto&quot;.</td>
</tr>
<tr>
<td>rho</td>
<td>The discounting factor for the gradient of the &quot;adadelta&quot; and &quot;rmsprop&quot; optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.95.</td>
</tr>
<tr>
<td>train_only_on_top_layer</td>
<td>If &quot;True&quot;, only the top classification layer parameters are fine-tuned. If &quot;False&quot;, all model parameters are fine-tuned. Valid values: string, either: (&quot;True&quot; or &quot;False&quot;). Default value: &quot;False&quot;.</td>
</tr>
</tbody>
</table>
Tune a TensorFlow Image Classification Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

Metrics computed by the TensorFlow Image Classification algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>

</tr>
</tbody>
</table>

Tunable TensorFlow Image Classification hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: batch_size, learning_rate, and optimizer. Tune the optimizer-related hyperparameters, such as momentum, regularizers_l2, beta_1, beta_2, and eps based on the selected optimizer. For example, use beta_1 and beta_2 only when adam is the optimizer.

For more information about which hyperparameters are used for each optimizer, see TensorFlow Image Classification Hyperparameters (p. 2132).

**Object Detection**

The Amazon SageMaker Object Detection algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the Single Shot multibox Detector (SSD) framework and supports two base networks: VGG and ResNet. The network can be trained from scratch, or trained with models that have been pre-trained on the ImageNet dataset.

**Topics**
- Input/Output Interface for the Object Detection Algorithm (p. 2137)
- EC2 Instance Recommendation for the Object Detection Algorithm (p. 2140)
- Object Detection Sample Notebooks (p. 2140)
- How Object Detection Works (p. 2140)
- Object Detection Hyperparameters (p. 2140)
- Tune an Object Detection Model (p. 2145)
- Object Detection Request and Response Formats (p. 2146)

**Input/Output Interface for the Object Detection Algorithm**

The SageMaker Object Detection algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpg, and application/x-image) content types for training in file mode and supports RecordIO (application/x-recordio) for training in pipe mode. However you can also train in pipe mode using the image files (image/png, image/jpg, and application/x-image), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker object detection algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. The algorithm supports only application/x-image for inference.

**Note**
To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

See the Object Detection Sample Notebooks (p. 2140) for more details on data formats.

**Train with the RecordIO Format**

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the MXNet's GluonCV to generate RecordIO files for popular datasets like the PASCAL Visual Object Classes and Common Objects in Context (COCO).

**Train with the Image Format**

If you use the image format for training, specify train, validation, train_annotation, and validation_annotation channels as values for the InputDataConfig parameter of CreateTrainingJob request. Specify the individual image data (.jpg or .png) files for the train and...
validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the train_annotation and validation_annotation channels. Set the content type for all four channels to image/png or image/jpeg based on the image type. You can also use the content type application/x-image when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```json
{
    "file": "your_image_directory/sample_image1.jpg",
    "image_size": [
        {
            "width": 500,
            "height": 400,
            "depth": 3
        }
    ],
    "annotations": [
        {
            "class_id": 0,
            "left": 111,
            "top": 134,
            "width": 61,
            "height": 128
        },
        {
            "class_id": 0,
            "left": 161,
            "top": 250,
            "width": 79,
            "height": 143
        },
        {
            "class_id": 1,
            "left": 101,
            "top": 185,
            "width": 42,
            "height": 130
        }
    ],
    "categories": [
        {
            "class_id": 0,
            "name": "dog"
        },
        {
            "class_id": 1,
            "name": "cat"
        }
    ]
}
```

Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://your_bucket/train/sample_image and s3://your_bucket/train_annotation, specify the path for your train and train_annotation channels as s3://your_bucket/train and s3://your_bucket/train_annotation, respectively.

In the .json file, the relative path for an image named sample_image1.jpg should be sample_image/sample_image1.jpg. The "image_size" property specifies the overall image dimensions. The SageMaker object detection algorithm currently only supports 3-channel images. The "annotations" property specifies the categories and bounding boxes for objects within the image. Each object is
annotated by a "class_id" index and by four bounding box coordinates ("left", "top", "width", "height"). The "left" (x-coordinate) and "top" (y-coordinate) values represent the upper-left corner of the bounding box. The "width" (x-coordinate) and "height" (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The "categories" property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The "categories" property is optional for the annotation .json file.

Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames are contained in the list ["source-ref", "bounding-box"]:

```json
{"source-ref": "s3://your_bucket/image1.jpg", "bounding-box": {"image_size": [{ "width": 500, "height": 400, "depth": 3 }], "annotations": [{"class_id": 0, "left": 111, "top": 134, "width": 61, "height": 128}, {"class_id": 5, "left": 161, "top": 250, "width": 80, "height": 50}], "bounding-box-metadata": {"class-map": {"0": "dog", "5": "horse"}, "type": "groundtruth/object-detection"}}
{"source-ref": "s3://your_bucket/image2.jpg", "bounding-box": {"image_size": [{ "width": 400, "height": 300, "depth": 3 }], "annotations": [{"class_id": 1, "left": 100, "top": 120, "width": 43, "height": 78}], "bounding-box-metadata": {"class-map": {"1": "cat"}, "type": "groundtruth/object-detection"}}
```

The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with image first, followed by annotations. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter RecordWrapperType must be set as "RecordIO".

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2608).

Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker object detection models can be seeded only with another built-in object detection model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the base_network and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 2587).
EC2 Instance Recommendation for the Object Detection Algorithm

The object detection algorithm supports P2, P3, G4dn, and G5 GPU instance families. We recommend using GPU instances with more memory for training with large batch sizes. You can run the object detection algorithm on multi-GPU and multi-machine settings for distributed training.

You can use both CPU (such as C5 and M5) and GPU (such as P3 and G4dn) instances for inference.

Object Detection Sample Notebooks

For a sample notebook that shows how to use the SageMaker Object Detection algorithm to train and host a model on the Caltech Birds (CUB 200 2011) dataset using the Single Shot multibox Detector algorithm, see Amazon SageMaker Object Detection for Bird Species. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The object detection example notebook using the Object Detection algorithm is located in the Introduction to Amazon Algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Object Detection Works

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object's location and scale with a rectangular bounding box. Amazon SageMaker Object Detection uses the Single Shot multibox Detector (SSD) algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as VGG and ResNet have achieved great performance on the image classification task. Object detection in Amazon SageMaker supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

Object Detection Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker for training the object detection algorithm. For more information about how object training works, see How Object Detection Works (p. 2140).

<table>

</table>
| kv_store      | The weight update synchronization mode used for distributed training. The weights can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See the Distributed Training MXNet tutorial for details.  
**Note**  
This parameter is not applicable to single machine training.  
**Optional**  
Valid values: 'dist_sync' or 'dist_async'  
- 'dist_sync': The gradients are synchronized after every batch with all the workers. With 'dist_sync', batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like a single machine with batch size n*b.  
- 'dist_async': Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed.  
Default: - |
| label_width   | The force padding label width used to sync across training and validation data. For example, if one image in the data contains at most 10 objects, and each object's annotation is specified with 5 numbers, [class_id, left, top, width, height], then the label_width should be no smaller than (10*5 + header information length). The header information length is usually 2. We recommend using a slightly larger label_width for the training, such as 60 for this example.  
**Optional**  
Valid values: Positive integer large enough to accommodate the largest annotation information length in the data.  
Default: 350 |
| learning_rate | The initial learning rate.  
**Optional**  
Valid values: float in (0, 1]  
Default: 0.001 |
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>

<tr>
<td>mini_batch_size</td>
<td>The batch size for training. In a single-machine multi-gpu setting, each GPU handles ( mini_batch_size/num_gpu ) training samples. For the multi-machine training in dist_sync mode, the actual batch size is ( mini_batch_size\times)number of machines. A large ( mini_batch_size ) usually leads to faster training, but it may cause out of memory problem. The memory usage is related to ( mini_batch_size, image_shape, and base_network ) architecture. For example, on a single p3.2xlarge instance, the largest ( mini_batch_size ) without an out of memory error is 32 with the base_network set to &quot;resnet-50&quot; and an image_shape of 300. With the same instance, you can use 64 as the ( mini_batch_size ) with the base network vgg-16 and an image_shape of 300.</td>

### Tune an Object Detection Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

### Metrics Computed by the Object Detection Algorithm

The object detection algorithm reports on a single metric during training: validation:mAP. When tuning a model, choose this metric as the objective metric.

<table>

Object Detection Request and Response Formats

Request Format

Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats with image/jpeg and image/png content-types.

Response Formats

The response is the class index with a confidence score and bounding box coordinates for all objects within the image encoded in JSON format. The following is an example of response .json file:

```json
{"prediction": [ [4.0, 0.8641945540949988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244], [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571, 0.9712159633636475], [4.0, 0.32643985450267792, 0.3677481412887573, 0.034883320331573486, 0.6318609714508057, 0.5967587828636169], [8.0, 0.22552496790885925, 0.6152569651603699, 0.5722782611846924, 0.882301390171051, 0.8985623121261597], [3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702, 0.39093565940856934, 0.9574796557426453] ]}
```

Each row in this .json file contains an array that represents a detected object. Each of these object arrays consists of a list of six numbers. The first number is the predicted class label. The second number is the associated confidence score for the detection. The last four numbers represent the bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices are normalized by the overall image size. Note that this encoding is different than that use by the input .json format. For example, in the first entry of the detection result, 0.3088374733924866 is the left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of
lower-right corner) of the bounding box as a ratio of the overall image width, and 0.9345266819000244 is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the overall image height.

To avoid unreliable detection results, you might want to filter out the detection results with low confidence scores. In the object detection sample notebook, we provide examples of scripts that use a threshold to remove low confidence detections and to plot bounding boxes on the original images.

For batch transform, the response is in JSON format, where the format is identical to the JSON format described above. The detection results of each image is represented as a JSON file. For example:

```
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id, confidence_score, xmin, ymin, xmax, ymax]]}
```

For more details on training and inference, see the Object Detection Sample Notebooks (p. 2140).

**OUTPUT: JSON Response Format**

```

    ]
}
```

**Semantic Segmentation Algorithm**

The SageMaker semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an
increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker Image Classification - MXNet (p. 2113) is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The Object Detection (p. 2137) is a supervised learning algorithm that detects and classifies all instances of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is represented as a grayscale image, called a segmentation mask. A segmentation mask is a grayscale image with the same shape as the input image.

The SageMaker semantic segmentation algorithm is built using the MXNet Gluon framework and the Gluon CV toolkit. It provides you with a choice of three built-in algorithms to train a deep neural network. You can use the Fully-Convolutional Network (FCN) algorithm, Pyramid Scene Parsing (PSP) algorithm, or DeepLabV3.

Each of the three algorithms has two distinct components:

- The *backbone* (or *encoder*)—A network that produces reliable activation maps of features.
- The *decoder*—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: ResNet50 or ResNet101. These backbones include pretrained artifacts that were originally trained on the ImageNet classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

Semantic Segmentation Sample Notebooks

For a sample Jupyter notebook that uses the SageMaker semantic segmentation algorithm to train a model and deploy it to perform inferences, see the Semantic Segmentation Example. For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283).

To see a list of all of the SageMaker samples, create and open a notebook instance, and choose the SageMaker Examples tab. The example semantic segmentation notebooks are located under Introduction to Amazon algorithms. To open a notebook, choose its Use tab, and choose Create copy.

Input/Output Interface for the Semantic Segmentation Algorithm

SageMaker semantic segmentation expects the customer's training dataset to be on Amazon Simple Storage Service (Amazon S3). Once trained, it produces the resulting model artifacts on Amazon S3. The
input interface format for the SageMaker semantic segmentation is similar to that of most standardized
semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented
in two channels, one for train and one for validation using four directories, two for images and two
for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have
a label map that describes how the annotation mappings are established. If not, the algorithm uses a
default. It also supports the augmented manifest image format (application/x-image) for training
in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an image/
jpeg content type.

How Training Works

The training data is split into four directories: train, train_annotation, validation, and
validation_annotation. There is a channel for each of these directories. The dataset also expected
to have one label_map.json file per channel for train_annotation and validation_annotation
respectively. If you don’t provide these JSON files, SageMaker provides the default set label map.

The dataset specifying these files should look similar to the following example:

```
s3://bucket_name
|-- train
|   |-- 0000.jpg
|   |-- coffee.jpg
|-- validation
|   |-- 00a0.jpg
|   |-- banana.jpg
|-- train_annotation
|   |-- 0000.png
|   |-- coffee.png
|-- validation_annotation
|   |-- 00a0.png
|   |-- banana.png
|-- label_map
|   |-- train_label_map.json
|   |-- validation_label_map.json
```

Every JPG image in the train and validation directories has a corresponding PNG label image with
the same name in the train_annotation and validation_annotation directories. This naming
convention helps the algorithm to associate a label with its corresponding image during training. The
train, train_annotation, validation, and validation_annotation channels are mandatory.
The annotations are single-channel PNG images. The format works as long as the metadata (modes) in
the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer.
For more information on our support for modes, see the Python Image Library documentation. We
recommend using the 8-bit pixel, true color P mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a
map of a label, the algorithm uses one mapping file per channel, called the label map. The label map is
used to map the values in the image with actual label indices. In the default label map, which is provided
by default if you don’t provide one, the pixel value in an annotation matrix (image) directly index the
label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the
unscaled default case is the following:

```
{
    "scale": "1"
}
```
To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn't convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```json
{
    "scale": "3"
}
```

The following example shows how this "scale" value is used to rescale the encoded_label values of the input annotation image when they are mapped to the mapped_label values to be used in training. The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```plaintext
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a label_map file:

```json
{
    "map": {
        "0": 5,
        "1": 0,
        "2": 2
    }
}
```

This label mapping for this example is:

```plaintext
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]
```

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the label_map channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

**Training with the Augmented Manifest Format**

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be in JSON Lines format, as described in the CreateTrainingJob request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a source-ref key. The source-ref key should contain the value of the Amazon S3 URI to the image. The labels are provided under the AttributeNames parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the example below, the AttributeNames are contained in the list of image and annotation references ["source-ref", "city-streets-ref"]. These names must have -ref appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be “RecordIO” and value of the ContentType parameter must be application/x-recordio.
For more information on augmented manifest files, see "Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2608)."  

**Incremental Training**

You can also seed the training of a new model with a model that you trained previously using SageMaker. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker Semantic Segmentation.

To use your own pre-trained model, specify the ChannelName as "model" in the InputDataConfig for the CreateTrainingJob request. Set the ContentType for the model channel to application/x-sagemaker-model. The backbone, algorithm, crop_size, and num_classes input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker outputs. You can only use Image formats for input data. For more information on incremental training and for instructions on how to use it, see "Incremental Training in Amazon SageMaker (p. 2587)."

**Produce Inferences**

To query a trained model that is deployed to an endpoint, you need to provide an image and an AcceptType that denotes the type of output required. The endpoint takes JPEG images with an image/jpeg content type. If you request an AcceptType of image/png, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of application/x-recordio-protobuf, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.

**EC2 Instance Recommendation for the Semantic Segmentation Algorithm**

The SageMaker semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using P2, P3, G4dn, or G5 instances in single machine configurations.

For inference, you can use either CPU instances (such as C5 and M5) and GPU instances (such as P3 and G4dn) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see "Amazon SageMaker ML Instance Types."

**Semantic Segmentation Hyperparameters**

The following tables list the hyperparameters supported by the Amazon SageMaker semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the AlgorithmName of the CreateTrainingJob request.

**Network Architecture Hyperparameters**

### Tuning a Semantic Segmentation Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

### Metrics Computed by the Semantic Segmentation Algorithm

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>

Use Reinforcement Learning with Amazon SageMaker

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent’s current state. Furthermore, the learning agent’s goals should correlate strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

What are the differences between reinforcement, supervised, and unsupervised learning paradigms?

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.
Why is Reinforcement Learning Important?

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles. Because RL models learn by a continuous process of receiving rewards and punishments for every action taken by the agent, it is possible to train systems to make decisions under uncertainty and in dynamic environments.

Markov Decision Process (MDP)

RL is based on models called Markov Decision Processes (MDPs). An MDP consists of a series of time steps. Each time step consists of the following:

Environment

Defines the space in which the RL model operates. This can be either a real-world environment or a simulator. For example, if you train a physical autonomous vehicle on a physical road, that would be a real-world environment. If you train a computer program that models an autonomous vehicle driving on a road, that would be a simulator.

State

Specifies all information about the environment and past steps that is relevant to the future. For example, in an RL model in which a robot can move in any direction at any time step, the position of the robot at the current time step is the state, because if we know where the robot is, it isn't necessary to know the steps it took to get there.

Action

What the agent does. For example, the robot takes a step forward.

Reward

A number that represents the value of the state that resulted from the last action that the agent took. For example, if the goal is for a robot to find treasure, the reward for finding treasure might be 5, and the reward for not finding treasure might be 0. The RL model attempts to find a strategy that optimizes the cumulative reward over the long term. This strategy is called a policy.

Observation

Information about the state of the environment that is available to the agent at each step. This might be the entire state, or it might be just a part of the state. For example, the agent in a chess-playing model would be able to observe the entire state of the board at any step, but a robot in a maze might only be able to observe a small portion of the maze that it currently occupies.

Typically, training in RL consists of many episodes. An episode consists of all of the time steps in an MDP from the initial state until the environment reaches the terminal state.
Key Features of Amazon SageMaker RL

To train RL models in SageMaker RL, use the following components:

- An RL toolkit. An RL toolkit manages the interaction between the agent and the environment and provides a wide selection of state of the art RL algorithms. SageMaker supports the Intel Coach and Ray RLlib toolkits. For information about Intel Coach, see https://nervanasystems.github.io/coach/.
- An RL environment. You can use custom environments, open-source environments, or commercial environments. For information, see RL Environments in Amazon SageMaker (p. 2162).

The following diagram shows the RL components that are supported in SageMaker RL.
Reinforcement Learning Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker reinforcement learning.

<table>
<thead>
<tr>

Sample RL Workflow Using Amazon SageMaker RL

The following example describes the steps for developing RL models using Amazon SageMaker RL.

For complete code examples, see the sample notebooks at https://github.com/awslabs/amazon-sagemaker-examples/tree/master/reinforcement-learning.

1. **Formulate the RL problem**—First, formulate the business problem into an RL problem. For example, auto scaling enables services to dynamically increase or decrease capacity depending on conditions that you define. Currently, this requires setting up alarms, scaling policies, thresholds, and other manual steps. To solve this with RL, we define the components of the Markov Decision Process:
   a. **Objective**—Scale instance capacity so that it matches the desired load profile.
   b. **Environment**—A custom environment that includes the load profile. It generates a simulated load with daily and weekly variations and occasional spikes. The simulated system has a delay between when new resources are requested and when they become available for serving requests.
   c. **State**—The current load, number of failed jobs, and number of active machines.
   d. **Action**—Remove, add, or keep the same number of instances.
   e. **Reward**—A positive reward for successful transactions and a high penalty for failing transactions beyond a specified threshold.

2. **Define the RL environment**—The RL environment can be the real world where the RL agent interacts or a simulation of the real world. You can connect open source and custom environments developed using Gym interfaces and commercial simulation environments such as MATLAB and Simulink.

3. **Define the presets**—The presets configure the RL training jobs and define the hyperparameters for the RL algorithms.

4. **Write the training code**—Write training code as a Python script and pass the script to a SageMaker training job. In your training code, import the environment files and the preset files, and then define the `main()` function.

5. **Train the RL Model**—Use the SageMaker `RLEstimator` in the Amazon SageMaker Python SDK to start an RL training job. If you are using local mode, the training job runs on the notebook instance.
When you use SageMaker for training, you can select GPU or CPU instances. Store the output from the training job in a local directory if you train in local mode, or on Amazon S3 if you use SageMaker training.

The `RLEstimator` requires the following information as parameters.

a. The source directory where the environment, presets, and training code are uploaded.
b. The path to the training script.
c. The RL toolkit and deep learning framework you want to use. This automatically resolves to the Amazon ECR path for the RL container.
d. The training parameters, such as the instance count, job name, and S3 path for output.
e. Metric definitions that you want to capture in your logs. These can also be visualized in CloudWatch and in SageMaker notebooks.

6. **Visualize training metrics and output**—After a training job that uses an RL model completes, you can view the metrics you defined in the training jobs in CloudWatch. You can also plot the metrics in a notebook by using the Amazon SageMaker Python SDK analytics library. Visualizing metrics helps you understand how the performance of the model as measured by the reward improves over time.

   **Note**

   If you train in local mode, you can't visualize metrics in CloudWatch.

7. **Evaluate the model**—Checkpointed data from the previously trained models can be passed on for evaluation and inference in the checkpoint channel. In local mode, use the local directory. In SageMaker training mode, you need to upload the data to S3 first.

8. **Deploy RL models**—Finally, deploy the trained model on an endpoint hosted on SageMaker containers or on an edge device by using AWS IoT Greengrass.

For more information on RL with SageMaker, see [Using RL with the SageMaker Python SDK](#).

### RL Environments in Amazon SageMaker

Amazon SageMaker RL uses environments to mimic real-world scenarios. Given the current state of the environment and an action taken by the agent or agents, the simulator processes the impact of the action, and returns the next state and a reward. Simulators are useful in cases where it is not safe to train an agent in the real world (for example, flying a drone) or if the RL algorithm takes a long time to converge (for example, when playing chess).

The following diagram shows an example of the interactions with a simulator for a car racing game.
The simulation environment consists of an agent and a simulator. Here, a convolutional neural network (CNN) consumes images from the simulator and generates actions to control the game controller. With multiple simulations, this environment generates training data of the form $state_t, action, state_{t+1}$, and $reward_{t+1}$. Defining the reward is not trivial and impacts the RL model quality. We want to provide a few examples of reward functions, but would like to make it user-configurable.

**Topics**

- Use OpenAI Gym Interface for Environments in SageMaker RL (p. 2163)
- Use Open-Source Environments (p. 2164)
- Use Commercial Environments (p. 2164)

**Use OpenAI Gym Interface for Environments in SageMaker RL**

To use OpenAI Gym environments in SageMaker RL, use the following API elements. For more information about OpenAI Gym, see https://gym.openai.com/docs/.

- `env.action_space`—Defines the actions the agent can take, specifies whether each action is continuous or discrete, and specifies the minimum and maximum if the action is continuous.
- `env.observation_space`—Defines the observations the agent receives from the environment, as well as minimum and maximum for continuous observations.
- `env.reset()`—Initializes a training episode. The `reset()` function returns the initial state of the environment, and the agent uses the initial state to take its first action. The action is then sent to `step()` repeatedly until the episode reaches a terminal state. When `step()` returns `done = True`, the episode ends. The RL toolkit re-initializes the environment by calling `reset()`.
- `step()`—Takes the agent action as input and outputs the next state of the environment, the reward, whether the episode has terminated, and an `info` dictionary to communicate debugging information. It is the responsibility of the environment to validate the inputs.
- `env.render()`—Used for environments that have visualization. The RL toolkit calls this function to capture visualizations of the environment after each call to the `step()` function.
Use Open-Source Environments

You can use open-source environments, such as EnergyPlus and RoboSchool, in SageMaker RL by building your own container. For more information about EnergyPlus, see https://energyplus.net/. For more information about RoboSchool, see https://github.com/openai/roboschool. The HVAC and RoboSchool examples in the SageMaker examples repository show how to build a custom container to use with SageMaker RL.

Use Commercial Environments

You can use commercial environments, such as MATLAB and Simulink, in SageMaker RL by building your own container. You need to manage your own licenses.

Distributed Training with Amazon SageMaker RL

Amazon SageMaker RL supports multi-core and multi-instance distributed training. Depending on your use case, training and/or environment rollout can be distributed. For example, SageMaker RL works for the following distributed scenarios:

- Single training instance and multiple rollout instances of the same instance type. For an example, see the Neural Network Compression example in the SageMaker examples repository.
- Single trainer instance and multiple rollout instances, where different instance types for training and rollouts. For an example, see the AWS DeepRacer / AWS RoboMaker example in the SageMaker examples repository.
- Single trainer instance that uses multiple cores for rollout. For an example, see the Roboschool example in the SageMaker examples repository. This is useful if the simulation environment is lightweight and can run on a single thread.
- Multiple instances for training and rollouts. For an example, see the Roboschool example in the SageMaker examples repository.

Hyperparameter Tuning with Amazon SageMaker RL

You can run a hyperparameter tuning job to optimize hyperparameters for Amazon SageMaker RL. The Roboschool example in the sample notebooks in the SageMaker examples repository shows how you can do this with RL Coach. The launcher script shows how you can abstract parameters from the Coach preset file and optimize them.

Manage Machine Learning with Amazon SageMaker Experiments

Amazon SageMaker Experiments is a capability of Amazon SageMaker that lets you organize, track, compare, and evaluate your machine learning experiments.

Machine learning is an iterative process. You need to experiment with multiple combinations of data, algorithm and parameters, all the while observing the impact of incremental changes on model accuracy. Over time this iterative experimentation can result in thousands of model training runs and model versions. This makes it hard to track the best performing models and their input configurations. It’s also difficult to compare active experiments with past experiments to identify opportunities for further incremental improvements.

SageMaker Experiments automatically tracks the inputs, parameters, configurations, and results of your iterations as trials. You can assign, group, and organize these trials into experiments. SageMaker
Experiments is integrated with Amazon SageMaker Studio providing a visual interface to browse your active and past experiments, compare trials on key performance metrics, and identify the best performing models.

SageMaker Experiments comes with its own Experiments Python SDK which makes the analytics capabilities easily accessible in Amazon SageMaker Notebooks. Because SageMaker Experiments enables tracking of all the steps and artifacts that went into creating a model, you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

Topics
- SageMaker Experiments Features (p. 2165)
- Create an Amazon SageMaker Experiment (p. 2166)
- View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 2170)
- Track and Compare Tutorial (p. 2173)

- Search Using the Amazon SageMaker Console and API (p. 2186)

**SageMaker Experiments Features**

The following sections provide a brief overview of the features provided by SageMaker Experiments.

Topics
- Organize Experiments (p. 2165)
- Track Experiments (p. 2165)
- Compare and Evaluate Experiments (p. 2166)
- Amazon SageMaker Autopilot (p. 2166)

**Organize Experiments**

Amazon SageMaker Experiments offers a structured organization scheme to help users group and organize their machine learning iterations. The top level entity, an experiment, is a collection of trials that are observed, compared, and evaluated as a group. A trial is a set of steps called trial components. Each trial component can include a combination of inputs such as datasets, algorithms, and parameters, and produce specific outputs such as models, metrics, datasets, and checkpoints. Examples of trial components are data pre-processing jobs, training jobs, and batch transform jobs.

The goal of an experiment is to determine the trial that produces the best model. Multiple trials are performed, each one isolating and measuring the impact of a change to one or more inputs, while keeping the remaining inputs constant. By analyzing the trials, you can determine which features have the most effect on the model.

**Track Experiments**

Amazon SageMaker Experiments enables tracking of experiments.

**Automated Tracking**

SageMaker Experiments automatically tracks Amazon SageMaker Autopilot jobs as experiments with their underlying training jobs tracked as trials. SageMaker Experiments also automatically tracks
SageMaker independently executed training, batch transform, and processing jobs as trial components, whether assigned to a trial or left unassigned. Unassigned trial components can be associated with a trial at a later time. All experiment artifacts including datasets, algorithms, hyperparameters, and model metrics are tracked and recorded. This data allows customers to trace the complete lineage of a model which helps with model governance, auditing, and compliance verifications.

**Manual Tracking**

SageMaker Experiments provides tracking APIs for recording and tracking machine learning workflows running locally on SageMaker Studio notebooks, including classic SageMaker notebooks. These experiments must be part of a SageMaker training, batch transform, or processing job.

**Compare and Evaluate Experiments**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Studio. When you use SageMaker Studio, SageMaker Experiments automatically tracks your experiments and trials, and presents visualizations of the tracked data and an interface to search the data.

SageMaker Experiments automatically organizes, ranks, and sorts trials based on a chosen metric using the concept of a trial leaderboard. SageMaker Studio produces real-time data visualizations, such as metric charts and graphs, to quickly compare and identify the best performing models. These are updated in real-time as the experiment progresses.

**Amazon SageMaker Autopilot**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Autopilot. When you perform an Autopilot job, SageMaker Experiments creates an experiment for the job, and trials for each of the different combinations of the available trial components, parameters, and artifacts. You can visually drill into all trials and components using SageMaker Studio.

**Create an Amazon SageMaker Experiment**

Create an Amazon SageMaker experiment to track your SageMaker training, processing, and transform jobs.

The following procedure shows you how to create a SageMaker experiment for a SageMaker training, processing, or transform job. Steps labeled as (Studio) describe how to view the experiment in Amazon SageMaker Studio. You don't have to run the experiment in Studio to view the experiment in Studio.

For a tutorial that shows this functionality in an existing SageMaker Studio notebook, see [Track and Compare Tutorial](p. 2173).

1. Import the `sys` module to install the SDKs.

   ```python
   import sys
   ```

2. (Optional) The Amazon SageMaker Python SDK, comes preinstalled in SageMaker Studio. If you plan to run your code outside Studio, install the SageMaker Python SDK.

   ```bash
   !{sys.executable} -m pip install sagemaker
   ```

3. Install the SageMaker Experiments Python SDK.

   ```bash
   !{sys.executable} -m pip install sagemaker-experiments
   ```

4. Import modules.
5. Get the execution role and create the SageMaker session.

```python
role = sagemaker.get_execution_role()
sm_sess = sagemaker.session.Session()
```

6. Create a SageMaker experiment. The experiment name must be unique in your account.

   **Note**
   
The `tags` parameter is optional. You can search for the tag using Studio, the SageMaker console, and the SDK. Tags can also be applied to trials and trial components. For information on how to search tags using Studio, see Search by Tag (p. 2183).

```python
create_date = strftime("%Y-%m-%d-%H-%M-%S")
demo_experiment = Experiment.create(experiment_name = "DEMO-{}/".format(create_date),
    description = "Demo experiment",
    tags = [{'Key': 'demo-experiments', 'Value': 'demo1'}])
```

7. (Studio) To view the experiment in SageMaker Studio, in the left sidebar, choose the **SageMaker resources** icon (`🔍`). In the drop-down menu, select **Experiments and trials** to display the experiments browser.

   After the code runs, the experiment list contains the new experiment. It might take a moment for the list to refresh and display the experiment. The filter on the experiment tag is also displayed. Only experiments that have a matching tag are displayed. Your list should look similar to the following:
8. Create a trial for the experiment. The trial name must be unique in your account.

```python
demo_trial = Trial.create(trial_name = "DEMO-{}".format(create_date),
                          experiment_name = demo_experiment.experiment_name,
                          tags = [{"Key": 'demo-trials', 'Value': 'demo1'}])
```

9. (Studio) In the experiment list, double-click the experiment to display a list of the trials in the experiment (this example has one trial). Your list should look similar to the following:
10. Create a trial component as part of the trial. The trial component is the SageMaker job.

Add the ExperimentConfig parameter to the appropriate method. The SageMaker jobs listed in the following table are supported.

<table>
<thead>
<tr>
<th>Job</th>
<th>SageMaker Python SDK method</th>
<th>Boto3 method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training</td>
<td>Estimator.fit</td>
<td>CreateTrainingJob</td>
</tr>
<tr>
<td>Processing</td>
<td>Processor.run</td>
<td>CreateProcessingJob</td>
</tr>
<tr>
<td>Transform</td>
<td>Transformer.transform</td>
<td>CreateTransformJob</td>
</tr>
</tbody>
</table>

The following examples are for a training job. The Tags parameter adds a tag to the trial component. ExperimentName isn’t specified because the trial was associated with the experiment when the trial was created in an earlier step.

**Using the SageMaker Python SDK**

```python
sagemaker.estimator.Estimator(
    ...
    sagemaker_session = sm_sess,
    tags = [{'Key': 'demo-jobs', 'Value': 'demo2'}])

estimator.fit(
    ...,
    experiment_config = {
        # "ExperimentName"  
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    })
```

**Using Boto3**
create_training_job(
  ...
  "ExperimentConfig": {
    # "ExperimentName"
    "TrialName": demo_trial.trial_name,
    "TrialComponentDisplayName": "TrainingJob",
  },
  "Tags": [{"Key": 'demo-jobs', 'Value': 'demo2'}])

11. (Studio) In the trial list, double-click the trial to display a list of the components in the trial (this example has one trial). Your list should look similar to the following:

12. (Studio) To view information about the experiment, trial, and job (trial component), see View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 2170).

To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources (p. 2184).

View and Compare Amazon SageMaker Experiments, Trials, and Trial Components

An Amazon SageMaker experiment consists of multiple trials with a related objective. A trial consists of one or more trial components, such as a data preprocessing job and a training job.

You use the experiments browser to display a list of these entities. You can filter the list by entity name, type, and tags. The entities are presented in a hierarchical view (that is, experiments > trials > trial components). Double-click an entity to see other entities that are at a lower level in the hierarchy. Use the breadcrumbs above the list to move to a higher level in the hierarchy.

For a tutorial using a SageMaker example notebook, see Track and Compare Tutorial (p. 2173). For an overview of the Studio user interface, see Amazon SageMaker Studio UI Overview (p. 117).

Topics

- View Experiments, Trials, and Trial Components (p. 2171)
- Compare Experiments, Trials, and Trial Components (p. 2172)
View Experiments, Trials, and Trial Components

Amazon SageMaker Studio provides an experiments browser that you can use to view lists of experiments, trials, and trial components. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison.

To view experiments, trials, and trial components

1. In the left sidebar of Studio, choose the SageMaker resources icon ( ). In the drop-down menu, select Experiments and trials to display the experiments browser.

A list of experiments and their properties is displayed. The list includes all the SageMaker experiments in your account, including experiments created outside of SageMaker Studio.

   **Note**
   To view all the properties, you might have to expand the width of the experiments browser by dragging the right border.

2. In the experiments list, double-click an experiment to display a list of the trials in the experiment.

3. Double-click a trial to display a list of the components in the trial.
4. Double-click one of the components to open the Describe Trial Component tab.

5. On the Describe Trial Component tab, choose any of the following column headings to see available information about each trial component:
   - **Charts** – Build your own charts.
   - **Metrics** – Metrics that are logged by a Tracker during a trial run.
   - **Parameters** – Hyperparameter values and instance information.
   - **Artifacts** – Amazon S3 bucket storage locations for the input dataset and the output model.
   - **AWS Settings** – Job name, ARN, status, creation time, training time, billable time, instance information, and others.
   - **Debugger** – A list of debugger rules and any issues found.
   - **Trial Mappings**

For information about comparing Experiments entities, see View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 2170).

**Compare Experiments, Trials, and Trial Components**

You can compare experiments, trials, and trial components by selecting the entities and opening them in the trial components list. The trial components list is referred to as the Studio Leaderboard. In the Leaderboard you can do the following:

- View detailed information about the entities
- Compare entities
To compare experiments, trials, and trial components

1. In the left sidebar of SageMaker Studio, choose the **SageMaker Experiment List** icon.
2. In the **Experiments** browser, choose either the experiment or trial list. For more information, see View Experiments, Trials, and Trial Components (p. 2171).
3. Choose the experiments or trials that you want to compare, right-click the selection, and then choose **Open in trial component list**. The Leaderboard opens and lists the associated Experiments entities as shown in the following screenshot.

![Leaderboard screenshot](image)

The Leaderboard has a **TABLE PROPERTIES** pane on the right side. Use the **Settings** icon to open and close the pane. You can hide or display properties by category or by individual columns. When you display a chart, the pane changes to display chart properties.

For information on searching the Experiments entities, see Search Experiments Using Amazon SageMaker Studio (p. 2179).

**Track and Compare Tutorial**

This tutorial demonstrates how to visually track and compare trials in a model training experiment using Amazon SageMaker Studio. The basis of the tutorial is the MNIST Handwritten Digits Classification Experiment notebook.

It is intended that this topic be viewed alongside Studio with the MNIST notebook open. As you run through the cells, the sections in this document highlight the relevant code and show you how to observe the results in Studio. Some of the code snippets have been edited for brevity.

To clean up the resources created by the notebook, see Clean Up Amazon SageMaker Experiment Resources (p. 2184).

For a tutorial that showcases additional features of Studio, see Amazon SageMaker Studio Tour (p. 131).

**Prerequisites**
• A local copy of the MNIST example notebook and the companion mnist.py file. Both files are available from the sagemaker_experiments/mnist-handwritten-digits-classification-experiment folder in the aws/amazon-sagemaker-examples repository. To download the files, choose each link, right-click on the Raw button, and then choose Save as.

• An IAM Identity Center or IAM account to sign-on to SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).

Topics

• Open the Notebook in Studio (p. 2174)
• Install the Experiments SDK and Import Modules (p. 2174)
• Transform and Track the Input Data (p. 2175)
• Create and Track an Experiment (p. 2175)
• Compare and Analyze Trials (p. 2177)

Open the Notebook in Studio

To open the notebook

1. Sign-on to Studio.
2. In the left sidebar, choose the File Browser icon ( ).
3. At the top of the file browser pane, choose the Up arrow icon and then a File Upload dialog opens. Browse to and choose your local versions of the mnist-handwritten-digits-classification-experiment.ipynb and mnist.py files, and then choose Open.
4. The two files are listed in the file browser. Double-click the uploaded notebook file to open the notebook in a new tab.
5. At the top right of the notebook, make sure the kernel is Python 3 (Data Science). If not, choose the current kernel name to open the Select Kernel dropdown. Choose Python 3 (Data Science) and then choose Select.

Install the Experiments SDK and Import Modules

The Amazon SageMaker Experiments Python SDK is separate from the Amazon SageMaker Python SDK, which comes preinstalled in SageMaker Studio. Run the first few cells in the notebook to install the Experiments SDK and import the Experiments modules. The relevant sections of the notebook cells are displayed below.

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments

import sagemaker
from sagemaker import get_execution_role
from sagemaker.session import Session
from sagemaker.analytics import ExperimentAnalytics
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker
```
Transform and Track the Input Data

The next few cells create an Amazon S3 bucket and a folder in the bucket named `mnist`. In Studio, the file browser displays the `mnist` folder. The input data is downloaded to the `mnist/MNIST/raw` folder, normalized, and then the transformed data is uploaded to the `mnist/MNIST/processed` folder. You can drill down into the `mnist` folder to display, but not open, the data files.

Your screen should look similar to the following:

The last cell in the Dataset section creates a Tracker for the transform job. The tracker logs the normalization parameters and the URI of the Amazon S3 bucket where the transformed dataset is stored. In a later section, we show how to find this information in Studio. In the next section, the tracker is used to track the experiment and trial runs.

```python
with Tracker.create(display_name="Preprocessing", sagemaker_boto_client=sm) as tracker:
    tracker.log_parameters(
        "normalization_mean": 0.1307,
        "normalization_std": 0.3081,
    )
    tracker.log_input(name="mnist-dataset", media_type="s3/uri", value=inputs)
```

Create and Track an Experiment

The following procedure creates and tracks an experiment to determine the effect of the model's `num_hidden_channel` hyperparameter. As part of the experiment, five trials are created inside a loop, one for each value of the `num_hidden_channel` hyperparameter. Later in the notebook, you'll compare the results of these five trials.

1. In the left sidebar of Studio, choose the SageMaker resources icon (🔎). In the dropdown menu, choose Experiments and trials to display the list of experiments in your account.
2. Run the following cell.

```python
mnist_experiment = Experiment.create(
    experiment_name=f"mnist-hand-written-digits-classification-{int(time.time())}"),
    description="Classification of mnist hand-written digits",
    sagemaker_boto_client=sm)
print(mnist_experiment)
```

Output:

```python
Experiment(sagemaker_boto_client=<botocore.client.SageMaker object at 0x7f7152b326d8>,
    experiment_name='mnist-hand-written-digits-classification-1575947870',
    description='Classification of mnist hand-written digits',
```

After the code runs, the experiments list contains an entry for the experiment. It might take a moment to display and you might have to refresh the experiments list. Your screen should look similar to the following:
3. Run the following cell.

```python
preprocessing_trial_component = tracker.trial_component
```

After the code runs, the experiments list contains an entry labeled **Unassigned trial components**. The trial component entry is the data preprocessing step previously created. Double-click the trial component for verification. The trial component isn't associated with an experiment at this time. Your screen should look similar to the following:

4. Choose the **Home** icon in the navigation breadcrumb at the top on the experiments browser. From there, double-click on your experiment to display a list of the trials in the experiment.

5. The following code create trials for the experiment. Each trial trains a model using a different number for the `num_hidden_channel` hyperparameter. The preprocessing trial component is added to each trial for complete tracking (for example, for auditing purposes). The code also specifies definitions for the following metrics:

- Train loss
- Test loss
- Test accuracy

The definitions tell SageMaker to capture those metrics from the algorithm's log output. The metrics are used later to evaluate and compare the models.

```python
preprocessing_trial_component = tracker.trial_component

for i, num_hidden_channel in enumerate([2, 5, 10, 20, 32]):
    trial_name = f"cnn-training-job-{num_hidden_channel}-hidden-channels-{int(time.time())}"
    cnn_trial = Trial.create(
        trial_name=trial_name,
        experiment_name=mnist_experiment.experiment_name,
        sagemaker_boto_client=sm,
    )
    hidden_channel_trial_name_map[num_hidden_channel] = trial_name

    cnn_trial.add_trial_component(preprocessing_trial_component)
```
estimator = PyTorch(
    py_version='py3',
    framework_version='1.1.0',
    ...
    hyperparameters={
        'hidden_channels': num_hidden_channel,
        ...
    },
    metric_definitions=
        [{
            'Name': 'train:loss',
            'Regex': 'Train Loss: (.*)';
        },
        {
            'Name': 'test:loss',
            'Regex': 'Test Average loss: (.*)';
        },
        {
            'Name': 'test:accuracy',
            'Regex': 'Test Accuracy: (.*)%;'
        }],
    enable_sagemaker_metrics=True,
)

cnn_training_job_name = "cnn-training-job-{}".format(int(time.time()))

estimator.fit(
    inputs={'training': inputs},
    job_name=cnn_training_job_name,
    experiment_config={
        "TrialName": cnn_trial.trial_name,
        "TrialComponentDisplayName": "Training",
    },
)

The trial list automatically updates as each training job runs. It takes a few minutes for each trial to be displayed. Your screen should look similar to the following:

**Compare and Analyze Trials**

This section deviates from the notebook and shows you how to compare and analyze the trained models using the SageMaker Studio UI.

**To view the details of a trial**

1. Double-click one of the trials to display a list of the trial components associated with the trial. There's a preprocessing job and training job for each trial. Double-click one of the components to open a new tab that displays information about each component.

2. Under **Trial stages**, choose **Preprocessing**. On the **Describe Trial Component** menu, choose **Parameters** to display the normalization parameters that were previously logged. Next, choose **Artifacts** to display the URI of the Amazon S3 bucket where the transformed dataset was stored.

3. Under **Trial stages**, choose **Training**. On the **Describe Trial Component** menu, choose the following items to display information about the training job trial component.
• **Metrics** – test:loss, test:accuracy, and train:loss
• **Parameters** – hyperparameter values and instance information
• **Artifacts** – Amazon S3 storage for the input dataset and the output model
• **AWS Settings** – job name, ARN, status, creation time, training time, billable time, instance information, and others

**To view a list of trials ordered by test:accuracy**

1. Choose the experiment name on the navigation breadcrumb above **TRIAL COMPONENTS** to display the trial list.
2. Choose all five trials. Hold down the CTRL/CMD key and select each trial. Right-click the selection and then choose **Open in trial component list**. A new tab opens that displays each trial and trial component.
3. If the **TABLE PROPERTIES** pane isn't open, choose the **Settings** icon (pearance) in the upper right corner to open it. Deselect everything except **Trial, Metrics**, and **Training job**. Choose the **Settings** icon to close the pane.
4. Choose the **test:accuracy** column header to sort the list by decreasing maximum test accuracy. Your screen should look similar to the following:

   ![Screenshot of trial component list](image)

**To view a chart of test:loss versus num_hidden_channel**

1. In the **TRIAL COMPONENTS** pane, choose all five trials and then choose **Add chart**. Select inside the chart area to open the preferences pane for **CHART PROPERTIES**.
2. In **CHART PROPERTIES**, choose the following:
   - **Data type** - Summary statistics
   - **Chart type** - Line
   - **X-axis** - hidden-channels
   - **Y-axis** - test:loss_last
Search Experiments Using Amazon SageMaker Studio

You can search your experiments, trials, and trial components using the experiments browser. After choosing the entities, you can search on properties of these entities on the Amazon SageMaker Leaderboard.

Topics
  • Search Experiments, Trials, and Trial Components (p. 2179)
  • Search the SageMaker Studio Leaderboard (p. 2180)
  • Search by Tag (p. 2183)

Search Experiments, Trials, and Trial Components

You can search and create multiple filters to display a subset of experiments, trials, and trial components in the experiments browser. After you search and filter your list, you can open the entities in the Leaderboard and search on additional properties.

To search for experiments, trials, and trial components, and apply filters

For more information about the following steps, along with screenshots, see Search the SageMaker Studio Leaderboard (p. 2180).

1. In the experiments browser, navigate to the entity type you want to search for: experiment, trial, or trial component.
2. Place your cursor in the search box to display the list of column that are searchable.
3. Choose the column that you want to search on and one of the following dialog boxes opens that's specific to the column you chose.
Search Experiments Using Studio

- **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that’s part of the component’s property value. This filter limits the list to those components with a property value that contains the text string.

- **Discrete values** – Choose one or more property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values.

- **Date** – Enter a date in **From Date** and **To Date**, or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.

- **Tag** – In **Search tag key**, start entering the tag’s key. A list of tag keys is filtered to only those keys with a name that starts with the text string that you enter. Choose the tag key that you want to search on from the list. In **Search tag value**, enter the complete tag value, and then choose **Apply**.

4. To create the filter, choose **Apply**.

5. To apply additional filters, repeat the preceding steps. You can have a maximum of 20 filters. An entity must match all filters to be displayed.

### Search the SageMaker Studio Leaderboard

The Amazon SageMaker Studio trial components list is referred to as the Leaderboard. You can use the Leaderboard to compare your trials and experiments. The Leaderboard lists properties of the trials, such as the trial status, debugger status, tags, metrics, hyperparameters, and input and output artifacts.

You can search the Leaderboard to find specific trial components. You apply the results of a search to create a filter that displays only those components that satisfy the filter. You can apply up to 20 filters. A component is displayed only if it matches all filters. To remove a filter, choose the **X** that displays to the right of the filter.

### To search the Leaderboard and apply filters

1. If the **TABLE PROPERTIES** pane isn’t open in SageMaker Studio, choose the **Settings** icon (⚙️) in the upper-right corner to open it.

2. In the **Settings** pane, select the check boxes for the columns that you want to view, and then choose the **Settings** icon to close the pane.

3. Place your cursor in the **Search column name** box to display the following list of **TABLE PROPERTIES** column names that are searchable:

   **Summary section**
   - Trial component name
   - Trial component type
   - Created
   - Last modified
   - Created by
   - Tags

   **Detail sections** (all columns)
   - Metrics
   - Parameters
   - Input artifacts
   - Output artifacts
4. To limit the column names when you search the detail sections, start typing the column name. The list displays only those columns with a name that starts with the text string that you enter.

5. Choose the column that you want to search on. This opens a dialog that's specific to the type of data in that column.

6. Enter your search criteria in the dialog for the appropriate data type:

   - **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.

   - **Discrete values** – Choose one or more of the property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values. For the **Trial component type** column, **Others** matches components with no value in the column.
• **Date** – Enter a date in **From Date** and **To Date** or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.

• **Created by** – Select **Me** or **Everyone else**. This filter limits the list to those components that were created by the currently signed-in user or everyone but the currently signed-in user.

• **Tag** – Choose the tag to search. For more information, see Search by Tag (p. 2183).

• **Detail columns** – Specify the conditions that the component's property value must satisfy.
7. To create the filter, choose **Apply**.
8. To apply additional filters, repeat the preceding steps. A component must match all filters to be displayed. You can have a maximum of 20 filters.

**Search by Tag**

You can add searchable tags to experiments, trials, and trial components when the entities are created or afterwards using the **AddTags** API. A tag consists of a unique case-sensitive key and an optional value. Multiple tags can be added to an entity. You can add the same tag to multiple entities.

**To search by tag and apply filters**

1. If the **TABLE PROPERTIES** pane isn't open in SageMaker Studio, choose the **Settings** icon in the upper-right corner to open it.
2. In the **Settings** pane, select **Tags** if it isn't selected, and then choose the **Settings** icon to close the pane.
3. Place your cursor in the **Search column name** box and then choose **Tags**.

4. In **Search tag key**, start entering the tag's key. A list of tag keys displays only those keys with a name that starts with the text string that you enter.
5. Choose the tag key that you want to search on from the list.
6. In **Search tag value**, enter the complete tag value, and then choose **Apply**.

7. The trial component list displays only those components that have tags that match the key-value pair you chose.

8. To add more tag filters, repeat the previous steps. A tag must match all filters for the component to be displayed.

### Clean Up Amazon SageMaker Experiment Resources

To avoid incurring unnecessary charges, delete the Amazon SageMaker Experiment resources you no longer need. You can't delete Experiment resources through the SageMaker Management Console or the Amazon SageMaker Studio UI. This topic shows you how to clean up these resources using Boto3 and the Experiments SDK. For more information about the Experiments SDK, see [sagemaker-experiments](#).

To delete the experiment, you must delete all trials in the experiment. To delete a trial, you must remove all trial components from the trial. To delete a trial component, you must remove the component from all trials.

**Note**

Trial components can exist independent of trials and experiments. You do not have to delete them. If you want to reuse them, comment out `tc.delete()` in the code.

**Topics**
Clean Up Using the Experiments SDK

To clean up using the Experiments SDK

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments

import time

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent

Define cleanup_sme_sdk

def cleanup_sme_sdk(experiment):
    for trial_summary in experiment.list_trials():
        trial = Trial.load(trial_name=trial_summary.trial_name)
        for trial_component_summary in trial.list_trial_components():
            tc = TrialComponent.load(
                trial_component_name=trial_component_summary.trial_component_name)
            trial.remove_trial_component(tc)
            try:
                # comment out to keep trial components
                tc.delete()
            except:
                # tc is associated with another trial
                continue
            # to prevent throttling
            time.sleep(.5)
            trial.delete()
            experiment_name = experiment.experiment_name
            experiment.delete()
            print(f"\nExperiment {experiment_name} deleted")

Call cleanup_sme_sdk

experiment_to_cleanup = Experiment.load(
    # Use experiment name not display name
    experiment_name="experiment-name")
cleanup_sme_sdk(experiment_to_cleanup)
```

Clean Up Using the Python SDK (Boto3)

To clean up using Boto 3

```python
import boto3
sm = boto3.Session().client('sagemaker')

Define cleanup_boto3
```
Search Using the Amazon SageMaker Console and API

Developing a machine learning model typically requires extensive experimenting with different datasets, algorithms, and hyperparameter values. To manage up to thousands of machine learning model experiments, use the search capabilities in SageMaker.

You can use SageMaker search to:

- Organize, find, and evaluate training jobs using properties, hyperparameters, performance metrics, or any metadata.
- Find the best performing model by reviewing training job and model metrics, such as training loss or validation accuracy.
- Trace a model's lineage to the training job and its related resources, such as the training datasets.

This topic covers searching from the SageMaker console and the SageMaker API. For information on searching in Amazon SageMaker Studio, see Search Experiments Using Studio (p. 2179).

Topics

- Sample Notebooks for Managing ML Experiments (p. 2187)
- Organize, Find, and Evaluate Training Jobs (Console) (p. 2187)
- Find and Evaluate Training Jobs (API) (p. 2189)
- Verify the Datasets Used by Your Training Jobs (p. 2190)
Sample Notebooks for Managing ML Experiments

For a sample notebook that uses Amazon SageMaker model tracking capability to manage ML experiments, see Managing ML Experimentation using Amazon SageMaker Model Tracking Capability.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The notebook for managing ML experiments is located in the Advanced Functionality section. To open a notebook, choose its Use tab, and choose Create copy. If you have questions, post them on the Amazon Machine Learning Developer Forum.

Organize, Find, and Evaluate Training Jobs (Console)

To organize training jobs, assign one or more tags to them.

To find a specific training job, model, or resource, use model tracking to search on keywords assigned to any searchable items. Searchable items include training jobs, models, hyperparameters, metadata, tags, and URLs. To refine your tracking results, you can search using multiple criteria.

To choose the best model for deployment, evaluate how all models performed against one or more metrics. You can use model tracking results to list, sort, and evaluate the performance of the models in your experiments.

Topics
- Use Tags to Track Training Jobs (Console) (p. 2187)
- Find Training Jobs (Console) (p. 2188)
- Evaluate Models (Console) (p. 2188)

Use Tags to Track Training Jobs (Console)

To group training jobs, create tags with descriptive keys and a value. For example, create tag keys for: project, owner, customer, and industry.

Add tags to training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Training jobs and Create training job.
3. Scroll to the bottom of the page and enter a key and value for the tag.

4. To add another tag, choose Add tag, and add another key-value pair.
Find Training Jobs (Console)

You can search for training jobs using a variety of job attributes. Note that some search parameters
appear only if you have created a training job with that attribute. For example, Tags appears only if you
have added a tag for a training job.

To find training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search.
3. Add Parameters.
   a. In the search box, enter a parameter and choose a parameter type, for example TrainingJobName.
   b. Choose a conditional operation. For numeric values, use operators such as is equals to, lesser
      than, or or greater than. For text-based values, use operators such as equals to or contains.
   c. Enter a value for the parameter.
4. (Optional) To refine your search, add additional search criteria. Choose Add row and enter the
   parameter values.
5. Choose Search.

Evaluate Models (Console)

To evaluate a model's performance, review its metadata, hyperparameters, and metrics. To highlight
metrics, adjust the view to show only metrics and important hyperparameters.

To evaluate a model (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search and search for training jobs by specifying relevant
   search parameters. The results are displayed in a table.

Results: Training jobs

<table>
<thead>
<tr>
<th>HyperParameter mini_batch_size</th>
<th>HyperParameter predictor_type</th>
<th>Metric train:binary_f_beta</th>
<th>Metric train:progress</th>
<th>Metric train:objective_loss</th>
</tr>
</thead>
<tbody>
<tr>
<td>300</td>
<td>binary_classifier</td>
<td>0.966639518737793</td>
<td>100</td>
<td>0.02381423674523</td>
</tr>
<tr>
<td>100</td>
<td>binary_classifier</td>
<td>0.9652714133262634</td>
<td>100</td>
<td>0.02350491285324</td>
</tr>
<tr>
<td>200</td>
<td>binary_classifier</td>
<td>0.9647442698478699</td>
<td>100</td>
<td>0.02325980737805</td>
</tr>
</tbody>
</table>

3. Open the preferences window by choosing the settings icon in the search results table.
4. To show or hide a hyperparameter or metric, turn it on or off by choosing **Hyperparameter** or **Metric**.

5. Make necessary changes, then choose **Update view**.

6. After viewing metrics and important hyperparameters, you can compare and contrast the result. Then, you can choose the best model to host or investigate the models that are performing poorly.

**Find and Evaluate Training Jobs (API)**

To find and evaluate training jobs or to get suggestions for items used in experiments that are searchable, you can use the **Search API**.

**Topics**
- Find Training Jobs (API) (p. 2189)
- Evaluate Models (API) (p. 2189)
- Get Suggestions for a Search (API) (p. 2190)

**Find Training Jobs (API)**

To find training jobs, create a search parameter using the `search_params` parameter. Then use the `search` function in the `smclient` subprocess in the AWS SDK for Python (Boto3).

The following example shows how to use the **Search API** to find training jobs.

```python
import boto3

search_params = {
    "MaxResults": 10,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [{
            "Name": "Tags.Project",
            "Operator": "Equals",
            "Value": "Project_Binary_Classifier"
        }],
        "SortBy": "Metrics.train:binary_classification_accuracy",
        "SortOrder": "Descending"
    }
}

smclient = boto3.client(service_name='sagemaker')
results = smclient.search(**search_params)
```

**Evaluate Models (API)**

To evaluate models, run a search as described in Find Training Jobs (API) (p. 2189), review model metrics, then, use the AWS SDK for Python (Boto3) to create a table and plot it.

The following example shows how to evaluate models and to display the results in a table.

```python
import pandas

headers = ["Training Job Name", "Training Job Status", "Batch Size", "Binary Classification Accuracy"]
rows = []
for result in results["Results"]:  
    trainingJob = result["TrainingJob"]
    metrics = trainingJob["FinalMetricDataList"]
    rows.append([trainingJob["TrainingJobName"],
```
Get Suggestions for a Search (API)

To get suggestions for a search, use the `GetSearchSuggestions` API.

The following example for AWS SDK for Python (Boto3) is a `get_search_suggestions` request for items containing `linear`.

```python
search_suggestion_params=
    "Resource": "TrainingJob",
    "SuggestionQuery": {
        "PropertyNameQuery": {
            "PropertyNameHint": "linear"
        }
    }
}
```

The following is an example response for a `get_search_suggestions` request.

```json
{
    'PropertyNameSuggestions': [
        {'PropertyName': 'hyperparameters.linear_init_method'},
        {'PropertyName': 'hyperparameters.linear_init_value'},
        {'PropertyName': 'hyperparameters.linear_init_sigma'},
        {'PropertyName': 'hyperparameters.linear_lr'},
        {'PropertyName': 'hyperparameters.linear_wd'}
    ]
}
```

After getting search suggestions, you can use one of the property names in a search.

Verify the Datasets Used by Your Training Jobs

You can use model tracking capability to verify which datasets were used in training, where holdout datasets were used, and other details about training jobs. For example, use model tracking capability to verify that a specific dataset was used in a training job for an audit or to verify compliance.

To check whether a specific dataset was used in a training job, you search for the URL to its location in Amazon Simple Storage Service (Amazon S3). Model tracking capability returns the training jobs that used the dataset that you specify. If your search doesn't return the dataset (the result is empty), the dataset wasn't used in a training job. An empty result confirms, for example, that a holdout dataset wasn't used.

Trace Model Lineage

You can use model tracking capability to get information about the lineage of training jobs and the model resources that were used for them, including the dataset, algorithm, hyperparameters, and metrics. For example, if you find that the performance of a hosted model has declined, you can review its training job and the resources it used to determine what's causing the problem.
• Trace Model Lineage (Console) (p. 2191)
• Trace Model Lineage (API) (p. 2191)

**Trace Model Lineage (Console)**

To trace a model's lineage (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose **Endpoints**, and choose the relevant endpoint.
3. Scroll to the **Endpoint configuration settings** section. This section lists all of the model versions deployed at the endpoint, with a hyperlink to the training job that created each.

**Trace Model Lineage (API)**

To trace a model's lineage, get the model's name, then use it to search for training jobs.

The following example shows how to trace a model's lineage using the API.

```python
# Get the name of model deployed at endpoint
endpoint_config = smclient.describe_endpoint_config(EndpointConfigName=endpointName)
model_name = endpoint_config['ProductionVariants'][0]['ModelName']

# Get the model's name
model = smclient.describe_model(ModelName=model_name)

# Search the training job by the location of model artifacts in Amazon S3
search_params={
    "MaxResults": 1,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [
            {
                "Name": "ModelArtifacts.S3ModelArtifacts",
                "Operator": "Equals",
                "Value": model['PrimaryContainer'] ['ModelDataUrl']
            }
        ]
    }
}
results = smclient.search(**search_params)```

After finding the training job, you can review the resources used to train the model.

---

**Amazon SageMaker Debugger**

Debug, monitor, and profile training jobs in real time, detect non-converging conditions, optimize resource utilization by eliminating bottlenecks, improve training time, and reduce costs of your machine learning models using Amazon SageMaker Debugger.

**Amazon SageMaker Debugger Features**

A machine learning (ML) training job can have problems such as system bottlenecks, overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.

SageMaker Debugger profiles and debugs training jobs to help resolve such problems and improve your ML model's compute resource utilization and performance. Debugger offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.
SageMaker Debugger supports Apache MXNet, TensorFlow, PyTorch, and XGBoost. For more information about available frameworks and versions, see Supported Frameworks and Algorithms (p. 2193).

The high-level Debugger workflow is as follows:

1. Configure a SageMaker training job with Debugger.
   - Configure using the SageMaker Estimator API (for Python SDK).
   - Configure using the SageMaker CreateTrainingJob request (for Boto3 or CLI).
   - Configure custom training containers (p. 2285) with Debugger.
2. Start a training job and monitor training issues in real time.
   - SageMaker Studio Debugger dashboards in Studio Experiments and trials (p. 2298).
   - List of Debugger Built-in Rules (p. 2239).
3. Get alerts and take prompt actions against the training issues.
   - Receive texts and emails and stop training jobs when training issues are found using Debugger Built-in Actions for Rules (p. 2289).
   - Set up your own actions using Amazon CloudWatch Events and AWS Lambda (p. 2293).
4. Receive training reports, suggestions to fix the issues, and insights into your training jobs.
   - Studio Debugger Insights dashboard for deep learning frameworks
   - Deep learning framework profiling report
   - SageMaker XGBoost training report
5. Explore deep analysis of the training issues and bottlenecks.
   - For profiling training jobs, see Analyze Data Using the SMDebug Client Library (p. 2338).
   - For debugging model parameters, see Visualize Debugger Output Tensors in TensorBoard (p. ).
6. Fix the issues, considering the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

Topics
- Supported Frameworks and Algorithms (p. 2193)
- Amazon SageMaker Debugger Architecture (p. 2195)
- Get Started with Debugger Tutorials (p. 2197)
- Configure Debugger Using Amazon SageMaker Python SDK (p. 2206)
- Configure Debugger Using Amazon SageMaker API (p. 2228)
- List of Debugger Built-in Rules (p. 2239)
- Create Debugger Custom Rules for Training Job Analysis (p. 2283)
Supported Frameworks and Algorithms

The following table shows SageMaker machine learning frameworks and algorithms supported by Debugger.

<table>

- **Monitoring system bottlenecks** – Monitor the system utilization rate for resources such as CPU, GPU, memories, network, and data I/O metrics. This is a framework and model agnostic feature and available for any training jobs in SageMaker.
- **Profiling deep learning framework operations** – Profile the deep learning operations of the TensorFlow and PyTorch frameworks, such as step durations, data loaders, forward and backward operations, Python profiling metrics, and framework-specific metrics.
- **Debugging output tensors** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.
Important
For the TensorFlow framework with Keras, SageMaker Debugger deprecates the zero code change support for debugging models built using the `tf.keras` modules of TensorFlow 2.6 and later. This is due to breaking changes announced in the TensorFlow 2.6.0 release note. SageMaker Debugger continues to support the zero code change experience for the native TensorFlow (which excludes the `tf.keras` modules).

Important
For PyTorch v1.12 and later, SageMaker Debugger deprecates the zero code change support for debugging models.

This is due to breaking changes that cause SageMaker Debugger to interfere with the `torch.jit` functionality. For instructions on how to update your training script, see How to register the `smdebug` hook for PyTorch in the `smdebug Python SDK documentation`.

If the framework or algorithm that you want to train and debug is not listed in the table, go to the AWS Discussion Forum and leave feedback on SageMaker Debugger.

AWS Regions
Amazon SageMaker Debugger is available in all regions where Amazon SageMaker is in service except the following region.

- Asia Pacific (Jakarta): ap-southeast-3

To find if Amazon SageMaker is in service in your AWS Region, see AWS Regional Services.

Use Debugger with Custom Training Containers
Bring your training containers to SageMaker and gain insights into your training jobs using Debugger.
Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.

For more information about how to build your training container with the `smdebug` client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see Use Debugger with Custom Training Containers (p. 2285).

Debugger Open-Source GitHub Repositories
Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker `CreateTrainingJob` and `DescribeTrainingJob` API operations. The `smdebug` client library provides tools to register hooks and access the training data through its `trial` feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and `smdebug` API operations, see the following links:

- The Amazon SageMaker Python SDK documentation
- The Amazon SageMaker Python SDK - Debugger APIs
- The `smdebug` Python SDK documentation for the Amazon SageMaker Debugger open source client library
- The `smdebug` PyPI

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:
Amazon SageMaker Debugger Architecture

This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for performance optimization to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger's debugging functionality for model optimization is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.
Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **System metrics** – Hardware resource utilization data, such as CPU, GPU, CPU and GPU memory, network, and data input and output (I/O) metrics.
- **Framework metrics** – Metrics to track each framework operation per call or sampling, such as convolutional layer operations in the forward pass, batch normalization operations in the backward pass, data loader processes between steps, and gradient descent algorithm operations to calculate and update the loss function.
- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

**Note**
By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics.
every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the `ProfilerReport` rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured Amazon S3 bucket.

The Debugger built-in rules run on processing containers, which are designed to evaluate machine learning models by processing the training data collected in your S3 bucket (see Process Data and Evaluate Models). The built-in rules are fully managed by Debugger. You can also create your own rules customized to your model to watch for any issues you want to monitor.

See the following topics for best practices to improve the performance of your model using SageMaker Debugger.

## Get Started with Debugger Tutorials

The following topics walk you through tutorials from the basics to advanced use cases of monitoring, profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and learn how you can debug and improve your machine learning models efficiently by using Debugger.

### Topics

- Debugger Tutorial Videos (p. 2197)
- Debugger Example Notebooks (p. 2198)
- Debugger Advanced Demos and Visualization (p. 2200)

### Debugger Tutorial Videos

The following videos provide a tour of Amazon SageMaker Debugger capabilities using SageMaker Studio and SageMaker notebook instances.

### Topics

- Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger (p. 2197)
- Debug Models with Amazon SageMaker Debugger in Studio (p. 2197)
- Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor (p. 2198)

### Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger

_Edited by Emily Webber, AWS Machine Learning Specialist | Length: 13 minutes 54 seconds_

This tutorial video gives you a tour of Amazon SageMaker Debugger to capture, debug, and visualize model output data from a training model with MXNet. Learn how Amazon SageMaker Debugger makes the training process transparent by automatically capturing metrics, analyzing training runs, and detecting problems.

_Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger_

You can find the example notebook in this video at Visualizing Debugging Tensors of MXNet training in the Amazon SageMaker Examples GitHub repository.

### Debug Models with Amazon SageMaker Debugger in Studio

_Edited by Julien Simon, AWS Technical Evangelist | Length: 14 minutes 17 seconds_

2197
This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect debugging information from a training model. The example training model used in this video is a simple convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker in a TensorFlow framework and Debugger enable you to build an estimator directly using the training script and debug the training job.

**Debug Models with Amazon SageMaker Debugger (part 1)**

You can find the example notebook in the video in this Studio Demo repository provided by the author. You need to clone the debugger.ipynb notebook file and the mnist_keras_tf.py training script to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the path keras_script_path to the mnist_keras_tf.py file inside the debugger.ipynb notebook. For example, if you cloned the two files in the same directory, set it as keras_script_path = "mnist_keras_tf.py".

**Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor**

*Julien Simon, AWS Technical Evangelist | Length: 44 minutes 34 seconds*

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

**Debug Models with Debugger (part 2)**

You can find the example notebook in the video in this AWS Dev Days 2020 repository offered by the author.

**Debugger Example Notebooks**

*SageMaker Debugger example notebooks are provided in the aws/amazon-sagemaker-examples repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.*

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at Amazon SageMaker Studio Tour.

To find the examples in a SageMaker Notebook instance, follow the instructions at SageMaker Notebook Instance Example Notebooks.

**Important**

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Debugger Example Notebooks for Profiling Training Jobs**

The following list shows Debugger example notebooks introducing Debugger's adaptability to monitor and profile training jobs for various machine learning models, datasets, and frameworks.
### Debugger Example Notebooks for Analyzing Model Parameters

To find advanced visualizations of model parameters and use cases, see the next topic at Debugger Advanced Demos and Visualization (p. 2200).

**Debugger Advanced Demos and Visualization**

The following demos walk you through advanced use cases and visualization scripts using Debugger.

**Topics**
- **Train and Tune Your Models with Amazon SageMaker Experiments and Debugger** (p. 2200)
- **Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training** (p. 2203)
- **Using SageMaker Debugger to Monitor Attentions in BERT Model Training** (p. 2203)
- **Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)** (p. 2206)

**Train and Tune Your Models with Amazon SageMaker Experiments and Debugger**

*Dr. Nathalie Rauschmayr, AWS Applied Scientist | Length: 49 minutes 26 seconds*

**Train and Prune Models with SageMaker Experiments and Debugger**

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as trials through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a model pruning technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.
SageMaker Estimator trains those algorithms supplied from the PyTorch model zoo in an AWS Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an AWS Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.

Learning objectives are as follows:

- Learn how to use SageMaker to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from SageMaker Debugger PyTorch Iterative Model Pruning.

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

Total params: 50,883,321
Trainable params: 50,883,321
Non-trainable params: 0

Input size (MB): 0.57
Forward/backward pass size (MB): 7.27
Params size (MB): 194.19
Estimated Total Size (MB): 201.95
You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.

In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

**Note**

To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the `train` function in the `train.py` script.

```python
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
    print('acc:{:.4f}'.format(correct/total))
    hook.save_scalar("accuracy", correct/total, sm_metric=True)

    # Add the following code to line 128 of the train.py script to save the pruned models
    # under the current SageMaker Studio model directory
    torch.save(model.state_dict(), os.environ['SM_MODEL_DIR'] + '/model.pt')
```
Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size (1, 20) from an original input image of size (28, 28) and significantly reduces the size of data for training by 40 times.

The decoder has two deconvolutional layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.

Using SageMaker Debugger to Monitor Attentions in BERT Model Training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on transfer learning and the Transformer model for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple example, the BERT model can give a high attention to appropriate verb tokens or pronoun tokens from a subject token.
The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.

Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called attention.

This notebook demonstrates how to use the pre-trained BERT model from the GluonNLP model zoo on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting attention scores and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker Debugger, you can retrieve the tensors and plot the attention-head view in real time as training progresses and understand what the model is learning.

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.
Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a convolutional neural network (CNN or ConvNet) is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on the German Traffic Sign Dataset, which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.

During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a saliency map) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

Configure Debugger Using Amazon SageMaker Python SDK

To configure Debugger, use Amazon SageMaker Python SDK and specify Debugger-specific parameters while constructing SageMaker estimators. There are three parameters you need to configure: profiler_config, debugger_hook_config, and rules.

Note
By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured S3 bucket.
Important
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Construct a SageMaker Estimator with Debugger

The following example codes show how to construct a SageMaker estimator with the Debugger-specific parameters depending on a framework of your choice. Throughout the documentation in the following topics, you can find more information about how to configure the Debugger-specific parameters that you can mix and match as you want.

**Note**
The following example codes are not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

TensorFlow

To access the deep profiling feature for TensorFlow, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```python
# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltinRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```
PyTorch

To access the deep profiling feature for PyTorch, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```python
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)

rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04",
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

MXNet

```python
# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)

rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",
)```
# Debugger-specific parameters

```
profiler_config=profiler_config,
debugger_hook_config=debugger_hook_config,
rules=rules
```

estimator.fit(wait=False)

**Note**

For MXNet, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for MXNet.

### XGBoost

```
# An example of constructing a SageMaker XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.2-1",
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

**Note**

For XGBoost, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

### Generic estimator

```
# An example of constructing a SageMaker generic estimator using the XGBoost algorithm
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=Estimator(
    image=image_uris.xgboost_cpu_latest(),
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.2-1",
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```
region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")
estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)
estimator.fit(wait=False)

Where you configure the following parameters:

- **profiler_config** parameter – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the profiler_config parameter, see Configure Debugger Monitoring Hardware System Resource Utilization (p. 2211) and Configure Debugger Framework Profiling (p. 2211).

- **debugger_hook_config** parameter – Configure Debugger to collect output tensors from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the debugger_hook_config parameter, see Configure Debugger Hook to Save Tensors (p. 2215).

- **rules** parameter – Configure this parameter to enable Debugger built-in rules that you want to run in parallel. The rules automatically analyze your training job and find training issues. The ProfilerReport rule saves the Debugger profiling reports in your secured S3 bucket URI. To learn how to configure the rules parameter, see Configure Debugger Built-in Rules (p. 2221).

**Note**

Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are three subfolders created by Debugger: `debug-output`, `profiler-output`, and `rule-output`. You can also retrieve the default S3 bucket URIs using the SageMaker estimator classmethods (p. 2227).

See the following topics to find out how to configure the Debugger-specific parameters in detail.

**Topics**

- Configure Debugger Monitoring Hardware System Resource Utilization (p. 2211)
- Configure Debugger Framework Profiling (p. 2211)
- Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 2215)
- Configure Debugger Hook to Save Tensors (p. 2215)
- Configure Debugger Built-in Rules (p. 2221)
- Turn Off Debugger (p. 2227)
- Useful SageMaker Estimator Classmethods for Debugger (p. 2227)
Configure Debugger Monitoring Hardware System Resource Utilization

To adjust Debugger system monitoring time intervals, use the ProfilerConfig API operation to create a parameter object while constructing a SageMaker framework or generic estimator depending on your preference.

**Note**
By default, for all SageMaker training jobs, Debugger collects hardware system utilization data from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the system metrics in a default S3 bucket. The format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/.

The following example code shows how to set up the profiler_config parameter with a system monitoring time interval of 1000 milliseconds.

```python
from sagemaker.debugger import ProfilerConfig
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

- `system_monitor_interval_millis` (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see Open the Amazon SageMaker Debugger Insights Dashboard (p. 2299).

Configure Debugger Framework Profiling

To enable Debugger framework profiling, configure the framework_profile_params parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the FrameworkProfile class, you can configure custom framework profiling options.

**Note**
Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see Supported Frameworks and Algorithms (p. 2193).

Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/.

Start a Training Job with the Default System Monitoring and Framework Profiling

The following example code is the simplest profiler_config parameter setting to start the default system monitoring and the default framework profiling. The FrameworkProfile class in the following example code initiates the default framework profiling when a training job starts. Debugger framework profiling includes the following options: detailed profiling, data loader profiling, and Python profiling.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
```
With this `profiler_config` parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options (p. 2213) and SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

If you want to change the system monitoring interval and enable the default framework profiling, you can specify the `system_monitor_interval_millis` parameter explicitly with the `framework_profile_params` parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile()
)
```

For more information about the `FrameworkProfile` class, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

**Start a Training Job with the Default System Monitoring and Customized Framework Profiling for Target Steps or a Target Time Range**

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the `FrameworkProfile` class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  
  profiler_config=ProfilerConfig(
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  
  profiler_config=ProfilerConfig(
      system_monitor_interval_millis=1000,
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

- **For a target time range**
With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
        duration=600)
)
```

With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
        duration=600)
)
```

The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

The next section shows you how to script the available profiling options.

### Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options

You can use the following profiling configuration classes to manage the framework profiling options:

- **DetailedProfilingConfig** – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  **Note**
  Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

- **DataloaderProfilingConfig** – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.

  **Note**
  Data loader profiling might lower the training performance while collecting information from data loaders. We don’t recommend enabling data loader profiling for more than a couple of steps.
  Debugger is preconfigured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes from any other custom or external training containers.

- **PythonProfilingConfig** – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.
• *cProfile* – The standard Python profiler. cProfile collects information for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation for each function call, providing complete detail about Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function call executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

• *Pyinstrument* – Pyinstrument is a low-overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wall-clock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noise (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

**Note**

Enabling Python profiling might slow down the overall training time. cProfile profiles the most frequently called Python operators at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling options with specified values.

```python
import time
from sagemaker.debugger import (ProfilerConfig,
                                 FrameworkProfile,
                                 DetailedProfilingConfig,
                                 DataloaderProfilingConfig,
                                 PythonProfilingConfig,
                                 PythonProfiler, cProfileTimer)

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloader_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
        python_profiling_config=PythonProfilingConfig(
            start_step=9,
            num_steps=1,
            python_profiler=PythonProfiler.CPROFILE,
            cprofile_timer=cProfileTimer.TOTAL_TIME
        )
    )
)
```

For more information about available profiling options, see *DetailedProfilingConfig, DataloaderProfilingConfig, and PythonProfilingConfig* in the Amazon SageMaker Python SDK.
Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running

If you want to enable or update the Debugger monitoring and profiling configuration for a training job that is currently running, use the following SageMaker estimator extension methods:

- To enable Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:

```python
estimator.enable_default_profiling()
```

When you use the `enable_default_profiling` method, Debugger initiates the default system monitoring and the `ProfileReport` built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

For more information, see `estimator.enable_default_profiling` in the Amazon SageMaker Python SDK.

- To enable Debugger built-in rules, system monitoring, and framework profiling with customizable configuration parameters, use the following:

```python
estimator.update_profiler(
    rules=[ProfilerRule.sagemaker(rule_configs.BuiltinRule()),
          system_monitor_interval_millis=500,
          framework_profile_params=FrameworkProfile()]
)
```

For more information, see `estimator.update_profiler` in the Amazon SageMaker Python SDK.

Configure Debugger Hook to Save Tensors

_Tensors_ are data collections of updated parameters from the backward and forward pass of each training iteration, and Debugger collects output tensors to analyze the state of a training job. The Amazon SageMaker Debugger CollectionConfig and DebuggerHookConfig API operations provide methods for grouping tensors into _collections_ and saving them to a target S3 bucket.

**Note**

By default, for all SageMaker training jobs, Debugger collects loss and accuracy output scalars from the training jobs every 500 steps, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the output data in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

While constructing a SageMaker estimator, enable Debugger by specifying the hook configuration parameter, `debugger_hook_config`. The following steps include examples of how to set up the `debugger_hook_config` using the CollectionConfig and DebuggerHookConfig API operations to pull tensors out of your training jobs and save them. If you use Debugger-supported AWS containers for zero script change, you can simply run the training job without changing your training script. You can also use Debugger for training jobs running in any other Debugger-supported AWS containers with script mode, making minimal changes to your training script.

Configure Debugger Tensor Collections Using the CollectionConfig API Operation

Use the CollectionConfig API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-
supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=
    [CollectionConfig(name="weights"),
     CollectionConfig(name="gradients")]
```

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default "save_interval" value.

For a full list of available Debugger built-in collections, see Debugger Built-in Collections.

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following `CollectionConfig` template to adjust parameters.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=
    [CollectionConfig(  
        name="tensor_collection",  
        parameters={  
        "key_1": "value_1",  
        "key_2": "value_2",  
        ...  
        "key_n": "value_n"
    }
]
```

For more information about available parameter keys, see `CollectionConfig` in the Amazon SageMaker Python SDK. For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=
    [CollectionConfig(  
        name="losses",  
        parameters={  
            "train.save_interval": "100",  
            "eval.save_interval": "10"
    }
]
```

**Tip**

This tensor collection configuration object can be used for both `DebuggerHookConfig` and `Rule API` operations.

**Configure Debugger Hook to Save Tensors**

Use the `DebuggerHookConfig` class to create a `debugger_hook_config` object using the `collection_configs` object you created in the previous step.

```python
from sagemaker.debugger import DebuggerHookConfig
```
Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```python
from sagemaker.debugger import DebuggerHookConfig
designer_hook_config=DebuggerHookConfig(
    s3_output_path="specify-your-s3-bucket-uri",
    collection_configs=collection_configs
)
```

For more information, see `DebuggerHookConfig` in the Amazon SageMaker Python SDK.

### Example Notebooks and Code Samples to Configure Debugger Hook

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

**Topics**
- **Tensor Visualization Example Notebooks** (p. 2217)
- **Save Tensors Using Debugger Built-in Collections** (p. 2219)
- **Save Tensors Using Debugger Modified Built-in Collections** (p. 2220)
- **Save Tensors Using Debugger Custom Collections** (p. 2220)

**Tensor Visualization Example Notebooks**

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

- **Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet**

  This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.
This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

- Visualizing and Debugging Tensors from MXNet Model Training

This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLu activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLu activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.

In this notebook, the TensorPlot class imported from tensor_plot.py is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The tensor_plot.py script provided with the notebook retrieves tensors using Debugger and visualizes
the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- **Real-time Tensor Analysis in a SageMaker Notebook with MXNet**

  This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

**Save Tensors Using Debugger Built-in Collections**

You can use built-in collections of tensors using the `CollectionConfig` API and save them using the `DebuggerHookConfig` API. The following example shows how to use the default settings of Debugger hook configurations to construct a SageMaker TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

**Note**

In the following example code, the `s3_output_path` parameter for `DebuggerHookConfig` is optional. If you do not specify it, Debugger saves the tensors at `s3://<output_path>/debug-output/`, where the `<output_path>` is the default output path of SageMaker training jobs. For example:

```
"s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"
```

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients"),
    CollectionConfig(name="losses"),
    CollectionConfig(name="biases")
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-built-in-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
    LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",
)```
To see a list of Debugger built-in collections, see Debugger Built-in Collections.

**Save Tensors Using Debugger Modified Built-in Collections**

You can modify the Debugger built-in collections using the CollectionConfig API operation. The following example shows how to tweak the built-in losses collection and construct a SageMaker TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs = [
    CollectionConfig(
        name="losses",
        parameters={"save_interval": "50"})
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session = sagemaker.Session()
BUCKET_NAME = sagemaker_session.default_bucket()
LOCATION_IN_BUCKET = 'debugger-modified-collections-hook'

hook_config = DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME, LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator = TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

For a full list of CollectionConfig parameters, see Debugger CollectionConfig API.

**Save Tensors Using Debugger Custom Collections**

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs = [
    CollectionConfig(
        name="losses",
        parameters={"save_interval": "50"})
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session = sagemaker.Session()
BUCKET_NAME = sagemaker_session.default_bucket()
LOCATION_IN_BUCKET = 'debugger-modified-collections-hook'

hook_config = DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME, LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator = TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection

collection_configs = [
    CollectionConfig(
        name="custom_activations_collection",
        parameters={
            "include_regex": "relu|tanh", # Required
            "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
        }
    )
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session = sagemaker.Session()
BUCKET_NAME = sagemaker_session.default_bucket()
LOCATION_IN_BUCKET = 'debugger-custom-collections-hook'

hook_config = DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                            LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator = TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of CollectionConfig parameters, see Debugger CollectionConfig.

### Configure Debugger Built-in Rules

Amazon SageMaker Debugger rules analyze tensors emitted during the training of a model. Debugger offers the Rule API operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger Built-in Rules (p. 2239).

**Note**

The built-in rules are prepared in Amazon SageMaker processing containers and fully managed by SageMaker Debugger. By default, Debugger initiates the ProfilerReport (p. 2241) rule for all SageMaker training jobs, without any Debugger-specific rule parameter specified to the SageMaker estimators. The ProfilerReport rule invokes all of the following built-in rules for monitoring system bottlenecks and profiling framework metrics:

- BatchSize (p. 2242)
• CPUBottleneck (p. 2244)
• GPUMemoryIncrease (p. 2245)
• IOBottleneck (p. 2246)
• LoadBalancing (p. 2247)
• LowGPUtilization (p. 2248)
• OverallSystemUsage (p. 2249)
• MaxInitializationTime (p. 2249)
• OverallFrameworkMetrics (p. 2250)
• StepOutlier (p. 2250)

Debugger saves the profiling report in a default S3 bucket. The format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/rule-output/. For more information about how to download the profiling report, see SageMaker Debugger Profiling Report (p. 2315). SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the Amazon SageMaker Studio is available at no additional charge section of the Amazon SageMaker Pricing page.

In the following topics, learn how to use the Debugger built-in rules.

Topics
• Use Debugger Built-in Rules with the Default Parameter Settings (p. 2222)
• Use Debugger Built-in Rules with Custom Parameter Values (p. 2223)
• Example Notebooks and Code Samples to Configure Debugger Rules (p. 2224)

Use Debugger Built-in Rules with the Default Parameter Settings

To specify Debugger built-in rules in an estimator, you need to configure a rules list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_n()),
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n())
]
```

For more information about default parameter values and descriptions of the built-in rule, see List of Debugger Built-in Rules (p. 2239).

For example, to inspect the overall training performance and progress of your model, construct a SageMaker estimator with the following built-in rule configuration.

```python
from sagemaker.debugger import Rule, rule_configs

rules=[
```
When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. The loss_not_decreasing, overfit, overtraining, and stalled_training_rule monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to IssueFound. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules (p. 2288).

Use Debugger Built-in Rules with Custom Parameter Values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the base_config and rule_parameters parameters for the ProfilerRule.sagemaker and Rule.sagemaker class methods. In case of the Rule.sagemaker class methods, you can also customize tensor collections through the collections_to_save parameter. The instruction of how to use the CollectionConfig class is provided at Configure Debugger Tensor Collections Using the CollectionConfig API Operation (p. 2215).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The base_config argument is where you call the built-in rule methods.
- The rule_parameters argument is to adjust the default key values of the built-in rules listed in List of Debugger Built-in Rules (p. 2239).
- The collections_to_save argument takes in a tensor configuration through the CollectionConfig API, which requires name and parameters arguments.
  - To find available tensor collections for name, see Debugger Built-in Tensor Collections.
  - For a full list of adjustable parameters, see Debugger CollectionConfig API.

For more information about the Debugger rule class, methods, and parameters, see SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig

rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.ProfileReport(),
        rule_parameters={
            "key": "value"
        }
    ),
    Rule.sagemaker(
        base_config=rule_configs.loss_not_decreasing(),
        rule_parameters={
            "key": "value"
        },
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                })
        ]
    )
]
```
The parameter descriptions and value customization examples are provided for each rule at List of Debugger Built-in Rules (p. 2239).

Example Notebooks and Code Samples to Configure Debugger Rules

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

Topics
- Debugger Built-in Rules Example Notebooks (p. 2224)
- Debugger Built-in Rules Example Code (p. 2225)
- Use Debugger Built-in Rules with Parameter Modifications (p. 2226)

Debugger Built-in Rules Example Notebooks

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker:

- Using a SageMaker Debugger built-in rule with TensorFlow
- Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet
- Using a SageMaker Debugger built-in rule with XGBoost
- Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost

While running the example notebooks in SageMaker Studio, you can find the training job trial created on the Studio Experiment List tab. For example, as shown in the following screenshot, you can find and open a Describe Trial Component window of your current training job. On the Debugger tab, you can check if the Debugger rules, vanishing_gradient() and loss_not_decreasing(), are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see SageMaker Studio - View Experiments, Trials, and Trial Components.
There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

**Debugger Built-in Rules Example Code**

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see List of Debugger Built-in Rules (p. 2239).

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

rules = [
    Rule.sagemaker(rule_configs.vanishing_gradient()),
    Rule.sagemaker(
        base_config=rule_configs.loss_not_decreasing(),
        collections_to_save=[
            CollectionConfig(
                name='rules',
                parameters={
                    '#Save_interval': '50',
                    #'TrainSaveInterval': '2000',
                    '--TrainSaveInterval': '10000'
                }
            )
        ]
    )
]

estimator = TensorFlow(
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    # call built-in rules that you want to use.
    built_in_rules=[
        Rule.sagemaker(rule_configs.vanishing_gradient()),
        Rule.sagemaker(rule_configs.loss_not_decreasing())
    ]
)
```

# construct a SageMaker estimator with the Debugger built-in rules
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    )
```
instance_count=1,
instance_type="ml.m4.xlarge",
framework_version="2.1.0",
py_version="py3",

# debugger-specific arguments below
rules=built_in_rules
)
sagemaker_estimator.fit()

Note
The Debugger built-in rules run in parallel with your training job. The maximum number of
built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the SageMaker
Debugger Rule class in the Amazon SageMaker Python SDK.

To find an example of how to adjust the Debugger rule parameters, see the following Use Debugger
Built-in Rules with Parameter Modifications (p. 2226) section.

Use Debugger Built-in Rules with Parameter Modifications

The following code example shows the structure of built-in rules to adjust parameters. In this example,
the stalled_training_rule collects the losses tensor collection from a training job at every 50
steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting
tensor outputs for 120 seconds, the stalled_training_rule stops the training job.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters
base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))
built_in_rules_modified=

# construct a SageMaker estimator with the modified Debugger built-in rule
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name=base_job_name_prefix,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.1.0",
    py_version="py3",
```
For an advanced configuration of the Debugger built-in rules using the CreateTrainingJob API, see Configure Debugger Using Amazon SageMaker API (p. 2228).

**Turn Off Debugger**

If you want to completely turn off Debugger, do one of the following:

- **Before starting a training job, do the following:**

  To disable both monitoring and profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

  **Warning**
  
  If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To disable debugging, set the `debugger_hook_config` parameter to `False`.

  **Warning**
  
  If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

```python
estimator=Estimator(
    ...
    disable_profiler=True
    debugger_hook_config=False
)
```

For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- **While a training job is running, do the following:**

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

```python
estimator.disable_profiling()
```

To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

```python
estimator.update_profiler(disable_framework_metrics=true)
```

For more information about the estimator extension methods, see the `estimator.disable_profiling` and `estimator.update_profiler` classmethods in the Amazon SageMaker Python SDK documentation.

**Useful SageMaker Estimator Classmethods for Debugger**

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the `estimator.fit()` method.
• To check the base S3 bucket URI of a SageMaker training job:
  ```python
  estimator.output_path
  ```

• To check the base job name of a SageMaker training job:
  ```python
  estimator.latest_training_job.job_name
  ```

• To see a full `CreateTrainingJob` API operation configuration of a SageMaker training job:
  ```python
  estimator.latest_training_job.describe()
  ```

• To check a full list of the Debugger rules while a SageMaker training job is running:
  ```python
  estimator.latest_training_job.rule_job_summary()
  ```

• To check the S3 bucket URI where the model parameter data (output tensors) are saved:
  ```python
  estimator.latest_job_debugger_artifacts_path()
  ```

• To check the S3 bucket URI where the model performance data (system and framework metrics) are saved:
  ```python
  estimator.latest_job_profiler_artifacts_path()
  ```

• To check the Debugger rule configuration for debugging output tensors:
  ```python
  estimator.debugger_rule_configs
  ```

• To check the list of the Debugger rules for debugging while a SageMaker training job is running:
  ```python
  estimator.debugger_rules
  ```

• To check the Debugger rule configuration for monitoring and profiling system and framework metrics:
  ```python
  estimator.profiler_rule_configs
  ```

• To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:
  ```python
  estimator.profiler_rules
  ```

For more information about the SageMaker estimator class and its methods, see Estimator API in the Amazon SageMaker Python SDK.

**Configure Debugger Using Amazon SageMaker API**

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This offers a high-level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this guide covers how to configure `CreateTrainingJob`, `UpdateTrainingJob`, Debugger configuration APIs, and their parameters to use the Debugger built-in and custom rules.

**Topics**
Configure Debugger Using SageMaker API

- JSON (AWS CLI) (p. 2229)
- AWS Boto3 (p. 2233)

**JSON (AWS CLI)**

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `DebugHookConfig`, `DebugRuleConfiguration`, `ProfilerConfig`, and `ProfilerRuleConfiguration` objects through the SageMaker `CreateTrainingJob` API operation. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the JSON strings to request `CreateTrainingJob`.

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using AWS CLI. For example, save the following code as `debugger-training-job-cli.json`.

**Note**

Ensure that you use the correct Docker container images. To find AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2353).

```json
{
  "TrainingJobName": "debugger-aws-cli-test",
  "RoleArn": "arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-YYYYMMDDT123456",
  "AlgorithmSpecification": {
    "TrainingInputMode": "File",
    "EnableSageMakerMetricsTimeSeries": false
  },
  "HyperParameters": {
    "sagemaker_program": "entry_point/tf-hvd-train.py",
    "sagemaker_submit_directory": "s3://sagemaker-us-west-2-111122223333/debugger-boto3-profiling-test/source.tar.gz"
  },
  "OutputDataConfig": {
    "S3OutputPath": "s3://sagemaker-us-west-2-111122223333/debugger-aws-cli-test/output"
  },
  "DebugHookConfig": {
    "S3OutputPath": "s3://sagemaker-us-west-2-111122223333/debugger-aws-cli-test/debug-output",
    "CollectionConfigurations": [
      {
        "CollectionName": "losses",
        "CollectionParameters": {
          "train.save_interval": "50"
        }
      }
    ],
  } "DebugRuleConfigurations": [
    {
      "RuleConfigurationName": "LossNotDecreasing",
      "RuleParameters": {"rule_to_invoke": "LossNotDecreasing"}
    }
  ],
  "ProfilerConfig": {
}
After saving the JSON file, run the following command in your terminal. (Use `!` at the beginning of the line if you use a Jupyter notebook.)

```bash
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-cli.json
```

### To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

### To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```json
"DebugHookConfig": {
   "S3OutputPath": "/opt/ml/output/debugger-aws-cli-test/ProfilerRuleConfigurations": [
      "ProfilerRuleConfigurationName": "ProfilerReport",
      "RuleParameters": {"rule_to_invoke": "ProfilerReport"}
   ]
},
"ResourceConfig": {
   "InstanceType": "ml.p3.8xlarge",
   "InstanceCount": 1,
   "VolumeSizeInGB": 30
},
"StoppingCondition": {
   "MaxRuntimeInSeconds": 86400
}
```
To enable Debugger rules for debugging the output tensors

The following `DebugRuleConfigurations` API example shows how to run the built-in `VanishingGradient` rule on the saved gradients collection.

```
"DebugRuleConfigurations": [
    {
        "RuleConfigurationName": "VanishingGradient",
        "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "VanishingGradient",
            "threshold": "20.0"
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the `VanishingGradient` rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2353). To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules (p. 2239).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the `ProfilerConfig` API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataloaderProfilingConfig": "{ "StartStep": 5, "NumSteps": 3, "MetricsRegex": ".*" }",
        "DetailedProfilingConfig": "{ "StartStep": 5, "NumSteps": 3 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pynstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
        "PythonProfilingConfig": "{ "StartStep": 5, "NumSteps": 3, "ProfilerName ": "cProfile", "cProfileTimer": "total_time" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```

Target Time Duration

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataloaderProfilingConfig": "{ "StartStep": 5, "NumSteps": 3, "MetricsRegex": ".*" }",
        "DetailedProfilingConfig": "{ "StartStep": 5, "NumSteps": 3 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pynstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
        "PythonProfilingConfig": "{ "StartStep": 5, "NumSteps": 3, "ProfilerName ": "cProfile", "cProfileTimer": "total_time" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```
"ProfilingIntervalInMilliseconds": 500,
"ProfilingParameters": {
  "DataloaderProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789,
  "DurationInSeconds": 10, "MetricsRegex": ".*" },
  "DetailedProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789,
  "DurationInSeconds": 10 },"
  // For PythonProfilingConfig,
  // available ProfilerName options: cProfile, Pyinstrument
  // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
  "PythonProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789,
  "DurationInSeconds": 10, "ProfilerName": "cProfile",
  "cProfileTimer": "total_time" }",
  // Optional. Local path for profiling outputs
  "LocalPath": "/opt/ml/output/profiler/"
}
}

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

"ProfilerRuleConfigurations": [
  {
    "RuleConfigurationName": "ProfilerReport",
    "RuleParameters": {
      "rule_to_invoke": "ProfilerReport",
      "CPUBottleneck_cpu_threshold": "90",
      "IOBottleneck_threshold": "90"
    }
  }
]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2353). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 2239).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

{  "ProfilerConfig": {  
      "DisableProfiler": boolean,
      "ProfilingIntervalInMilliseconds": number,
      "ProfilingParameters": {  
        "string" : "string"
      }
    },
  "ProfilerRuleConfigurations": [  
    {  
      "RuleConfigurationName": "string",
      "RuleEvaluatorImage": "string",
      "RuleParameters": {  
        "string" : "string"
      }
    }
  ]
}
Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the `DebugHookConfig` and `DebugRuleConfiguration` objects in the `CreateTrainingJob` API operation. The following code sample shows how to configure a custom `ImproperActivation` rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2354). You specify the URL registry address for the pre-built Docker images in the `RuleEvaluatorImage` parameter.

```json
"DebugHookConfig": {
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
  "CollectionConfigurations": [
    {
      "CollectionName": "relu_activations",
      "CollectionParameters": {
        "include_regex": "relu",
        "save_interval": "500",
        "end_step": "5000"
      }
    }
  ],
  "DebugRulesConfigurations": [
    {
      "RuleConfigurationName": "improper_activation_job",
      "InstanceType": "ml.c4.xlarge",
      "VolumeSizeInGB": 400,
      "RuleParameters": {
        "source_s3_uri": "s3://bucket/custom_rules.py",
        "rule_to_invoke": "ImproperActivation",
        "collection_names": "relu_activations"
      }
    }
  ]
}
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2353). To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules (p. 2239).

### AWS Boto3

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `create_training_job()` function of the AWS Boto3 SageMaker client. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the request body for the `create_training_job()` function.

The following code shows a complete example of how to configure Debugger for the `create_training_job()` request body and start a training job in `us-west-2`, assuming that a
training script `entry_point/train.py` is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

**Note**
Ensure that you use the correct Docker container images. To find available AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2353).

```python
import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()

# Upload a training script to a default Amazon S3 bucket of the current SageMaker session
source = 'source.tar.gz'
project = 'debugger-boto3-test'
tar = tarfile.open(source, 'w:gz')
tar.add('entry_point/train.py') # Specify the directory and name of your training script
tar.close()

s3 = boto3.client('s3')
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    TrainingJobName='debugger-boto3-'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/source',
        'sagemaker_program': '/entry_point/train.py' # training script file location and name under the sagemaker_submit_directory
    },
    AlgorithmSpecification={
        'TrainingInputMode': 'File',
        'EnableSageMakerMetricsTimeSeries': False
    },
    RoleArn='arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20201014T161125',
    OutputDataConfig={'S3OutputPath': 's3://'+bucket+'/'+project+'/output'},
    ResourceConfig={
        'InstanceType': 'ml.p3.8xlarge',
        'InstanceCount': 1,
        'VolumeSizeInGB': 30
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 86400
    },
    DebugHookConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/debug-output',
        'CollectionConfigurations': [
            {
                'CollectionName': 'losses',
            }
        ]
    }
)
```
To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```python
DebugHookConfig=
   'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
   'CollectionConfigurations': [
       {
           'CollectionName': 'gradients',
           'CollectionParameters': {
               'train.save_interval': '500',
               'eval.save_interval': '50'
           }
       }
   ]
```

This will make the training job save a tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client
library documentation. To find available CollectionParameters parameter keys and values, see the sagemaker.debugger.CollectionConfig class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```python
DebugRuleConfigurations=[
    {
        'RuleConfigurationName': 'VanishingGradient',
        'RuleParameters': {
            'rule_to_invoke': 'VanishingGradient',
            'threshold': '20.0'
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2353). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 2239).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```python
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "MetricsRegex": ".*"
        },
        'DetailedProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3
        },
        'PythonProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
            "CProfileTimer": "total_time" # Include only when using cprofile.
        }
    }
}
```

Available options: cpu, off_cpu, total_time

'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs

2236
Configure Debugger Using SageMaker API

Target Time Duration

```python
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 1234567789,
            "DurationInSeconds": 10,
            "MetricsRegex": ".*"
        },
        'DetailedProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 1234567789,
            "DurationInSeconds": 10
        },
        'PythonProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 1234567789,
            "DurationInSeconds": 10,
            "ProfilerName": "cprofile"едактор, # Available options: cprofile, pyinstrument
            "ProfilerTimer": "total_time" # Include only when using cprofile.
            Available options: cpu, off_cpu, total_time
        },
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
    }
}
```

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

```python
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'CPUBottleneck_cpu_threshold': '90',
            'IOBottleneck_threshold': '90'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2353). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 2239).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the `update_training_job()` function of the AWS Boto3 SageMaker client. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.
Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the `DebugHookConfig` and `DebugRuleConfiguration` objects using the AWS Boto3 SageMaker client's `create_training_job()` function. The following code sample shows how to configure a custom `ImproperActivation` rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2354). You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```python
ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string': 'string'
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'string',
        'RuleEvaluatorImage': 'string',
        'RuleParameters': {
            'string': 'string'
        }
    }
],
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2353). To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules (p. 2239).
List of Debugger Built-in Rules

Use the Debugger built-in rules provided by Amazon SageMaker Debugger and analyze tensors emitted while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. Depending on deep learning frameworks of your choice, there are four scopes of validity for the built-in rules as shown in the following table.

**Note**
The maximum numbers of built-in rules for a training job are 20 for `ProfilerRule` and 20 for `Rule`. SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the **Amazon SageMaker Studio is available at no additional charge** section of the Amazon SageMaker Pricing page.

**Important**
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

### Debugger ProfilerRule

The following rules are the Debugger built-in rules that are callable using the `ProfilerRule.sagemaker` classmethod.

#### To use the built-in rules with default parameter values – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
rules = [
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),
    ...
]```

2240
To use the built-in rules with customizing the parameter values – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(
        base_config=rule_configs.ProfilerReport(),
        rule_parameters={
            "key": "value"
        }
    ),
    Rule.sagemaker(
        base_config=rule_configs.ProfilerReport(),
        rule_parameters={
            "key": "value"
        },
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    ),
]
```

To find available keys for the rule_parameters parameter, see the parameter description tables. Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger Built-in Rules Example Code (p. 2225).
- For a full instruction of using the built-in rules with the low-level SageMaker API operations, see Configure Debugger Using Amazon SageMaker API (p. 2228).

**ProfilerReport**

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```python
rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.ProfilerReport(),
        rule_parameters={
            "<BuiltInRuleName>_<parameter_name> = value"
        }
    )
]
```
If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```
rules=[ProfilerRule.sagemaker(rule_config.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's `cpu_threshold` parameter and the IOBottleneck rule's `threshold` parameter.

```
rules=[
    ProfilerRule.sagemaker(
        rule_config.ProfilerReport(
            CPUBottleneck_cpu_threshold = 90,
            IOBottleneck_threshold = 90
        )
    )
]
```

</tbody>
</table>

### BatchSize

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

</tr>
</tbody>
</table>
**LowGPUUtilization**

The LowGPUUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below threshold_p95 which indicates underutilization. Rule returns true if 95th quantile is above threshold_p95 and 5th quantile is below threshold_p5 which indicates fluctuations.

**Parameter Descriptions for the LowGPUUtilization Rule**

<table>

</tbody>
</table>
### OverallSystemUsage

The OverallSystemUsage rule measures overall system usage per worker node. The rule currently only aggregates values per node and computes their percentiles.

**Parameter Descriptions for the OverallSystemUsage Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td>scan_interval_us</td>
<td>Time interval to scan timeline files.</td>
</tr>
</tbody>
</table>

### MaxInitializationTime

The MaxInitializationTime rule helps detect if the training initialization is taking too much time. The rule waits until the first step is available.

**Parameter Descriptions for the MaxInitializationTime Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td>threshold</td>
<td>Defines the threshold in minutes to wait for the first step to become available.</td>
</tr>
</tbody>
</table>
### List of Built-in Rules

</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default values: 60000000 (in microseconds)</td>
</tr>
</tbody>
</table>

### StepOutlier

The `StepOutlier` rule helps detect outliers in step durations. This rule returns `True` if there are outliers with step durations larger than `stddev` sigmas of the entire step durations in a time range.

#### Parameter Descriptions for the `StepOutlier` Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>base_trial</code></td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
<tr>
<td><code>stddev</code></td>
<td>Defines a factor by which to multiply the standard deviation. For example, the rule is invoked by default when a step duration is larger or smaller than 5 times the standard deviation.</td>
</tr>
</tbody>
</table>
### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>

</tbody>
</table>

#### CreateXgboostReport

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerates a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- **hyperparameters** – Saves at the first step
- **metrics** – Saves loss and accuracy every 5 steps
- **feature_importance** – Saves every 5 steps
- **predictions** – Saves every 5 steps
- **labels** – Saves every 5 steps

#### Parameter Descriptions for the CreateXgboostReport Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>base_trial</strong></td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
</tbody>
</table>
rules=[
    Rule.sagemaker(
        rule_configs.create_xgboost_report()
    )
]

### DeadRelu

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the `threshold_layer` value of inactive ReLUs, the rule returns `True`.

#### Parameter Descriptions for the DeadRelu Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td>tensor_regex</td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. Optional Valid values: List of strings or a comma-separated string Default value: &quot;.*relu_output&quot;</td>
</tr>
<tr>
<td>threshold_inactivity</td>
<td>Defines a level of activity below which a ReLU is considered to be dead. A ReLU might be active in the beginning of a trial and then slowly die during the training process. If the ReLU is active less than the <code>threshold_inactivity</code>, it is considered to be dead. Optional Valid values: Float Default values: 1.0 (in percentage)</td>
</tr>
</tbody>
</table>
### threshold_layer

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>threshold_layer</td>
<td>Returns True if the percentage of inactive ReLUs in a layer is greater than threshold_layer.</td>
</tr>
<tr>
<td></td>
<td>Returns False if the percentage of inactive ReLUs in a layer is less than threshold_layer.</td>
</tr>
<tr>
<td>Optional</td>
<td></td>
</tr>
<tr>
<td>Valid values</td>
<td>Float</td>
</tr>
<tr>
<td>Default values</td>
<td>50.0 (in percentage)</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.dead_relu(),
        rule_parameters={
            "tensor_regex": ".*relu_output|.ReLU_output",
            "threshold_inactivity": "1.0",
            "threshold_layer": "50.0"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_relu_collection",
                parameters={
                    "include_regex": ".*relu_output|.ReLU_output",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

**Note**

This rule is not available for the XGBoost algorithm.

### ExplodingTensor

This rule detects whether the tensors emitted during training have non-finite values, either infinite or NaN (not a number). If a non-finite value is detected, the rule returns True.

#### Parameter Descriptions for the ExplodingTensor Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

Valid values: String  
Default value: None |
| only_nan       | True to monitor the base_trial tensors only for NaN values and not for infinity. False to treat both NaN and infinity as exploding values and to monitor for both. | Optional  
Default value: False |

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.exploding_tensor(),
        rule_parameters={
            "tensor_regex": ".*gradient",
            "only_nan": "False"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

**Note**

This rule is not available for the XGBoost algorithm.

**PoorWeightInitialization**

This rule detects if your model parameters have been poorly initialized.
Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

**Parameter Descriptions for the PoorWeightInitialization Rule**

</tbody>
</table>

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](p. 2221).

**Note**

This rule is not available for the XGBoost algorithm.

### SaturatedActivation

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective `min_threshold` and `max_thresholds` values. If the activity of a node drops below the `threshold_inactivity` percentage, it is considered saturated. If more than a `threshold_layer` percent of the nodes are saturated, the rule returns `True`.

      "threshold": "0.0000001"
    },
    collections_to_save=[
      CollectionConfig(
        name="gradients",
    ]
  
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

**Note**
This rule is not available for the XGBoost algorithm.

### WeightUpdateRatio

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the `large_threshold` value or if this ratio is smaller than `small_threshold`, the rule returns `True`.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and `train.save_interval` needs to be set equal to `num_steps`.

#### Parameter Descriptions for the WeightUpdateRatio Rule

                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

**Note**<br>This rule is not available for the XGBoost algorithm.

**AllZero**

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

                parameters={
```
ClassImbalance

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.

Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the threshold_imbalance, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above threshold_misprediction, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

            CollectionConfig(name="custom_output_collection",
        ]
    )
```
LossNotDecreasing

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

Overfit

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

**Note**

A standard way to prevent overfitting is to regularize your model.

Parameter Descriptions for the Overfit Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>

</tr>
</tbody>
</table>

| | Valid values: List of strings or a comma-separated string |
| | Default value: None |
### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| start_step      | The step from which to start comparing the validation and training loss.  
Optional  
Valid values: Integer  
Default value: 0 |
| patience        | The number of steps for which the ratio_threshold is allowed to exceed the value set before the model is considered to be overfit.  
Optional  
Valid values: Integer  
Default value: 1 |
| ratio_threshold | The maximum ratio of the difference between the mean validation loss and mean training loss to the mean training loss. If this threshold is exceeded for a patience number of steps, the model is being overfit and the rule returns True.  
Optional  
Valid values: Float  
Default value: 0.1 |

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overfit(),
        rule_parameters={
            "tensor_regex": ".*",
            "start_step": "0",
            "patience": "1",
            "ratio_threshold": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "train.save_interval": "100",
                    "eval.save_interval": "10"
                }
            )
        ]
    )
]
```

### Overtraining

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum of the loss function and does not improve anymore. If the model continues training it can happen that validation
loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to
determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet,
and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in
Rules (p. 2221).

**Note**
Overtraining can be avoided by early stopping. For information on early stopping, see Stop
Training Jobs Early (p. 2380). For an example that shows how to use spot training with
Debugger, see Enable Spot Training with Amazon SageMaker Debugger.

### Parameter Descriptions for the Overtraining Rule

]
]
```

**SimilarAcrossRuns**

This rule compares tensors gathered from a base trial with tensors from another trial.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

**Parameter Descriptions for the SimilarAcrossRuns Rule**

<table>
<thead>

<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</td>
</tr>
</tbody>
</table>
### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td>threshold</td>
<td>A threshold that defines by how much time in seconds the rule waits for a tensor output until it fires a stalled training issue. Default value is 1800 seconds. Optional</td>
</tr>
<tr>
<td>stop_training_on_fire</td>
<td>If set to True, watches if the base training job outputs tensors in &quot;threshold&quot; seconds.</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.similar_across_runs(),
        rule_parameters={
            "other_trials": "<specify-another-job-name>",
            "collection_names": "losses",
            "tensor_regex": ".*"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

**StalledTrainingRule**

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its `threshold` parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.

### Parameter Descriptions for the StalledTrainingRule Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

```
```

2271
### Parameter Name | Description
--- | ---
| Optional | Valid values: Boolean
| Default value: False

| training_job_name_prefix | The prefix of base training job name. If stop_training_on_fire is true, the rule searches for SageMaker training jobs with this prefix in the same account. If there is an inactivity found, the rule takes a StopTrainingJob action. Note if there are multiple jobs found with same prefix, the rule skips termination. It is important that the prefix is set unique per each training job.
| Optional | Valid values: String

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            "threshold": "1800",
            "stop_training_on_fire": "True",
            "training_job_name_prefix": "<specify-training-base-job-name>"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

**TensorVariance**

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the collection_names or tensor_regex parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).
### Parameter Descriptions for the TensorVariance Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tensor_variance(),
        rule_parameters={
            "collection_names": "weights",
.. ```
UnchangedTensor

This rule detects whether a tensor is no longer changing across steps.

This rule runs the numpy.allclose method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the collection_names or tensor_regex parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

        }
    )
]
]

CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.check_input_images(),
        rule_parameters={
            "threshold_mean": "0.2",
            "threshold_samples": "500",
            "regex": ".*hybridsequential0_input_0",
            "channel": "1"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*hybridsequential0_input_0",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

**NLPSequenceRatio**

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

**Parameter Descriptions for the NLPSequenceRatio Rule**

<tr>
<td>tensor_regex</td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</td>
</tr>
<tr>
<td>token_values</td>
<td>A string of a list of the numerical values of the tokens. For example, &quot;3, 0&quot;.</td>
</tr>
<tr>
<td>token_thresholds_percent</td>
<td>A string of a list of thresholds (in percentages) that correspond to each of the token_values. For example,&quot;50.0, 50.0&quot;.</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [  
    Rule.sagemaker(  
        base_config=rule_configs.nlp_sequence_ratio(),  
        rule_parameters={  
            "tensor_regex": ".*embedding0_input_0",  
            "token_values": "0",  
            "token_thresholds_percent": "50"  
        },  
        collections_to_save=[  
            CollectionConfig(  
                name="custom_inputs_collection",  
                parameters={  
                    "include_regex": ".*embedding0_input_0"  
                }  
            )  
        ]  
    )
]```
Confusion

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size \( \text{category\_no} \times \text{category\_no} \) and populates it with data coming from \((\text{labels}, \text{predictions})\) pairs. For each \((\text{labels}, \text{predictions})\) pair, the count in \(\text{confusion}[\text{labels}][\text{predictions}]\) is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: \(\frac{\text{confusion}[i][i]}{\sum_j \text{confusion}[j][j]} \geq \text{min\_diag}\)
- For elements off the diagonal: \(\frac{\text{confusion}[j][i]}{\sum_j \text{confusion}[j][i]} \leq \text{max\_off\_diag}\)

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

            "predictions_collection": "predictions",
            "min_diag": "0.9",
            "max_off_diag": "0.1"
        },
        collections_to_save=[
            CollectionConfig(name="labels",
                             parameters={
                                "save_interval": "500"
                             } ),
            CollectionConfig(name="predictions",
                             parameters={
                                "include_regex": "500"
                             })
        ]
    )
]
```
Note
This rule infers default values for the optional parameters if their values aren't specified.

**FeatureImportanceOverweight**

This rule accumulates the weights of the \( n \) largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

**Parameter Descriptions for the FeatureImportanceOverweight Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| base_trial     | The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  
  **Required**  
  Valid values: String |
| threshold      | Defines the threshold for the proportion of the cumulative sum of the \( n \) largest features. The number \( n \) is defined by the nfeatures parameter.  
  **Optional**  
  Valid values: Float  
  Default value: 0.8 |
| nfeatures      | The number of largest features.  
  **Optional**  
  Valid values: Integer  
  Default value: 3 |
| tensor_regex   | Regular expression (regex) of tensor names the rule to analyze.  
  **Optional**  
  Valid values: String  
  Default value: ".*feature_importance/weight" |

```
built_in_rules = [  
```
Rule.sagemaker(
    base_config=rule_configs.feature_importance_overweight(),
    rule_parameters={
        "threshold": "0.8",
        "nfeatures": "3",
        "tensor_regex": ".*feature_importance/weight"
    },
    collections_to_save=[
        CollectionConfig(

            }
        )
    ]
)

TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the depth parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2221).

Create Debugger Custom Rules for Training Job Analysis

You can create custom rules to monitor your training job using the Debugger Rule APIs and the open source smdebug Python library that provide tools to build your own rule containers.

Topics
- Prerequisites for Creating Debugger Custom Rules (p. 2283)
- Use the Debugger Client Library smdebug to Create a Custom Rule Python Script (p. 2283)
- Use the Debugger APIs to Run Your Own Custom Rules (p. 2284)

Prerequisites for Creating Debugger Custom Rules

To create Debugger custom rules, you need the following prerequisites.

- SageMaker Debugger Rule.custom API
- The open source smdebug Python library
- Your own custom rule python script
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2354)

Use the Debugger Client Library smdebug to Create a Custom Rule Python Script

The smdebug Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, CustomGradientRule. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker estimator when it initiates training job.

```python
from smdebug.rules.rule import Rule
class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.

parameters={
    "save_interval": "500"
}
Use the Debugger APIs to Run Your Own Custom Rules

The following code sample shows how to configure a custom rule with the Amazon SageMaker Python SDK. This example assumes that the custom rule script you created in the previous step is located at `path/to/my_custom_rule.py`.

```python
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
    rule_to_invoke='CustomGradientRule',
    collections_to_save=[CollectionConfig("gradients")],
    rule_parameters={"threshold": "20.0"}
)
```

The following list explains the Debugger `Rule.custom` API arguments.

- **name (str):** Specify a custom rule name as you want.
- **image_uri (str):** This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job. You can find the list of open source SageMaker rule evaluator images from Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2354).
- **instance_type (str):** You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- **source (str):** This is the local path or the Amazon S3 URI to your custom rule script.
- **rule_to_invoke (str):** This specifies the particular Rule class implementation in your custom rule script. SageMaker supports only one rule to be evaluated at a time in a rule job.
- **collections_to_save (str):** This specifies which tensor collections you will save for the rule to run.
- **rule_parameters (dictionary):** This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the `custom_rule` object, you can use it for building a SageMaker estimator for any training jobs. Specify the `entry_point` to your training script. You do not need to make any change of your training script.

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    role=sagemaker.get_execution_role(),
    base_job_name='smdebug-custom-rule-demo-tf-keras',
    entry_point='path/to/your_training_script.py'
    train_instance_type='ml.p2.xlarge'
    ...
    
    # debugger-specific arguments below
    rules = [custom_rule]
)
estimator.fit()
```

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.
Use Debugger with Custom Training Containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The AWS CLI, SageMaker Estimator API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger.

- Amazon SageMaker Python SDK
- The SMDebug open source client library
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger Hook to Your Training Script (p. 2285).

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- Build a Custom Training Container and Debug Training Jobs with Debugger

Tip
This custom container with Debugger guide is an extension of the Adapting Your Own Training Container (p. 3016) guide which walks you thorough how to build and push your custom training container to Amazon ECR.

Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

```markdown
### debugger_custom_container_test_notebook.ipynb      # a notebook to run python snippet codes
### debugger_custom_container_test_folder              # this is a docker folder
   ### your-training-script.py                       # your training script with Debugger hook
   ### Dockerfile                                    # a Dockerfile to build your own container
```

Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

**Note**
This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the `debugger_hook_config` parameter when constructing an estimator.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.
# An example of training script (your-training-script.py)
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):
    ...
    model.fit(X_train, Y_train,
               batch_size=batch_size,
               epochs=epoch,
               validation_data=(X_valid, Y_valid),
               shuffle=True,
               # smdebug modification: Pass the Debugger hook in the main() as a Keras
               callbacks=[hook])

def main():
    parser = argparse.ArgumentParser(description="Train resnet50 cifar10")
    # hyperparameter settings
    parser.add_argument(...)
    args = parser.parse_args() 
    model = ResNet50(weights=None, input_shape=(32,32,3), classes=10)
    # Add the following line to register the Debugger hook for Keras.
    hook = smd.KerasHook.create_from_json_file()
    # Start the training.
    train(args.batch_size, args.epoch, model, hook)

if __name__ == "__main__":
    main()

For more information about registering the Debugger hook for the supported frameworks and
algorithm, see the following links in the SMDebug client library:

- SMDebug TensorFlow hook
- SMDebug PyTorch hook
- SMDebug MXNet hook
- SMDebug XGBoost hook

In the following example notebooks' training scripts, you can find more examples about how to add the
Debugger hooks to training scripts and collect output tensors in detail:

- Debugger in script mode with the TensorFlow 2.1 framework

To see the difference between using Debugger in a Deep Learning Container and in script mode, open
this notebook and put it and the previous Debugger in a Deep Learning Container TensorFlow v2.1
notebook example side by side.

In script mode, the hook configuration part is removed from the script in which you set the estimator.
Instead, the Debugger hook feature is merged into the training script, TensorFlow Keras ResNet
training script in script mode. The training script imports the smdebug library in the required
TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also
manually implements the smdebug hook functionality by adding the callbacks=[hook] argument
inside the `train` function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.

This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example. The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by AWS Deep Learning Containers.

- Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode

This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker containers, and this example shows details of how to modify a training script.

The SageMaker PyTorch estimator is already in script mode by default. In the notebook, the line to activate `script_mode` is not included in the estimator configuration.

This notebook shows detailed steps to change an original PyTorch training script to a modified version with Debugger enabled. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and Dockerfile. The following code example is a Dockerfile that includes essential docker build commands. Paste the following code into the Dockerfile text file and save it. Upload your training script to the same folder.

```bash
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf

# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug
CMD ["bin/bash"]
```

If you want to use a pre-built AWS Deep Learning Container image, see Available AWS Deep Learning Containers Images.

Build and Push the Custom Training Container to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```python
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'
region = boto3.session.Session().region_name

uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
```
byoc_image_uri = '{}.dkr.ecr.{}.{}'.format(account_id, region, uri_suffix, ecr_repository + tag)

docker build -t $ecr_repository docker

aws ecr get-login --region $region --registry-ids $account_id --no-include-email

aws ecr create-repository --repository-name $ecr_repository
docker tag {ecr_repository + tag} $byoc_image_uri
docker push $byoc_image_uri

Tip
If you use one of the AWS Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.

aws ecr get-login-password --region {region} | docker login --username AWS --password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com

Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the estimator.fit(), Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the smdebug core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

import sagemaker
from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs

profiler_config=ProfilerConfig(...)  
debugger_hook_config=DebuggerHookConfig(...)  
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltinRule())
]

estimator=Estimator(
    image_uri=byoc_image_uri,
    entry_point='./debugger_custom_container_test_folder/your-training-script.py'
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-custom-container-test',
    instance_count=1,
    instance_type='ml.p3.2xlarge',

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

# start training
estimator.fit()

Action on Amazon SageMaker Debugger Rules

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can
also create your own actions using Amazon CloudWatch Events and AWS Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

**Topics**
- Debugger Built-in Actions for Rules (p. 2289)
- Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 2293)

**Debugger Built-in Actions for Rules**

Use Debugger built-in actions to respond to issues found by Debugger Rule (p. 2240). The Debugger `rule_config` class provides tools to configure a list of actions, including automatically stopping training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues.

**Step 1: Set Up Amazon SNS, Create an SMDebugRules Topic, and Subscribe to the Topic**

This section walks you through how to set up an Amazon SNS `SMDebugRules` topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

**Note**
For more information about billing for Amazon SNS, see Amazon SNS pricing and Amazon SNS FAQs.

**To create a SMDebugRules topic**

2. In the left navigation pane, choose **Topics**.
3. On the **Topics** page, choose **Create topic**.
4. On the **Create topic** page, in the **Details** section, do the following:
   a. For **Type**, choose **Standard** for topic type.
   b. In **Name**, enter **SMDebugRules**.
5. Skip all other optional settings and choose **Create topic**. If you want to learn more about the optional settings, see Creating an Amazon SNS topic.

**To subscribe to the SMDebugRules topic**

2. In the left navigation pane, choose **Subscriptions**.
3. On the **Subscriptions** page, choose **Create subscription**.
4. On the **Create subscription** page, in the **Details** section, do the following:
   b. For **Protocol**, choose **Email** or **SMS**.
   c. For **Endpoint**, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.

**Note**
Make sure you type the correct email address and phone number. Phone numbers must include `+`, a country code, and phone number, with no special characters or spaces. For example, the phone number `+1 (222) 333-4444` is formatted as `+12223334444`.
5. Skip all other optional settings and choose Create subscription. If you want to learn more about the optional settings, see Subscribing to an Amazon SNS topic.

After you subscribe to the SMDebugRules topic, you receive the following confirmation message in email or by phone:

**AWS Notification - Subscription Confirmation**

SMTPulsionRules <no-reply@sm.amazonaws.com>
To:

You have chosen to subscribe to the topic: arn:aws:sns:us-east-1:111122223333:SMDebugRules

To confirm this subscription, click or visit the link below (if this was in error no action is necessary):

Confirm subscription

Please do not reply directly to this email. If you wish to remove yourself from receiving all future SNS subscription confirmation requests please send an email to sns-opt-out

For more information about Amazon SNS, see Mobile text messaging (SMS) and Email notifications in the Amazon SNS Developer Guide.

**Step 2: Set Up Your IAM Role to Attach Required Policies**

In this step, you add the required policies to your IAM role.

**To add the required policies to your IAM role**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Policies, and choose Create policy.
3. On the Create policy page, do the following to create a new sns-access policy:
   a. Choose the JSON tab.
   b. Paste the JSON strings formatted in bold in the following code into the "Statement", replacing the 12-digit AWS account ID with your AWS account ID.

   ```json
   { 
   "Version": "2012-10-17",
   "Statement": [
   { 
   "Sid": "VisualEditor0",
   "Effect": "Allow",
   "Action": [ 
   "sns:Publish",
   "sns:CreateTopic",
   "sns:Subscribe"
   ],
   "Resource": "arn:aws:sns:*:111122223333:SMDebugRules"
   }
   ]
   }
   ```
   c. At the bottom of the page, choose Review policy.
   d. On the Review page, for Name, enter sns-access.
   e. At the bottom of the page, choose Create policy.
4. Go back to the IAM console, and choose Roles in the left navigation pane.
5. Look up the IAM role that you use for SageMaker model training and choose that IAM role.
6. On the Permissions tab of the Summary page, choose Attach policies.
7. Search for the sns-access policy, select the check box next to the policy, and then choose Attach policy.

For more examples of setting up IAM policies for Amazon SNS, see Example cases for Amazon SNS access control.

Step 3: Configure Debugger Rules with the Built-in Actions

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the actions list object. The rule_configs is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- rule_configs.StopTraining() – Stops a training job when the Debugger rule finds an issue.
- rule_configs.Email("abc@abc.com") – Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- rule_configs.SMS("+1234567890") – Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

Note
Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.

You can use all of the built-in actions or a subset of actions by wrapping up using the rule_configs.ActionList() method, which takes the built-in actions and configures a list of actions.

To add all of the three built-in actions to a single rule

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```python
from sagemaker.debugger import Rule, rule_configs

# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
    Rule.sagemaker(
        base_config=rule_configs.builtin_rule(),  # Required
        rule_parameters={"paramter_key": value},  # Optional
        actions=actions
    )
]

estimator = Estimator(
    ...
)"
To create multiple built-in action objects to assign different actions to a single rule

If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules’ name attribute) as shown in the following example script template. This example shows how to set up StalledTrainingRule (p. 2271) to take two different actions: send an email to abc@abc.com when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```python
from sagemaker.debugger import Rule, rule_configs
import time

base_job_name_prefix = 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)

# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

# Configure a rule with the Email built-in action to trigger if a training job stalls for 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "60",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_email
)

stalled_training_job_rule_email.name = "StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "120",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_stop_training
)

stalled_training_job_rule.name = "StalledTrainingJobRuleStopTraining"

estimator = Estimator(...
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)

estimator.fit(wait=False)
```

While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.
The following screenshot shows an example text notification that Debugger sends when the rule finds a StalledTraining issue.

Considerations for Using the Debugger Built-in Actions

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker or Amazon VPC.
- The built-in actions cannot be used for Debugger ProfilerRule (p. 2239).
- The built-in actions cannot be used on training jobs with spot training interruptions.
- In email or text notifications, None appears at the end of messages. This does not have any meaning, so you can disregard the text None.

Create Actions on Rules Using Amazon CloudWatch and AWS Lambda

Amazon CloudWatch collects Amazon SageMaker model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and AWS Lambda to take action based on Debugger rule evaluation status.

CloudWatch Logs for Debugger Rules and Training Jobs

To find training job logs and Debugger rule job logs

2. In the left navigation pane under the Log node, choose Log Groups.
3. In the log groups list, do the following:
   - Choose /aws/sagemaker/TrainingJobs for training job logs.
Choose /aws/sagemaker/ProcessingJobs for Debugger rule job logs.

You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues.

For more information about monitoring training jobs using CloudWatch, see Monitor Amazon SageMaker.

**Set Up Debugger for Automated Training Job Termination Using CloudWatch and Lambda**

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status.

**Step 1: Create a Lambda Function**

**To create a Lambda function**

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose Functions and then choose Create function.
3. On the Create function page, choose Author from scratch option.
4. In the Basic information section, enter a Function name (for example, debugger-rule-stop-training-job).
5. For Runtime, choose Python 3.7.
6. For Permissions, expand the drop down option, and choose Change default execution role.
7. For Execution role, choose Use an existing role and choose the IAM role that you use for training jobs on SageMaker.
   
   **Note**
   
   Make sure you use the execution role with AmazonSageMakerFullAccess and AWSLambdaBasicExecutionRole attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:

   ```python
   import sagemaker
   sagemaker.get_execution_role()
   ```

8. At the bottom of the page, choose Create function.

The following figure shows an example of the Create function page with the input fields and selections completed.
Step 2: Configure the Lambda function

To configure the Lambda function

1. In the Function code section of the configuration page, paste the following Python script in the Lambda code editor pane. The lambda_handler function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the StopTrainingJob API operation. The AWS SDK for Python (Boto3) client for SageMaker provides a high-level method, stop_training_job, which triggers the StopTrainingJob API operation.

```python
import json
import boto3
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)

def lambda_handler(event, context):
    training_job_name = event.get("detail").get("TrainingJobName")
    logging.info(f'Evaluating Debugger rules for training job: {training_job_name}')
```

```python
    // Code snippet
```
```python
eval_statuses = event.get("detail").get("DebugRuleEvaluationStatuses", None)
if eval_statuses is None or len(eval_statuses) == 0:
    logging.info("Couldn't find any debug rule statuses, skipping...")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

# should only attempt stopping jobs with InProgress status
training_job_status = event.get("detail").get("TrainingJobStatus", None)
if training_job_status != 'InProgress':
    logging.debug(f"Current Training job status({training_job_status}) is not 'InProgress'. Exiting")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

client = boto3.client('sagemaker')
for status in eval_statuses:
    logging.info(status.get("RuleEvaluationStatus") + ', RuleEvaluationStatus=' + str(status))
    if status.get("RuleEvaluationStatus") == "IssuesFound":
        secondary_status = event.get("detail").get("SecondaryStatus", None)
        logging.info(f'About to stop training job, since evaluation of rule configuration {status.get("RuleConfigurationName")} resulted in "IssuesFound". ' + f'\n\ntraining job "{training_job_name}" status is "{training_job_status}", secondary status is "{secondary_status}"' + f'\n\nAttempting to stop training job "{training_job_name}"')
        try:
            client.stop_training_job(
                TrainingJobName=training_job_name
            )
        except Exception as e:
            logging.error("Encountered error while trying to " + "stop training job {}": {}.format(
                training_job_name, str(e)
            )
        return None
```

For more information about the Lambda code editor interface, see Creating functions using the AWS Lambda console editor.

2. Skip all other settings and choose Save at the top of the configuration page.

**Step 3: Create a CloudWatch Events Rule and Link to the Lambda Function for Debugger**

To create a CloudWatch Events rule and link to the Lambda function for Debugger

2. In the left navigation pane, choose Rules under the Events node.
3. Choose Create rule.
4. In the **Event Source** section of the **Step 1: Create rule** page, choose **SageMaker** for **Service Name**, and choose **SageMaker Training Job State Change** for **Event Type**. The Event Pattern Preview should look like the following example JSON strings:

```json
{
  "source": [
    "aws.sagemaker"
  ],
  "detail-type": [
    "SageMaker Training Job State Change"
  ]
}
```

5. In the **Targets** section, choose **Add target***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.

6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.

7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.

8. Choose **Create rule** to finish.

9. Go back to the Lambda function configuration page and refresh the page. Confirm that it's configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:

![Designer Panel](image)

Run Example Notebooks to Test Automated Training Job Termination

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using Debugger's built-in rules.

- Amazon SageMaker Debugger - Reacting to CloudWatch Events from Rules
This example notebook runs a training job that has a vanishing gradient issue. The Debugger VanishingGradient (p. 2259) built-in rule is used while constructing the SageMaker TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.

- **Detect Stalled Training and Invoke Actions Using SageMaker Debugger Rule**

This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger StalledTrainingRule (p. 2271) built-in rule invokes issues and stops the training job.

**Disable the CloudWatch Events Rule to Stop Using the Automated Training Job Termination**

If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda Designer panel, choose the **EventBridge (CloudWatch Events)** block linked to the Lambda function. This shows an **EventBridge** panel below the **Designer** panel (for example, see the previous screen shot). Select the check box next to **EventBridge (CloudWatch Events): debugger-cw-event-rule**, and then choose **Disable**. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

**Amazon SageMaker Debugger in Amazon SageMaker Studio**

Use the Amazon SageMaker Debugger dashboards in Amazon SageMaker Studio to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud (Amazon EC2) instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, CPU and GPU memory, network, and data I/O) every 500 milliseconds and basic output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio UI or using the Amazon SageMaker Python SDK.

**Important**

If you're using existing Studio apps, restart them to use the new features. For instructions on how to restart and update your Studio environment, see Update Amazon SageMaker Studio.
Topics

- Open the Amazon SageMaker Debugger Insights Dashboard (p. 2299)
- Amazon SageMaker Debugger Insights Dashboard Controller (p. 2300)
- Amazon SageMaker Debugger Insights Dashboard (p. 2304)
- Shut Down the Amazon SageMaker Debugger Insights Instance (p. 2311)
- Amazon SageMaker Debugger in Studio Experiments (p. 2312)

Open the Amazon SageMaker Debugger Insights Dashboard

Open the Debugger insights dashboard in Studio to see profiling progress, results of resource utilization, and system bottlenecks of your training job running on Amazon EC2 instances.

**Note**
The Studio Debugger insights dashboard runs a Studio app on an `ml.m5.4xlarge` instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the `ml.m5.4xlarge` instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

**Important**
When you are done using the Debugger insights dashboard, you must shut down the `ml.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the Amazon SageMaker Debugger Insights Instance (p. 2311).

To open the Debugger insights dashboard

1. Choose the SageMaker Components and registries icon ( ).
2. Open the dropdown list, and choose Experiments and trials.
3. Look up your training job name. If you have not assigned a SageMaker Experiments trial component to the training job, the job is collected under the Unassigned trial components list.
4. **Right-click** (or an equivalent UI interaction) to open the context menu of the training job trial component. There are two menu items to access the Debugger features in Studio: **Open Debugger for insights** and **Open in trial details**.

5. Choose **Open Debugger for insights**. This opens a **Debug [your-training-job-name]** tab. On this tab, Debugger provides an overview of your model training performance on Amazon EC2 instances and identifies system bottleneck problems. While **monitoring** the system resource utilization, you can also enable **profiling** to capture framework metrics that consist of data from neural network operations executed during the forward and backward pass and data loading. For more information about how to enable **profiling** using the Debugger insights dashboard controller, see Enable and Configure Debugger Profiling for Detailed Insights (p. 2301).

Debugger correlates the system resource utilization metrics with the framework metrics and helps identify resource-intensive operators that might be the root cause of the system bottlenecks. You can also download an aggregated Debugger profiling report. For more information, see Amazon SageMaker Debugger Insights Dashboard Controller (p. 2300).

**Amazon SageMaker Debugger Insights Dashboard Controller**

There are different components of the Debugger controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

**Note**

The Studio Debugger insights dashboard runs a Studio app on an m1.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the m1.m5.4xlarge instance usage. For more information about pricing, see the Amazon SageMaker Pricing page.

**Important**

When you are done using the Debugger insights dashboard, shut down the m1.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the Amazon SageMaker Debugger Insights Instance (p. 2311).

**SageMaker Debugger Insights Controller UI**

Using the Debugger controller located at the upper-left corner of the insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics and profiling framework metrics, stop a training job, and download a Debugger profiling report.

- **SageMaker Debugger**
  - **Monitor and profile your training jobs in real time.**
  - **Monitoring**
  - **Profiling**
  - Configure profiling
  - Stop training
  - Download report

- If you want to manually refresh the **Debug [your-training-job-name]** page, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceding screenshot.
- **Monitoring** is on by default for any SageMaker training job. By monitoring your training job, Debugger only collects system metrics to detect resource utilization problems, such as CPU bottlenecks.
and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics) (p. 2239).

- To download a comprehensive Debugger profiling report with details and analysis of a training job, choose Download report. For more information about the Debugger profiling report, see SageMaker Debugger Profiling Report (p. 2315).

Enable and Configure Debugger Profiling for Detailed Insights

When you enable Profiling, Debugger starts collecting framework metrics. Framework metrics are model data collected from the ML framework operations of your model, such as forward pass, backward pass, batch normalization, and data loader processes. Debugger correlates system performance bottlenecks with the framework operations and runs the Debugger Built-in Rules for Profiling Framework Metrics (p. 2239).

Note
After you've enabled profiling, Debugger collects every framework operation call that's executed in each step: operations for convolving down input layers during forward pass, updating weights of millions of neurons during backward pass, and data loader processes. While profiling can help you understand model performance at a deeper level, collecting framework metrics might impact your training time and performance. We recommend that you enable profiling to inspect your model up to two steps at a time. For more information about how to configure Debugger for framework profiling using Amazon SageMaker Python SDK, see Configure Debugger Framework Profiling (p. 2211) and Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 2215).

If you want to enable profiling while your training job is running, use the following steps to start profiling.

1. In Studio, turn on Profiling to enable Debugger framework profiling. This opens a Debugger monitoring and profiling configuration page.

2. The Configure Debugger monitoring and profiling, S3 bucket URI and Collect monitoring data every fields are already set to the default values.

   You can choose to change the monitoring interval using the dropdown list. Select from the following available options: 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.
Specify values for the following fields:

- **S3 bucket URI**: Specify the base S3 bucket URI.
- **Collect monitoring data every**: Select a time interval to collect system metrics.

  **Note**
  
  If you choose one of the lower time intervals, you increase the granularity of monitoring system metrics. It allows you to capture spikes and anomalies with a higher time resolution. However, as the size of system metrics to process proportionally increases, it might impact the overall training and processing time.

3. In **Advanced settings for profiling**, configure framework metrics profiling options. Specify **Start step** (or **Start time**) and **Number of steps to profile** (or **Time duration to profile**) to profile. You can also leave the input fields blank. The default values are automatically configured to use the current step and for 1-step duration.
• **Detailed profiling:** Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if you're using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  **Note**  
  The detailed profiling might significantly increase GPU memory consumption. It is not recommended to enable the detailed profiling for more than a couple of steps.

• **Python profiling:** Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.

  • cProfile – The standard Python profiler. cProfile collects for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation of each function call, providing a complete detail of Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function calls executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

  • Pyinstrument – Pyinstrument is a low overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wallclock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noises (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

  **Note**  
  Enabling Python profiling might result in slowing down the overall training time. In case of cProfile, Python operators that are the most frequently called are profiled at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

• **Dataloader profiling:** Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.
Note
The data loader profiling can lower the training performance while collecting information from data loaders. We don't recommend that you enable the data loader profiling for more than a couple of steps. Debugger is pre-configured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes on any other custom or external containers.

4. Choose Confirm to finish your profiling configuration. When the configuration is successfully updated, you should be able to see a Debugger configuration updated successfully confirmation message, as shown in following image.

Amazon SageMaker Debugger Insights Dashboard

When you initiate a SageMaker training job, Debugger starts monitoring hardware system resource utilization of Amazon EC2 instances by default. You can track the system utilization rate, statistics overview, and bottleneck detection status through the insights dashboard. This guide walks you through the content of the Debugger insights dashboard under the following tabs: Overview, Nodes, and Model insights.

Note
The Studio Debugger insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important
When you are done using the Debugger insights dashboard, shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the Amazon SageMaker Debugger Insights Instance (p. 2311).

Important
In the reports, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- Debugger Insights – Overview (p. 2304)
- Debugger Insights – Nodes (p. 2307)
- Debugger Insights – Model Insights (p. 2310)

Debugger Insights – Overview

On the Overview tab, you can find a training job summary, resource utilization summary, resource intensive operations, and insights.

Training job summary

The Training job summary section shows the overall training time spent on different phases of training: initialization, training loop, and finalization. The pie chart shows the time usage percentage and absolute
time amount spent on the different training phases. For example, you can have a high-level overview of how long it takes for initializing a training job, check if the initialization is taking too long due to data downloading, leaving the GPUs idle.

This section has the following features:

- The Training progress over time chart shows the timeline of the different training phases over time. If you're using spot training, you can also find the spot interruptions in the timeline chart.
- The Training job details panel shows the exact time stamps and utilization rate percentage numbers.
  - **Start time**: The exact time when the training job started.
  - **End time**: The exact time when the training job finished.
  - **Job duration**: The total training time from the Start time to the End time.
  - **Training loop start**: The exact time when the first step of the first epoch has started.
  - **Training loop end**: The exact time when the last step of the last epoch has finished.
  - **Training loop duration**: The total time between the training loop start time and the training loop end time.
  - **Initialization**: Time spent on initializing the training job, such as compiling the training script, initiating Amazon EC2 instances, and downloading training data.
  - **Finalization**: Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the Amazon EC2 instances.
  - **Initialization (%)**: The percentage of time spent on Initialization over the total Job duration.
  - **Training loop (%)**: The percentage of time spent on Training loop over the total Job duration.
  - **Finalization (%)**: The percentage of time spent on Finalization over the total Job duration.

Resource utilization summary

This summary table shows hardware system resource utilization statistics of all workers (algo-n). System metrics include total CPU utilization, total GPU utilization, total CPU memory utilization, total GPU memory utilization, total I/O wait time, and total network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.
Resource intensive operations

The Resource intensive operations section provides more detailed profiling results that show which training job operations were compute intensive. In the following example, it shows that the convolutional neural network backward pass operators were the most resource intensive on the GPUs.

<table>
<thead>
<tr>
<th>Top operations on GPU</th>
<th>Cumulative time</th>
<th>GPU operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>34.51</td>
<td>13905349</td>
<td>CudnnConvolutionBackward</td>
</tr>
<tr>

</tbody>
</table>

Insights

In the Insights pane, you can find training issues detected by Debugger built-in rules. You can expand each entry in the list to find useful insights, suggestions, a description of the rule, and criteria for initiating the rule.

For more information about the Debugger built-in rules, see List of Debugger Built-in Rules (p. 2239).
Debugger Insights – Nodes

On the **Nodes** tab, Debugger provides detailed graphs that track each compute node on which your training jobs are running.

**CPU and Network utilization**

The first two graphs show CPU utilization and network utilization over time. By default, the graphs show the mean values: the average of CPU and network utilization over the total number of CPU cores. You can select one or more CPU cores by selecting the labels to graph them on single chart and compare utilization across cores. The timeline graphs are interactive, and the two graphs are synced up. You can drag and zoom in and out to get a closer look at specific time windows.
The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of an Amazon EC2 instance. The following figure shows an example training job on an ml.p3.16xlarge instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.
Overall system utilization over time

The following heatmap shows the entire system utilization over time projected onto the two-dimensional plot. Every CPU and GPU core is listed in the vertical axis, and the utilization is recorded over time with colors. See the labeled colorbar on the right side of the plot to find out which color level corresponds to which utilization rate. For example, in the following heatmap, after the initialization phase has ended, around Sun 23:18, you can find that the training job fully utilizes an ml.p3.16xlarge instance: the GPU cores are fully utilized and the CPUs are moderately used for processing Python operations. There were several CPU bottleneck problems scattered across the CPUs at different times.

System resource utilization over time and framework event phase

The System metrics over time graph shows the overall CPU, GPU, and data I/O utilization. The Framework metrics over time graph shows the framework metrics, which are the framework event phases that you can correlate with the System metrics over time graph.

You can select a time interval of interest in the system resource usage timeline, and the framework event phase spots the interval to show what events happened during the selected time interval. In each event phase block, you can find which time interval was actually spent for the training loop and break the training loop into backward pass and forward pass events. Overall, you can see that actual training time intervals are occupying only a small percentage over the entire training time.
Time spent in training

The following graph shows framework metrics from the last 30 steps of the last training loop, with cumulative time spent by different events in each step.

Debugger Insights – Model Insights

On the Model insights tab, you can browse autogenerated training reports for SageMaker XGBoost training jobs. The report provides insights into XGBoost training jobs, such as improvement in accuracy over time, loss value with respect to iteration, class imbalance, and other statistics to evaluate model performance. Depending on the type of supervised learning (binary classification, multi classification,
and regression), the **Model insights** tab is rendered automatically based on the Debugger's XGBoost training HTML report.

**Note**
This feature is available for SageMaker XGBoost training jobs. The training jobs must be initiated using the SageMaker XGBoost training containers version 1.2-1 or later.

**Note**
In the report, plots and recommendations are provided for informational purposes only and are not definitive. You are responsible for making your own independent assessment of the information.

To load model insights content, enable the CreateXgboostReport (p. 2251) rule when you start the training job. For more information about enabling the rule through the SageMaker estimator, see Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule (p. 2326).

For more information about the content on the model insights tab, see Debugger XGBoost Training Report Walkthrough.

To download the HTML report, follow the instructions at Download the Debugger XGBoost Training Report.

The following GIF image shows an example view of the **Model insights** tab for a SageMaker XGBoost training job.

Shut Down the Amazon SageMaker Debugger Insights Instance

When you are not using the Debugger insights dashboard, shut down the instance on which it runs to avoid incurring additional fees.

To shut down the Debugger insights instance in Studio
1. In Studio, select the Running Instances and Kernels icon ( ).

2. Under the RUNNING APPS list, look for the sagemaker-debugger-1.0 app. Select the shutdown icon ( ) next to the app. The Debugger insights dashboards run on an ml.m5.4xlarge instance. This instance also disappears from the RUNNING INSTANCES when you shut down the sagemaker-debugger-1.0 app.

Amazon SageMaker Debugger in Studio Experiments

In this section, you learn how to use the Debugger in Studio Experiments. You can select any training jobs from the experiment trial list to see the model output data graphs, such as accuracy and loss curves, debugging built-in rule status, and Debugger configuration information for debugging.

Visualize Tensors Using Debugger and Studio

Studio provides visualizations to interpret tensor outputs that are captured by Debugger.

Loss Curves While Training Is in Progress

The following screenshot shows visualizations of loss curves for training. The training is in progress.
Analyzing Training Jobs: Comparing Loss Curves Across Multiple Jobs

Studio enables you to compare across multiple jobs (in this case, the loss). This helps you identify the best-performing training jobs.

Initiating Rules and Viewing Logs from Jobs

When rules are initiated for anomalous conditions, Studio presents logs for the failing rule to help you to analyze the causes of the condition.
SageMaker Debugger Interactive Reports

Receive training and profiling reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see SageMaker Debugger Profiling Report (p. 2315).

**Note**
You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

**Important**
In the reports, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- SageMaker Debugger Profiling Report (p. 2315)
- SageMaker Debugger XGBoost Training Report (p. 2326)
SageMaker Debugger Profiling Report

For any SageMaker training jobs, the Debugger ProfilerReport (p. 2241) rule invokes all of the monitoring and profiling rules (p. 2239) and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the Amazon SageMaker Python SDK or the S3 console, and learn what you can interpret from the profiling results.

**Important**

In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**

- Download a Debugger Profiling Report (p. 2315)
- Debugger Profiling Report Walkthrough (p. 2318)

**Download a Debugger Profiling Report**

Download the Debugger profiling report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

**Tip**

You can also download the report with one click and no additional scripting through the SageMaker Studio Debugger insights dashboard. To find out how to download the report from Studio, see Open the Amazon SageMaker Debugger Insights Dashboard (p. 2299).

Download using SageMaker Python SDK and AWS CLI

1. Check the current job’s default S3 output base URI.

   `estimator.output_path`
2. Check the current job name.

   estimator.latest_training_job.job_name

3. The Debugger profiling report is stored under <default-s3-output-base-uri>/<training-job-name>/rule-output. Configure the rule output path as follows:

   rule_output_path = estimator.output_path + estimator.latest_training_job.job_name + "/rule-output"

4. To check if the report is generated, list directories and files recursively under the rule_output_path using aws s3 ls with the --recursive option.

   ! aws s3 ls {rule_output_path} --recursive

   This should return a complete list of files under an autogenerated folder that's named ProfilerReport-1234567890. The folder name is a combination of strings: ProfilerReport and a unique 10-digit tag based on the Unix timestamp when the ProfilerReport rule is initiated.

   The profiler-report.html is an autogenerated profiling report by Debugger. The remaining files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are used to aggregate them into the report.

5. Download the files recursively using aws s3 cp. The following command saves all of the rule output files to the ProfilerReport-1234567890 folder under the current working directory.

   ! aws s3 cp {rule_output_path} ./ --recursive

   Tip
   If using a Jupyter notebook server, run !pwd to double check the current working directory.

6. Under the /ProfilerReport-1234567890/profiler-output directory, open profiler-report.html. If using JupyterLab, choose Trust HTML to see the autogenerated Debugger profiling report.

7. Open the profiler-report.ipynb file to explore how the report is generated. You can also customize and extend the profiling report using the Jupyter notebook file.

Download using Amazon S3 Console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Search for the base S3 bucket. For example, if you haven’t specified any base job name, the base S3 bucket name should be in the following format: `sagemaker--<region>--111122223333`. Look up the base S3 bucket through the Find bucket by name field.

3. In the base S3 bucket, look up the training job name by specifying your job name prefix into the Find objects by prefix input field. Choose the training job name.

4. In the training job’s S3 bucket, there must be three subfolders for training data collected by Debugger: `debug-output/`, `profiler-output/`, and `rule-output/`. Choose `rule-output/`.

5. In the `rule-output/` folder, choose `ProfilerReport-1234567890`, and choose `profiler-output/` folder. The `profiler-output/` folder contains `profiler-report.html` (the autogenerated profiling report in html), `profiler-report.ipynb` (a Jupyter notebook with scripts that are used for generating the report), and a `profiler-report/` folder (contains rule analysis JSON files that are used as components of the report).

6. Select the `profiler-report.html` file, choose Actions, and Download.
7. Open the downloaded `profiler-report.html` file in a web browser.

**Note**
If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics profiling and receive an extended Debugger profiling report, configure the `profiler_config` parameter when constructing or updating SageMaker estimators. To learn how to configure the `profiler_config` parameter before starting a training job, see [Configure Debugger Framework Profiling (p. 2211)](#). To update the current training job and enable framework metrics profiling, see [Update Debugger Framework Profiling Configuration (p. 2215)](#).

**Debugger Profiling Report Walkthrough**

This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

**Important**
In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- [Training Job Summary (p. 2319)](#)
- [System Usage Statistics (p. 2320)](#)
Training Job Summary

At the beginning of the report, Debugger provides a summary of your training job. In this section, you can overview the time durations and timestamps at different training phases.

**Training job summary**

The following table gives a summary about the training job. The table includes information about when the training job started and ended, how much time initialization, training loop and finalization took. Your training job started on 11/28/2020 at 23:12:42 and ran for 707 seconds.

<table>
<thead>
<tr>
<th>#</th>
<th>Job Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Start time 23:12:42 11/28/2020</td>
</tr>
<tr>
<td>1</td>
<td>End time 23:24:59 11/28/2020</td>
</tr>
<tr>
<td>2</td>
<td>Job duration 737 seconds</td>
</tr>
<tr>
<td>3</td>
<td>Training loop start 23:17:38 11/28/2020</td>
</tr>
<tr>
<td>4</td>
<td>Training loop end 23:24:59 11/28/2020</td>
</tr>
<tr>
<td>5</td>
<td>Training loop duration 446 seconds</td>
</tr>
<tr>
<td>6</td>
<td>Initialization time 288 seconds</td>
</tr>
<tr>
<td>7</td>
<td>Finalization time 9 seconds</td>
</tr>
<tr>
<td>8</td>
<td>Initialization 36 %</td>
</tr>
<tr>
<td>9</td>
<td>Training loop 60 %</td>
</tr>
<tr>
<td>10</td>
<td>Finalization 0 %</td>
</tr>
</tbody>
</table>

The summary table contains the following information:

- **start_time** – The exact time when the training job started.
- **end_time** – The exact time when the training job finished.
- **job_duration_in_seconds** – The total training time from the start_time to the end_time.
- **training_loop_start** – The exact time when the first step of the first epoch has started.
- **training_loop_end** – The exact time when the last step of the last epoch has finished.
- **training_loop_duration_in_seconds** – The total time between the training loop start time and the training loop end time.
- **initialization_in_seconds** – Time spent on initializing the training job. The initialization phase covers the period from the start_time to the training_loop_start time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
- **finalization_in_seconds** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the training_loop_end time to the end_time.
- **initialization (%)** – The percentage of time spent on initialization over the total job_duration_in_seconds.
- **Training loop (%)** – The percentage of time spent on training loop over the total job_duration_in_seconds.
- **Finalization (%)** – The percentage of time spent on finalization over the total job_duration_in_seconds.

**System Usage Statistics**

In this section, you can see an overview of system utilization statistics.

**Framework metrics summary**

In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.

The Debugger profiling report includes the following information:

- **Node** – Lists the name of nodes. If using distributed training on multi nodes (multiple EC2 instances), the node names are in format of algo-n.
- **Metric** – The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.
- **Unit** – The unit of the system metrics.
- **Max** – The maximum value of each system metric.
- **P99** – The 99th percentile of each system utilization.
- **P95** – The 95th percentile of each system utilization.
- **P50** – The 50th percentile (median) of each system utilization.
- **Min** – The minimum value of each system metric.
Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.

- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.

- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.

- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.

**Overview: CPU Operators**

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.
Overview: GPU Operators

This section provides information of the GPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called GPU operators.

<table>

Analyzing the Training Loop – Step Durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that's causing step duration outliers.

GPU Utilization Analysis

This section shows the detailed statistics about GPU core utilization based on LowGPUUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

Batch Size

This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.
In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above `cpu_threshold` (90% by default) and also if the GPU utilization is below `gpu_threshold` (10% by default).

The pie charts show the following information:

- **Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
• **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.

• **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

**I/O Bottlenecks**

In this section, you can find a summary of I/O bottlenecks. The rule evaluates the I/O wait time and GPU utilization rates and monitors if the time spent on the I/O requests exceeds a threshold percent of the total training time. It might indicate I/O bottlenecks where GPUs are waiting for data to arrive from storage.

**LoadBalancing in Multi-GPU Training**

In this section, you can identify workload balancing issue across GPUs.

**GPU Memory Analysis**

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.
SageMaker Debugger XGBoost Training Report

For SageMaker XGBoost training jobs, use the Debugger CreateXgboostReport (p. 2251) rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the CreateXgboostReport (p. 2251) rule while constructing an XGBoost estimator, download the report using the Amazon SageMaker Python SDK or the Amazon S3 console, and gain insights into the training results.

**Important**
In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule (p. 2326)
- Download the Debugger XGBoost Training Report (p. 2327)
- Debugger XGBoost Training Report Walkthrough (p. 2329)

**Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule**

The CreateXgboostReport (p. 2251) rule collects the following output tensors from your training job:

- **hyperparameters** – Saves at the first step.
- **metrics** – Saves loss and accuracy every 5 steps.
- **feature_importance** – Saves every 5 steps.
- **predictions** – Saves every 5 steps.
- **labels** – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/`

When you construct a SageMaker estimator for an XGBoost training job, specify the rule as shown in the following example code.

**Using the SageMaker generic estimator**

```python
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules = [Rule.sagemaker(rule_configs.create_xgboost_report())]

region = boto3.Session().region_name
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator = Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-xgboost-report-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",
)
```

2326
# Add the Debugger XGBoost report rule

```python
rules=rules
```

```python
estimator.fit(wait=False)
```

## Download the Debugger XGBoost Training Report

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

**Download using the SageMaker Python SDK and AWS CLI**

1. Check the current job's default S3 output base URI.

```python
estimator.output_path
```

2. Check the current job name.

```python
estimator.latest_training_job.job_name
```

3. The Debugger XGBoost report is stored under `<default-s3-output-base-uri>/ <training-job-name>/rule-output`. Configure the rule output path as follows:

```python
rule_output_path = estimator.output_path + "="/ + estimator.latest_training_job.job_name + "="/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

```bash
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under autogenerated folders that are named `CreateXgboostReport` and `ProfilerReport-1234567890`. The XGBoost training report is stored in the `CreateXgboostReport`, and the profiling report is stored in the `ProfilerReport-1234567890` folder. To learn more about the profiling report generated by default with the XGBoost training job, see SageMaker Debugger Profiling Report (p. 2315).

The `xgboost_report.html` is an autogenerated XGBoost training report by Debugger. The `xgboost_report.ipynb` is a Jupyter notebook that's used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```bash
! aws s3 cp {rule_output_path} ./ --recursive
```
Tip
If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger training report.

7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).

2. Search for the base S3 bucket. For example, if you haven’t specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the **Find bucket by name** field.

3. In the base S3 bucket, look up the training job name by entering your job name prefix in **Find objects by prefix** and then choosing the training job name.
4. In the training job's S3 bucket, choose `rule-output/` subfolder. There must be three subfolders for training data collected by Debugger: `debug-output/`, `profiler-output/`, and `rule-output/`.

5. In the `rule-output/` folder, choose the `CreateXgboostReport/` folder. The folder contains `xbgoost_report.html` (the autogenerated report in html) and `xbgoost_report.ipynb` (a Jupyter notebook with scripts that are used for generating the report).

6. Choose the `xbgoost_report.html` file, choose **Download actions**, and then choose **Download**.

7. Open the downloaded `xbgoost_report.html` file in a web browser.

**Debugger XGBoost Training Report Walkthrough**

This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.
Important
In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- Distribution of True Labels of the Dataset (p. 2330)
- Loss versus Step Graph (p. 2330)
- Feature Importance (p. 2331)
- Confusion Matrix (p. 2332)
- Evaluation of the Confusion Matrix (p. 2333)
- Accuracy Rate of Each Diagonal Element Over Iteration (p. 2334)
- Receiver Operating Characteristic Curve (p. 2335)
- Distribution of Residuals at the Last Saved Step (p. 2336)
- Absolute Validation Error per Label Bin Over Iteration (p. 2337)

Distribution of True Labels of the Dataset
This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.

Loss versus Step Graph
This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.
Feature Importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.
Confusion Matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it's also important to know the false positive rate and false negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.
Evaluation of the Confusion Matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.
Accuracy Rate of Each Diagonal Element Over Iteration

This visualization is only applicable to binary classification and multiclass classification models. This is a line chart that plots the diagonal values in the confusion matrix throughout the training steps for each class. This plot shows you how the accuracy of each class progresses throughout the training steps. You can identify the under-performing classes from this plot.
**Receiver Operating Characteristic Curve**

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPF) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).
Distribution of Residuals at the Last Saved Step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that’s centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.
Absolute Validation Error per Label Bin Over Iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.
Analyze Data Using the SMDebug Client Library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the Amazon SageMaker Python SDK and the SMDebug client library. The SMDebug library provides analysis and visualization tools that enable you to drill down into your training job data.

To install the library and use the SMDebug analysis tools (in a JupyterLab notebook or an iPython kernel):

```
! pip install -U smdebug
```

The following topics walk you through how to use the SMDebug tools to visualize and analyze the training data collected by Debugger.

### Analyze system and framework metrics

- Access the Monitoring and Profiling Data (p. 2338)
- Plot the System Metrics and Framework Metrics Data (p. 2339)
- Access the Profiling Data Using the Pandas Data Parsing Tool (p. 2340)
- Access the Python Profiling Stats Data (p. 2341)
- Merge Timelines of Different Profiling Trace Files (p. 2343)
- Profiling Data Loader (p. 2345)

### Access the Monitoring and Profiling Data

The SMDebug `TrainingJob` class reads data from the S3 bucket where the system and framework metrics are saved.

**To set up a TrainingJob object and retrieve profiling event files of a training job**

```
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob
tj = TrainingJob(training_job_name, region)
```

**Tip**

You need to specify the `training_job_name` and `region` parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.

```
import sagemaker
training_job_name=estimator.latest_training_job.job_name
region=sagemaker.Session().boto_region_name
```

- Pass strings directly.

```
training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
region="us-west-2"
```

**Note**

By default, SageMaker Debugger collects system metrics to monitor hardware resource utilization and system bottlenecks. Running the following functions, you might receive error messages regarding unavailability of framework metrics. To retrieve framework profiling data and gain insights into framework operations, you must enable framework profiling.
• If you use SageMaker Python SDK to manipulate your training job request, pass the `framework_profile_params` to the `profiler_config` argument of your estimator. To learn more, see Configure SageMaker Debugger Framework Profiling.

• If you use Studio, turn on profiling using the Profiling toggle button in the Debugger insights dashboard. To learn more, see SageMaker Debugger Insights Dashboard Controller.

To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved

```python
tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()
```

To check if the system and framework metrics are available from the S3 URI

```python
tj.wait_for_sys_profiling_data_to_be_available()
tj.wait_for_framework_profiling_data_to_be_available()
```

To create system and framework reader objects after the metric data become available

```python
system_metrics_reader = tj.get_systems_metrics_reader()
framework_metrics_reader = tj.get_framework_metrics_reader()
```

To refresh and retrieve the latest training event files

The reader objects have an extended method, refresh_event_file_list(), to retrieve the latest training event files.

```python
system_metrics_reader.refresh_event_file_list()
framework_metrics_reader.refresh_event_file_list()
```

Plot the System Metrics and Framework Metrics Data

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

**Note**

To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify select_dimensions and select_events parameters. For example, if you specify `select_dimensions=\["GPU"\]`, the plot methods filter the metrics that include the "GPU" keyword. If you specify `select_events=\["total"\]`, the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

• The MetricsHistogram class

```python
from smdebug.profiler.analysis.notebook_utils.metrics_histogram import MetricsHistogram
metrics_histogram = MetricsHistogram(system_metrics_reader)
metrics_histogram.plot(
    starttime=0,
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),
    select_dimensions=\["CPU", "GPU", "I/O"\], # optional
    select_events=\["total"\] # optional
)
• The StepTimelineChart class

```python
from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import StepTimelineChart

view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)
```

• The StepHistogram class

```python
from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram

step_histogram = StepHistogram(framework_metrics_reader)
step_histogram.plot(
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
    endtime=step_histogram.last_timestamp,
    show_workers=True
)
```

• The TimelineCharts class

```python
from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts

view_timeline_charts = TimelineCharts(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=['CPU', 'GPU', 'I/O'],  # optional
    select_events=['total']                  # optional
)

view_timeline_charts.plot_detailed_profiler_data([700, 710])
```

• The Heatmap class

```python
from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap

view_heatmap = Heatmap(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=['CPU', 'GPU', 'I/O'],  # optional
    select_events=['total'],                # optional
    plot_height=450
)
```

Access the Profiling Data Using the Pandas Data Parsing Tool

The following PandasFrame class provides tools to convert the collected profiling data to Pandas data frame.

```python
from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame

pf = PandasFrame(tj.profiler_s3_output_path)
system_metrics_df = pf.get_all_system_metrics()
framework_metrics_df = pf.get_all_framework_metrics()
```

2340
Access the Python Profiling Stats Data

The Python profiling provides framework metrics related to Python functions and operators in your training scripts and the SageMaker deep learning frameworks.

Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger provides tools to set modes and phases.

For training modes, use the following `PythonProfileModes` class:

```python
from smdebug.profiler.python_profile_utils import PythonProfileModes
```

This class provides the following options:

- `PythonProfileModes.TRAIN` – Use if you want to profile the target steps in the training phase. This mode option available only for TensorFlow.
- `PythonProfileModes.EVAL` – Use if you want to profile the target steps in the evaluation phase. This mode option available only for TensorFlow.
- `PythonProfileModes.PREDICT` – Use if you want to profile the target steps in the prediction phase. This mode option available only for TensorFlow.
- `PythonProfileModes.GLOBAL` – Use if you want to profile the target steps in the global phase, which includes the previous three phases. This mode option available only for PyTorch.
- `PythonProfileModes.PRE_STEP_ZERO` – Use if you want to profile the target steps in the initialization stage before the first training step of the first epoch starts. This phase includes the initial job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and downloading input data. This mode option available for both TensorFlow and PyTorch.
- `PythonProfileModes.POST_HOOK_CLOSE` – Use if you want to profile the target steps in the finalization stage after the training job has done and the Debugger hook is closed. This phase includes profiling data while the training jobs are finalized and completed. This mode option available for both TensorFlow and PyTorch.

For training phases, use the following `StepPhase` class:

```python
from smdebug.profiler.analysis.utils.python_profile_analysis_utils import StepPhase
```

This class provides the following options:

- `StepPhase.START` – Use to specify the start point of the initialization phase.
- `StepPhase.STEP_START` – Use to specify the start step of the training phase.
- `StepPhase.FORWARD_PASS_END` – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- `StepPhase.STEP_END` – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- `StepPhase.END` – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

Python Profiling Analysis Tools
Debugger supports the Python profiling with two profiling tools:

- **cProfile** – The standard python profiler. cProfile collects framework metrics on CPU time for every function called when profiling was enabled.
- **Pyinstrument** – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see [Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options](p. 2213).

The following methods of the `PythonProfileAnalysis`, `cProfileAnalysis`, `PyinstrumentAnalysis` classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.

```python
from smdebug.profiler.analysis.python_profile_analysis import PythonProfileAnalysis, cProfileAnalysis, PyinstrumentAnalysis
```

To set Python profiling objects for analysis, use the `cProfileAnalysis` or `PyinstrumentAnalysis` classes as shown in the following example code. It shows how to set a `cProfileAnalysis` object, and if you want to use `PyinstrumentAnalysis`, replace the class name.

```python
python_analysis = cProfileAnalysis(
    local_profile_dir=tf_python_stats_dir,
    s3_path=tj.profiler_s3_output_path
)
```

The following methods are available for the `cProfileAnalysis` and `PyinstrumentAnalysis` classes to fetch the Python profiling stats data:

- `python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_secs, end_time_since_epoch_in_secs)` – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.
- `python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)` – Takes in a start step and end step and returns the function stats of all step stats whose profiled step satisfies `start_step <= step < end_step`.
- `python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)` – Fetches stats from the Python profiling between the start and end modes.
- `python_analysis.fetch_pre_step_zero_profile_stats()` – Fetches the stats from the Python profiling until step 0.
- `python_analysis.fetch_post_hook_close_profile_stats()` – Fetches stats from the Python profiling after the hook is closed.

2342
• `python_analysis.list_profile_stats()` – Returns a DataFrame of the Python profiling stats. Each row holds the metadata for each instance of profiling and the corresponding stats file (one per step).

• `python_analysis.list_available_node_ids()` – Returns a list the available node IDs for the Python profiling stats.

The `cProfileAnalysis` class specific methods:

• `fetch_profile_stats_by_training_phase()` – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are `(PRE_STEP_ZERO, TRAIN), (TRAIN, TRAIN), (TRAIN, EVAL), (EVAL, EVAL), and (EVAL, POST_HOOK_CLOSE)`. All stats files within each of these combinations are aggregated.

• `fetch_profile_stats_by_job_phase()` – Fetches and aggregates the Python profiling stats by job phase. The job phases are `initialization` (profiling until step 0), `training_loop` (training and validation), and `finalization` (profiling after the hook is closed).

### Merge Timelines of Different Profiling Trace Files

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

**Tip**
Before proceeding, you need to set a TrainingJob object that will be utilized throughout the examples in this page. For more information about setting up a TrainingJob object, see Access the Monitoring and Profiling Data (p. 2338).

The `MergedTimeline` class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default `tracefolder` directory.

- For annotations in the Python layers, the trace files are saved in `*pythontimeline.json`.
- For annotations in the TensorFlow C++ layers, the trace files are saved in `*model_timeline.json`.
- Tensorflow profiler saves events in a `*trace.json.gz` file.

**Tip**
If you want to list all of the JSON trace files, use the following AWS CLI command:

```
aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '\.json$'
```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.
Tip
To interact with the merged timeline on the tracing app using a keyboard, use the W key for zooming in, the A key for shifting to the left, the S key for zooming out, and the D key for shifting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file using the following `MergedTimeline` API operation and class method from the `smdebug.profiler.analysis.utils.merge_timelines` module.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The `MergedTimeline` API operation passes the following parameters:

- **path** (str) – Specify a root folder (`/profiler-output`) that contains system and framework profiling trace files. You can locate the profiler-output using the SageMaker estimator classmethod or the `TrainingJob` object. For example, `estimator.latest_job_profiler_artifacts_path()` or `tj.profiler_s3_output_path`.
- **file_suffix_filter** (list) – Specify a list of file suffix filters to merge timelines. Available suffix filters are `["model_timeline.json", "pythontimeline.json", "trace.json.gz"]`. If this parameter is not manually specified, all of the trace files are merged by default.
- **output_directory** (str) – Specify a path to save the merged timeline JSON file. The default is to the directory specified for the `path` parameter.

The `merge_timeline()` classmethod passes the following parameters to execute the merging process:

- **start** (int) – Specify start time (in microseconds and in Unix time format) or start step to merge timelines.
- **end** (int) – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
• unit (str) – Choose between "time" and "step". The default is "time".

Using the following example codes, execute the `merge_timeline()` method and download the merged JSON file.

• Merge timeline with the "time" unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```python
import time
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

• Merge timeline with the "step" unit option. The following example code merges all available timelines between step 3 and step 9.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(3, 9, unit="step")
```

Open the Chrome tracing app at chrome://tracing on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

**Profiling Data Loader**

In PyTorch, data loader iterators, such as `SingleProcessingDataLoaderIter` and `MultiProcessingDataLoaderIter`, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and `pin_memory` threads.

To use the PyTorch data loader profiling analysis tool, import the following `PT_dataloader_analysis` class:

```python
from smdebug.profiler.analysis.utils.pytorch_dataloader_analysis import PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the Access the Profiling Data Using the Pandas Data Parsing Tool (p. 2340) section:

```python
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the `pt_analysis` object:

The SMDebug S3SystemMetricsReader class reads the system metrics from the S3 bucket specified to the `s3_trial_path` parameter.

• `pt_analysis.analyze_dataloaderIter_initialization()`

The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e duration is greater than 2 * median), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.
The following list shows what analysis is available from this class method:

- Which type of data loader iterators were initialized.
- The number of workers per iterator.
- Inspect whether the iterator was initialized with or without pin_memory.
- Number of times the iterators were initialized during training.

```
pt_analysis.analyze_dataloaderWorkers()
```

The following list shows what analysis is available from this class method:

- The number of worker processes that were spun off during the entire training.
- Median and maximum duration for the worker processes.
- Start and end time for the worker processes that are outliers.

```
pt_analysis.analyze_dataloader_getnext()
```

The following list shows what analysis is available from this class method:

- Number of GetNext calls made during the training.
- Median and maximum duration in microseconds for GetNext calls.
- Start time, End time, duration and worker id for the outlier GetNext call duration.

```
pt_analysis.analyze_batchtime(start_timestamp, end_timestamp, select_events=[".*"], select_dimensions=[".*"])
```

Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.

```
pt_analysis.plot_the_window()
```

Plots a timeline charts between a start timestamp and the end timestamp.

**Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard**

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.
You can enable this by passing `DebuggerHookConfig` and `TensorBoardOutputConfig` objects to an estimator.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container's local path (the default path is `/opt/ml/output/tensors`) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

**To save TensorBoard compatible output tensor files using Debugger**

1. Set up a `tensorboard_output_config` configuration object to save TensorBoard output using the Debugger `TensorBoardOutputConfig` class. For the `s3_output_path` parameter, specify the default S3 bucket of the current SageMaker session or a preferred S3 bucket. This example does not add the `container_local_output_path` parameter; instead, it is set to the default local path `/opt/ml/output/tensors`.

   ```python
   import sagemaker
   from sagemaker.debugger import TensorBoardOutputConfig
   bucket = sagemaker.Session().default_bucket()
   tensorboard_output_config = TensorBoardOutputConfig(
       s3_output_path='s3://{}'.format(bucket)
   )
   ```

   For additional information, see the Debugger `TensorBoardOutputConfig` API in the Amazon SageMaker Python SDK.

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the weights parameters every 500 steps (the default save_interval value for saving tensor collections is 500), and the bias parameters every 10 global steps until the global step reaches 500.

   ```python
   from sagemaker.debugger import CollectionConfig, DebuggerHookConfig
   hook_config = DebuggerHookConfig(
       hook_parameters={
           "train.save_interval": "100",
           "eval.save_interval": "10"
       },
   )
   ```
collection_configs=[
    CollectionConfig("weights"),
    CollectionConfig(
        name="biases",
        parameters={
            "save_interval": "10",
            "end_step": "500",
            "save_histogram": "True"
        }
    ),
  ],
)

For more information about the Debugger configuration APIs, see the Debugger CollectionConfig and DebuggerHookConfig APIs in the Amazon SageMaker Python SDK.

3. Construct a SageMaker estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker estimator. You can replace estimator and Estimator with other SageMaker frameworks' estimator parent classes and estimator classes. Available SageMaker framework estimators for this functionality are TensorFlow, PyTorch, and MXNet.

from sagemaker import Estimator
estimator = Estimator(
    ...
    # Debugger parameters
dar = debugger_hook_config=hook_config,
tensorboard_output_config=tensorboard_output_config
)
estimator.fit()

The estimator.fit() method starts a training job, and Debugger writes the output tensor files in real time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:

• For the Debugger S3 output path, use estimator.latest_job_debugger_artifacts_path().
• For the TensorBoard S3 output path, use estimator.latest_job_tensorboard_artifacts_path().

4. After the training has completed, check the names of saved output tensors:

from smdebug.trials import create_trial
trial = create_trial(estimator.latest_job_debugger_artifacts_path())
trial.tensor_names()

5. Check the TensorBoard output data in Amazon S3:

    tensorboard_output_path=estimator.latest_job_tensorboard_artifacts_path()
    print(tensorboard_output_path)
    !aws s3 ls {tensorboard_output_path}/

6. Download the TensorBoard output data to your notebook instance. For example, the following AWS CLI command downloads the TensorBoard files to /logs/fit under the current working directory of your notebook instance.

    !aws s3 cp --recursive {tensorboard_output_path} ./logs/fit

7. Compress the file directory to a TAR file to download to your local machine.
8. Download and extract the Tensorboard TAR file to a directory on your device, launch a Jupyter notebook server, open a new notebook, and run the TensorBoard app.

```
tar -xf logs.tar
%load_ext tensorboard
%tensorboard --logdir logs/fit
```

# Best Practices for Amazon SageMaker Debugger

Use the following guidelines when you run training jobs with Debugger.

## Topics
- Choose a Machine Learning Framework (p. 2349)
- Use Studio Debugger Insights Dashboard (p. 2349)
- Download Debugger Reports and Gain More Insights (p. 2349)
- Capture Data from Your Training Job and Save Data to Amazon S3 (p. 2350)
- Analyze the Data with a Fleet of Debugger Built-in Rules (p. 2350)
- Take Actions Based on the Built-in Rule Status (p. 2350)
- Dive Deep into the Data Using the SMDebug Client Library (p. 2350)
- Monitor and Analyze Training Job Metrics (p. 2350)
- Monitoring System Utilization and Detect Bottlenecks (p. 2351)
- Profiling Framework Operations (p. 2351)
- Debugging Model Output Tensors (p. 2351)

## Choose a Machine Learning Framework

You can choose a machine learning framework and use SageMaker pre-built training containers or your own containers. Use Debugger to detect training and performance issues, and analyze training progress of your training job in SageMaker. SageMaker provides you options to use pre-built containers that are prepared for a number of machine learning framework environments to train your model on Amazon EC2. Any training job can be adapted to run in AWS Deep Learning Containers, SageMaker training containers, and custom containers. To learn more, see Configure Debugger Using Amazon SageMaker Python SDK (p. 2206) and Use Debugger with Custom Training Containers (p. 2285).

## Use Studio Debugger Insights Dashboard

With Studio Debugger insights dashboard, you are in control of your training jobs. Use the Studio Debugger dashboards to keep your model performance on Amazon EC2 instances in control and optimized. For any SageMaker training jobs running on Amazon EC2 instance, Debugger monitors resource utilization and basic model output data (loss and accuracy values). Through the Studio Debugger dashboards, gain insights into your training jobs and improve your model training performance. To learn more, see Amazon SageMaker Debugger in Amazon SageMaker Studio (p. 2298).

## Download Debugger Reports and Gain More Insights

You can view aggregated results and gain insights in Debugger reports. Debugger aggregates training and profiling results collected from the built-in rule analysis into a report per training job. You can find
more detailed information about your training results through the Debugger reports. To learn more, see SageMaker Debugger Interactive Reports (p. 2314).

**Capture Data from Your Training Job and Save Data to Amazon S3**

You can use a Debugger hook to save output tensors. After you choose a container and a framework that fit your training script, use a Debugger hook to configure which tensors to save and to which directory to save them, such as a Amazon S3 bucket. A Debugger hook helps you to build the configuration and to keep it in your account to use in subsequent analyses, where it is secured for use with the most privacy-sensitive applications. To learn more, see Configure Debugger Hook to Save Tensors (p. 2215).

**Analyze the Data with a Fleet of Debugger Built-in Rules**

You can use Debugger built-in rules to inspect tensors in parallel with a training job. To analyze the training performance data, Debugger provides built-in rules that watch for abnormal training process behaviors. For example, a Debugger rule detects issues when the training process suffers from system bottleneck issues or training issues, such as vanishing gradients, exploding tensors, overfitting, or overtraining. If necessary, you can also build customized rules by creating a rule definition with your own criteria to define a training issue. To learn more about the Debugger rules, see Configure Debugger Built-in Rules (p. 2221) for detailed instructions of using the Amazon SageMaker Python SDK. For a full list of the Debugger built-in rules, see List of Debugger Built-in Rules (p. 2239). If you want to create a custom rule, see Create Debugger Custom Rules for Training Job Analysis (p. 2283).

**Take Actions Based on the Built-in Rule Status**

You can use Debugger with Amazon CloudWatch Events and AWS Lambda. You can automate actions based on the rule status, such as stopping training jobs early and setting up notifications through email or text. When the Debugger rules detect problems and triggers an "IssuesFound" evaluation status, CloudWatch Events detects the rule status changes and invokes the Lambda function to take actions. To configure automated actions to your training issues, see Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 2293).

**Dive Deep into the Data Using the SMDebug Client Library**

You can use the SMDebug tools to access and analyze training data collected by Debugger. The TrainingJob and create_trial classes load the metrics and tensors saved by Debugger. These classes provide extended class methods to analyze the data in real time or after the training has finished. The SMDebug library also provides visualization tools: merge timelines of framework metrics to aggregate different profiling, line charts and heatmap to track the system utilization, and histograms to find step duration outliers. To learn more about the SMDebug library tools, see Analyze Data Using the SMDebug Client Library (p. 2338).

**Monitor and Analyze Training Job Metrics**

Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see GetMetricStatistics in the Amazon CloudWatch API Reference.

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as
CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors).

SageMaker Debugger also provides visualizations through Studio and its profiling report. Unlike CloudWatch metrics, which accumulates resource utilization rates of CPU and GPU cores and averages those out across multiple instances, Debugger tracks the utilization rate of each core. This enables you to identify unbalanced usage of hardware resources as you scale up to larger compute clusters. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

Monitoring System Utilization and Detect Bottlenecks

With Amazon SageMaker Debugger monitoring, you can measure hardware system resource utilization of Amazon EC2 instances. Monitoring is available for any SageMaker training job constructed with the SageMaker framework estimators (TensorFlow, PyTorch, and MXNet) and the generic SageMaker estimator (SageMaker built-in algorithms and your own custom containers). Debugger built-in rules for monitoring detect system bottleneck issues and notify you when they detect the bottleneck issues.

To learn how to enable Debugger system monitoring, see Configure Debugger Using Amazon SageMaker Python SDK (p. 2206) and then Configure Debugger Monitoring Hardware System Resource Utilization (p. 2211).

For a full list of available built-in rules for monitoring, see Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics) (p. 2239).

Profiling Framework Operations

With Amazon SageMaker Debugger profiling you can profile deep learning frameworks operations. You can profile your model training with the SageMaker TensorFlow training containers, the SageMaker PyTorch framework containers, and your own training containers. Using the profiling feature of Debugger, you can drill down into the Python operators and functions that are executed to perform the training job. Debugger supports detailed profiling, Python profiling, data loader profiling, and Horovod distributed training profiling. You can merge the profiled timelines to correlate with the system bottlenecks. Debugger built-in rules for profiling watch framework operation related issues, including excessive training initialization time due to data downloading before training starts and step duration outliers in training loops.

To learn how to configure Debugger for framework profiling, see Configure Debugger Using Amazon SageMaker Python SDK (p. 2206) and then Configure Debugger Framework Profiling (p. 2211).

For a complete list of available built-in rules for profiling, see Debugger Built-in Rules for Profiling Framework Metrics (p. 2239).

Debugging Model Output Tensors

Debugging is available for deep learning frameworks using AWS Deep Learning Containers and the SageMaker training containers. For fully supported framework versions (see the versions at Supported Frameworks and Algorithms (p. 2193)), Debugger automatically registers hooks to collect output tensors, and you can directly run your training script. For the versions with one asterisk sign, you need to manually register the hooks to collect tensors. Debugger provides preconfigured tensor collections with generalized names that you can utilize across the different frameworks. If you want to customize output tensor configuration, you can also use the CollectionConfig and DebuggerHookConfig API operations and the Amazon SageMaker Python SDK to configure your own tensor collections. Debugger built-in rules for debugging analyze the output tensors and identifies model optimization problems that blocks your model from minimizing the loss function. For example, the rules identify overfitting, overtraining, loss not decreasing, exploding tensors, and vanishing gradients.
To learn how to configure Debugger for debugging output tensors, see Configure Debugger Using Amazon SageMaker Python SDK (p. 2206) and then Configure Debugger Hook to Save Tensors (p. 2215).

For a full list of available built-in rules for debugging, see Debugger Built-in Rules for Debugging Model Training Data (Output Tensors) (p. 2240).

**Amazon SageMaker Debugger Advanced Topics and Reference Documentation**

The following sections contain advanced topics, reference documentation for the API operations, exceptions, and known limitations for Debugger.

**Topics**
- Amazon SageMaker Debugger API Operations (p. 2352)
- Use Debugger Docker Images for Built-in or Custom Rules (p. 2353)
- Amazon SageMaker Debugger Exceptions (p. 2355)
- Considerations for Amazon SageMaker Debugger (p. 2356)
- Amazon SageMaker Debugger Usage Statistics (p. 2358)

**Amazon SageMaker Debugger API Operations**

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source SMDebug Python library at awslabs/sagemaker-debugger that is used to configure built-in rules, define custom rules, and register hooks to collect output tensor data from training jobs.

The Amazon SageMaker Python SDK is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the SMDebug Python library to monitor and analyze these tensors using SageMaker estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- `CreateTrainingJob` and `UpdateTrainingJob` use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - `CollectionConfiguration`
  - `DebugHookConfig`
  - `DebugRuleConfiguration`
  - `TensorBoardOutputConfig`
  - `ProfilerConfig`
  - `ProfilerRuleConfiguration`
- `DescribeTrainingJob` provides a full description of a training job, including the following Debugger configurations and rule evaluation statuses:
  - `DebugHookConfig`
  - `DebugRuleConfiguration`
  - `DebugRuleEvaluationStatus`
  - `ProfilerConfig`
  - `ProfilerRuleConfiguration`
The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see Process Data (p. 976).

Use Debugger Docker Images for Built-in or Custom Rules

Amazon SageMaker provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the Amazon SageMaker Python SDK, you can simply use SageMaker high-level Debugger API operations with SageMaker Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the ConfigureTrainingJob API.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry URL of the image using the CreateTrainingJob API. SageMaker uses the following URL patterns for the Debugger rule container image registry address.

```
<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>
```

For the account ID in each AWS Region, Amazon ECR repository name, and tag value, see the following topics.

Topics
- Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators (p. 2353)
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2354)

Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators

Use the following values for the components of the registry URLs for the images that provide built-in rules for Amazon SageMaker Debugger. For account IDs, see the following table.

**ECR Repository Name:** sagemaker-debugger-rules

**Tag:** latest

**Example of a full registry URL:**

904829902805.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rules:latest

### Account IDs for Built-in Rules Container Images by AWS Region

Amazon SageMaker Debugger Exceptions

Amazon SageMaker Debugger is designed to be aware that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the smdebug.exceptions module. You can import them as follows:

```python
from smdebug.exceptions import *
```

The following exceptions are available:

- `TensorUnavailableForStep` – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.
- **TensorUnavailable** – This tensor is not being saved or has not been saved by the `smdebug` API. This means that this tensor is never seen for any step in `smdebug`.
- **StepUnavailable** – The step was not saved and Debugger has no data from the step.
- **StepNotYetAvailable** – The step has not yet been seen by `smdebug`. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.
- **NoMoreData** – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.
- **IndexReaderException** – The index reader is not valid.
- **InvalidWorker** – A worker was invoked that was not valid.
- **RuleEvaluationConditionMet** – Evaluation of the rule at the step resulted in the condition being met.
- **InsufficientInformationForRuleInvocation** – Insufficient information was provided to invoke the rule.

### Considerations for Amazon SageMaker Debugger

Consider the following when using Amazon SageMaker Debugger.

### Considerations for Distributed Training

The following list shows the scope of validity and considerations for using Debugger on training jobs with deep learning frameworks and various distributed training options.

- **Horovod**

#### Scope of validity of using Debugger for training jobs with Horovod

<table>
<thead>
<tr>
<th>Deep Learning Framework</th>
<th>Apache MXNet</th>

<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

* Debugger does not support framework profiling for TensorFlow 2.x.

** SageMaker distributed data parallel does not support TensorFlow 2.x with Keras implementation.

- **SageMaker distributed model parallel** – Debugger does not support SageMaker distributed model parallel training.
- **Distributed training with SageMaker checkpoints** – Debugger is not available for training jobs when both the distributed training option and SageMaker checkpoints are enabled. You might see an error that looks like the following:

  SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled

To use Debugger for training jobs with distributed training options, you need to disable SageMaker checkpointing and add manual checkpointing functions to your training script. For more information about using Debugger with distributed training options and checkpoints, see Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints (p. 2426) and Saving Checkpoints (p. 2490).

- **Parameter Server** – Debugger does not support parameter server-based distributed training.
- **Profiling distributed training framework operations**, such as the `AllReduced` operation of SageMaker distributed data parallel and Horovod operations, is not available.

### Considerations for Monitoring System Bottlenecks and Profiling Framework Operations

- For AWS TensorFlow, data loader metrics cannot be collected using the default `local_path` setting of the `FrameworkProfile` class. The path has to be manually configured and end in "/". For example:

  ```python
  FrameworkProfile(local_path="/opt/ml/outputProfiler/")
  ```

- For AWS TensorFlow, the data loader profiling configuration cannot be updated while a training job is running.
- For AWS TensorFlow, a `NoneType` error might occur when you use analysis tools and notebook examples with TensorFlow 2.3 training jobs and the detailed profiling option.
- Python profiling and detailed profiling are only supported for Keras API.
- To access the deep profiling feature for TensorFlow and PyTorch, currently you must specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI in the TensorFlow and PyTorch estimator as follows:
  - For TensorFlow

    ```python
    image_uri = "763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"
    ```
  - For PyTorch

    ```python
    image_uri = "763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04"
    ```

2357
Considerations for Debugging Model Output Tensors

- Avoid using functional API operations. Debugger cannot collect model output tensors from PyTorch and MXNet training scripts composed of functional API operations.
- Debugger cannot collect model output tensors from the `torch.nn.functional` API operations. When you write a PyTorch training script, it is recommended to use the `torch.nn` modules instead.
- Debugger cannot collect model output tensors from MXNet functional objects in hybrid blocks. For example, the ReLu activation (`F.relu`) outputs cannot be collected from the following example of `mxnet.gluon.HybridBlock` with `F` in the `hybrid_forward` function.

```python
import mxnet as mx
from mxnet.gluon import HybridBlock, nn

class Model(HybridBlock):
    def __init__(self, **kwargs):
        super(Model, self).__init__(**kwargs)
        # use name_scope to give child Blocks appropriate names.
        with self.name_scope():
            self.dense0 = nn.Dense(20)
            self.dense1 = nn.Dense(20)

    def hybrid_forward(self, F, x):
        x = F.relu(self.dense0(x))
        return F.relu(self.dense1(x))

model = Model()
model.initialize(ctx=mx.cpu(0))
model.hybridize()
model(mx.nd.zeros((10, 10), ctx=mx.cpu(0)))
```

Amazon SageMaker Debugger Usage Statistics

Consider the following when using autogenerated reports by Amazon SageMaker Debugger.

**Debugger Profiling Report Usage**

For all SageMaker training jobs, Amazon SageMaker Debugger runs the `ProfilerReport` rule and autogenerates a `SageMaker Debugger Profiling Report`. The `ProfilerReport` rule provides a Jupyter notebook file (`profiler-report.ipynb`) that generates a corresponding HTML file (`profiler-report.html`).

Debugger collects profiling report usage statistics by including code in the Jupyter notebook that collects the unique `ProfilerReport` rule's processing job ARN if the user opens the final HTML report.

Debugger only collects information about whether a user opens the final HTML report. It **DOES NOT** collect any information from training jobs, training data, training scripts, processing jobs, logs, or the content of the profiling report itself.

You can opt out of the collection of usage statistics using either of the following options.

**(Recommended) Option 1: Opt Out before Running a Training Job**

To opt out, you need to add the following Debugger `ProfilerReport` rule configuration to your training job request.

```python
estimator=sagemaker.estimator.Estimator(
```
... rules=ProfilerRule.sagemaker(
    base_config=rule_configs.ProfilerReport()
    rule_parameters={"opt_out telemetry": "True"}
) )

AWS CLI

"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport-1234567890",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
            "opt_out telemetry": "True"
        }
    }
]

AWS SDK for Python (Boto3)

ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport-1234567890',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'opt_out telemetry': 'True'
        }
    }
]

Option 2: Opt Out after a Training Job Has Completed

To opt out after training has completed, you need to modify the profiler-report.ipynb file.

Note

HTML reports autogenerated without Option 1 already added to your training job request still report the usage statistics even after you opt out using Option 2.

1. Follow the instructions on downloading the Debugger profiling report files in the Download a Debugger Profiling Report (p. 2315) page.
2. In the /ProfilerReport-1234567890/profiler-output directory, open profiler-report.ipynb.
3. Add opt_out=True to the setup_profiler_report() function in the fifth code cell as shown in the following example code:

   setup_profiler_report(processing_job_arn, opt_out=True)

4. Run the code cell to finish opting out.
Perform Automatic Model Tuning with SageMaker

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose.

For example, suppose that you want to solve a binary classification problem on a marketing dataset. Your goal is to maximize the area under the curve (auc) metric of the algorithm by training an XGBoost Algorithm (p. 1990) model. You don't know which values of the eta, alpha, min_child_weight, and max_depth hyperparameters to use to train the best model. To find the best values for these hyperparameters, you can specify ranges of values that SageMaker hyperparameter tuning searches to find the combination of values that results in the training job that performs the best as measured by the objective metric that you chose. Hyperparameter tuning launches training jobs that use hyperparameter values in the ranges that you specified, and returns the training job with highest auc.

You can use SageMaker automatic model tuning with built-in algorithms, custom algorithms, and SageMaker pre-built containers for machine learning frameworks.

Amazon SageMaker automatic model tuning can use Amazon EC2 Spot instance to optimize costs when running training jobs. For more information on managed spot training, see Managed Spot Training in Amazon SageMaker (p. 2603).

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

- A dataset
- An understanding of the type of algorithm you need to train
- A clear understanding of how you measure success

You should also prepare your dataset and algorithm so that they work in SageMaker and successfully run a training job at least once. For information about setting up and running a training job, see Get Started with Amazon SageMaker (p. 33).

How Hyperparameter Tuning Works

Random Search

In a random search, hyperparameter tuning chooses a random combination of values from within the ranges that you specify for hyperparameters for each training job it launches. Because the choice of hyperparameter values doesn't depend on the results of previous training jobs, you can run the maximum number of concurrent training jobs without affecting the performance of the search.
Bayesian Search

Bayesian search treats hyperparameter tuning like a [regression] problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose. To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results, and runs training jobs to test these values. After testing the first set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.

Hyperparameter tuning uses a Amazon SageMaker implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to exploit the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not well understood. The explore/exploit trade-off is common in many machine learning problems.

Note

Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions, and, as such, should be considered part of the scientific development process. When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate...
your productivity by trying many variations of a model, focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you need to choose the right ranges to explore. Because the algorithm itself is stochastic, it's possible that the hyperparameter tuning model will fail to converge on the best answer, even if the best possible combination of values is within the ranges that you choose.

Define Metrics

When you use one of the Amazon SageMaker built-in algorithms, you don't need to define metrics. Built-in algorithms automatically send metrics to hyperparameter tuning. You do need to choose one of the metrics that the built-in algorithm emits as the objective metric for the tuning job. For a list of metrics that a built-in algorithm emits, see the model tuning section for the appropriate algorithm listed in Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1051).

To optimize hyperparameters for a machine learning model, a tuning job evaluates the training jobs it launches by using a metric that the training algorithm writes to logs. Amazon SageMaker hyperparameter tuning parses your algorithm's stdout and stderr streams to find algorithm metrics, such as loss or validation-accuracy, that show how well the model is performing on the dataset.

**Note**

These are the same metrics that SageMaker sends to CloudWatch Logs. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3510).

If you use your own algorithm for hyperparameter tuning, make sure that your algorithm emits at least one metric by writing evaluation data to stdout or stderr.

**Note**

Hyperparameter tuning sends an additional hyperparameter, _tuning_objective_metric to the training algorithm. This hyperparameter specifies the objective metric being used for the hyperparameter tuning job, so that your algorithm can use that information during training.

You can define up to 20 metrics for your tuning job to monitor. You choose one of those metrics to be the objective metric, which hyperparameter tuning uses to evaluate the training jobs. The hyperparameter tuning job returns the training job that returned the best value for the objective metric as the best training job.

You define metrics for a tuning job by specifying a name and a regular expression for each metric that your tuning job monitors. Design the regular expressions to capture the values of metrics that your algorithm emits. You pass these metrics to the CreateHyperParameterTuningJob operation in the TrainingJobDefinition parameter as the MetricDefinitions field of the AlgorithmSpecification field.

The following example defines 4 metrics:

```json
[
    {
        "Name": "loss",
        "Regex": "Loss = (.*)\n",
    },
    {
        "Name": "ganloss",
        "Regex": "GAN_loss=(.*)\n",
    },
    {
        "Name": "discloss",
        "Regex": "disc_train_loss=(.*)\n",
    },
    {
        "Name": "disc-combined",
        "Regex": "disc-combined=(.*)\n",
    }
]
```
The following is an example of the log that the algorithm writes:

```
GAN_loss=0.138318;  Scaled_reg=2.654134; disc: [-0.017371, 0.102429] real 93.3% gen 0.0%
disc-combined=0.000000; disc_train_loss=1.374587;  Loss = 16.020744; Iteration 0 took 0.704s;  Elapsed=0s
```

Use the regular expression (regex) to match the algorithm's log output and capture the numeric values of metrics. For example, in the regex for the loss metric defined above, the first part of the regex finds the exact text "Loss = ", and the expression (.*)?; captures zero or more of any character until the first semicolon character. In this expression, the parenthesis tell the regex to capture what is inside them, . means any character, * means zero or more, and ? means capture only until the first instance of the ; character.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the API, specify the value of the name key in the HyperParameterTuningJobObjective field of the HyperParameterTuningJobConfig parameter that you send to the CreateHyperParameterTuningJob operation.

## Define Hyperparameter Ranges

Hyperparameter tuning finds the best hyperparameter values for your model by searching over a set of values that you specify for each of the hyperparameters that are tunable. Choosing hyperparameters and ranges significantly affects the performance of your tuning job. For guidance on choosing hyperparameters and ranges, see [Best Practices for Hyperparameter Tuning](p. 2386).

To define hyperparameter ranges by using the low-level API, you specify the names of hyperparameters and ranges of values in the ParameterRanges field of the HyperParameterTuningJobConfig parameter that you pass to the CreateHyperParameterTuningJob operation. The ParameterRanges field has three subfields, one for each of the categorical, integer, and continuous hyperparameter ranges. You can define up to 20 hyperparameters to search over. Each value of a categorical hyperparameter range counts as a hyperparameter against the limit. Hyperparameter ranges have the following structure:

```
"ParameterRanges": {
  "CategoricalParameterRanges": [
    {
      "Name": "tree_method",
      "Values": ["auto", "exact", "approx", "hist"]
    }
  ],
  "ContinuousParameterRanges": [
    {
      "Name": "eta",
      "MaxValue": "0.5",
      "MinValue": "0",
      "ScalingType": "Auto"
    }
  ],
  "IntegerParameterRanges": [
    {
      "Name": "max_depth",
      "MaxValue": "10",
      "MinValue": "1",
      "ScalingType": "Auto"
    }
  ]
}
```
Hyperparameter Scaling

For integer and continuous hyperparameter ranges, you can choose the scale you want hyperparameter tuning to use to search the range of values by specifying a value for the ScalingType field of the hyperparameter range. You can choose from the following scaling types:

Auto

SageMaker hyperparameter tuning chooses the best scale for the hyperparameter.

Linear

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude), because uniformly searching values from the range will give you a reasonable exploration of the entire range.

Logarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale.

Logarithmic scaling works only for ranges that have only values greater than 0.

Choose logarithmic scaling when you are searching a range that spans several orders of magnitude. For example, if you are tuning a Tune a linear learner model (p. 1966) model, and you specify a range of values between .0001 and 1.0 for the learning_rate hyperparameter, searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would, because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between .1 and 1.0, leaving only 10 percent of your training budget for the values between .0001 and .1.

ReverseLogarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. Reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Reverse logarithmic scaling works only for ranges that are entirely within the range 0<=x<1.0.

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

For an example notebook that uses hyperparameter scaling, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb.

Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model

To create a new hyperparameter optimization (HPO) job with Amazon SageMaker that tunes multiple algorithms, you must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources you want to use for the tuning job.

- The **job settings** to configure include warm starting, early stopping, and the tuning strategy. Warm starting and early stopping are available only when tuning a single algorithm.

- The **training job definition** to specify the name, algorithm source, objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job. It
configures the channels for data inputs, data output locations, and any checkpoint storage locations for each training job. The definition also configures the resources to deploy for each training job, including instance types and counts, managed spot training, and stopping conditions.

- **The tuning job resources**: to deploy, including the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently and the maximum number of training jobs that the hyperparameter tuning job can run.

### Get Started

You can create a new hyperparameter tuning job, clone a job, add or edit tags to a job from the console. You can also use the search feature to find jobs by their name, creation time, or status. Alternatively, you can also hyperparameter tuning jobs with the SageMaker API.

- **In the console**: To create a new job, open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/, choose **Hyperparameter tuning jobs** from the **Training** menu, and then choose **Create hyperparameter tuning job**. Then following the configuration steps to create a training job for each algorithm that you want to use. These steps are documented in the Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) (p. 2365) topic.

  **Note**

  When you start the configuration steps, note that the warm start and early stopping features are not available to use with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.

- **With the API**: For instructions on using the SageMaker API to create a hyperparameter tuning job, see Example: Hyperparameter Tuning Job. When you call `CreateHyperParameterTuningJob` to tune multiple algorithms, you must provide a list of training definitions using `TrainingJobDefinitions` instead of specifying a single `TrainingJobDefinition`. You must choose just one of these definition types depending on the number of algorithms being tuned.

**Topics**

- Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) (p. 2365)
- Manage Hyperparameter Tuning and Training Jobs (p. 2369)

### Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)

To create a new hyperparameter optimization (HPO) tuning job for one or more algorithms, you need to define the settings for the tuning job, create training job definitions for each algorithm being tuned, and configure the resources for the tuning job.

**Topics**

- Define job settings (p. 2365)
- Create Training Job Definitions (p. 2366)
- Configure Tuning Job Resources (p. 2368)
- Review and Create HPO Tuning Job (p. 2368)

### Define job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when tuning a single algorithm. After you define the job settings you will create individual training definitions for each algorithm or variation you want to tune.
Warm Start

If you cloned this job, you can choose to use the results from a previous tuning job to improve the performance of this new tuning job. This is the warm start feature and it is only available when tuning a single algorithm. When you choose this option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

**Note**
Warm start is compatible only with tuning jobs created after October 1, 2018. For more information, see [Run a warm start job](#).

Early Stopping

To reduce compute time and avoid overfitting your model, training jobs can be stopped early when they are unlikely to improve the current best objective metric of the hyperparameter tuning job. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it's disabled by default. For more information on how early stopping works, the algorithms that support it, and how to use it with your own algorithms, see [Stop Training Jobs Early](#).

Tuning Strategy

Tuning strategy can be either random or Bayesian. It specifies how the automatic tuning searches over specified hyperparameter ranges. You specify the ranges in a later step. Random search chooses random combinations of values from the specified ranges and can be run concurrently. Bayesian search chooses values based on what is likely to get the best result given what is known about the history of previous selections. For more information search strategies, see [How Hyperparameter Tuning Works](#).

Tags

You enter tags as key-value pairs to assign metadata to tuning jobs to help you manage them. Values are not required. You can use just the key. To see the keys associated with a job, choose the Tags tab on the details page for tuning job. For more information about using tags for tuning jobs, see [Manage Hyperparameter Tuning and Training Jobs](#).

Create Training Job Definitions

To create a training job definition, you need to configure the algorithm and parameters, define the data input and output, and configure resources. You must provide at least one `TrainingJobDefinition` for each HPO tuning job. Each training definition specifies the configuration for an algorithm. To create several definitions for your training job you can clone a job definition. Cloning a job can save time as it copies all of the job settings, including data channels, S3 storage locations for output artifacts. You can then edit the cloned job just for changes needed to configure the algorithm options.

Topics
- Configure algorithm and parameters (p. 2366)
- Define Data Input and Output (p. 2367)
- Configure Training Job Resources (p. 2368)
- Add or Clone a Training Job (p. 2368)

Configure algorithm and parameters

Each training job definition for a tuning job requires a name, permission to access services, and the specification of algorithm options, an objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job.

Name
Provide a unique name for the training definition.

Permissions

Amazon SageMaker requires permissions to call other services on your behalf. Choose an IAM role or let AWS create a role that has the AmazonSageMakerFullAccess IAM policy attached.

Optional Security Settings

The network isolation setting prevents the container from making any outbound network calls. This is required for AWS Marketplace machine learning offerings.

You can also choose to use a private VPC.

Note
Inter-container encryption is only available when creating job definitions from the API.

Algorithm Options

You can choose one of the built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from AWS Marketplace.

- If you choose a built-in algorithm, it has the ECR image information prepopulated.
- If you choose your own container, you must specify the ECR image information. You can select the input mode for the algorithm as file or pipe.
- If you plan to supply your data using a .CSV file from Amazon S3, you should select the file.

Metrics

When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you need to define your metrics. You can define up to 20 metrics for your tuning job to monitor, one of which must be chosen as the objective metric. For more information on how to define a metric for a tuning job, see Define Metrics (p. 2362).

Objective Metric

To find the best training job, set an objective metric and whether to maximize or minimize it. After the training job is complete, you can view the tuning job detail page for a summary of the best training job found using this objective metric.

Hyperparameter Configuration

When you choose a built-in algorithm, the default values for its hyperparameters are set for you, using ranges that are optimized for the algorithm being tuned. You can change these values as you see fit. For example, instead of a range, you can set a fixed value for a hyperparameter by setting the parameter's type to static. Each algorithm has different required and optional parameters. For more information, see Best Practices for Hyperparameter Tuning and Define Hyperparameter Ranges.

Define Data Input and Output

Each training job definition for a tuning job must configures the channels for data inputs, data output locations, and optionally any checkpoint storage locations for each training job.

Input Data Configuration

Input data is defined by channels, each with their own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the...
algorithm you chose supports multiple input channels, you can specify those too. For example, when using the XGBoost churn prediction notebook, you could add two channels: train and validation.

Checkpoint Configuration

Checkpoints are periodically generated during training. You must choose an Amazon S3 location for the checkpoints to be saved. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs. For more information, see Use Checkpoints in Amazon SageMaker (p. 2604).

Output Data Configuration

You must define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an AWS Key Management Service (AWS KMS) key.

Configure Training Job Resources

Each training job definition for a tuning job must configure the resources to deploy, including instance types and counts, managed spot training, and stopping conditions.

Resource Configuration

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

Managed spot training

You can save computer costs for jobs if you have flexibility in start and end times by allowing SageMaker to use spare capacity to run jobs. For more information, see Managed Spot Training in Amazon SageMaker (p. 2603).

Stopping condition

The stopping condition specifies the maximum duration allowed per training job.

Add or Clone a Training Job

Once you have created a training job definition for a tuning job, you are returned to the Training Job Definition(s) panel where you can create additional training job definitions to train additional algorithms. You can select the Add training job definition and work through the steps to define a training job again or choose Clone from the Action menu to replicate an existing training job definition and edit it for the new algorithm. The clone option can save time as it copies all of the job's settings, including the data channels, S3 storage locations. For more information on cloning, see Manage Hyperparameter Tuning and Training Jobs (p. 2369)

Configure Tuning Job Resources

Resource Limits

You can specify the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently (10 at most) and the maximum number of training jobs that the hyperparameter tuning job can run (500 at most). The number of parallel jobs should not exceed the number of nodes you have requested across all of your training definitions. The total number of jobs can't exceed the number of jobs that your definitions are expected to run.

Review and Create HPO Tuning Job

Review the job settings, the training job definition(s), and resource limits. Then select Create hyperparameter tuning job.
Manage Hyperparameter Tuning and Training Jobs

A tuning job can contain many training jobs and creating and managing these jobs and their definitions can become a complex and onerous task. SageMaker provides tools to help facilitate the management of these jobs. Tuning jobs you have run can be accessed from the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/. Select Hyperparameter tuning job from the Training menu to see the list. This page is also where you start the procedure to create a new tuning job by selecting Create hyperparameter tuning job.

To see the training jobs run a part of a tuning job, select one of the hyperparameter tuning jobs from the list. The tabs on the tuning job page allow you to inspect the training jobs, their definitions, the tags and configuration used for the tuning job, and the best training job found during tuning. You can select the best training job or any of the other training jobs that belong to the tuning job to see all of their settings. From here you can create a model that uses the hyperparameter values found by a training job by selecting Create Model or you can clone the training job by selecting Clone.

Cloning

You can save time by cloning a training job that belongs to a hyperparameter tuning job. Cloning copies all of the job's settings, including data channels, S3 storage locations for output artifacts. You can do this for training jobs you have already run from the tuning job page, as just described, or when you are creating additional training job definitions while creating a hyperparameter tuning job, as described in Add or Clone a Training Job (p. 2368) step of that procedure.

Tagging

Automatic Model Tuning launches multiple training jobs within a single parent tuning job to discover the ideal weighting of model hyperparameters. Tags can be added to the parent tuning job as described in the Define job settings (p. 2365) section and these tags are then propagated to the individual training jobs underneath. Customers can use these tags for purposes such as cost allocation or access control. To add tags using the SageMaker SDK, use AddTags API. For more information about using tagging for AWS resources, see Tagging AWS resources.

Example: Hyperparameter Tuning Job

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the XGBoost Algorithm (p. 1990) to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level AWS SDK for Python (Boto) to configure and launch the hyperparameter tuning job, and the AWS Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker high-level Amazon SageMaker Python SDK to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see https://github.com/aws/sagemaker-python-sdk.

Prerequisites

To run the code in this example, you need

- An AWS account and an administrator user (p. 34)
- An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
- A running SageMaker notebook instance (p. 74)

Topics

- Create a Notebook (p. 2370)
Create a Notebook

Create a Jupyter notebook that contains a pre-installed environment with the default Anaconda installation and Python3.

To create a Jupyter notebook

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Open a running notebook instance, by choosing Open next to its name. The Jupyter notebook server page appears:

   ![Jupyter Notebook Server](image)

3. To create a notebook, choose Files, New, and conda_python3.
4. Name the notebook.

Next Step

Get the Amazon SageMaker Boto 3 Client (p. 2370)

Get the Amazon SageMaker Boto 3 Client

Import Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```python
import sagemaker
import boto3
import numpy as np # For performing matrix operations and numerical processing
import pandas as pd # For manipulating tabular data
from time import gmtime, strftime
import os

region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')
```

The preceding code cell defines `region` and `smclient` objects that you will use to call the built-in XGBoost algorithm and set the SageMaker hyperparameter tuning job.
Next Step

Get the SageMaker Execution Role (p. 2371)

Get the SageMaker Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance. You pass the role to the tuning job.

```python
from sagemaker import get_execution_role
role = get_execution_role()
print(role)
```

Next Step

Specify a S3 Bucket to Upload Training Datasets and Store Output Data (p. 2371)

Specify a S3 Bucket to Upload Training Datasets and Store Output Data

Set up a S3 bucket to upload training datasets and save training output data.

To use a default S3 bucket

Use the following code to specify the default S3 bucket allocated for your SageMaker session. `prefix` is the path within the bucket where SageMaker stores the data for the current training job.

```python
sess = sagemaker.Session()
bucket = sess.default_bucket()                  # Set a default S3 bucket
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

(Optional) To use a specific S3 bucket

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain `sagemaker`, and be globally unique. The bucket must be in the same AWS Region as the notebook instance that you use for this example.

```python
bucket = "sagemaker-your-preferred-s3-bucket"
```

Note

The name of the bucket doesn't need to contain `sagemaker` if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the `S3FullAccess` permission.

Next Step

Download, Prepare, and Upload Training Data (p. 2371)

Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.
For more information about the dataset and the data transformation that the example performs, see the hpo_xgboost_direct_marketing_sagemaker_APIs notebook in the Hyperparameter Tuning section of the SageMaker Examples tab in your notebook instance.

Download and Explore the Training Dataset

To download and explore the dataset, run the following code in your notebook:

```bash
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500)  # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)  # Keep the output on one page
data
```

Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```python
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0)  # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired', 'unemployed']), 1, 0)  # Indicator for individuals not actively employed
model_data = pd.get_dummies(data)  # Convert categorical variables to sets of indicators
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx', 'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)
train_data, validation_data, test_data = np.split(model_data.sample(frac=1, random_state=1729), [int(0.7 * len(model_data)), int(0.9*len(model_data))])
pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('test.csv', index=False, header=False)
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/validation.csv')).upload_file('validation.csv')
```

Next Step

Configure and Launch a Hyperparameter Tuning Job (p. 2372)

Configure and Launch a Hyperparameter Tuning Job

To configure and launch a hyperparameter tuning job, complete the following steps.

Topics
- Specify the Hyperparameter Tuning Job Settings (p. 2373)
- Configure the Training Jobs (p. 2374)
Specify the Hyperparameter Tuning Job Settings

To specify settings for the hyperparameter tuning job, you define a JSON object. You pass the object as the value of the `HyperParameterTuningJobConfig` parameter to `CreateHyperParameterTuningJob` when you create the tuning job.

In this JSON object, you specify:

- The ranges of hyperparameters that you want to tune. For more information, see Define Hyperparameter Ranges (p. 2363)
- The limits of the resource that the hyperparameter tuning job can consume.
- The objective metric for the hyperparameter tuning job. An objective metric is the metric that the hyperparameter tuning job uses to evaluate the training job that it launches.

**Note**

To use your own algorithm for hyperparameter tuning, you need to define metrics for your algorithm. For information, see Define Metrics (p. 2362).

The hyperparameter tuning job defines ranges for the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters of the XGBoost Algorithm (p. 1990) built-in algorithm. The objective metric for the hyperparameter tuning job maximizes the `validation:auc` metric that the algorithm sends to CloudWatch Logs.

```json
tuning_job_config = {
  "ParameterRanges": {
    "CategoricalParameterRanges": [],
    "ContinuousParameterRanges": [
      {
        "MaxValue": "1",
        "MinValue": "0",
        "Name": "eta"
      },
      {
        "MaxValue": "2",
        "MinValue": "0",
        "Name": "alpha"
      },
      {
        "MaxValue": "10",
        "MinValue": "1",
        "Name": "min_child_weight"
      }
    ],
    "IntegerParameterRanges": [
      {
        "MaxValue": "10",
        "MinValue": "1",
        "Name": "max_depth"
      }
    ]
  },
  "ResourceLimits": {
    "MaxNumberOfTrainingJobs": 20,
    "MaxParallelTrainingJobs": 3
  },
  "Strategy": "Bayesian",
  "HyperParameterTuningJobObjective": {
```
Configure the Training Jobs

To configure the training jobs that the tuning job launches, define a JSON object that you pass as the value of the `TrainingJobDefinition` parameter of the `CreateHyperParameterTuningJob` call.

In this JSON object, you specify:

- Optional—Metrics that the training jobs emit.
  
  **Note**
  
  Define metrics only when you use a custom training algorithm. Because this example uses a built-in algorithm, you don't specify metrics. For information about defining metrics, see Define Metrics (p. 2362).

- The container image that specifies the training algorithm.
- The input configuration for your training and test data.
- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.
- The values of algorithm hyperparameters that are not tuned in the tuning job.
- The type of instance to use for the training jobs.
- The stopping condition for the training jobs. This is the maximum duration for each training job.

In this example, we set static values for the `eval_metric`, `num_round`, `objective`, `rate_drop`, and `tweedie_variance_power` parameters of the XGBoost Algorithm (p. 1990) built-in algorithm.

SageMaker Python SDK v1

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')

s3_input_train = 's3://{}/{}/train'.format(bucket, prefix)
s3_input_validation = 's3://{}/{}/validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
    {
        "ChannelName": "train",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
            "S3DataSource": {
                "S3DataDistributionType": "FullyReplicated",
                "S3DataType": "S3Prefix",
                "S3Uri": s3_input_train
            }
        }
    },
    {
        "ChannelName": "validation",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
            "S3DataSource": {
                "S3DataDistributionType": "FullyReplicated",
                "S3DataType": "S3Prefix",
                "S3Uri": s3_input_validation
            }
        }
    }
]}
```

```json
"MetricName": "validation:auc",
"Type": "Maximize"
}
}
"DataSource": {
    "S3DataSource": {
        "S3DataDistributionType": "FullyReplicated",
        "S3DataType": "S3Prefix",
        "S3Uri": s3_input_validation
    }
},
"OutputDataConfig": {
    "S3OutputPath": "s3:///{}/{}\/output".format(bucket, prefix)
},
"ResourceConfig": {
    "InstanceCount": 2,
    "InstanceType": "ml.c4.2xlarge",
    "VolumeSizeInGB": 10
},
"RoleArn": role,
"StaticHyperParameters": {
    "eval_metric": "auc",
    "num_round": "100",
    "objective": "binary:logistic",
    "rate_drop": "0.3",
    "tweedie_variance_power": "1.4"
},
"StoppingCondition": {
    "MaxRuntimeInSeconds": 43200
}
}

SageMaker Python SDK v2

training_image = sagemaker.image_uris.retrieve('xgboost', region, '1.0-1')

s3_input_train = 's3://{}//{}//train'.format(bucket, prefix)
s3_input_validation = 's3://{}//{}//validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_train
                }
            }
        },
        {
            "ChannelName": "validation",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_validation
                }
            }
        }]
}
Example: Hyperparameter Tuning Job

```json
{
    "HyperParameterTuningJobName": "MyTuningJob",
    "TuningJobConfig": {
        "OutputDataConfig": {
            "S3OutputPath": "s3://{}/{}\output\".format(bucket,prefix)
        },
        "ResourceConfig": {
            "InstanceCount": 2,
            "InstanceType": "ml.c4.2xlarge",
            "VolumeSizeInGB": 10
        },
        "RoleArn": role,
        "StaticHyperParameters": {
            "eval_metric": "auc",
            "num_round": "100",
            "objective": "binary:logistic",
            "rate_drop": "0.3",
            "tweedie_variance_power": "1.4"
        },
        "StoppingCondition": {
            "MaxRuntimeInSeconds": 43200
        }
    }
}
```

### Name and Launch the Hyperparameter Tuning Job

Now you can provide a name for the hyperparameter tuning job and then launch it by calling the `CreateHyperParameterTuningJob` API. Pass `tuning_job_config`, and `training_job_definition` that you created in previous steps as the values of the parameters.

```python
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = tuning_job_name,
                                          HyperParameterTuningJobConfig = tuning_job_config,
                                          TrainingJobDefinition = training_job_definition)
```

### Next Step

Monitor the Progress of a Hyperparameter Tuning Job (p. 2376)

### Monitor the Progress of a Hyperparameter Tuning Job

To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker console.

#### Topics
- View the Status of the Hyperparameter Tuning Job (p. 2376)
- View the Status of the Training Jobs (p. 2378)
- View the Best Training Job (p. 2379)

### View the Status of the Hyperparameter Tuning Job

To view the status of the hyperparameter tuning job:

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Hyperparameter tuning jobs**.
3. In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:

- **Completed**—The hyperparameter tuning job successfully completed.
- **InProgress**—The hyperparameter tuning job is in progress. One or more training jobs are still running.
- **Failed**—The hyperparameter tuning job failed.
- **Stopped**—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
- **Stopping**—The hyperparameter tuning job is in the process of stopping.

### View the Status of the Training Jobs

**To view the status of the training jobs that the hyperparameter tuning job launched**

1. In the list of hyperparameter tuning jobs, choose the job that you launched.
2. Choose **Training jobs**.

   ![Training jobs screenshot](image)

3. View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.

A training job can be:

- **Completed**—The training job successfully completed.
- **InProgress**—The training job is in progress.
- **Stopped**—The training job was manually stopped before it completed.
- **Failed (Retryable)**—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
- **Failed (Non-retryable)**—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.
Note
Hyperparameter tuning jobs can be stopped and the underlying resources deleted, but the jobs themselves cannot be deleted.

View the Best Training Job

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose Best training job.

To deploy the best training job as a model that you can host at a SageMaker endpoint, choose Create model.

Next Step

Clean up (p. 2379)

Clean up

To avoid incurring unnecessary charges, when you are done with the example, use the AWS Management Console to delete the resources that you created for it.

Note
If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and delete the notebook instance. Stop the instance before deleting it.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/ and delete the bucket that you created to store model artifacts and the training dataset.
3. Open the IAM console at https://console.aws.amazon.com/iam/ and delete the IAM role. If you created permission policies, you can delete them, too.

4. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/ and delete all of the log groups that have names starting with /aws/sagemaker/.

**Stop Training Jobs Early**

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the AWS SDK for Python (Boto 3), set the `TrainingJobEarlyStoppingType` field of the `HyperParameterTuningJobConfig` object that you use to configure the tuning job to `AUTO`.
- If you are using the Amazon SageMaker Python SDK, set the `early_stopping_type` parameter of the `HyperParameterTuner` object to `Auto`.
- In the Amazon SageMaker console, in the **Create hyperparameter tuning job** workflow, under **Early stopping**, choose **Auto**.

For a sample notebook that demonstrates how to use early stopping, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb or open the hpo_image_classification_early_stopping.ipynb notebook in the **Hyperparameter Tuning** section of the **SageMaker Examples** in a notebook instance. For information about using sample notebooks in a notebook instance, see Example Notebooks (p. 298).

**How Early Stopping Works**

When you enable early stopping for a hyperparameter tuning job, SageMaker evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.
- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker stops the current training job.

**Algorithms That Support Early Stopping**

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker algorithms support early stopping:

- **LightGBM** (p. 1957)
- **CatBoost** (p. 1930)
- **AutoGluon-Tabular** (p. 1923)
- **TabTransformer** (p. 1983)
- **Linear Learner Algorithm** (p. 1966)—Supported only if you use `objective_loss` as the objective metric.
- **XGBoost Algorithm** (p. 1990)
• **Image Classification - MXNet** (p. 2113)
• **Object Detection** (p. 2137)
• **Sequence-to-Sequence Algorithm** (p. 2055)
• **IP Insights** (p. 2083)

**Note**
This list of built-in algorithms that support early stopping is current as of December 13, 2018. Other built-in algorithms might support early stopping in the future. If an algorithm emits a metric that can be used as an objective metric for a hyperparameter tuning job (preferably a validation metric), then it supports early stopping.

To use early stopping with your own algorithm, you must write your algorithms such that it emits the value of the objective metric after each epoch. The following list shows how you can do that in different frameworks:

**TensorFlow**
Use the `tf.keras.callbacks.ProgbarLogger` class. For information, see the `tf.keras.callbacks.ProgbarLogger API`.

**MXNet**
Use the `mxnet.callback.LogValidationMetricsCallback`. For information, see the `mxnet.callback APIs`.

**Chainer**
Extend chainer by using the `extensions.Evaluator` class. For information, see the `chainer.training.extensions.Evaluator API`.

**PyTorch and Spark**
There is no high-level support. You must explicitly write your training code so that it computes objective metrics and writes them to logs after each epoch.

---

**Run a Warm Start Hyperparameter Tuning Job**

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see *How Hyperparameter Tuning Works* (p. 2360). Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

**Note**
Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

**Reasons you might want to consider warm start include:**

• You want to gradually increase the number of training jobs over several tuning jobs based on the results you see after each iteration.
• You get new data, and want to tune a model using the new data.
• You want to change the ranges of hyperparameters that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.
• You stopped a previous hyperparameter job early or it stopped unexpectedly.

Topics
• Types of Warm Start Tuning Jobs (p. 2382)
• Warm Start Tuning Restrictions (p. 2382)
• Warm Start Tuning Sample Notebook (p. 2383)
• Create a Warm Start Tuning Job (p. 2383)

Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

IDENTICAL_DATA_AND_ALGORITHM

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run a warm start tuning job of type IDENTICAL_DATA_AND_ALGORITHM, there is an additional field in the response to DescribeHyperParameterTuningJob named OverallBestTrainingJob. The value of this field is the TrainingJobSummary for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

TRANSFER_LEARNING

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

• A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (Completed, Stopped, or Failed) before you start the new tuning job.
• The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
• The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.
• The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.

• The number of total changes from tunable hyperparameters in the parent jobs to static hyperparameters in the new tuning job, plus the number of changes in the values of static hyperparameters cannot be more than 10. Each value in a categorical hyperparameter counts against this limit. For example, if the parent job has a tunable categorical hyperparameter with the possible values red and blue, you change that hyperparameter to static in the new tuning job, that counts as 2 changes against the allowed total of 10. If the same hyperparameter had a static value of red in the parent job, and you change the static value to blue in the new tuning job, it also counts as 2 changes.

• Warm start tuning is not recursive. For example, if you create MyTuningJob3 as a warm start tuning job with MyTuningJob2 as a parent job, and MyTuningJob2 is itself an warm start tuning job with a parent job MyTuningJob1, the information that was learned when running MyTuningJob1 is not used for MyTuningJob3. If you want to use the information from MyTuningJob1, you must explicitly add it as a parent for MyTuningJob3.

• The training jobs launched by every parent job in a warm start tuning job count against the 500 maximum training jobs for a tuning job.

• Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm start tuning jobs.

Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/hpo_image_classification_warmstart.ipynb. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Example Notebooks (p. 298). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The warm start tuning example notebook is located in the Hyperparameter tuning section, and is named hpo_image_classification_warmstart.ipynb. To open a notebook, click on its Use tab and select Create copy.

Create a Warm Start Tuning Job

You can use either the low-level AWS SDK for Python (Boto 3) or the high-level SageMaker Python SDK to create a warm start tuning job.

Topics

• Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3)) (p. 2383)
• Create a Warm Start Tuning Job (SageMaker Python SDK) (p. 2384)

Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3))

To use warm start tuning, you specify the values of a HyperParameterTuningJobWarmStartConfig object, and pass that as the WarmStartConfig field in a call to CreateHyperParameterTuningJob.

The following code shows how to create a HyperParameterTuningJobWarmStartConfig object and pass it to CreateHyperParameterTuningJobJob by using the low-level SageMaker API for Python (Boto 3).

Create the HyperParameterTuningJobWarmStartConfig object:

```python
warm_start_config = {
    "ParentHyperParameterTuningJobs" : [
        {"HyperParameterTuningJobName" : 'MyParentTuningJob'}
    ]
}  
```
Create the warm start tuning job:

```python
smclient = boto3.Session().client('sagemaker')
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = 'MyWarmStartTuningJob',
                                           HyperParameterTuningJobConfig = tuning_job_config, # See notebook for tuning configuration
                                           TrainingJobDefinition = training_job_definition, # See notebook for job definition
                                           WarmStartConfig = warm_start_config)
```

Create a Warm Start Tuning Job (SageMaker Python SDK)

To use the Amazon SageMaker Python SDK to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a `WarmStartConfig` object.
- Pass the `WarmStartConfig` object as the value of the `warm_start_config` argument of a `HyperparameterTuner` object.
- Call the `fit` method of the `HyperparameterTuner` object.

For more information about using the Amazon SageMaker Python SDK for hyperparameter tuning, see https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning.

This example uses an estimator that uses the Image Classification - MXNet (p. 2113) algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see Define Hyperparameter Ranges (p. 2363).

```python
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                        'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a `WarmStartConfig` object.

```python
from sagemaker.tuner import WarmStartConfig, WarmStartTypes
parent_tuning_job_name = "MyParentTuningJob"
warm_start_config = WarmStartConfig(warm_start_type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM,
                                     parents=(parent_tuning_job_name))
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, `imageclassification` is an estimator that was created previously.

```python
imageclassification.set_hyperparameters(num_layers=18,
                                        image_shape='3,224,224',
                                        num_classes=257,
                                        num_training_samples=15420,
                                        mini_batch_size=128,
                                        epochs=30,
                                        optimizer='sgd',
                                        top_k='2',
                                        precision_dtype='float32',
                                        )
```

2384
Now create the HyperparameterTuner object and pass the WarmStartConfig object that you previously created as the warm_start_config argument.

```
tuner_warm_start = HyperparameterTuner(imageclassification,
    'validation:accuracy',
    hyperparameter_ranges,
    objective_type='Maximize',
    max_jobs=10,
    max_parallel_jobs=2,
    base_tuning_job_name='warmstart',
    warm_start_config=warm_start_config)
```

Finally, call the `fit` method of the HyperparameterTuner object to launch the warm start tuning job.

```
tuner_warm_start.fit(
    {'train': s3_input_train, 'validation': s3_input_validation},
    include_cls_metadata=False)
```

### Resource Limits for Automatic Model Tuning

SageMaker sets the following default limits for resources used by automatic model tuning:

- **Number of parallel (concurrent) hyperparameter tuning jobs:** 100
- **Number of hyperparameters that can be searched:** 30
  
  **Note**
  
  Every possible value in a categorical hyperparameter counts against this limit.

- **Number of metrics defined per hyperparameter tuning job:** 20
- **Number of parallel (concurrent) training jobs per hyperparameter tuning job:** 10
  
  **Note**
  
  This can be increased to 100 jobs.

- **[Bayesian search strategy] Number of training jobs per hyperparameter tuning job:** 750
- **[Random search strategy] Number of training jobs per hyperparameter tuning job:** 750
  
  **Note**
  
  This can be increased up to 10,000 jobs.

- **Maximum run time for a hyperparameter tuning job:** 30 days

When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker training jobs, see [SageMaker Limits](#). Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one `ml.m4.xlarge` instance. The following limits apply:

- **Number of concurrent hyperparameter tuning jobs:** You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- **Number of training jobs per hyperparameter tuning job:** You don't need to increase the limit, because 100 training jobs is below the limit of 750.
- **Number of concurrent training jobs per hyperparameter tuning job:** You need to request a limit increase to 20, because the default limit is 10.
• SageMaker training `ml.m4.xlarge` instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.

• SageMaker training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.

To request a quota increase:

1. Open the AWS Support Center page, sign in if necessary, and then choose Create case.
2. On the Create case page, choose Service limit increase.
4. On the Requests panel for Request 1, select the Region, the resource Limit to increase and the New Limit value you are requesting. Select Add another request if you have additional requests for quota increases.
5. In the Case description panel, provide a description of your use case.
6. In the Contact options panel, select your preferred Contact methods (Web, Chat or Phone) and then choose Submit.

Best Practices for Hyperparameter Tuning

Hyperparameter optimization is not a fully-automated process. To improve optimization, use the following guidelines when you create hyperparameters.
Choosing the Number of Hyperparameters

The computational complexity of a hyperparameter tuning job depends primarily on the number of hyperparameters whose range of values Amazon SageMaker has to search through during optimization. Although you can simultaneously specify up to 20 hyperparameters to optimize for a tuning job, limiting your search to a much smaller number is likely to give you better results.

Choosing Hyperparameter Ranges

The range of values for hyperparameters that you choose to search can significantly affect the success of hyperparameter optimization. Although you might want to specify a very large range that covers every possible value for a hyperparameter, you get better results by limiting your search to a small range of values. If you know that you get the best metric values within a subset of the possible range, consider limiting the range to that subset.

Using Logarithmic Scales for Hyperparameters

During hyperparameter tuning, SageMaker attempts to figure out if your hyperparameters are log-scaled or linear-scaled. Initially, it assumes that hyperparameters are linear-scaled. If they are in fact log-scaled, it might take some time for SageMaker to discover that fact. If you know that a hyperparameter is log-scaled and can convert it yourself, doing so could improve hyperparameter optimization.

Choosing the Best Number of Concurrent Training Jobs

When setting the resource limit `MaxParallelTrainingJobs` for the maximum number of concurrent training jobs that a hyperparameter tuning job can launch, consider the following tradeoff. Running more hyperparameter tuning jobs concurrently gets more work done quickly, but a tuning job improves only through successive rounds of experiments. Typically, running one training job at a time achieves the best results with the least amount of compute time.

Running Training Jobs on Multiple Instances

When a training job runs on multiple instances, hyperparameter tuning uses the last-reported objective metric value from all instances of that training job as the value of the objective metric for that training job. Design distributed training jobs so that the objective metric reported is the one that you want.

Amazon SageMaker Distributed Training Libraries

SageMaker provides distributed training libraries for data parallelism and model parallelism. The libraries are optimized for the SageMaker training environment, help adapt your distributed training jobs to SageMaker, and improve training speed and throughput.
Get Started with Distributed Training

If you're familiar with distributed training, follow one of the links to your preferred strategy or framework to get started. Otherwise, continue on to the next section to learn some distributed training concepts.

SageMaker distributed training libraries:

- SageMaker's Distributed Data Parallel Library (p. 2396)
- SageMaker's Distributed Model Parallel (p. 2428)

Note

The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Basic Distributed Training Concepts

SageMaker’s distributed training libraries use the following distributed training terms and features.

Datasets and Batches

- **Training Dataset**: All of the data you use to train the model.
- **Global batch size**: The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: \[ \text{global batch size} = (\text{the number of model replicas}) \times (\text{per-replica batch size}) \]. A single batch of global batch size is often referred to as the *mini-batch* in machine learning literature.
- **Per-replica batch size**: When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.
- **Micro-batch**: A subset of the mini-batch or, if hybrid model and data parallelism is used, it is a subset of the per-replica sized batch. When you use SageMaker’s distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an *execution schedule* defined by the library’s runtime.
Training

- **Epoch**: One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.

- **Iteration**: A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the global batch size and the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.

- **Learning rate**: A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model's ability to converge as well as the speed and optimality of convergence.

Instances and GPUs

- **Instances**: An AWS machine learning compute instance. These are also referred to as nodes.

- **Cluster size**: When using SageMaker's distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise, communication between the nodes can add overhead and lead to slower training times. The SageMaker distributed training library is designed to optimize communication between AWS ML compute instances, leading to higher device utilization and faster training times.

Distributed Training Solutions

- **Data parallelism**: A strategy in distributed training where a training dataset is split up across multiple processing nodes (such as AWS ML Instances), and each processing node contains a replica of the model. Each node receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.

- **Model parallelism**: A strategy in distributed training where the model partitioned across multiple processing nodes (such as AWS ML Instances). The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single node. Each node carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.

- **Pipeline Execution Schedule (Pipelining)**: The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see Pipeline Execution Schedule.

Example

The following example demonstrates how these terms might be used to describe a training job that uses hybrid model and data parallelism:

A 2-way data parallelism and 4-way model parallelism training job is launched with a global batch size of 64 images. This training job requires a total of 8 GPUs. Each of the two model replicas processes a per-replica batch of size 32. During the forward and backward pass, a per-replica batch is further divided up into micro-batches. These micro-batches are processed in an interleaved fashion using a pipelined execution schedule.

The training dataset includes 640 images, and so a single epoch takes 10 iterations.
Advanced Concepts

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: scaling model size and scaling training data. While model size and complexity can result in better accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.

Not all models handle training data scaling equally well because they need to ingest all the training data in memory for training. They only scale vertically, and to bigger and bigger instance types. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD). In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called mini-batches. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an epoch. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called data parallel distributed training, and is the most commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called allreduce that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware subtracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing device, such as a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called model-parallel distributed training.

Strategies

Distributed training is usually split by two approaches: data parallel and model parallel. Data parallel is the most common approach to distributed training: You have a lot of data, batch it up, and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A model parallel approach is used with large models that won’t fit in a node’s memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms network and model are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading the model back onto the network with all your pre-trained parameters and their weights loads a large model into memory. When you break apart a model to split it across nodes, you’re also breaking apart the underlying network. A network consists of layers, and to split up the network, you put layers on different compute devices.
A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is inherently sequential in both forward and backward passes, and at a given time, only one GPU can actively compute, while the others wait on the activations to be sent. Modern model parallel libraries solve this problem by using pipeline execution schedules to improve device utilization. However, only the Amazon SageMaker’s distributed model parallel library includes automatic model splitting. The two core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the process of implementing model parallelism by making automated decisions that lead to efficient device utilization.

**Train with Data Parallel and Model Parallel**

If you are training with a large dataset, start with a data parallel approach. If you run out of memory during training, you may want to switch to a model parallel approach, or try hybrid model and data parallelism. You can also try the following to improve performance with data parallel:

- Change your model's hyperparameters.
- Reduce the batch size.
- Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory, then you should try model-parallel training.

Try gradient compression (FP16, INT8):

- On NVIDIA TensorCore-equipped hardware, using mixed precision training creates both speed-up and memory consumption reduction.
- SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:
  - **Automatic Mixed Precision for Deep Learning** in the [NVIDIA Developer Docs](https://developer.nvidia.com/deeplearning/amp)
  - **Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs** in the [PyTorch Blog](https://pytorch.org/blog/)
  - **TensorFlow mixed precision APIs** in the [TensorFlow documentation](https://www.tensorflow.org/)

Try reducing the input size:

- Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down, or adjust the GPUs up to spread the batch.
- Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error rate thereby disrupting the model from converging. For example, if you prototyped your network on a single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a single node.

Start with model-parallel training when:

- Your model does not fit on a single device.
- Due to your model size, you're facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.
Optimize Distributed Training

Customize hyperparameters for your use case and your data to get the best scaling efficiency. In the following discussion, we highlight some of the most impactful training variables and provide references to state-of-the-art implementations so you can learn more about your options. Also, we recommend that you refer to your preferred framework’s distributed training documentation.

• Apache MXNet distributed training
• PyTorch distributed training
• TensorFlow distributed training

Batch Size

SageMaker distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

Tip
Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.

A number of techniques have been developed to maintain good model convergence when batch is increased.

Mini-Batch Size

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

• Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Goya et al.
• PowerAI DDL, Cho et al.

• Large Batch Optimization for Deep Learning: Training BERT in 76 Minutes, You et al.
• Accelerated Large Batch Optimization of BERT Pretraining in 54 minutes, Zheng et al.
• Deep Gradient Compression, Lin et al.
Scenarios

The following sections cover scenarios in which you may want to scale up training, and how you can do so using AWS resources.

Scaling from a Single GPU to Many GPUs

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer that you are willing to wait. Sometimes, the training doesn't work at all because the model or the training data is too large. One solution is to increase the number of GPUs you use for training. On an instance with multiple GPUs, like a p3.16xlarge that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on p3.2xlarge with one GPU.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>GPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>p3.2xlarge</td>
<td>1</td>
</tr>
<tr>
<td>p3.8xlarge</td>
<td>4</td>
</tr>
<tr>
<td>p3.16xlarge</td>
<td>8</td>
</tr>
<tr>
<td>p3dn.24xlarge</td>
<td>8</td>
</tr>
</tbody>
</table>

Note

The ml instance types used by SageMaker training have the same number of GPUs as the corresponding p3 instance types. For example, ml.p3.8xlarge has the same number of GPUs as p3.8xlarge - 4.

Scaling from a Single Instance to Multiple Instances

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each p3 instance type.

If you have made the jump from a single GPU on a p3.2xlarge to four GPUs on a p3.8xlarge, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a p3.16xlarge before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker Python SDK estimator function by setting your instance_count. For example, you can set instance_type = p3.16xlarge and instance_count = 2. Instead of the eight GPUs on a single p3.16xlarge, you have 16 GPUs across two identical instances. The following chart shows scaling and throughput starting with eight GPUs on a single instance and increasing to 64 instances for a total of 256 GPUs.
Availability Zones and Network Backplane

With multiple instances, it's important to understand the network that connects the instances, how they read the training data, and how they share information between themselves (for example, communication between the nodes in the cluster when doing an AllReduce operation).

First, your instances need to be in the same Region and same Availability Zone. For example, instances in us-west-2 must all be in us-west-2a. When you use the SageMaker Python SDK, this is handled for you. If you use Amazon EC2 and orchestrate your own training clusters, you need to be aware of this, or your training speeds suffer.

Your training data should also be in the same Availability Zone. When you use a SageMaker estimator, you pass in the Region and the S3 bucket, and if the data is not in the Region you set, you get an error.

Optimized GPU, Network, and Storage

The p3dn.24xlarge instance type was designed for fast local storage and a fast network backplane with up to 100 gigabits, and we highly recommend it as the most performant option for distributed training. SageMaker supports streaming data modes from S3, referred to as pipe mode. For HPC loads like distributed training, we recommend Amazon FSx for your file storage.

Custom Training Scripts

While SageMaker makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker's container guide for Deep Learning Containers, and various example notebooks that demonstrate implementations.

SageMaker Distributed Training Features and Libraries

The SageMaker built-in algorithms consists of 18 popular machine learning algorithms: 17 ML algorithms and the Reinforcement Learning algorithm. Many of them are rewritten from scratch to be scalable and distributed out of the box.

If you want to use distributed training strategies for deep learning tasks such as computer vision and natural language processing, we recommend that you use Amazon SageMaker's distributed training libraries. SageMaker's distributed training libraries make it easier for you to write highly scalable and cost-effective custom data parallel and model parallel deep learning training jobs.

SageMaker distributed training libraries offer both data parallel and model parallel training strategies. It combines software and hardware technologies to improve inter-GPU and inter-node communications. It extends SageMaker's training capabilities with built-in options that require only small code changes to your training scripts.

- SageMaker's Distributed Data Parallel Library (p. 2396)
- SageMaker's Distributed Model Parallel (p. 2428)

If you want to use open source distributed training frameworks such as Horovod and MPI, follow instructions in the following pages in the SageMaker Python SDK documentation:

- PyTorch Distributed Training and SageMaker PyTorch Estimator's distribution argument
SageMaker's Distributed Data Parallel Library

The SageMaker distributed data parallel library extends SageMaker training capabilities on deep learning models with near-linear scaling efficiency, achieving fast time-to-train with minimal code changes.

When training a model on a large amount of data, machine learning practitioners often turn to distributed training to reduce the time to train. In some cases, where time is of the essence, the business requirement is to finish training as quickly as possible or at least within a constrained time period. Then, distributed training is scaled to use a cluster of multiple nodes—not just multiple GPUs in a computing instance, but multiple instances with multiple GPUs. As the cluster size increases, so does the significant drop in performance. This drop in performance is primarily caused by the communications overhead between nodes in a cluster.

To resolve such overhead problems, SageMaker offers two distributed training options: SageMaker model parallel and SageMaker data parallel. This guide focuses on how to train models using the SageMaker data parallel library.

- The library optimizes your training job for AWS network infrastructure and Amazon EC2 instance topology.
- The library takes advantage of gradient updates to communicate between nodes with a custom AllReduce algorithm.

To track the latest updates of the library, see the SageMaker Distributed Data Parallel Release Notes in the SageMaker Python SDK documentation.

For more information about training with a model-parallel strategy, see SageMaker's Distributed Model Parallel (p. 2428).

Introduction to SageMaker's Distributed Data Parallel Library

Why Use SageMaker Distributed Data Parallel Library?

SageMaker's distributed data parallel library addresses communications overhead in two ways:

1. The library performs AllReduce, a key operation during distributed training that is responsible for a large portion of communication overhead.
2. The library performs optimized node-to-node communication by fully utilizing AWS's network infrastructure and Amazon EC2 instance topology.

Use this data parallel library to increase speed by up to 25% in training models such as BERT. While implementations like Horovod offer sub-linear performance at scale, this library offers near-linear performance at scale. This means that you get a faster training time and a lower cost to train a model.
Note
The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Training Benchmarks

</tr>
</tbody>
</table>

Using instance type p3dn.24xlarge and on 2, 4, and 8 node clusters:

- **BERT**: When used with PyTorch, the SageMaker library is 41%, 52%, and 13% faster than PyTorch-DDP.
- **MaskRCNN**: When used with PyTorch, the SageMaker library is 4%, 19%, and 15% faster than PyTorch-DDP.

These benchmarks were run on PyTorch v1.6 using ml.p3dn.24xlarge instances. You can find the training code on the SageMaker examples website. The examples website also has benchmark training code for these models using TensorFlow 2.3.

Optimal Bandwidth Use with Balanced Fusion Buffer

SageMaker's distributed data parallel library uses a communication pattern similar to parameter servers to reduce the amount of data transferred and the number of steps involved in averaging gradients from multiple GPUs. It also uses a new technique called balanced fusion buffers to make optimal use of the bandwidth available across all nodes in the cluster.

One key disadvantage of traditional parameter servers is their suboptimal use of available network bandwidth. Parameter servers treat variables as atomic units and place each variable on one server. Since gradients become available sequentially during the backward pass, at any given instant, there is imbalance in the volume of data being sent and received from different servers. Some servers are receiving and sending more data, some less, and some none. This problem becomes worse as the number of parameter servers increases.

The library addresses these problems by introducing **balanced fusion buffers**. A balanced fusion buffer is a buffer in the GPU that holds the gradients until the size of the buffer exceeds a threshold. In a setup with N parameter servers, when the buffer exceeds the threshold, the balanced fusion buffer is copied to CPU memory, sharded into N parts, and the ith part is sent to the ith parameter server. Each server receives...
exactly the same number of bytes from a balanced fusion buffer. The ith server receives the ith partition of the balanced fusion buffer from all workers, sums them up, and sends the results back to all workers. Since all the servers participate equally in averaging each balanced fusion buffer, server bandwidth is efficiently utilized.

**Optimal GPU Usage with Efficient AllReduce Overlapping with a Backward Pass**

SageMaker's distributed data parallel library achieves optimal overlapping of the AllReduce operation with the backward pass, significantly improving the GPU utilization, and achieves near-linear scaling efficiency and faster time to train by optimizing tasks between CPUs and GPUs. The library performs AllReduce in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library faster.

- **Leverages CPUs**: The library uses CPUs to AllReduce gradients, offloading this task from the GPUs.
- **Improved GPU usage**: The cluster's GPUs focus on computing gradients, improving their utilization throughout training.

**SageMaker Distributed Data Parallel Architecture**

The library supports larger compute instances that have 8 GPUs per node: `ml.p3.16xlarge`, `ml.p3dn.24xlarge`, and `ml.p4d.24xlarge`. The high-level workflow of the SageMaker distributed data parallel library is as following:

1. The library assigns ranks to GPUs (workers).
2. At each iteration, the library divides each global batch by the total number of workers (world size) and assigns small batches (batch shards) to the workers.
   - The size of the global batch is `(number of nodes in a cluster) * (number of GPUs per node) * (per batch shard)`.
   - A batch shard (small batch) is a subset of dataset assigned to each GPU (worker) per iteration.
3. The library launches a training script on each worker.
4. The library manages copies of model weights and gradients from the workers at the end of every iteration.
5. The library synchronizes model weights and gradients across the workers to aggregate a single trained model.

The following architecture diagram shows an example of how the library sets up data parallelism for a cluster of 3 nodes.
To start using the SageMaker distributed data parallel library, see Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2411) to set up a SageMaker estimator through Amazon SageMaker Python SDK, and Run a SageMaker Distributed Training Job with Data Parallelism (p. 2403) to adapt your training script using the SageMaker distributed data parallel library.

**Supported Frameworks, AWS Regions, and Instances Types**

Before using the SageMaker data parallel library, check what are the supported ML frameworks and instance types and if there are enough quotas in your AWS account and AWS Region.

**Supported Frameworks**

The following tables show the deep learning frameworks and their versions that SageMaker and the SageMaker distributed data parallel library support. The SageMaker data parallel library is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.

**Topics**

- PyTorch (p. 2400)
- PyTorch Lightning (p. 2401)
- TensorFlow (p. 2402)
- Hugging Face Transformers (p. 2402)

** Note

PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the PyTorch DLCs. When you construct a SageMaker PyTorch estimator and submit a training job request in Step 2, you need to provide requirements.txt to install pytorch-lightning and lightning-bolts in the SageMaker PyTorch training container.

```bash
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the requirements.txt file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.
## TensorFlow

### Hugging Face Transformers

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

### AWS Regions

The SageMaker data parallel library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker are in service. For more information, see Available Deep Learning Containers Images.

### Supported Instance Types

The SageMaker data parallel library requires one of the following ML instance types.

<table>
<thead>
<tr>
<th>Instance type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.p3.16xlarge</td>
</tr>
</tbody>
</table>
Instance type

<table>
<thead>
<tr>
<th>Instance type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.p3dn.24xlarge</td>
</tr>
<tr>
<td>ml.p4d.24xlarge</td>
</tr>
</tbody>
</table>

For specs of the instance types, see the **Accelerated Computing** section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge for training job usage' is 0 Instances, with current utilization of 0 Instances and a request delta of 1 Instances.
Please contact AWS support to request an increase for this limit.
```

**Run a SageMaker Distributed Training Job with Data Parallelism**

SageMaker's distributed data parallel library APIs are designed for ease of use and to provide seamless integration with existing distributed training toolkits.

- **SageMaker Python SDK with the library API** – In most cases, all you have to change in your training script is the data parallel library import statements. Swap these out with the SageMaker data parallel library equivalents.
- **Focus on your model training without infrastructure management** – When training a deep learning model with the library on SageMaker, you can focus on writing your training script and model training. You can run a training job using estimator classes provided by the SageMaker Python SDK. The estimator classes help prepare ML instances, load datasets from specified data resources, submit the training job using your training script, and shut down the instances after the training job is completed.

To begin, you need to adapt TensorFlow or PyTorch training scripts to use the library. The following topics provide instructions on how to modify your training script.

**Topics**

- Step 1: Modify Your Own Training Script (p. 2403)
- Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2411)

**Step 1: Modify Your Own Training Script**

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker distributed data parallel library. To use the library-specific API functions and parameters, we recommend you use this documentation alongside the SageMaker data parallel library APIs in the SageMaker Python SDK documentation.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed data parallel library, see Amazon SageMaker Distributed Training Notebook Examples (p. 2493).

**Topics**

- Modify a TensorFlow Training Script (p. 2404)
- Modify a PyTorch Training Script (p. 2406)
• Modify a PyTorch Lightning Script (p. 2409)

Modify a TensorFlow Training Script

The following steps show you how to modify a TensorFlow training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. For additional details on each API that the library offers for TensorFlow, see the SageMaker distributed data parallel TensorFlow API documentation.

Note
SageMaker distributed data parallel is adaptable to TensorFlow training scripts composed of \texttt{tf} core modules except \texttt{tf.keras} modules. SageMaker distributed data parallel does not support TensorFlow with Keras implementation.

Note
SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its \texttt{AllReduce} operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
- Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
- TensorFlow mixed precision APIs in the TensorFlow documentation

1. Import the library's TensorFlow client and initialize it.

```python
import smdistributed.dataparallel.tensorflow as sdp
sdp.init()
```

2. Pin each GPU to a single \texttt{smdistributed.dataparallel} process with \texttt{local_rank}—this refers to the relative rank of the process within a given node. The \texttt{sdp.tensorflow.local_rank()} API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the following code block as \texttt{sdp.local_rank()}.

```python
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')
```

3. Scale the learning rate by the number of workers. The \texttt{sdp.tensorflow.size()} API provides you the number of workers in the cluster. This is invoked in the following code block as \texttt{sdp.size()}.

```python
learning_rate = learning_rate * sdp.size()
```

4. Use the library's \texttt{DistributedGradientTape} to optimize \texttt{AllReduce} operations during training. This wraps \texttt{tf.GradientTape}.

```python
with tf.GradientTape() as tape:
    output = model(input)
    loss_value = loss(label, output)

# SageMaker data parallel: Wrap tf.GradientTape with the library's DistributedGradientTape
```
5. Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. Use the sdp.tensorflow.broadcast_variables API after the model and optimizer variables are initialized. This is invoked in the following code block as sdp.broadcast_variables().

   ```python
   sdp.broadcast_variables(model.variables, root_rank=0)
   sdp.broadcast_variables(opt.variables(), root_rank=0)
   ```

6. Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

   ```python
   if sdp.rank() == 0:
       checkpoint.save(checkpoint_dir)
   ```

The following is an example TensorFlow training script for distributed training with the library.

```python
import tensorflow as tf
# SageMaker data parallel: Import the library TF API
import smdistributed.dataparallel.tensorflow as sdp
# SageMaker data parallel: Initialize the library
sdp.init()
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    # SageMaker data parallel: Pin GPUs to a single library process
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)

# Define Model
mnist_model = tf.keras.Sequential(...)
loss = tf.losses.SparseCategoricalCrossentropy()

# SageMaker data parallel: Scale Learning Rate
# LR for 8 node run : 0.000125
# LR for single node run : 0.001
opt = tf.optimizers.Adam(0.000125 / sdp.size())

@tf.function
def training_step(images, labels, first_batch):
    with tf.GradientTape() as tape:
        probs = mnist_model(images, training=True)
        loss_value = loss(labels, probs)

        # SageMaker data parallel: Wrap tf.GradientTape with the library's DistributedGradientTape
        tape = sdp.DistributedGradientTape(tape)

        grads = tape.gradient(loss_value, mnist_model.trainable_variables)
        opt.apply_gradients(zip(grads, mnist_model.trainable_variables))

    if first_batch:
        # SageMaker data parallel: Broadcast model and optimizer variables
```
After you have completed adapting your training script, move on to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2411).

Modify a PyTorch Training Script

In the SageMaker data parallel library v1.4.0 and later, the library is available as a backend option for the PyTorch distributed package. You only need to import the library once at the top of your training script and set it as the PyTorch distributed backend during initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. To find the latest API documentation for the library, see the SageMaker distributed data parallel APIs for PyTorch in the SageMaker Python SDK documentation. To learn more about the PyTorch distributed package and backend options, see Distributed communication package - torch.distributed.

Important
Because the SageMaker distributed data parallelism library v1.4.0 and later works as a backend of PyTorch distributed, the following smdistributed APIs for the PyTorch distributed package are deprecated.

- smdistributed.dataparallel.torch.distributed is deprecated. Use the torch.distributed package instead.
- smdistributed.dataparallel.torch.parallel.DistributedDataParallel is deprecated. Use the torch.nn.parallel.DistributedDataParallel API instead.

If you need to use the previous versions of the library (v1.3.0 or before), see the archived SageMaker distributed data parallel library documentation in the SageMaker Python SDK documentation.

Use the SageMaker Distributed Data Parallel Library as the Backend of torch.distributed

To use the SageMaker distributed data parallel library, the only thing you need to do is to import the SageMaker distributed data parallel library's PyTorch client (smdistributed.dataparallel.torch.torch_smdatap). The client registers smddp as a backend for PyTorch. When you initialize the PyTorch distributed process group using the torch.distributed.init_process_group API, make sure you specify 'smdatap' to the backend argument.

```python
import smdistributed.dataparallel.torch.torch_smdatap
import torch.distributed as dist

dist.init_process_group(backend='smdatap')
```

Note
The smdatap backend currently does not support creating subprocess groups with the torch.distributed.new_group() API. You cannot use the smdatap backend concurrently with other process group backends such as NCCL and Gloo.
If you already have a working PyTorch script and only need to add the backend specification, you can proceed to Using the SageMaker Framework Estimators For PyTorch and TensorFlow (p. 2411) in the Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2411) topic.

If you still need to modify your training script to properly use the PyTorch distributed package, follow the rest of the procedures on this page.

**Preparing a PyTorch Training Script for Distributed Training**

The following steps provide additional tips on how to prepare your training script to successfully run a distributed training job using PyTorch.

**Note**

In v1.4.0, the SageMaker distributed data parallel library supports the following collective primitive data types of the torch.distributed interface: `all_reduce`, `broadcast`, `reduce`, `all_gather`, and `barrier`.

1. Import the PyTorch distributed modules.

```python
import torch
import torch.distributed as dist
from torch.nn.parallel import DistributedDataParallel as DDP
```

2. After parsing arguments and defining a batch size parameter (for example, `batch_size=args.batch_size`), add two lines of code to resize the batch size per worker (GPU). PyTorch's DataLoader operation does not automatically handle the batch resizing for distributed training.

```python
batch_size //= dist.get_world_size()
batch_size = max(batch_size, 1)
```

3. Pin each GPU to a single SageMaker data parallel library process with `local_rank`—this refers to the relative rank of the process within a given node.

You can retrieve the rank of the process from the `LOCAL_RANK` environment variable.

```python
import os
local_rank = os.environ['LOCAL_RANK']
torch.cuda.set_device(local_rank)
```

4. After defining a model, wrap it with the PyTorch `DistributedDataParallel` API.

```python
model = ...

# Wrap the model with the PyTorch DistributedDataParallel API
model = DDP(model)
```

5. When you call the `torch.utils.data.distributed.DistributedSampler` API, specify the total number of processes (GPUs) participating in training across all the nodes in the cluster. This is called `world_size`, and you can retrieve the number from the `torch.distributed.get_world_size()` API. Also, specify the rank of each process among all processes using the `torch.distributed.get_rank()` API.

```python
from torch.utils.data.distributed import DistributedSampler

train_sampler = DistributedSampler(
    train_dataset,
    num_replicas = dist.get_world_size(),
    rank = dist.get_rank()
)
6. Modify your script to save checkpoints only on the leader process (rank 0). The leader process has a synchronized model. This also avoids other processes overwriting the checkpoints and possibly corrupting the checkpoints.

```python
if dist.get_rank() == 0:
    torch.save(...)
```

The following example code shows the structure of a PyTorch training script with `smddp` as the backend.

```python
import os
import torch

# SageMaker data parallel: Import the library PyTorch API
import smdistributed.dataparallel.torch.torch_smddp

# SageMaker data parallel: Import PyTorch's distributed API
import torch.distributed as dist
from torch.nn.parallel import DistributedDataParallel as DDP

# SageMaker data parallel: Initialize the process group
dist.init_process_group(backend='smddp')

class Net(nn.Module):
    ...
    # Define model
def train(...):
        ...
        # Model training
def test(...):
            ...
            # Model evaluation
def main():
    # SageMaker data parallel: Scale batch size by world size
    batch_size //= dist.get_world_size()
    batch_size = max(batch_size, 1)
    # Prepare dataset
    train_dataset = torchvision.datasets.MNIST(...)
    
    # SageMaker data parallel: Set num_replicas and rank in DistributedSampler
    train_sampler = torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=dist.get_world_size(),
        rank=dist.get_rank())
    
    train_loader = torch.utils.data.DataLoader(..)
    
    # SageMaker data parallel: Wrap the PyTorch model with the library's DDP
    model = DDP(Net().to(device))
    
    # SageMaker data parallel: Pin each GPU to a single library process.
    local_rank = os.environ["LOCAL_RANK"]
    torch.cuda.set_device(local_rank)
    model.cuda(local_rank)
    # Train
optimizer = optim.Adadelta(...)  
scheduler = StepLR(...)  
for epoch in range(1, args.epochs + 1):  
    train(...)  
    if rank == 0:  
        test(...)  
    scheduler.step()  

    # SageMaker data parallel: Save model on master node.  
    if dist.get_rank() == 0:  
        torch.save(...)  

if __name__ == '__main__':  
    main()  

After you have completed adapting your training script, proceed to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2411).

Modify a PyTorch Lightning Script

If you want to bring your PyTorch Lightning training script and run a distributed data parallel training job in SageMaker, you can run the training job with minimal changes in your training script. The necessary changes include the following: import the smdistributed.dataparallel library's PyTorch modules, set up the environment variables for PyTorch Lightning to accept the SageMaker environment variables that are preset by the SageMaker training toolkit, and activate the SageMaker data parallel library by setting the process group backend to "smddp". To learn more, walk through the following instructions that break down the steps with code examples.

**Note**
The PyTorch Lightning support is available in the SageMaker data parallel library v1.5.0 and later.

1. Import the `pytorch_lightning` library and the `smdistributed.dataparallel.torch` modules.

```python
import pytorch_lightning as pl
import smdistributed.dataparallel.torch.torch_smddp
```

2. Set the world size and the rank for the `LightningEnvironment` class object. When launching a training job in SageMaker, the SageMaker training toolkit sets up the environment variables "RANK", "LOCAL_RANK", and "WORLD_SIZE". These environment variables represent the processes' global ranks, their local ranks, and the world size, respectively. Use these SageMaker environment variables to configure the `LightningEnvironment`.

```python
import os
from pytorch_lightning.plugins.environments.lightning_environment import LightningEnvironment

env = LightningEnvironment()  
env.world_size = lambda: int(os.environ['WORLD_SIZE'])  
env.global_rank = lambda: int(os.environ['RANK'])
```

3. Set distributed training strategy using the `PyTorch Lightning DDPStrategy` module, create a `PyTorch Lightning Trainer` object, and adapt them to use the SageMaker data parallel library.

(Recommended) For PyTorch Lightning v1.6.0 and later

Create an object (ddp in the following code example) of the `DDPStrategy` class, and specify "smddp" to the `process_group_backend` parameter. When configuring a PyTorch Lightning Trainer object, use the SageMaker environment variables to specify the scale of the GPU cluster and the ddp object to set up the distributed training strategy.
Note
We recommend that you check the versions of PyTorch Lightning tested for compatibility with the SageMaker data parallel library in the section called “Supported Frameworks and AWS Regions” (p. 2437) page.

```python
from pytorch_lightning.strategies import DDPStrategy

ddp = DDPStrategy(
    cluster_environment=env,
    process_group_backend="smddp",
    accelerator="gpu"
)

world_size = int(os.environ["WORLD_SIZE"])
num_gpus = int(os.environ["SM_NUM_GPUS"])
num_nodes = int(world_size/num_gpus)

trainer = pl.Trainer(
    devices=num_gpus,
    num_nodes=num_nodes,
    max_epochs=10,
    strategy=ddp
)
```

(Optional) For PyTorch Lightning v1.5.10

If you are using DDPPlugin, which is a deprecated functionality, set the distributed strategy as shown in the following code.

```python
from pytorch_lightning.plugins.training_type.ddp import DDPPlugin

os.environ["PL_TORCH_DISTRIBUTED_BACKEND"] = "smddp"

ddp = DDPPlugin(
    parallel_devices=[torch.device("cuda", d) for d in range(num_gpus)],
    cluster_environment=env
)

world_size = int(os.environ["WORLD_SIZE"])
num_gpus = int(os.environ["SM_NUM_GPUS"])
num_nodes = int(world_size/num_gpus)

trainer = pl.Trainer(
    gpus=num_gpus,
    num_nodes=num_nodes,
    max_epochs=10,
    strategy=ddp
)
```

4. Run `trainer.fit` to start the training job of a PyTorch model. The following code example shows a PyTorch model object wrapped by the PyTorch Lightning Trainer’s `fit` method with the PyTorch Lightning MNIST data module.

```python
from pl_bolts.datamodules import MNISTDataModule

trainer.fit(model, datamodule=MNISTDataModule(batch_size=32))
```

After you have completed adapting your training script, proceed to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2411).
Note
When you construct a SageMaker PyTorch estimator and submit a training job request in Step 2, you need to provide requirements.txt to install pytorch-lightning and lightning-bolts in the SageMaker PyTorch training container.

```bash
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the requirements.txt file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.

Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK

To run your adapted script in Step 1: Modify Your Own Training Script (p. 2403), start with creating a SageMaker framework or generic estimator object with the prepared training script and the distributed training configuration parameter. You can use the library in any kind of SageMaker environment and web IDEs, such as SageMaker notebook instance and SageMaker Studio.

Use the high-level SageMaker Python SDK to do one of the following:

- If you want to achieve a quick adoption of your distributed training job in SageMaker, configure a SageMaker PyTorch or TensorFlow framework estimator class. The framework estimator picks up your training script and automatically matches the right image URI of the pre-built PyTorch or TensorFlow Deep Learning Containers (DLC), given the value specified to the framework_version parameter.
- If you want to extend one of the pre-built containers or build a custom container to create your own ML environment with SageMaker, use the SageMaker generic Estimator class and specify the image URI of the custom Docker container hosted in your Amazon Elastic Container Registry (Amazon ECR).

Your training datasets should be stored in Amazon S3 or Amazon FSx for Lustre in the AWS Region in which you are launching your training job. If you use Jupyter notebooks, you should have a SageMaker notebook instance or a SageMaker Studio app running in the same AWS Region. For more information about storing your training data, see the SageMaker Python SDK data inputs documentation.

Tip
We highly recommend that you use Amazon FSx for Lustre instead of Amazon S3 to increase training performance. Amazon FSx has higher throughput and lower latency than Amazon S3.

Choose one of the following topics for instructions on how to run your TensorFlow or PyTorch training scripts. After you launch a training job, you can monitor system utilization and model performance using Amazon SageMaker Debugger (p. 2191) or Amazon CloudWatch.

While you follow instructions in the following topics to learn more about technical details, we also recommend that you try the Amazon SageMaker Distributed Training Notebook Examples (p. 2493) to get started.

Topics
- Using the SageMaker Framework Estimators For PyTorch and TensorFlow (p. 2411)
- Using the SageMaker Generic Estimator to Extend Prebuilt Containers (p. 2413)
- Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2414)

Using the SageMaker Framework Estimators For PyTorch and TensorFlow

You can activate the SageMaker distributed data parallel library by specifying it as the distribution strategy in the SageMaker framework estimator class.
SageMaker PyTorch

```python
from sagemaker.pytorch import PyTorch

pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    source_dir="sub-folder-for-your-code",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    py_version="py38",
    framework_version="1.12.0",

    # For running a multi-node distributed training job, specify a value greater than 1
    # Example: 2,3,4,...8
    instance_count=2,

    # Instance types supported by the SageMaker data parallel library:
    # ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge
    instance_type="ml.p3.16xlarge",

    # Training using the SageMaker data parallel distributed training strategy
    distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
)

pt_estimator.fit("s3://bucket/path/to/training/data")
```

**Note**

PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the SageMaker PyTorch DLCs. Create the following `requirements.txt` file and save in the source directory where you save the training script.

```plaintext
# requirements.txt
pytorch-lightning
lightning-bolts
```

For example, the tree-structured directory should look like the following.

```plaintext
### pytorch_training_launcher_jupyter_notebook.ipynb
### sub-folder-for-your-code
### adapted-training-script.py
### requirements.txt
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.

SageMaker TensorFlow

```python
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name="training_job_name_prefix",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    framework_version="2.9.1",
    py_version="py38",

    # For running a multi-node distributed training job, specify a value greater than 1
    # Example: 2,3,4,...8
    instance_count=2,
```

2412
The following two parameters of the SageMaker framework estimator are required to activate the SageMaker data parallelism.

**distribution** (dict): A dictionary with information on how to run distributed training (default: None).

- To use `smdistributed.dataparallel` as a distribution strategy, configure a dictionary as shown in the following code:

```python
distribution = { "smdistributed": { "dataparallel": { "enabled": True } } }
```

- **custom_mpi_options** (str)(optional): Custom MPI options. The following is an example of how you can use this parameter when defining distribution. To learn more, see Custom MPI Options (p. 2423).

```python
distribution = {
    "smdistributed": {
        "dataparallel": {
            "enabled": True,
            "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
        }
    }
}
```

**instance_type** (str): A type of Amazon EC2 instance to use.

- If using the `smdistributed` with `dataparallel` distribution strategy, you must use one of the following instance types: `ml.p4d.24xlarge`, `ml.p3dn.24xlarge`, and `ml.p3.16xlarge`. For best performance, we recommend that you use an EFA-enabled instance, which are `ml.p3dn.24xlarge` and `ml.p4d.24xlarge`.

### Using the SageMaker Generic Estimator to Extend Prebuilt Containers

You can customize SageMaker prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

To extend a prebuilt container or adapt your own container to use the library, you must use one of the images listed in Supported Frameworks (p. 2399).

**Important**

From TensorFlow 2.4.1 and PyTorch 1.8.1, the framework DLCs supports EFA-enabled instance types (`ml.p3dn.24xlarge`, `ml.p4d.24xlarge`). We recommend that you use the DLC images that contain TensorFlow 2.4.1 or later and PyTorch 1.8.1 or later.

For example, if you use PyTorch, your Dockerfile should contain a `FROM` statement similar to the following:
You can further customize your own Docker container to work with SageMaker using the SageMaker Training toolkit and the binary file of the SageMaker distributed data parallel library. To learn more, see the instructions in the following section.

Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library

To build your own Docker container for training and use the SageMaker data parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides instructions on how to create a complete Dockerfile with the minimum set of dependencies for distributed training in SageMaker using the data parallel library.

**Note**
This custom Docker option with the SageMaker data parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the data parallel library

1. Start with a Docker image from NVIDIA CUDA. Use the cuDNN developer versions that contain CUDA runtime and development tools (headers and libraries) to build from the PyTorch source code.

   ```
   FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04
   ```

   **Tip**
The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

   To use versions of the third party libraries other than the ones provided in the following code example, we recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find versions that are tested, compatible, and suitable for your application.

   To find URLs for the SMDATAPARALLEL_BINARY argument, see the look up tables at Supported Frameworks (p. 2399).

   ```
   ARG PYTORCH_VERSION=1.10.2
   ARG PYTHON_SHORT_VERSION=3.8
   ARG EFA_VERSION=1.14.1
   ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/
   #{PYTORCH_VERSION}/cui13/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-
   linux_x86_64.whl
   ```
3. Set the following environment variables to properly build SageMaker training components and run the data parallel library. You use these variables for the components in the subsequent steps.

```
# Set ENV variables required to build PyTorch
ENV TORCHCUDA_ARCH_LIST="7.0+PTX 8.0"
ENV TORCH_NVCC_FLAGS="-Xfatbin -compress-all"
ENV NCCL_VERSION=2.10.3

# Add OpenMPI to the path.
ENV PATH /opt/amazon/openmpi/bin:$PATH

# Add Conda to path
ENV PATH $CONDA_PREFIX/bin:$PATH

# Set this environment variable for SageMaker to launch SMDDP correctly.
ENV SAGEMAKER_TRAINING_MODULE=sagemaker_pytorch_container.training:main

# Add environment variable for processes to be able to call fork()
ENV RDMAV_FORK_SAFE=1

# Indicate the container type
ENV DLC_CONTAINER_TYPE=training

# Add EFA and SMDDP to LD library path
ENV LD_LIBRARY_PATH="/opt/conda/lib/python${PYTHON_SHORT_VERSION}/site-packages/smdistributed/dataparallel/lib:$LD_LIBRARY_PATH"
ENV LD_LIBRARY_PATH=/opt/amazon/efa/lib/:$LD_LIBRARY_PATH
```

4. Install or update `curl`, `wget`, and `git` to download and build packages in the subsequent steps.

```
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \
    apt-get update && apt-get install -y  --no-install-recommends \
    curl \ 
    wget \ 
    git \ 
    && rm -rf /var/lib/apt/lists/*
```

5. Install Elastic Fabric Adapter (EFA) software for Amazon EC2 network communication.

```
RUN DEBIAN_FRONTEND=noninteractive apt-get update
RUN mkdir /tmp/efa \ 
    && cd /tmp/efa \ 
    && curl --silent -O https://efa-installer.amazonaws.com/aws-efa-installer-\${EFA_VERSION}.tar.gz \ 
    && tar -xf aws-efa-installer-\${EFA_VERSION}.tar.gz \ 
    && cd aws-efa-installer \ 
    && ./efa_installer.sh -y --skip-kmod -g \ 
    && rm -rf /tmp/efa
```

6. Install Conda to handle package management.

```
RUN curl -fssl -v -o ~/miniconda.sh -O https://repo.anaconda.com/miniconda/Miniconda3-\latest-Linux-x86_64.sh \&& \ 
    chmod +x ~/miniconda.sh \&& \ 
    ~/miniconda.sh -b -p $CONDA_PREFIX \&& \ 
    rm ~/miniconda.sh \&& \ 
    $CONDA_PREFIX/bin/conda install -y python=${PYTHON_SHORT_VERSION} conda-build pyyaml numpy ipython \&& \ 
```
7. Get, build, and install PyTorch and its dependencies. We build PyTorch from the source code because we need to have control of the NCCL version to guarantee compatibility with the AWS OFI NCCL plugin.

a. Following the steps in the PyTorch official dockerfile, install build dependencies and set up ccache to speed up recompilation.

```bash
RUN DEBIAN_FRONTEND=noninteractive \
    apt-get install -y --no-install-recommends \
    build-essential \
    ca-certificates \
    ccache \
    cmake \
    git \
    libjpeg-dev \
    libpng-dev \
    && rm -rf /var/lib/apt/lists/*
# Setup ccache
RUN /usr/sbin/update-ccache-symlinks
RUN mkdir /opt/ccache && ccache --set-config=cache_dir=/opt/ccache
```

b. Install PyTorch's common and Linux dependencies.

```bash
# Common dependencies for PyTorch
RUN conda install astunparse numpy ninja pyyaml mkl mkl-include setuptools cmake cffi
tyning_extensions future six requests dataclasses
# Linux specific dependency for PyTorch
RUN conda install -c pytorch magma-cuda113
```

c. Clone the PyTorch GitHub repository.

```bash
RUN --mount=type=cache,target=/opt/ccache \
    cd / \
    && git clone --recursive https://github.com/pytorch/pytorch -b v${PYTORCH_VERSION}
```

d. Install and build a specific NCCL version. To do this, replace the content in the PyTorch's default NCCL folder (/pytorch/third_party/nccl) with the specific NCCL version from the NVIDIA repository. The NCCL version was set in the step 3 of this guide.

```bash
RUN cd /pytorch/third_party/nccl \
    && rm -rf nccl \
    && git clone https://github.com/NVIDIA/nccl.git -b v${NCCL_VERSION}-1 \
    && cd nccl \
    && make -j64 src.build CUDA_HOME=/usr/local/cuda NVCC_GENCODE="-gencode=arch=compute_70,code=sm_70 -gencode=arch=compute_80,code=sm_80" \
    && make pkg.txz.build \
    && tar -xvf build/pkg/txz/nccl_*.txz -C $CONDA_PREFIX --strip-components=1
```
e. Build and install PyTorch. This process usually takes slightly more than one hour to complete. It is built using the NCCL version downloaded in a previous step.

```bash
RUN cd /pytorch \
    && CMAKE_PREFIX_PATH="$(dirname $(which conda))/.." \
    python setup.py install \ 
    && rm -rf /pytorch
```

8. Build and install AWS OFI NCCL plugin. This enables libfabric support for the SageMaker data parallel library.
RUN DEBIAN_FRONTEND=noninteractive apt-get update \\
    && apt-get install -y --no-install-recommends \\
    autoconf \\
    automake \\
    libtool \\
RUN mkdir /tmp/efa-ofi-nccl \\
    && cd /tmp/efa-ofi-nccl \\
    && git clone https://github.com/aws/aws-ofi-nccl.git -b v#{BRANCH_OFI} \\
    && cd aws-ofi-nccl \\
    && ./autogen.sh \\
    && ./configure --with-libfabric=/opt/amazon/efa \\
    --with-mpi=/opt/amazon/openmpi \\
    --with-cuda=/usr/local/cuda \\
    --with-nccl=$CONDA_PREFIX \\
    && make \\
    && make install \\
    && rm -rf /tmp/efa-ofi-nccl

RUN pip install --no-cache-dir -U \\
    packaging \\
    mpi4py==3.0.3 \\
RUN cd /tmp \\
    && git clone https://github.com/pytorch/vision.git -b v0.9.1 \\
    && cd vision \\
    && BUILD_VERSION="0.9.1+cu111" python setup.py install \\
    && cd /tmp \\
    && rm -rf vision

10. Install and configure OpenSSH. OpenSSH is required for MPI to communicate between containers. Allow OpenSSH to talk to containers without asking for confirmation.

RUN apt-get update \\
    && apt-get install -y --allow-downgrades --allow-change-held-packages --no-install-recommends \\
    && apt-get install -y --no-install-recommends openssh-client openssh-server \\
    && mkdir -p /var/run/sshd \\
    && cat /etc/ssh/ssh_config | grep -v StrictHostKeyChecking > /etc/ssh/ssh_config.new \\
    && echo "    StrictHostKeyChecking no" >> /etc/ssh/ssh_config.new \\
    && mv /etc/ssh/ssh_config.new /etc/ssh/ssh_config \\
    && rm -rf /var/lib/apt/lists/* \\
# Configure OpenSSH so that nodes can communicate with each other
RUN mkdir -p /var/run/sshd \\
    && sed 's@session @required @pam_loginuid.so@session optional pam_loginuid.so@g' -i /etc/pam.d/sshd \\
RUN rm -rf /root/.ssh/ \\
    && mkdir -p /root/.ssh/ \\
    && ssh-keygen -q -t rsa -N '' -f /root/.ssh/id_rsa \\
    && cp /root/.ssh/id_rsa.pub /root/.ssh/authorized_keys \\
    && printf "Host *
    StrictHostKeyChecking no\n" >> /root/.ssh/config

11. Install the PT S3 plug-in to efficiently access datasets in Amazon S3.

RUN pip install --no-cache-dir -U ${PT_S3_WHL_GPU} \\
RUN mkdir -p /etc/pki/tls/certs && cp /etc/ssl/certs/ca-certificates.crt /etc/pki/tls/certs/ca-bundle.crt

12. Install the libboost library. This package is needed for networking the asynchronous IO functionality of the SageMaker data parallel library.
13. Install the following SageMaker tools for PyTorch training.

```
WORKDIR /root
RUN pip install --no-cache-dir -U \
    smclarify \
    "sagemaker>=2,<3" \
    sagemaker-experiments==0.* \
    sagemaker-pytorch-training
```

14. Finally, install the SageMaker data parallel binary and the remaining dependencies.

```
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \
    apt-get update & & apt-get install --no-install-recommends \
    jq \ 
    libhwloc-dev \ 
    libnuma1 \ 
    libnuma-dev \ 
    libssl1.1 \ 
    libtool \ 
    hwloc \ 
    & & rm -rf /var/lib/apt/lists/*
```

```
RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

15. After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container, host it in Amazon ECR, and run a training job using the SageMaker Python SDK.

The following example code shows a complete Dockerfile after combining all the previous code blocks.

```
# This file creates a docker image with minimum dependencies to run SageMaker data parallel training
FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04

# Set appropriate versions and location for components
ARG PYTORCH_VERSION=1.10.2
ARG PYTHON_SHORT_VERSION=3.8
ARG EFA_VERSION=1.14.1

Tip
For more general information about creating a custom Dockerfile for training in SageMaker, see Use Your Own Training Algorithms.

Tip
If you want to extend the custom Dockerfile to incorporate the SageMaker model parallel library, see Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library (p. 2459).

SageMaker Distributed Data Parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using SageMaker’s distributed data parallel library. This list includes tips that are applicable across frameworks.

Topics
- Data Preprocessing (p. 2422)
- Single Versus Multiple Nodes (p. 2422)
- Debug Scaling Efficiency with Debugger (p. 2422)
- Batch Size (p. 2423)
- Custom MPI Options (p. 2423)
- Use Amazon FSx and set up an optimal storage and throughput capacity (p. 2423)

Data Preprocessing

If you preprocess data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker distributed data parallel uses the CPU for AllReduce operations. You may be able to improve training time by moving preprocessing steps to a library that uses GPUs or by completing all preprocessing before training.

Single Versus Multiple Nodes

We recommend that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs); however, when you use two or more nodes, the library’s AllReduce operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node AllReduce efficiency.

Debug Scaling Efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization and other metrics of interest during training. You can use Debugger built-in rules to monitor computational performance issues, such as CPUBottleneck, LoadBalancing, and LowGPUUtilization. You can specify these rules with Debugger configurations when you define an Amazon SageMaker Python SDK estimator. If you use AWS CLI and AWS Boto3 for training on SageMaker, you can enable Debugger as shown in Configure Debugger Using Amazon SageMaker API.

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook examples in the SageMaker Notebook Examples GitHub repository. To learn more about Debugger, see Amazon SageMaker Debugger.
Batch Size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.

One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a Linear Scaling Rule where each time the mini-batch size is multiplied by k, the learning rate is also multiplied by k. To learn more about this technique, see the research paper, Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Sections 2 and 3.

Custom MPI Options

The SageMaker distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA's NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or Pytorch Estimator, the respective container sets up the MPI environment and executes the `mpirun` command to start jobs on the cluster nodes.

You can set custom MPI operations using the `custom_mpi_options` parameter in the Estimator. Any `mpirun` flags passed in this field are added to the `mpirun` command and executed by SageMaker for training. For example, you may define the `distribution` parameter of an Estimator using the following to use the `NCCL_DEBUG` variable to print the NCCL version at the start of the program:

```python
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"}}}
```

Use Amazon FSx and set up an optimal storage and throughput capacity

When training a model on multiple nodes with distributed data parallelism, it is highly recommended to use FSx for Lustre. Amazon FSx is a scalable and high-performance storage service that supports shared file storage with a faster throughput. Using Amazon FSx storage at scale, you can achieve a faster data loading speed across the compute nodes.

Typically, with distributed data parallelism, you would expect that the total training throughput scales near-linearly with the number of GPUs. However, if you use suboptimal Amazon FSx storage, the training performance might slow down due to a low Amazon FSx throughput.

For example, if you use the SCRATCH_2 deployment type of Amazon FSx file system with the minimum 1.2 TiB storage capacity, the I/O throughput capacity is 240 MB/s. Amazon FSx storage works in a way that you can assign physical storage devices, and the more devices assigned, the larger throughput you get. The smallest storage increment for the SRATCH_2 type is 1.2 TiB, and the corresponding throughput gain is 240 MB/s.

Assume that you have a model to train on a 4-node cluster over a 100 GB data set. With a given batch size that's optimized to the cluster, assume that the model can complete one epoch in about 30 seconds. In this case, the minimum required I/O speed is approximately 3 GB/s (100 GB / 30 s). This is apparently a much higher throughput requirement than 240 MB/s. With such a limited Amazon FSx capacity, scaling your distributed training job up to larger clusters might aggravate I/O bottleneck problems; model training throughput might improve in later epochs as cache builds up, but Amazon FSx throughput can still be a bottleneck.

To alleviate such I/O bottleneck problems, you should increase the Amazon FSx storage size to obtain a higher throughput capacity. Typically, to find an optimal I/O throughput, you may experiment with different Amazon FSx throughput capacities, assigning an equal to or slightly lower throughput than your estimate, until you find that it is sufficient to resolve the I/O bottleneck problems. In case of the aforementioned example, Amazon FSx storage with 2.4 GB/s throughput and 67 GB RAM cache would
be sufficient. If the file system has an optimal throughput, the model training throughput should reach maximum either immediately or after the first epoch as cache has built up.

To learn more about how to increase Amazon FSx storage and deployment types, see the following pages in the Amazon FSx for Lustre documentation:

- How to increase storage capacity
- Aggregate file system performance

**Amazon SageMaker Data Parallel Library FAQ**

Use the following to find answers to commonly asked questions about SageMaker's data parallelism library.

**Q:** When using the library, how are the allreduce-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker service create extra C5s for jobs that use the library?

The library uses the CPUs available with GPU instances. No additional C5 or CPU instances are launched; if your SageMaker training job is 8-node ml.p3dn.24xlarge clusters, only 8 ml.p3dn.24xlarge instances are used. No additional instances are provisioned.

**Q:** I have a training job taking 5 days on a single ml.p3.24xlarge instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is using SageMaker's data parallelism library and a five-time bigger cluster enough to achieve an approximate five-time speedup? Or do I have to revisit its training hyperparameters after activating the library?

The library changes the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

**Q:** Does the library support Spot?

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You save and restore checkpoints in their training script as mentioned in the last steps of the section called “TensorFlow” (p. 2404) and the section called “PyTorch” (p. 2406).

**Q:** Is the library relevant in a single-host, multi-device setup?

The library can be used in single-host multi-device training but the library offers performance improvements only in multi-host training.

**Q:** Can the library be used with PyTorch Lightning?

No. However, with the library's DDP for PyTorch, you can write custom DDP to achieve the functionality.

**Q:** Where should the training dataset be stored?

The training dataset can be stored in an Amazon S3 bucket or on an Amazon FSx drive. See this document for various supported input file systems for a training job.

**Q:** When using the library, is it mandatory to have training data in FSx for Lustre? Can Amazon EFS and Amazon S3 be used?

We generally recommend you use Amazon FSx because of its lower latency and higher throughput. If you prefer, you can use Amazon EFS or Amazon S3.

**Q:** Can the library be used with CPU nodes?

No. The library supports ml.p3.16xlarge, ml.p3dn.24xlarge, and ml.p4d.24xlarge instances at this time.
Q: What frameworks and framework versions are currently supported by the library at launch?

The library currently supports PyTorch v1.6.0 or later and TensorFlow v2.3.0 or later. It doesn't support TensorFlow 1.x. For more information about which version of the library is packaged within AWS deep learning containers, see Release Notes for Deep Learning Containers.

Q: Does the library support AMP?

Yes, SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to use AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

• Frameworks - PyTorch in the NVIDIA Deep Learning Performance documentation
• Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
• Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
• Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the PyTorch Blog
• TensorFlow mixed precision APIs in the TensorFlow documentation

Q: How do I identify if my distributed training job is slowed down due to I/O bottleneck?

With a larger cluster, the training job requires more I/O throughput, and therefore the training throughput might take longer (more epochs) to ramp up to the maximum performance. This indicates that I/O is being bottlenecked and cache is harder to build up as you scale nodes up (higher throughput requirement and more complex network topology). For more information about monitoring the Amazon FSx throughput on CloudWatch, see Monitoring FSx for Lustre in the FSx for Lustre User Guide.

Q: How do I resolve I/O bottlenecks when running a distributed training job with data parallelism?

We highly recommend that you use Amazon FSx as your data channel if you are using Amazon S3. If you are already using Amazon FSx but still having I/O bottleneck problems, you might have set up your Amazon FSx file system with a low I/O throughput and a small storage capacity. For more information about how to estimate and choose the right size of I/O throughput capacity, see Use Amazon FSx and set up an optimal storage and throughput capacity (p. 2423).

Q: (For the library v1.4.0 or later) How do I resolve the Invalid backend error while initializing process group.

If you encounter the error message ValueError: Invalid backend: 'smddp' when calling init_process_group, this is due to the breaking change in the library v1.4.0 and later. You must import the PyTorch client of the library, smdistributed.dataparallel.torch.torch_smddp, which registers smddp as a backend for PyTorch. To learn more, see Use the SageMaker Distributed Data Parallel Library as the Backend of torch.distributed (p. 2406).

Q: (For the library v1.4.0 or later) I would like to call the collective primitives of the torch.distributed interface. Which primitives does the smddp backend support?

In v1.4.0, the library supports all_reduce, broadcast, reduce, all_gather, and barrier.

Q: (For the library v1.4.0 or later) Does this new API work with other custom DDP classes or libraries like Apex DDP?

The SageMaker data parallel library is tested with other third-party distributed data parallel libraries and framework implementations that use the torch.distributed modules. Using the SageMaker data parallel library with custom DDP classes works as long as the collectives used by the custom DDP classes are supported by the library. See the preceding question for a list of supported collectives. If you have these use cases and need further support, reach out to the SageMaker team through the AWS Support Center or AWS Developer Forums for Amazon SageMaker.
Q: Does the library support the bring-your-own-container (BYOC) option? If so, how do I install the library and run a distributed training job by writing a custom Dockerfile?

If you want to integrate the SageMaker data parallel library and its minimum dependencies in your own Docker container, BYOC is the right approach. You can build your own container using the binary file of the library. The recommended process is to write a custom Dockerfile with the library and its dependencies, build the Docker container, host it in Amazon ECR, and use the ECR image URI to launch a training job using the SageMaker generic estimator class. For more instructions on how to prepare a custom Dockerfile for distributed training in SageMaker with the SageMaker data parallel library, see Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2414).

Data Parallel Troubleshooting

If you have problems in running a training job when you use the library, use the following list to try to troubleshoot. If you need further support, reach out to the SageMaker team through AWS Support Center or AWS Developer Forums for Amazon Amazon SageMaker.

Topics

- Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints (p. 2426)
- An Unexpected Prefix Attached to Model Parameter Keys (p. 2427)
- SageMaker Distributed Training Job Stalling During Initialization (p. 2427)
- SageMaker Distributed Training Job Stalling at the End of Training (p. 2428)
- Observing Scaling Efficiency Degradation Due to Amazon FSx Throughput Bottlenecks (p. 2428)
- SageMaker Distributed Training Job with PyTorch Returns Deprecation Warnings (p. 2428)

Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints

To monitor system bottlenecks, profile framework operations, and debug model output tensors for training jobs with SageMaker distributed data parallel, use Amazon SageMaker Debugger.

However, when you use SageMaker Debugger, SageMaker distributed data parallel, and SageMaker checkpoints, you might see an error that looks like the following example.

This is due to an internal error between Debugger and checkpoints, which occurs when you enable SageMaker distributed data parallel.

- If you enable all three features, SageMaker Python SDK automatically turns off Debugger by passing debugger_hook_config=False, which is equivalent to the following framework estimator example.

```python
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"
# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)
estimator = TensorFlow(...
    distribution={"smdistributed": {"dataparallel": {"enabled": True}}},
    checkpoint_s3_uri=checkpoint_s3_bucket,
```
If you want to keep using both SageMaker distributed data parallel and SageMaker Debugger, a workaround is manually adding checkpointing functions to your training script instead of specifying the `checkpoint_s3_uri` and `checkpoint_local_path` parameters from the estimator. For more information about setting up manual checkpointing in a training script, see Saving Checkpoints (p. 2490).

### An Unexpected Prefix Attached to Model Parameter Keys

For PyTorch distributed training jobs, an unexpected prefix (model for example) might be attached to `state_dict` keys (model parameters). The SageMaker data parallel library does not directly alter or prepend any model parameter names when PyTorch training jobs save model artifacts. The PyTorch's distributed training changes the names in the `state_dict` to go over the network, prepending the prefix. If you encounter any model failure problem due to different parameter names while you are using the SageMaker data parallel library and checkpointing for PyTorch training, adapt the following example code to remove the prefix at the step you load checkpoints in your training script.

```python
state_dict = {k.partition('model.')[2]:state_dict[k] for k in state_dict.keys()}
```

This takes each `state_dict` key as a string value, separates the string at the first occurrence of 'model.', and takes the third list item (with index 2) of the partitioned string.

For more information about the prefix issue, see a discussion thread at Prefix parameter names in saved model if trained by multi-GPU? in the PyTorch discussion forum.

For more information about the PyTorch methods for saving and loading models, see Saving & Loading Model Across Devices in the PyTorch documentation.

### SageMaker Distributed Training Job Stalling During Initialization

If your SageMaker distributed data parallel training job stalls during initialization when using EFA-enabled instances (ml.p3dn.24xlarge and ml.p4d.24xlarge), this might be due to a misconfiguration in the security group of the VPC subnet that's used for the training job. EFA requires a proper security group configuration to enable traffic between the nodes.

**To configure inbound and outbound rules for the security group**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose Security Groups in the left navigation pane.
3. Select the security group that's tied to the VPC subnet you use for training.
4. In the Details section, copy the Security group ID.
6. On the Edit inbound rules page, do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Source, choose Custom, paste the security group ID into the search box, and select the security group that pops up.
7. Choose Save rules to finish configuring the inbound rule for the security group.
9. Repeat the step 6 and 7 to add the same rule as an outbound rule.
After you complete the preceding steps for configuring the security group with the inbound and outbound rules, rerun the training job and verify if the stalling issue is resolved.

For more information about configuring security groups for VPC and EFA, see Security groups for your VPC and Elastic Fabric Adapter.

SageMaker Distributed Training Job Stalling at the End of Training

One of the root causes of stalling issues at the end of training is a mismatch in the number of batches that are processed per epoch across different ranks. All workers (GPUs) synchronize their local gradients in the backward pass to ensure they all have the same copy of the model at the end of the batch iteration. If the batch sizes are unevenly assigned to different worker groups during the final epoch of training, the training job stalls. For example, while a group of workers (group A) finishes processing all batches and exits the training loop, another group of workers (group B) starts processing another batch and still expects communication from group A to synchronize the gradients. This causes group B to wait for group A, which already completed training and does not have any gradients to synchronize.

Therefore, when setting up your training dataset, it is important that each worker gets the same number of data samples so that each worker goes through the same number of batches while training. Make sure each rank gets the same number of batches to avoid this stalling issue.

Observing Scaling Efficiency Degradation Due to Amazon FSx Throughput Bottlenecks

One potential cause of lowered scaling efficiency is the FSx throughput limit. If you observe a sudden drop in scaling efficiency when you switch to a larger training cluster, try using a larger FSx for Lustre file system with a higher throughput limit. For more information, see Aggregate file system performance and Managing storage and throughput capacity in the Amazon FSx for Lustre User Guide.

SageMaker Distributed Training Job with PyTorch Returns Deprecation Warnings

Since v1.4.0, the SageMaker distributed data parallelism library works as a backend of PyTorch distributed. Because of the breaking change of using the library with PyTorch, you might encounter a warning message that the `smdistributed` APIs for the PyTorch distributed package are deprecated. The warning message should be similar to the following:

```
smdistributed.dataparallel.torch.dist is deprecated in the SageMaker distributed data parallel library v1.4.0+
Please use torch.distributed and specify 'smddp' as a backend when initializing process group as follows:
torch.distributed.init_process_group(backend='smddp')
For more information, see the library's API documentation at https://docs.aws.amazon.com/sagemaker/latest/dg/data-parallel-modify-sdp-pt.html
```

In v1.4.0 and later, the library only needs to be imported once at the top of your training script and set as the backend during the PyTorch distributed initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. See Modify a PyTorch Training Script (p. 2406) to learn about the breaking changes and the new way to use the library with PyTorch.

SageMaker's Distributed Model Parallel

Use Amazon SageMaker's distributed model parallel library to train large deep learning (DL) models that are difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances. Using the library, you can achieve a target prediction accuracy faster by efficiently training larger DL models with billions or trillions of parameters.
You can use the library to automatically partition your own TensorFlow and PyTorch models across multiple GPUs and multiple nodes with minimal code changes. You can access the library's API through the SageMaker Python SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library's API documentation is located at Distributed Training APIs in the SageMaker Python SDK documentation.

To track the latest updates of the library, see the SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.

Introduction to Model Parallelism

Model parallelism is a distributed training method in which the deep learning model is partitioned across multiple devices, within or across instances. This introduction page provides a high-level overview about model parallelism, a description of how it can help overcome issues that arise when training DL models that are typically very large in size, and examples of what the SageMaker model parallel library offers to help manage model parallel strategies as well as memory consumption.

What is Model Parallelism?

Increasing the size of deep learning models (layers and parameters) yields better accuracy for complex tasks such as computer vision and natural language processing. However, there is a limit to the maximum model size you can fit in the memory of a single GPU. When training DL models, GPU memory limitations can be bottlenecks in the following ways:

- They limit the size of the model you can train, since the memory footprint of a model scales proportionally to the number of parameters.
- They limit the per-GPU batch size during training, driving down GPU utilization and training efficiency.

To overcome the limitations associated with training a model on a single GPU, SageMaker provides the model parallel library to help distribute and train DL models efficiently on multiple compute nodes. Furthermore, with the library, you can achieve most optimized distributed training using EFA-supported devices, which enhance the performance of inter-node communication with low latency, high throughput, and OS bypass.

Estimate Memory Requirements Before Using Model Parallelism

Before you use the SageMaker model parallel library, consider the following to get a sense of the memory requirements of training large DL models.

For a training job that uses AMP (FP16) and Adam optimizers, the required GPU memory per parameter is about 20 bytes, which we can break down as follows:

- An FP16 parameter ~ 2 bytes
• An FP16 gradient ~ 2 bytes
• An FP32 optimizer state ~ 8 bytes based on the Adam optimizers
• An FP32 copy of parameter ~ 4 bytes (needed for the optimizer apply (OA) operation)
• An FP32 copy of gradient ~ 4 bytes (needed for the OA operation)

Even for a relatively small DL model with 10 billion parameters, it can require at least 200GB of memory, which is much larger than the typical GPU memory (for example, NVIDIA A100 with 40GB/80GB memory and V100 with 16/32 GB) available on a single GPU. Note that on top of the memory requirements for model and optimizer states, there are other memory consumers such as activations generated in the forward pass. The memory required can be a lot greater than 200GB.

For distributed training, we recommend that you use Amazon EC2 P3 and P4 instances that have NVIDIA A100 or V100 Tensor Core GPUs. For more details about specifications such as CPU cores, RAM, attached storage volume, and network bandwidth, see the Accelerated Computing section in the Amazon EC2 Instance Types page.

Even with the accelerated computing instances, it is obvious that models with about 10 billion parameters such as Megatron-LM and T5 and even larger models with hundreds of billions of parameters such as GPT-3 cannot fit model replicas in each GPU device.

How the Library Employs Model Parallelism and Memory Saving Techniques

The library consists of two types of model parallelism features, pipeline parallelism and tensor parallelism, as well as other memory-saving features such as optimizer state sharding, activation checkpointing, and activation offloading. All these techniques can be combined to efficiently train large models, such as GPT-2, consisting of hundreds of billions of parameters.

Topics
• Pipeline parallelism (p. 2430)
• Tensor parallelism (available for PyTorch) (p. 2433)
• Optimizer state sharding (available for PyTorch) (p. 2435)
• Activation offloading and checkpointing (available for PyTorch) (p. 2437)
• Choosing the right techniques for your model (p. 2437)

Pipeline parallelism

Pipeline parallelism partitions the set of layers or operations across the set of devices, leaving each operation intact. When you specify a value for the number of model partitions (pipeline_parallel_degree), the total number of GPUs (processes_per_host) must be divisible by the number of the model partitions. To set this up properly, you have to specify the correct values for the pipeline_parallel_degree and processes_per_host parameters. The simple math is as follows:

\[(\text{pipeline}\_\text{parallel}\_\text{degree}) \times (\text{data}\_\text{parallel}\_\text{degree}) = \text{processes}\_\text{per}\_\text{host}\]

The library takes care of calculating the number of model replicas (also called data_parallel_degree) given the two input parameters you provide.

For example, if you set "pipeline_parallel_degree": 2 and "processes_per_host": 8 to use an ML instance with eight GPU workers such as ml.p3.16xlarge, the library automatically sets up the distributed model across the GPUs and four-way data parallelism. The following image illustrates how a model is distributed across the eight GPUs achieving four-way data parallelism and two-way pipeline parallelism. Each model replica, where we define it as a pipeline parallel group and label it as PP_GROUP, is partitioned across two GPUs. Each partition of the model is assigned to four GPUs, where the four
partition replicas are in a *data parallel group* and labeled as `DP_GROUP`. Without tensor parallelism, the pipeline parallel group is essentially the model parallel group.

To dive deep into pipeline parallelism, see Core Features of the SageMaker Model Parallel Library (p. 2439).

To get started with running your model using pipeline parallelism, see Run a SageMaker Distributed Training Job with the SageMaker Model Parallel Library.

Tensor parallelism (available for PyTorch)

Tensor parallelism splits individual layers, or `nn.Module`s, across devices, to be run in parallel. The following figure shows the simplest example of how the library splits a model with four layers to achieve two-way tensor parallelism (`"tensor_parallel_degree"`: 2). The layers of each model replica are bisected and distributed into two GPUs. In this example case, the model parallel configuration also includes "pipeline_parallel_degree": 1 and "ddp": True (uses PyTorch DistributedDataParallel package in the background), so the degree of data parallelism becomes eight. The library manages communication across the tensor-distributed model replicas.
The usefulness of this feature is in the fact that you can select specific layers or a subset of layers to apply tensor parallelism. To dive deep into tensor parallelism and other memory-saving features for PyTorch, and to learn how to set a combination of pipeline and tensor parallelism, see Extended Features of the SageMaker Model Parallel Library for PyTorch (p. 2461).
Optimizer state sharding (available for PyTorch)

To understand how the library performs optimizer state sharding, consider a simple example model with four layers. The key idea in optimizing state sharding is you don't need to replicate your optimizer state in all of your GPUs. Instead, a single replica of the optimizer state is sharded across data-parallel ranks, with no redundancy across devices. For example, GPU 0 holds the optimizer state for layer one, the next GPU 1 holds the optimizer state for L2, and so on. The following animated figure shows a backward propagation with the optimizer state sharding technique. At the end of the backward propagation, there's compute and network time for the optimizer apply (OA) operation to update optimizer states and the all-gather (AG) operation to update the model parameters for the next iteration. Most importantly, the reduce operation can overlap with the compute on GPU 0, resulting in a more memory-efficient and faster backward propagation. In the current implementation, AG and OA operations do not overlap with compute. It can result in an extended computation during the AG operation, so there might be a tradeoff.

For more information about how to use this feature, see Optimizer State Sharding.

Activation offloading and checkpointing (available for PyTorch)

To save GPU memory, the library supports activation checkpointing to avoid storing internal activations in the GPU memory for user-specified modules during the forward pass. The library recomputes these activations during the backward pass. In addition, the activation offloading feature offloads the stored activations to CPU memory and fetches back to GPU during the backward pass to further reduce activation memory footprint. For more information about how to use these features, see Activation Checkpointing and Activation Offloading.

Choosing the right techniques for your model

For more information about choosing the right techniques and configurations, see SageMaker Distributed Model Parallel Best Practices and Configuration Tips and Pitfalls.

Supported Frameworks and AWS Regions

Before using the SageMaker model parallel library, check the supported frameworks and instance types, and determine if there are enough quotas in your AWS account and AWS Region.

Supported Frameworks

The SageMaker model parallel library supports the following deep learning frameworks and is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.

**Hugging Face Transformers versions supported by SageMaker and the SageMaker distributed data parallel library**

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and
paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

**Note**
To check the latest updates and release history of the library, see the SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.

**AWS Regions**

The SageMaker data parallel library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker are in service. For more information, see Available Deep Learning Containers Images.

**Core Features of the SageMaker Model Parallel Library**

Amazon SageMaker's model parallel library makes model parallelism more accessible by providing automated model splitting and sophisticated pipeline execution scheduling. The model splitting algorithms can optimize for speed or memory consumption. The library also supports manual partitioning. When you use the library, training is executed in a pipelined fashion over microbatches to maximize GPU usage.

You can configure these features using a few lines of code when you create your training script and define your SageMaker PyTorch or TensorFlow estimators. Use the following sections to learn more about these core features of the library.

**Note**
The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

**Automated Model Splitting**

When you use SageMaker's model parallel library, you can take advantage of automated model splitting, also referred to as automated model partitioning. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.

**How It Works**

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for AWS infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The follow section reviews the specifics of the design in each framework.
Automated Model Splitting with PyTorch

During the first training step, the model parallel library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After this tracing step, the library constructs a tree, which consists of the nested nn.Module objects in the model, as well as additional data gathered from tracing, such as the amount of stored nn.Parameters, and execution time for each nn.Module.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each nn.Module to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored nn.Parameter size and activations). If multiple nn.Modules share the same nn.Parameter, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.

Automated Model Splitting with TensorFlow

The model parallel library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
- Balancing the number of operations executed in each device

If you specify speed for optimize (in the model parallel parameters in the Python SDK), the library tries to balance the number of operations and tf.Variable objects in each device. Otherwise, it tries to balance the total size of tf.Variables.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same tf.Variable and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a tf.Variable, then all operations that are part of these layers are placed on a single device.

Comparison of Automated Model Splitting Between Frameworks

In TensorFlow, the fundamental unit of computation is a tf.Operation, and TensorFlow represents the model as a directed acyclic graph (DAG) of tf.Operations, and therefore model parallel library partitions this DAG so that each node goes to one device. Crucially, tf.Operation objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an nn.Module, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

Manual Model Splitting

If you want to manually specify how your model is partitioned across devices, you can use manual model splitting by using smp.partition context managers.

To use this option, set auto_partition to False, and define a default_partition in the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the smp.partition context manager is executed on the default_partition. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallel library creates a pipelined execution schedule automatically.
Pipeline Execution Schedule

A core feature of SageMaker's distributed model parallel library is pipelined execution, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation.

Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A microbatch is a smaller subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by which device for every time slot.

For example, depending on the pipeline schedule and the model partition, GPU $i$ might perform (forward or backward) computation on microbatch $b$ while GPU $i+1$ performs computation on microbatch $b+1$, thereby keeping both GPUs active at the same time. During a single forward or backward pass, execution flow for a single microbatch might visit the same device multiple times, depending on the partitioning decision. For instance, an operation that is at the beginning of the model might be placed on the same device as an operation at the end of the model, while the operations in between are on different devices, which means this device is visited twice.

The library offers two different pipeline schedules, simple and interleaved, which can be configured using the pipeline parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve better performance by utilizing the GPUs more efficiently.

Interleaved Pipeline

In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This allows quicker release of the memory used for activations, using memory more efficiently. It also allows for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each device alternates between running forward and backward passes. This means that the backward pass of one microbatch may run before the forward pass of another microbatch finishes.

[Diagram of interleaved pipeline]

The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs. In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass for microbatch 1. Update represents the optimizer update of the parameters. GPU0 always prioritizes backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of the memory used for activations earlier.

Simple Pipeline

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting the backward pass. This means that it only pipelines the forward pass and backward pass stages within themselves. The following figure illustrates an example of how this works, over 2 GPUs.

[Diagram of simple pipeline]

Pipelining Execution in Specific Frameworks

Use the following sections to learn about the framework-specific pipeline scheduling decisions SageMaker's distributed model parallel library makes for Tensorflow and PyTorch.
Pipeline Execution with TensorFlow

The following image is an example of a TensorFlow graph partitioned by the model parallel library, using automated model splitting. When a graph is split, each resulting subgraph is replicated B times (except for the variables), where B is the number of microbatches. In this figure, each subgraph is replicated 2 times (B=2). An SMPInput operation is inserted at each input of a subgraph, and an SMPOutput operation is inserted at each output. These operations communicate with the library backend to transfer tensors to and from each other.

The following image is an example of 2 subgraphs split with B=2 with gradient operations added. The gradient of a SMPInput op is a SMPOutput op, and vice versa. This enables the gradients to flow backwards during back-propagation.

This GIF demonstrates an example interleaved pipeline execution schedule with B=2 microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As B grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue SMPInput operations to start executing.
Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

**Pipeline Execution with PyTorch**

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallel library's PyTorch feature uses a more dynamic pipelining paradigm.

As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch which the current device can actively work on. The prioritization of microbatches is determined by the chosen pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

**Run a SageMaker Distributed Training Job with Model Parallelism**

Learn how to run a distributed model parallel training job using the SageMaker Python SDK with your own training script and SageMaker's distributed model parallel library.

There are three use-case scenarios for running a SageMaker training job:

1. You can use one of the prebuilt AWS Deep Learning Container for TensorFlow and PyTorch. This option is recommended if it is the first time for you to use the model parallel library. To find a tutorial for how to run a SageMaker model parallel training job, see [MNIST with PyTorch 1.6 and Amazon SageMaker's distributed model parallel library](https://docs.aws.amazon.com/sagemaker/latest/dg/distributed-training.html).

2. You can extend the prebuilt containers to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. To find an example of how you can extend a pre-built container, see [Extend a Prebuilt Container](https://docs.aws.amazon.com/sagemaker/latest/dg/extend-prebuilt-container.html).

3. You can adapt your own Docker container to work with SageMaker using the [SageMaker Training toolkit](https://github.com/aws/sagemaker)[. For an example, see [Adapting Your Own Training Container](https://docs.aws.amazon.com/sagemaker/latest/dg/custom-container-prepare.html).

For options 2 and 3 in the preceding list, refer to [Extend a Prebuilt Docker Container that Contains SageMaker's Distributed Model Parallel Library (p. 2458)](https://docs.aws.amazon.com/sagemaker/latest/dg/extend-prebuilt-container.html) to learn how to install the model parallel library in an extended or customized Docker container.

In all cases, you launch your training job configuring a SageMaker TensorFlow or PyTorch estimator to initialize the library. To learn more, see the following topics.

**Topics**

- [Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library (p. 2443)](https://docs.aws.amazon.com/sagemaker/latest/dg/custom-container-prepare.html)

**Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library**

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker distributed model parallel library. To use the library-specific API functions and parameters,
we recommend you use this documentation alongside the SageMaker model parallel library APIs in the SageMaker Python SDK documentation.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed model parallel library, see Amazon SageMaker Distributed Training Notebook Examples (p. 2493).

Topics
- Modify a TensorFlow Training Script (p. 2444)
- Modify a PyTorch Training Script (p. 2449)

Modify a TensorFlow Training Script

In this section, you learn how to modify TensorFlow training scripts to configure the SageMaker distributed model parallel library for auto-partitioning and manual partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism.

Note
To find which TensorFlow versions are supported by the library, see the section called “Supported Frameworks and AWS Regions” (p. 2437).

The required modifications you must make to your training script to use the library are listed in TensorFlow (p. 2444).

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see TensorFlow with Horovod for Hybrid Model and Data Parallelism (p. 2446).

If you want to use manual partitioning, also review Manual partitioning with TensorFlow (p. 2448).

Tip
For end-to-end notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker distributed model parallel library, see TensorFlow Examples (p. 2494).

The following topics show examples of training scripts that you can use to configure SageMaker's model parallel library for auto-partitioning and manual partitioning TensorFlow models.

Note
Auto-partitioning is enabled by default. Unless otherwise specified, the example scripts use auto-partitioning.

Topics
- TensorFlow (p. 2444)
- TensorFlow with Horovod for Hybrid Model and Data Parallelism (p. 2446)
- Manual partitioning with TensorFlow (p. 2448)
- Unsupported Framework Features (p. 2449)

TensorFlow

The following training script changes are required to run a TensorFlow model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.
2. Define a Keras model by inheriting from `smp.DistributedModel` instead of the Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices,
incurs communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.

3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.

4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.

5. Put the forward and backward logic in a step function and decorate it with `smp.step`.

6. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`. The `smp.step` function must have a return value that depends on the output of `smp.DistributedModel`.

7. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput API`.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

The following Python script is an example of a training script after the changes are made.

```python
import tensorflow as tf

def __init__(self):
    super(MyModel, self).__init__

    def call(self, x, training=None):
        # define forward pass and return the model output
        model = MyModel()

        loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
        optimizer = tf.keras.optimizers.Adam()
        train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")
```
# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)
    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))
    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
        accuracy = train_accuracy.result()

If you are done preparing your training script, proceed to Step 2: Launch a Training Job Using the
SageMaker Python SDK (p. 2455). If you want to run a hybrid model and data parallel training job, continue to the next section.

TensorFlow with Horovod for Hybrid Model and Data Parallelism

You can use the SageMaker distributed model parallel library with Horovod for hybrid model and data parallelism. To read more about how the library splits a model for hybrid parallelism, see Pipeline parallelism (p. 2430).

In this step, we focus on how to modify your training script to adapt the SageMaker distributed model parallel library.

To properly set up your training script to pick up the hybrid parallelism configuration that you'll set in Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2455), use the library's helper functions, smp.dp_rank() and smp.mp_rank(), which automatically detect the data parallel rank and model parallel rank respectively.

To find all MPI primitives the library supports, see MPI Basics in the SageMaker Python SDK documentation.

The required changes needed in the script are:

- Adding hvd.allreduce
- Broadcasting variables after the first batch, as required by Horovod
- Seeding shuffling and/or sharding operations in the data pipeline with smp.dp_rank().

Note
When you use Horovod, you must not directly call hvd.init in your training script. Instead, you'll have to set "horovod" to True in the SageMaker Python SDK modelparallel...
parameters in Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2455). This allows the library to internally initialize Horovod based on the device assignments of model partitions. Calling \texttt{hvd.init()} directly in your training script can cause problems.

**Note**
Using the \texttt{hvd.DistributedOptimizer} API directly in your training script might result in a poor training performance and speed, because the API implicitly places the AllReduce operation inside \texttt{smp.step}. We recommend you to use the model parallel library with Horovod by directly calling \texttt{hvd.allreduce} after calling \texttt{accumulate()} or \texttt{reduce_mean()} on the gradients returned from \texttt{smp.step}, as will be shown in the following example.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import tensorflow as tf
import horovod.tensorflow as hvd
# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp
# smdistributed: Initialize
smp.init()
# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0
# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]
# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train)).shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)
# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers
        def call(self, x, training=None):
            # define forward pass and return model outputs

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)
    grads = optimizer.get_gradients(loss, model.trainable_variables)
```
return grads, loss, predictions

@tf.function
def train_step(images, labels, first_batch):
    gradients, loss, predictions = get_grads(images, labels)
    # smdistributed: Accumulate the gradients across microbatches
    # Horovod: Allreduce the accumulated gradients
    gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))
    # Horovod: Broadcast the variables after first batch
    if first_batch:
        hvd.broadcast_variables(model.variables, root_rank=0)
        hvd.broadcast_variables(optimizer.variables(), root_rank=0)
    # smdistributed: Merge predictions across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for batch, (images, labels) in enumerate(train_ds):
        loss = train_step(images, labels, tf.constant(batch == 0))

Manual partitioning with TensorFlow

Use smp.partition context managers to place operations in specific partition. Any operation not placed in any smp.partition contexts is placed in the default_partition. To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

import tensorflow as tf
# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = tf.data.Dataset.from_tensor_slices((x_train, y_train)).shuffle(10000, seed=smp.dp_rank()).batch(256, drop_remainder=True)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
class MyModel(smp.DistributedModel):
    def __init__(self):
# define layers

def call(self, x):
    with smp.partition(0):
        x = self.layer0(x)
    with smp.partition(1):
        return self.layer1(x)

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)
    
    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)
    
    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))
    
    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
        accuracy = train_accuracy.result()
Tip
For end-to-end notebook examples that demonstrate how to use a PyTorch training script with the SageMaker distributed model parallel library, see PyTorch Examples (p. 2494).

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following scripts use auto-partitioning.

Topics
• PyTorch (p. 2450)
• Manual Partitioning with PyTorch (p. 2452)
• Important Considerations (p. 2453)
• Unsupported Framework Features (p. 2455)

PyTorch
The following training script changes are required to run a PyTorch training script with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smdistributed.modelparallel.torch.init()`.
2. Wrap the model with `smdistributed.modelparallel.torch.DistributedModel`. Be mindful that any tensors returned from the `forward` method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.

   Note
   For FP16 training, you need to use the `smdistributed.modelparallel.torch.model_creation()` context manager to wrap the model. For more information, see FP16 Training with Model Parallelism (p. 2477).

3. Wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`.

   Note
   For FP16 training, you need to set up static or dynamic loss scaling. For more information, see FP16 Training with Model Parallelism (p. 2477).

4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smdistributed.modelparallel.torch.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).
9. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`.
10. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput` API.
11. Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import torch
import torch.nn as nn
```
import torch.nn.functional as F
import torch.optim as optim
from torchtext.data import Dataset
from torchvision import datasets
import smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        # define layers
        def forward(self, x):
            # define forward pass and return model outputs

            # smdistributed: Define smp.step. Return any tensors needed outside.
            @smp.step
            def train_step(model, data, target):
                output = model(data)
                loss = F.nll_loss(output, target, reduction="mean")
                model.backward(loss)
                return output, loss

            def train(model, device, train_loader, optimizer):
                model.train()
                for batch_idx, (data, target) in enumerate(train_loader):
                    # smdistributed: Move input tensors to the GPU ID used by the current process,
                    # based on the set_device call.
                    data, target = data.to(device), target.to(device)
                    optimizer.zero_grad()
                    # Return value, loss_mb is a StepOutput object
                    _, loss_mb = train_step(model, data, target)
                    # smdistributed: Average the loss across microbatches.
                    loss = loss_mb.reduce_mean()
                    optimizer.step()

                    # by the number of microbatches
                    train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

                    model = GroupedNet()
                    optimizer = optim.Adadelta(model.parameters(), lr=4.0)
Model Parallel Training

# sdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,  
# the returned DistributedModel object should be used in place of 
# the model provided for DistributedModel class instantiation. 
model = smp.DistributedModel(model) 
optimizer = smp.DistributedOptimizer(optimizer) 

train(model, device, train_loader, optimizer)

Manual Partitioning with PyTorch

Use smp.partition context managers to place modules in specific devices. Any module not placed in any smp.partition contexts is placed in the default_partition. The default_partition needs to be provided if auto_partition is set to False. The modules that are created within a specific smp.partition context are placed on the corresponding partition.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchtext.dataset import SplitDataset

optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

---

**Important Considerations**

When you configure a PyTorch training script using SageMaker's distributed model parallel library, you should be aware of the following:

- If you are using an optimization technique that relies on global gradient norms, for example gradient norm from the entire model, such as some variants of LAMB optimizer or global gradient clipping, you need to gather all the norms across the model partitions for correctness. You can use the library's communication basic data types to do this.
- All `torch.Tensor` arguments to the forward methods of the `nn.Modules` in your model must be used in the computation of the module output. In other words, the library does not support the case where there is a `torch.Tensor` argument to a module on which the module output does not depend.
- The argument to the `smp.DistributedModel.backward()` call must depend on all model outputs. In other words, there cannot be an output from the `smp.DistributedModel.forward` call that is not used in the computation of the tensor that is fed into the `smp.DistributedModel.backward` call.
- If there are `torch.cuda.synchronize()` calls in your code, you might need to call `torch.cuda.set_device(smp.local_rank())` immediately before the synchronize call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.
- Since the library places `nn.Modules` on different devices, the modules in the model must not depend on any global state that is modified inside `smp.step`. Any state that remains fixed throughout training, or that is modified outside `smp.step` in a way that is visible to all processes, is allowed.
- You don't need to move the model to GPU (for example, using `model.to(device)`) when using the library. If you try to move the model to GPU before the model is partitioned (before the first
Model Parallel Training

`smp.step` call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don't move the model to CPU and use it, as it won't have correct parameters for modules not assigned to the partition held by the process. If you want to retrain a model or use it for inference without the library after it was trained using the model parallel library, the recommended way is to save the full model using our checkpointing API and load it back to a regular PyTorch Module.

- If you have a list of modules such that output of one feeds into another, replacing that list with `nn.Sequential` can significantly improve performance.
- The weight update (`optimizer.step()`) needs to happen outside of `smp.step` because that is when the entire backward pass is done and gradients are ready. When using a hybrid model with model and data parallelism, at this point, Allreduce of gradients is also guaranteed to finish.
- When using the library in combination with data parallelism, make sure that the number of batches on all data parallel ranks is the same so that Allreduce does not hang waiting for a rank which is not participating in the step.
- If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), you must set the data loader variable `num_workers=0`. For example, you may define your `DataLoader` as follows:

```python
dataloader = torch.utils.data.DataLoader(  
data,  
batch_size=batch_size,  
num_workers=0,  
pin_memory=True,  
don_last=True,  
shuffle=shuffle,  
)
```

- The inputs to `smp.step` must be the model inputs generated by `DataLoader`. This is because `smp.step` internally splits the input tensors along the batch dimension and pipelines them. This means that passing `DataLoader` itself to the `smp.step` function to generate the model inputs inside does not work.

For example, if you define a `DataLoader` as follows:

```python
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

You should access the model inputs generated by `train_loader` and pass those to an `smp.step` decorated function. Do not pass `train_loader` directly to the `smp.step` function.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        ...
        _, loss_mb = train_step(model, data, target)
        ...
    @smp.step
    def train_step(model, data, target):
        ...
        return output, loss
```

- The input tensors to `smp.step` must be moved to the current device using `.to()` API, which must take place after the `torch.cuda.set_device(local_rank())` call.

For example, you may define the `train` function as follows. This function adds `data` and `target` to the current device using `.to()` API before using those input tensors to call `train_step`.

```python
def train(model, device, train_loader, optimizer):
    model.train()
for batch_idx, (data, target) in enumerate(train_loader):
    # smdistributed: Move input tensors to the GPU ID used by the current process,
    # based on the set_device call.
    data, target = data.to(device), target.to(device)
    optimizer.zero_grad()
    # Return value, loss_mb is a StepOutput object
    _, loss_mb = train_step(model, data, target)
    # smdistributed: Average the loss across microbatches.
    loss = loss_mb.reduce_mean()
    optimizer.step()

The input tensors to this `smp.set` decorated function have been moved to the current device in
the train function above. The model does not need to be moved to the current device. The library
automatically moves the part of the model assigned to a rank to its GPU.

```python
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss
```

Unsupported Framework Features

The following PyTorch features are unsupported by SageMaker's distributed model parallel library:

- If you use data parallelism with the native PyTorch DDP, the
  `torch.nn.parallel.DistributedDataParallel` wrapper module is not supported by the library.
  The library internally manages integrating with PyTorch DDP, including parameter broadcast and
  gradient AllReduce. When using the library, module buffers are only broadcast once at the start of
  training. If your model has module buffers that need to be synchronized across data parallel groups at
  each step, you can do so through the `torch.distributed` API, using the process group that can be
  obtained via `smp.get_dp_process_group()`.
- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use
  the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using
  `smp.amp.GradScaler` instead of the implementation in torch.
- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `smp.DistributedModel`.
- `apex`: `FusedLayerNorm`, `FusedAdam`, `FusedLAMB`, and `FusedNovoGrad` from apex are not
  supported. You can use the library implementations of these through `smp.optimizers` and `smp.nn`
  APIs instead.

Step 2: Launch a Training Job Using the SageMaker Python SDK

The SageMaker Python SDK supports managed training of models with ML frameworks such as
TensorFlow and PyTorch. To launch a training job using one of these frameworks, you define a
SageMaker `TensorFlow estimator`, a SageMaker `PyTorch estimator`, or a SageMaker generic `Estimator` to
use the modified training script and model parallelism configuration.

Topics

- Using the SageMaker TensorFlow and PyTorch Estimators (p. 2456)
- Extend a Prebuilt Docker Container that Contains SageMaker's Distributed Model Parallel
  Library (p. 2458)
- Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library (p. 2459)
Using the SageMaker TensorFlow and PyTorch Estimators

The TensorFlow and PyTorch estimator classes contain the `distribution` parameter, which you can use to specify configuration parameters for using distributed training frameworks. The SageMaker model parallel library internally uses MPI for hybrid data and model parallelism, so you must use the MPI option with the library.

The following template of a TensorFlow or PyTorch estimator shows how to configure the `distribution` parameter for using the SageMaker model parallel library with MPI.

Using the SageMaker TensorFlow estimator

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow

smp_options = {
    "enabled": True,  # Required
    "parameters": {
        "partitions": 2,  # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "horovod": True,  # Use this for hybrid model and data parallelism
    }
}

mpi_options = {
    "enabled": True,  # Required
    "processes_per_host": 8,  # Required
    # "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = TensorFlow(
    entry_point="your_training_script.py",  # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='2.6.3',
    py_version='py38',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Using the SageMaker PyTorch estimator

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,  # Required
    "parameters": {
        "pipeline_parallel_degree": 2,  # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "ddp": True,
```

2456
To enable the library, you need to pass configuration dictionaries to the "smdistributed" and "mpi" keys through the distribution argument of the SageMaker estimator constructors.

**Configuration parameters for SageMaker model parallelism**

- For the "smdistributed" key, pass a dictionary with the "modelparallel" key and the following inner dictionaries.
  
  **Note**
  
  Using "modelparallel" and "dataparallel" in one training job is not supported.
  
  - "enabled" – Required. To enable model parallelism, set "enabled": True.
  
  - "parameters" – Required. Specify a set of parameters for SageMaker model parallelism.
  
  For a complete list of common parameters, see Parameters for smdistributed in the SageMaker Python SDK documentation.
  
  For TensorFlow, see TensorFlow-specific Parameters.
  
  For PyTorch, see PyTorch-specific Parameters.
  
  - "pipeline_parallel_degree" (or "partitions" in smdistributed-modelparallel<1.6.0) – Required. Among the parameters for smdistributed, this parameter is required to specify how many model partitions you want to split into.
  
  **Important**
  
  There is a breaking change in the parameter name. The "pipeline_parallel_degree" parameter replaces the "partitions" since smdistributed-modelparallel v1.6.0. For more information, see Common Parameters for SageMaker model parallelism configuration and SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.
  
  - For the "mpi" key, pass a dictionary that contains the following:
    
    - "enabled" – Required. Set True to launch the distributed training job with MPI.
    
    - "processes_per_host" – Required. Specify the number of processes MPI should launch on each host. In SageMaker a host is a single Amazon EC2 ML instance. The SageMaker Python SDK maintains a one-to-one mapping between processes and GPUs across model and data parallelism.
This means that SageMaker schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`. To learn more, see PyTorch (p. 2450).

**Important**

`process_per_host` must not be greater than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

- "custom_mpi_options" (optional) – Use this key to pass any custom MPI options you might need. If you do not pass any MPI custom options to the key, the MPI option is set by default to the following flag.

```
--mca btl_vader_single_copy_mechanism none
```

**Note**

You do not need to explicitly specify this default flag to the key. If you explicitly specify it, your distributed model parallel training job might fail with the following error:

```
The following MCA parameter has been listed multiple times on the command line:
MCA param: btl_vader_single_copy_mechanism MCA parameters can only be listed once
on a command line to ensure there is no ambiguity as to its value.
Please correct the situation and try again.
```

**Tip**

If you launch a training job using an EFA-enabled instance type, such as `ml.p4d.24xlarge` and `ml.p3dn.24xlarge`, use the following flag for best performance:

```
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa -x RDMAV_FORK_SAFE=1
```

To launch the training job using the estimator and your SageMaker model parallel configured training script, run the `estimator.fit()` function.

Use the following resources to learn more about using the model parallelism features in the SageMaker Python SDK:

- Use TensorFlow with the SageMaker Python SDK
- Use PyTorch with the SageMaker Python SDK

We recommend you use a SageMaker notebook instance if you are new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see Amazon SageMaker Distributed Training Notebook Examples (p. 2493).

You can also submit a distributed training job from your machine using AWS CLI. To set up AWS CLI on your machine, see set up your AWS credentials and Region for development.

**Extend a Prebuilt Docker Container that Contains SageMaker's Distributed Model Parallel Library**

To extend a prebuilt container and use SageMaker's distributed model parallel library, you must use one of the available AWS Deep Learning Containers (DLC) images for PyTorch or TensorFlow. The SageMaker distributed model parallel library is included in the TensorFlow (2.3.0 and later) and PyTorch (1.6.0 and later) DLC images with CUDA (cuvyyz). For a complete list of DLC images, see Available Deep Learning Containers Images in the AWS Deep Learning Containers GitHub repository.
Tip
We recommend that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up-to-date version of the SageMaker distributed model parallel library.

For example, your Dockerfile should contain a FROM statement similar to the following:

```bash
# Use the SageMaker DLC image URI for TensorFlow or PyTorch
FROM aws-dlc-account-id.dkr.ecr.aws-region.amazonaws.com/framework-training:{framework-version-tag}

# Add your dependencies here
RUN ...

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
```

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the `entry_point` for your training script. This should be the same path identified with `ENV SAGEMAKER_SUBMIT_DIRECTORY` in your Dockerfile.

Tip
You must push this Docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (image_uri) to define a SageMaker estimator for training. For more information, see Extend a Prebuilt Container.

After you finish hosting the Docker container and retrieving the image URI of the container, create a SageMaker PyTorch estimator object as follows. This example assumes that you have already defined `smp_options` and `mpi_options`.

```python
smd_mp_estimator = Estimator(
    entry_point="your_training_script.py",
    role=sagemaker.get_execution_role(),
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    image_uri='your_aws_account_id.dkr.ecr.region.amazonaws.com/name:tag',
    instance_count=1,
    distribution={
        "smdistributed": smp_options,
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library

To build your own Docker container for training and use the SageMaker model parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides the minimum set of code blocks you must include to properly prepare a SageMaker training environment and the model parallel library in your own Docker container.

Note
This custom Docker option with the SageMaker model parallel library as a binary is available only for PyTorch.
To create a Dockerfile with the SageMaker training toolkit and the model parallel library

1. Start with one of the NVIDIA CUDA base images.

```
FROM <cuda-cudnn-base-image>
```

**Tip**
The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. We recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find which versions of the libraries you need to install and how to configure them. The official Dockerfiles are complete, benchmark tested, and managed by the SageMaker and Deep Learning Container service teams. In the provided link, choose the PyTorch version you use, choose the CUDA (cuxyz) folder, and choose the Dockerfile ending with .gpu or .sagemaker.gpu.

2. To set up a distributed training environment, you need to install software for communication and network devices, such as Elastic Fabric Adapter (EFA), NVIDIA Collective Communications Library (NCCL), and Open MPI. Depending on the PyTorch and CUDA versions you choose, you must install compatible versions of the libraries.

**Important**
Because the SageMaker model parallel library requires the SageMaker data parallel library in the subsequent steps, we highly recommend that you follow the instructions at Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2414) to properly set up a SageMaker training environment for distributed training.

For more information about setting up EFA with NCCL and Open MPI, see Get started with EFA and MPI and Get started with EFA and NCCL.

3. Add the following arguments to specify the URLs of the SageMaker distributed training packages for PyTorch. The SageMaker model parallel library requires the SageMaker data parallel library to use the cross-node Remote Direct Memory Access (RDMA).

```
ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/1.10.2/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-linux_x86_64.whl
```

4. Install dependencies that the SageMaker model parallel library requires.

   a. Install the METIS library.

```
ARG METIS=metis-5.1.0

RUN rm /etc/apt/sources.list.d/* 
&& wget -nv http://glaros.dtc.umn.edu/gkhome/fetch/sw/metis/${METIS}.tar.gz 
&& gunzip -f ${METIS}.tar.gz 
&& tar -xvf ${METIS}.tar 
&& cd ${METIS} 
&& apt-get update 
&& make config shared=1 
&& make install 
&& cd .. 
&& rm -rf $(METIS).tar* 
&& rm -rf $(METIS) 
&& rm -rf /var/lib/apt/lists/* 
&& apt-get clean
```

   b. Install the RAPIDS Memory Manager library. This requires CMake 3.14 or later.
ARG RMM_VERSION=0.15.0

RUN wget -nv https://github.com/rapidsai/rmm/archive/v${RMM_VERSION}.tar.gz \
    && tar -xvf v${RMM_VERSION}.tar.gz \
    && cd rmm-${RMM_VERSION} \
    && INSTALL_PREFIX=/usr/local ./build.sh librmm \
    && cd .. \
    && rm -rf v${RMM_VERSION}.tar* \
    && rm -rf rmm-${RMM_VERSION}

5. Install the SageMaker model parallel library.

RUN pip install --no-cache-dir -U ${SMD_MODEL_PARALLEL_URL}

6. Install the SageMaker data parallel library.

RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}

7. Install the sagemaker-training toolkit. The toolkit contains the common functionality that's necessary to create a container compatible with the SageMaker training platform and the SageMaker Python SDK.

RUN pip install sagemaker-training

8. After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container and host it in Amazon ECR.

Tip
For more general information about creating a custom Dockerfile for training in SageMaker, see Use Your Own Training Algorithms.

Extended Features of the SageMaker Model Parallel Library for PyTorch

In addition to its core features, the SageMaker distributed model parallel library offers memory-saving features for training deep learning models with PyTorch: tensor parallelism, optimizer state sharding, activation checkpointing, and activation offloading.

Note
Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker distributed model parallel library v1.6.0 or later.

For each of the following features, you keep the same two-step workflow shown in the Run a SageMaker Distributed Training Job with Model Parallelism (p. 2443) section and add few additional parameters and code lines to the SageMaker PyTorch estimator and your training script.

To find an example of how to use the extended features, see Train GPT-2 with PyTorch 1.8.1 and Tensor Parallelism Using the SageMaker Model Parallelism Library.

Topics
- Tensor Parallelism (p. 2462)
- Optimizer State Sharding (p. 2472)
- Activation Checkpointing (p. 2473)
- Activation Offloading (p. 2474)
Tensor Parallelism

Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. In contrast to pipeline parallelism, which keeps individual weights intact but partitions the set of weights, tensor parallelism splits individual weights. This typically involves distributed computation of specific operations, modules, or layers of the model.

Tensor parallelism is required in cases in which a single parameter consumes most of the GPU memory (such as large embedding tables with a large vocabulary size or a large softmax layer with a large number of classes). In this case, treating this large tensor or operation as an atomic unit is inefficient and impedes balance of the memory load.

Tensor parallelism is also useful for extremely large models in which a pure pipelining is simply not enough. For example, with GPT-3-scale models that require partitioning over tens of instances, a pure microbatch pipelining is inefficient because the pipeline depth becomes too high and the overhead becomes prohibitively large.

Topics

- How Tensor Parallelism Works (p. 2462)
- Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism (p. 2464)
- Instructions for Checkpointing with Tensor Parallelism (p. 2468)
- Support for Hugging Face Transformer Models (p. 2470)

How Tensor Parallelism Works

Tensor parallelism takes place at the level of `nn.Modules`; it partitions specific modules in the model across tensor parallel ranks. This is in addition to the existing partition of the set of modules used in pipeline parallelism.

When a module is partitioned through tensor parallelism, its forward and backward propagation are distributed. The library handles the necessary communication across devices to implement the distributed execution of these modules. The modules are partitioned across multiple data parallel ranks. Contrary to the traditional distribution of workloads, each data parallel rank does not have the complete model replica when the library's tensor parallelism is used. Instead, each data parallel rank may have only a partition of the distributed modules, in addition to the entirety of the modules that are not distributed.

Example: Consider tensor parallelism across data parallel ranks, where the degree of data parallelism is 4 and the degree of tensor parallelism is 2. Assume that you have a data parallel group that holds the following module tree, after partitioning the set of modules.

```
A
  ### B
  |   ### E
  |   ### F
  ### C
  ### D
  |   ### G
  |   ### H
```
Assume that tensor parallelism is supported for the modules B, G, and H. One possible outcome of tensor parallel partition of this model could be:

| dp_rank 0 (tensor parallel rank 0): A, B:0, C, D, G:0, H |
| dp_rank 1 (tensor parallel rank 1): A, B:1, C, D, G:1, H |
| dp_rank 2 (tensor parallel rank 0): A, B:0, C, D, G:0, H |
| dp_rank 3 (tensor parallel rank 1): A, B:1, C, D, G:1, H |

Each line represents the set of modules stored in that \( dp\_rank \), and the notation \( X:y \) represents the \( y \)th fraction of the module \( X \). Note the following:

1. Partitioning takes place across subsets of data parallel ranks, which we call \( TP\_GROUP \), not the entire \( DP\_GROUP \), so that the exact model partition is replicated across \( dp\_rank\) 0 and \( dp\_rank\) 2, and similarly across \( dp\_rank\) 1 and \( dp\_rank\) 3.
2. The modules E and F are no longer part of the model, since their parent module B is partitioned, and any execution that is normally a part of E and F takes place within the (partitioned) B module.
3. Even though H is supported for tensor parallelism, in this example it is not partitioned, which highlights that whether to partition a module depends on user input. The fact that a module is supported for tensor parallelism does not necessarily mean it is partitioned.

**How the library adapts tensor parallelism to PyTorch’s \( nn.Linear \) module**

When tensor parallelism is performed over data parallel ranks, a subset of the parameters, gradients, and optimizer states are partitioned across the tensor parallel devices for the modules that are partitioned. For the rest of the modules, the tensor parallel devices operate in a regular data parallel manner. To execute the partitioned module, a device first collects the necessary parts of all data samples across peer devices in the same tensor parallelism group. The device then runs the local fraction of the module on all these data samples, followed by another round of synchronization which both combines the parts of the output for each data sample and returns the combined data samples to the GPUs from which the data sample first originated. The following figure shows an example of this process over a partitioned \( nn.Linear \) module.
The first figure shows a small model with a large `nn.Linear` module with data parallelism over the two tensor parallelism ranks. The `nn.Linear` module is replicated into the two parallel ranks.

The second figure shows tensor parallelism applied on a larger model while splitting the `nn.Linear` module. Each `tp_rank` holds half the linear module, and the entirety of the rest of the operations. While the linear module runs, each `tp_rank` collects the relevant half of all data samples and passes it through their half of the `nn.Linear` module. The result needs to be reduce-scattered (with summation as the reduction operation) so that each rank has the final linear output for their own data samples. The rest of the model runs in the typical data parallel manner.

**Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism**

In this section, you learn:

- How to configure a SageMaker PyTorch estimator and the SageMaker distributed model parallelism option to use tensor parallelism.
- How to adapt your training script using the extended `smdistributed.modelparallel` modules for tensor parallelism.

To learn more about the `smdistributed.modelparallel` modules, see the SageMaker distributed model parallel APIs in the *SageMaker Python SDK documentation*.

**Topics**

- Tensor parallelism alone (p. 2464)
- Tensor parallelism combined with pipeline parallelism (p. 2466)

**Tensor parallelism alone**

The following is an example of a distributed training option to activate tensor parallelism alone, without pipeline parallelism. Configure the `mpi_options` and `smp_options` dictionaries to specify distributed training options to the SageMaker PyTorch estimator.

**Note**

Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker distributed model parallel library v1.6.0 or later.

**Configure a SageMaker PyTorch estimator**

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,  # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "pipeline_parallel_degree": 1,  # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 4,  # tp over 4 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(
    entry_point='your_training_script.py',  # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
```
Amazon SageMaker Developer Guide
Model Parallel Training

```python
framework_version='1.12.0',
py_version='py36',
instance_count=1,
distribution={
    "smdistributed": {"modelparallel": smp_options},
    "mpi": mpi_options
},
base_job_name="SMD-MP-demo",
)
smp_estimator.fit('s3://my_bucket/my_training_data/')
```

**Tip**
To find a complete list of parameters for distribution, see Configuration Parameters for Model Parallelism in the SageMaker Python SDK documentation.

**Adapt your PyTorch training script**

The following example training script shows how to adapt the SageMaker distributed model parallelism library to a training script. In this example, it is assumed that the script is named `your_training_script.py`.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

    def train(self, model, device, train_loader, optimizer):
        model.train()
        for batch_idx, (data, target) in enumerate(train_loader):
            # smdistributed: Move input tensors to the GPU ID used by
            # the current process, based on the set_device call.
            data, target = data.to(device), target.to(device)
            optimizer.zero_grad()
            output = model(data)
            loss = F.nll_loss(output, target, reduction="mean")
            loss.backward()
            optimizer.step()

            # smdistributed: Initialize the backend
```
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
if smp.local_rank() == 0:
dataset = datasets.MNIST("../data", train=True, download=False)
smp.barrier()

# smdistributed: Shard the dataset based on data parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
dataset = SplitDataset(dataset, partitions=partitions_dict)
dataset.select(f"{smp.dp_rank()}")

train_loader = torch.utils.data.DataLoader(dataset, batch_size=64)

# smdistributed: Enable tensor parallelism for all supported modules in the model
# i.e., nn.Linear in this case. Alternatively, we can use
# smp.set_tensor_parallelism(model.fc1, True)
with smp.tensor_parallelism():
    model = Net()

# smdistributed: Use the DistributedModel wrapper to distribute the
# modules for which tensor parallelism is enabled
model = smp.DistributedModel(model)

optimizer = optim.Adadelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

Tensor parallelism combined with pipeline parallelism

The following is an example of a distributed training option that enables tensor parallelism combined
with pipeline parallelism. Set up the mpi_options and smp_options parameters to specify distributed
model parallel options with tensor parallelism when you configure a SageMaker PyTorch estimator.

**Note**
Extended memory-saving features are available through Deep Learning Containers for PyTorch,
which implements the SageMaker distributed model parallel library v1.6.0 or later.

**Configure a SageMaker PyTorch estimator**

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,  # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,  # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,  # tp over 2 devices
        "ddp": True
    }
}
smp_estimator = PyTorch(
    entry_point='your_training_script.py', # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.12.0',
    py_version='py36',
    instance_count=1,
    distribution=
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
smp_estimator.fit('s3://my_bucket/my_training_data/')

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker distributed model parallelism library to a training script. Note that the training script now includes the smp.step decorator:

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

    @smp.step
    def train_step(model, data, target):
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        model.backward(loss)
        return output, loss

train(model, device, train_loader, optimizer):
```
model.train()

for batch_idx, (data, target) in enumerate(train_loader):
    # smdistributed: Move input tensors to the GPU ID used by
    # the current process, based on the set_device call.
    data, target = data.to(device), target.to(device)
    optimizer.zero_grad()
    # Return value, loss_mb is a StepOutput object
    _, loss_mb = train_step(model, data, target)

    # smdistributed: Average the loss across microbatches.
    loss = loss_mb.reduce_mean()

    optimizer.step()

    # smdistributed: Initialize the backend
    smp.init()

    # smdistributed: Set the device to the GPU ID used by the current process.
    # Input tensors should be transferred to this device.
    torch.cuda.set_device(smp.local_rank())
    device = torch.device("cuda")

    # smdistributed: Download only on a single process per instance.
    # When this is not present, the file is corrupted by multiple processes trying
    # to download and extract at the same time
    if smp.local_rank() == 0:
        dataset = datasets.MNIST("../data", train=True, download=False)
        smp.barrier()

    # smdistributed: Shard the dataset based on data parallel ranks
    if smp.dp_size() > 1:
        partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
        dataset = SplitDataset(dataset, partitions=partitions_dict)
        dataset.select(f"{smp.dp_rank()}")

    # smdistributed: Set drop_last=True to ensure that batch size is always divisible
    # by the number of microbatches
    train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = Net()

# smdistributed: enable tensor parallelism only for model.fc1
smp.set_tensor_parallelism(model.fc1, True)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)

optimizer = optim.AdaDelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

Instructions for Checkpointing with Tensor Parallelism

The SageMaker model parallel library supports saving partial or full checkpoints with tensor parallelism.
The following guide shows how to modify your script to save and load a checkpoint when you use tensor parallelism.

1. Prepare a model object and wrap it with the library's wrapper function \texttt{smp.DistributedModel()}.

```
model = MyModel(...)
```
model = smp.DistributedModel(model)

2. Prepare an optimizer for the model. A set of model parameters is an iterable argument required by optimizer functions. To prepare a set of model parameters, you must process `model.parameters()` to assign unique IDs to individual model parameters.

If there are parameters with duplicated IDs in the model parameter iterable, loading the checkpointed optimizer state fails. To create an iterable of model parameters with unique IDs for your optimizer, see the following:

```python
unique_params = []
unique_params_set = set()
for p in model.parameters():
    if p not in unique_params_set:
        unique_params.append(p)
        unique_params_set.add(p)
del unique_params_set

optimizer = MyOpt(unique_params, ...)
```

3. Wrap the optimizer using the library's wrapper function `smp.DistributedOptimizer()`.

```python
optimizer = smp.DistributedOptimizer(optimizer)
```

4. Save the model and the optimizer state using `smp.save()`. Depending on how you want to save checkpoints, choose one of the following two options:

- **Option 1:** Save a partial model on each `mp_rank` for a single `MP_GROUP`.

  ```python
  model_dict = model.local_state_dict()  # save a partial model
  opt_dict = optimizer.local_state_dict()  # save a partial optimizer state
  # Save the dictionaries at rdp_rank 0 as a checkpoint
  if smp.rdp_rank() == 0:
      smp.save(
          {"model_state_dict": model_dict, "optimizer_state_dict": opt_dict},
          f"/checkpoint.pt",
          partial=True,
      )
  ```

  With tensor parallelism, the library saves checkpointed files named in the following format: `checkpoint.pt_{pp_rank}_{tp_rank}`.

  **Note**
  With tensor parallelism, make sure you set the if statement as `if smp.rdp_rank() == 0` instead of if `smp.dp_rank() == 0`. When the optimizer state is sharded with tensor parallelism, all reduced-data parallel ranks must save their own partition of the optimizer state. Using a wrong `if` statement for checkpointing might result in a stalling training job. For more information about using `if smp.dp_rank() == 0` without tensor parallelism, see General Instruction for Saving and Loading in the SageMaker Python SDK documentation.

- **Option 2:** Save the full model.

  ```python
  if smp.rdp_rank() == 0:
      model_dict = model.state_dict(gather_to_rank0=True)  # save the full model
  if smp.rank() == 0:
      smp.save(
          {"model_state_dict": model_dict},
          "/checkpoint.pt",
          partial=False,
      )
  ```
Note
Consider the following for full checkpointing:

- If you set `gather_to_rank0=True`, all ranks other than 0 return empty dictionaries.
- For full checkpointing, you can only checkpoint the model. Full checkpointing of optimizer states is currently not supported.
- The full model only needs to be saved at `smp.rank() == 0`.

5. Load the checkpoints using `smp.load()`. Depending on how you checkpointed in the previous step, choose one of the following two options:

- **Option 1**: Load the partial checkpoints.

```python
checkpoint = smp.load("/checkpoint.pt", partial=True)
model.load_state_dict(checkpoint["model_state_dict"], same_partition_load=False)
optimizer.load_state_dict(checkpoint["optimizer_state_dict"])
```

You can set `same_partition_load=True` in `model.load_state_dict()` for a faster load, if you know that the partition will not change.

- **Option 2**: Load the full checkpoints.

```python
if smp.rdp_rank() == 0:
    checkpoint = smp.load("/checkpoint.pt", partial=False)
    model.load_state_dict(checkpoint["model_state_dict"])
```

The `if smp.rdp_rank() == 0` condition is not required, but it can help avoid redundant loading among different MP_GROUPS. Full checkpointing optimizer state dict is currently not supported with tensor parallelism.

Support for Hugging Face Transformer Models

The SageMaker model parallel library's tensor parallelism offers out-of-the-box support for the following Hugging Face Transformer models:

- GPT-2, BERT, and RoBERTa (Available in the SageMaker model parallel library v1.7.0 and later)
- GPT-J (Available in the SageMaker model parallel library v1.8.0 and later)
- GPT-Neo (Available in the SageMaker model parallel library v1.10.0 and later)

Note
For any other Transformers models, you need to use the `smdistributed.modelparallel.torch.tp_register_with_module()` API to apply tensor parallelism.

Note
To use tensor parallelism for training Hugging Face Transformer models, make sure you use Hugging Face Deep Learning Containers for PyTorch that has the SageMaker model parallel library v1.7.0 and later. For more information, see the SageMaker model parallel library release notes.

Supported Models Out of the Box

For the Hugging Face transformer models supported by the library out of the box, you don't need to manually implement hooks to translate Transformer APIs to `smdistributed` transformer layers. You can activate tensor parallelism by using the context manager `smdistributed.modelparallel.torch.tensor_parallelism()` and wrapping the model by `smdistributed.modelparallel.torch.DistributedModel()`. You don't need to manually register hooks for tensor parallelism using the `smp.tp_register` API.
The `state_dict` translation functions between Hugging Face Transformers and `smdistributed.modelparallel` can be accessed as follows.

- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_state_dict_to_hf_gpt2(state_dict, max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_hf_state_dict_to_smdistributed_gpt2(state_dict)`
- `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_state_dict_to_hf_bert(state_dict, max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_hf_state_dict_to_smdistributed_bert(state_dict)`
- `smdistributed.modelparallel.torch.nn.huggingface.roberta.translate_state_dict_to_hf_roberta(state_dict, max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.roberta.translate_hf_state_dict_to_smdistributed_roberta(state_dict)`
- `smdistributed.modelparallel.torch.nn.huggingface.gptj.translate_state_dict_to_hf_gptj(state_dict, max_seq_len=None)` (Available in the SageMaker model parallel library v1.8.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptj.translate_hf_gptj_state_dict_to_smdistributed_gptj(state_dict)` (Available in the SageMaker model parallel library v1.8.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptneo.translate_state_dict_to_hf_gptneo(state_dict, max_seq_len=None)` (Available in the SageMaker model parallel library v1.10.0 and later)
- `smdistributed.modelparallel.torch.nn.huggingface.gptneo.translate_hf_state_dict_to_smdistributed_gptneo(state_dict)` (Available in the SageMaker model parallel library v1.10.0 and later)

**Example usage of the GPT-2 translation function**

Start with wrapping the model as shown in the following code.

```python
from transformers import AutoModelForCausalLM
with smp.tensor_parallelism():
    model = AutoModelForCausalLM.from_config(hf_gpt2_config)
model = smp.DistributedModel(model)
```

Given a `state_dict` from the `DistributedModel` object, you can load the weights into the original Hugging Face GPT-2 model using the `translate_state_dict_to_hf_gpt2` function as shown in the following code.

```python
from smdistributed.modelparallel.torch.nn.huggingface.gpt2 import translate_state_dict_to_hf_gpt2
max_seq_len = 1024
# [... code block for training ...]
if smp.rdp_rank() == 0:
    state_dict = dist_model.state_dict()
    hf_state_dict = translate_state_dict_to_hf_gpt2(state_dict, max_seq_len)
    # can now call model.load_state_dict(hf_state_dict) to the original HF model
```

**Example usage of the RoBERTa translation function**

Similarly, given a supported HuggingFace model `state_dict`, you can use the `translate_hf_state_dict_to_smdistributed` function to convert it to a format readable by `smp.DistributedModel`. This can be useful in transfer learning use cases, where a pre-trained model is loaded into a `smp.DistributedModel` for model-parallel fine-tuning:
from smdistributed.modelparallel.torch.nn.huggingface.roberta  
   import translate_state_dict_to_smdistributed

model = AutoModelForMaskedLM.from_config(roberta_config)
model = smp.DistributedModel(model)

pretrained_model = AutoModelForMaskedLM.from_pretrained("roberta-large")
translated_state_dict =
   translate_state_dict_to_smdistributed(pretrained_model.state_dict())

# load the translated pretrained weights into the smp.DistributedModel
model.load_state_dict(translated_state_dict)

# start fine-tuning...

Optimizer State Sharding

**Optimizer state sharding** is a useful memory-saving technique that shards the optimizer state (the set of weights that describes the state of optimizer) across data parallel device groups. You can use optimizer state sharding whenever you use a stateful optimizer (such as Adam) or an FP16 optimizer (which stores both FP16 and FP32 copies of the parameters).

How to Use Optimizer State Sharding

You can turn on **optimizer state sharding** by setting "shard_optimizer_state": True in the modelparallel configuration.

When this feature is turned on, the library partitions the set of model parameters based on the data parallelism degree. The gradients corresponding to the $i$th partition get reduced only at the $i$th data parallel rank. At the end of the first call to an smp.step decorator function, the optimizer wrapped by smp.DistributedOptimizer redefines its parameters to be only limited to those parameters corresponding to the partition of the current data parallel rank. The redefined parameters are called virtual parameters and share underlying storage with the original parameters. During the first call to optimizer.step, the optimizer states are created based on these redefined parameters, which are sharded because of the original partition. After the optimizer update, the AllGather operation (as part of the optimizer.step call) runs across the data parallel ranks to achieve consistent parameter states.

**Tip**

Optimizer state sharding can be useful when the degree of data parallelism is greater than 1 and the model has more than a billion parameters.

The degree of data parallelism is calculated by $(\text{processes\_per\_host} \times \text{instance\_count}) / \text{pipeline\_parallel\_degree}$, and the smp.dp.size() function handles the sizing in the background.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
   "enabled" : True,
   "processes_per_host" : 8,               # 8 processes
   "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
   "enabled":True,
   "parameters": {
      "microbatches": 4,
      "pipeline_parallel_degree": 2,       # alias for "partitions"
      "placement_strategy": "cluster",
      "tensor_parallel_degree": 2,        # tp over 2 devices
      "ddp": True,
   }
}```

Adapt your PyTorch training script

See Adapt your PyTorch training script (p. 2467) in the Tensor parallelism combined with pipeline parallelism section. There's no additional modification required for the script.

Activation Checkpointing

Activation checkpointing (or gradient checkpointing) is a technique to reduce memory usage by clearing activations of certain layers and recomputing them during a backward pass. Effectively, this trades extra computation time for reduced memory usage. If a module is checkpointed, at the end of a forward pass, the inputs to and outputs from the module stay in memory. Any intermediate tensors that would have been part of the computation inside that module are freed up during the forward pass. During the backward pass of checkpointed modules, these tensors are recomputed. At this point, the layers beyond this checkpointed module have finished their backward pass, so the peak memory usage with checkpointing can be lower.

How to Use Activation Checkpointing

With smdistributed.modelparallel, you can use activation checkpointing at the granularity of a module. For all torch.nn modules except torch.nn.Sequential, you can only checkpoint a module tree if it lies within one partition from the perspective of pipeline parallelism. In case of the torch.nn.Sequential module, each module tree inside the sequential module must lie completely within one partition for activation checkpointing to work. When you use manual partitioning, be aware of these restrictions.

When you use automated model partitioning, you can find the partitioning assignment logs starting with Partition assignments: in the training job logs. If a module is partitioned across multiple ranks (for example, with one descendant on one rank and another descendant on a different rank), the library ignores the attempt to checkpoint the module and raises a warning message that the module won't be checkpointed.

Note
The SageMaker model parallel library supports both overlapping and non-overlapping allreduce operation in combination with checkpointing.

Note
PyTorch's native checkpointing API is not compatible with smdistributed.modelparallel.

Example 1: The following sample code shows how to use activation checkpointing when you have a model definition in your script.

```python
import torch.nn as nn
import torch.nn.functional as F
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
```

"shard_optimizer_state": True

x = self.conv1(x)
x = self.conv2(x)
x = F.max_pool2d(x, 2)
x = torch.flatten(x, 1)
# This call of fc1 will be checkpointed
x = checkpoint(self.fc1, x)
x = self.fc2(x)
return F.log_softmax(x, 1)

Example 2: The following sample code shows how to use activation checkpointing when you have a sequential model in your script.

```python
import torch.nn as nn
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint_sequential
class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.seq = nn.Sequential(
            nn.Conv2d(1,20,5),
            nn.ReLU(),
            nn.Conv2d(20,64,5),
            nn.ReLU()
        )
    def forward(self, x):
        # This call of self.seq will be checkpointed
        x = checkpoint_sequential(self.seq, x)
        return F.log_softmax(x, 1)
```

Example 3: The following sample code shows how to use activation checkpointing when you import a prebuilt model from a library, such as PyTorch and Hugging Face Transformers. Whether you checkpoint sequential modules or not, do the following:

1. Wrap the model by `smp.DistributedModel()`.
2. Define an object for sequential layers.
3. Wrap the sequential layer object by `smp.set_activation_checkpointing()`.

```python
import smdistributed.modelparallel.torch as smp
from transformers import AutoModelForCausalLM
smp.init()
model = AutoModelForCausalLM(*args, **kwargs)
model = smp.DistributedModel(model)
# Call set_activation_checkpointing API
transformer_layers = model.module.module.module.transformer.seq_layers
smp.set_activation_checkpointing(transformer_layers, pack_args_as_tuple=True, strategy='each')
```

Activation Offloading

When activation checkpointing and pipeline parallelism are turned on and the number of microbatches is greater than one, *activation offloading* is an additional feature that can further reduce memory usage. Activation offloading asynchronously moves the checkpointed activations corresponding to their microbatches that are not currently running in the CPU. Right before the GPU needs the activations for the microbatch’s backward pass, this functionality prefetches the offloaded activations back from the CPU.
How to Use Activation Offloading

Use activation offloading to reduce memory usage when the number of microbatches is greater than 1, and activation checkpointing is turned on (see Activation Checkpointing (p. 2473)). When the activation checkpointing is not used, activation offloading has no effect. When it is used with only one microbatch, it does not save memory.

To use activation offloading, set "offload_activations": True in the modelparallel configuration.

Activation offloading moves the checkpointed activations in nn.Sequential modules to CPU asynchronously. The data transfer over the PCIe link overlaps with GPU computation. The offloading happens immediately, as soon as the forward pass for a particular checkpointed layer is computed. The activations are loaded back to the GPU shortly before they are needed for the backward pass of a particular microbatch. The CPU-GPU transfer similarly overlaps with computation.

To adjust how early the activations are loaded back into the GPU, you can use the configuration parameter "activation_loading_horizon" (default is set to 4, must be int larger than 0). A larger activation loading horizon would cause the activations to be loaded back to the GPU earlier. If the horizon is too large, the memory-saving impact of activation offloading might be diminished. If the horizon is too small, the activations may not be loaded back in time, reducing the amount of overlap and degrading performance.

**Tip**

Activation offloading can be useful for large models with over a hundred billion parameters.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,  # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,  # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,  # tp over 2 devices
        "ddp": True,
        "offload_activations": True,
        "activation_loading_horizon": 4  # optional. default is 4.
    }
}
```

Ranking Mechanism

This section explains how the ranking mechanism of model parallelism works with tensor parallelism. This is extended from the Ranking Basics for Core Features of the SageMaker Model Parallel Library (p. 2439). With tensor parallelism, the library introduces three types of ranking and process group APIs: `smp.tp_rank()` for tensor parallel rank, `smp.pp_rank()` for pipeline parallel rank, and `smp.rdp_rank()` for reduced-data parallel rank. The corresponding communication process groups are tensor parallel group (TP_GROUP), pipeline parallel group (PP_GROUP), and reduced-data parallel group (RDP_GROUP). These groups are defined as follows:

- A tensor parallel group (TP_GROUP) is an evenly divisible subset of the data parallel group, over which tensor parallel distribution of modules takes place. When the degree of pipeline parallelism is 1, TP_GROUP is the same as model parallel group (MP_GROUP).
A pipeline parallel group (PP_GROUP) is the group of processes over which pipeline parallelism takes place. When the tensor parallelism degree is 1, PP_GROUP is the same as MP_GROUP.

A reduced-data parallel group (RDP_GROUP) is a set of processes that hold both the same pipeline parallelism partitions and the same tensor parallel partitions, and perform data parallelism among themselves. This is called the reduced data parallel group because it is a subset of the entire data parallelism group, DP_GROUP. For the model parameters that are distributed within the TP_GROUP, the gradient allreduce operation is performed only for reduced-data parallel group, while for the parameters that are not distributed, the gradient allreduce takes place over the entire DP_GROUP.

A model parallel group (MP_GROUP) refers to a group of processes that collectively store the entire model. It consists of the union of the PP_GROUPs of all the ranks that are in the TP_GROUP of the current process. When the degree of tensor parallelism is 1, MP_GROUP is equivalent to PP_GROUP. It is also consistent with the existing definition of MP_GROUP from previous smdistributed releases. Note that the current TP_GROUP is a subset of both the current DP_GROUP and the current MP_GROUP.

To learn more about the communication process APIs in the SageMaker distributed model parallelism library, see the Common API and the PyTorch-specific APIs in the SageMaker Python SDK documentation.
PP_GROUP, and TP_GROUP. The lower right figure shows RDP_GROUP, DP_GROUP, and WORLD over the same set of GPUs. The gradients for the layers and layer slices that have the same color are allreduced together for data parallelism. For example, the first layer (light blue) gets the allreduce operations across DP_GROUP, whereas the dark orange slice in the second layer only gets the allreduce operations within the RDP_GROUP of its process. The bold dark red arrows represent tensors with the batch of its entire TP_GROUP.

| GPU0: pp_rank 0, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 0 |
| GPU1: pp_rank 1, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 1 |
| GPU2: pp_rank 0, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 2 |
| GPU3: pp_rank 1, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 3 |
| GPU4: pp_rank 0, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 0 |
| GPU5: pp_rank 1, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 1 |
| GPU6: pp_rank 0, tp_rank 1, rdp_rank 1, dp_rank 3, mp_rank 2 |
| GPU7: pp_rank 1, tp_rank 1, rdp_rank 1, dp_rank 3, mp_rank 3 |

In this example, pipeline parallelism occurs across the GPU pairs (0,1); (2,3); (4,5) and (6,7). In addition, data parallelism (allreduce) takes place across GPUs 0, 2, 4, 6, and independently over GPUs 1, 3, 5, 7. Tensor parallelism happens over subsets of DP_GROUPS, across the GPU pairs (0,2); (1,3); (4,6) and (5,7).

**FP16 Training with Model Parallelism**

For FP16 training, apply the following modifications to your training script and estimator.

**Note**
This feature is available in the SageMaker model parallel library v1.10.0 and later.

**Adapt your PyTorch training script**

1. Wrap your model using the `smdistributed.moxdp.parallel.torch.model_creation()` context manager.

```python
# fp16_training_script.py
import torch
import smdistributed.moxdp.parallel.torch as smp

with smp.model_creation(
    dtype=torch.float16 if args.fp16 else torch.get_default_dtype()
):
    model = ...
```

**Tip**
If you are using tensor parallelism, add `tensor_parallelism=smp.tp_size() > 1` to the `smp.model_creation` context manager. Adding this line also helps automatically detect whether tensor parallelism is activated or not.

```python
with smp.model_creation(
    ...,
    tensor_parallelism=smp.tp_size() > 1
):
    model = ...
```

2. When you wrap the optimizer with `smdistributed.moxdp.parallel.torch.DistributedOptimizer`, set either the `static_loss_scaling` or `dynamic_loss_scaling` argument. By default, `static_loss_scaling` is set to 1.0, and `dynamic_loss_scaling` is set to `False`. If you set `dynamic_loss_scale=True`, you can feed dynamic loss scaling options as a dictionary through the `dynamic_loss_args` argument. In most cases, we recommend you use dynamic loss scaling with the
default options. For more information, options, and examples of the optimizer wrapper function, see
the `smdistributed.modelparallel.torch.DistributedOptimizer` API.

The following code is an example of wrapping an `Adadelta` optimizer object with dynamic loss
scaling for FP16 training.

```python
optimizer = torch.optim.Adadelta(...)
optimizer = smp.DistributedOptimizer(
    optimizer,
    static_loss_scale=None,
    dynamic_loss_scale=True,
    dynamic_loss_args={
        "scale_window": 1000,
        "min_scale": 1,
        "delayed_shift": 2
    }
)
```

**Configure a SageMaker PyTorch estimator**

Add the FP16 parameter ("fp16") to the distribution configuration for model parallelism when creating
a SageMaker PyTorch estimator object. For a complete list of the configuration parameters for model
parallelism, see Parameters for smdistributed.

```python
from sagemaker.pytorch import PyTorch
smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,
        "tensor_parallel_degree": 2,
        ...,
        "fp16": True
    }
}
fp16_estimator = PyTorch(
    entry_point="fp16_training_script.py", # Specify your train script
    ...,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": {"...}
    }
)
fp16_estimator.fit(...)
```

When FP16 training starts, the model and the optimizer are wrapped by `FP16_Module` and
`FP16_Optimizer` respectively, which are modified smdistributed versions of the Apex utils.
`FP16_Module` converts the model to FP16 dtype and deals with the forward pass in FP16.

**Tip**
You can apply gradient clipping by calling `clip_master_grads` before `optimizer.step`.

```python
optimizer.clip_master_grads(max_norm)     # max_norm(float or int): max norm of the
                                          # gradients
```
Tip
When using `torch.optim.lr_scheduler` and FP16 training, you need to pass `optimizer.optimizer` to the LR scheduler rather than the optimizer. See the following example code.

```python
from torch.optim.lr_scheduler import StepLR

scheduler = StepLR(
    optimizer.optimizer if smp.state.cfg.fp16 else optimizer,
    step_size=1,
    gamma=args.gamma
)
```

Checkpointing Distributed Models and Optimizer States

The SageMaker model parallel library provides checkpoint APIs to save and load distributed models and optimizer states.

**Note**
This feature is available in the SageMaker model parallel library v1.10.0 and later.

To save a checkpoint of a model trained with model parallelism, use the `smdistributed.modelparallel.torch.save_checkpoint` API with the partial checkpointing (`partial=True`) that saves each model partition individually. In addition to the model and the optimizer state, you can also save any additional custom data through the `user_content` argument.

The checkpointed model, optimizer, and user content are saved as separate files. The `save_checkpoint` API call creates checkpoint folders in the following structure.

```
- path
  - $(tag)_partial (folder for partial checkpoints)
    - model_rankinfo.pt
    - optimizer_rankinfo.pt
    - fp16_states_rankinfo.pt
    - user_content.pt
  - $tag (checkpoint file for full checkpoints)
  - user_content_$tag (user_content file for full checkpoints)
  - newest (a file that indicates the newest checkpoint)
```

To resume training from a checkpoint, use the `smdistributed.modelparallel.torch.resume_from_checkpoint` API with `partial=True`, using the checkpoint directory and the tag used while saving the checkpoint. Note that the actual loading of model weights happens after model partitioning, during the first run of the `smdistributed.modelparallel.torch.step`-decorated training step function.

When saving a partial checkpoint, the library also saves the model partition decision as files with `.pt` file extension. Conversely, when resuming from the partial checkpoint, the library loads the partition decision files together. Once the partition decision is loaded, you can't change the partition.

To save the final model artifact for inference purposes, use the `smdistributed.modelparallel.torch.save_checkpoint` API with `partial=False`, which combines the model partitions to create a single model artifact. Note that this does not combine the optimizer states.

To initialize training with particular weights, given a full model checkpoint, you can use the `smdistributed.modelparallel.torch.resume_from_checkpoint` API with `partial=False`. Note that this does not load optimizer states.

**Note**
With tensor parallelism, in general, the `state_dict` must be translated between the original model implementation and the `DistributedModel` implementation.
Optionally, you can provide the state_dict translation function as an argument to the `smdistributed.modelparallel.torch.resume_from_checkpoint`. However, for the section called "Supported Models Out of the Box" (p. 2470), the library takes care of this translation automatically.

The following code shows an example of how to use the checkpoint APIs for saving and loading a model trained with model parallelism.

```python
import smdistributed.modelparallel.torch as smp

model = ...
model = smp.DistributedModel(model)
optimizer = ...
optimizer = smp.DistributedOptimizer(optimizer)
user_content = ...  # additional custom data
checkpoint_path = "~/opt/ml/checkpoint/model_parallel"

# Save a checkpoint.
smp.save_checkpoint(
    path=checkpoint_path,
    tag="total_steps(total_steps)",
    partial=True,
    model=model,
    optimizer=optimizer,
    user_content=user_content
    num_kept_partial_checkpoints=5
)

# Load a checkpoint.
# This automatically loads the most recently saved checkpoint.
smp_checkpoint = smp.resume_from_checkpoint(path=checkpoint_path, partial=True)
```

**Sharded Data Parallelism**

*Sharded data parallelism* is a memory-saving distributed training technique that splits the training state of a model (model parameters, gradients, and optimizer states) across GPUs in a data parallel group.

**Note**

This feature is available in the SageMaker model parallel library v1.11.0 and later.

When scaling up your training job to a large GPU cluster, you can reduce the per-GPU memory footprint of the model by sharding the training state over multiple GPUs. This returns two benefits: you can fit larger models, which would otherwise run out of memory with standard data parallelism, or you can increase the batch size using the freed-up GPU memory.

The standard data parallelism technique replicates the training states across the GPUs in the data parallel group, and performs gradient aggregation based on the *AllReduce* operation. Sharded data parallelism modifies the standard data-parallel distributed training procedure to account for the sharded nature of the optimizer states. A group of ranks over which the model and optimizer states are sharded is called a *sharding group*. The sharded data parallelism technique shards the trainable parameters of a model and corresponding gradients and optimizer states across the GPUs in the *sharding group*.

SageMaker implements sharded data parallelism through the MiCS implementation, which is discussed in the AWS blog post *Near-linear scaling of gigantic-model training on AWS*. In this implementation, you can set the sharding degree as a configurable parameter, which must be less than the data parallelism degree. During each forward and backward pass, MiCS temporarily recombines the model parameters in all GPUs through the *AllGather* operation. After the forward or backward pass of each layer, MiCS shards the parameters again to save GPU memory. During the backward pass, MiCS reduces gradients and simultaneously shards them across GPUs through the *ReduceScatter* operation. Finally, MiCS applies the local reduced and sharded gradients to their corresponding local parameter shards, using
the local shards of optimizer states. To bring down communication overhead, the SageMaker model parallel library prefetches the upcoming layers in forward or backward pass, and overlaps the network communication with the computation.

The training state of the model is replicated across the sharding groups. This means that before gradients are applied to the parameters, the \texttt{AllReduce} operation must take place across the sharding groups, in addition to the \texttt{ReduceScatter} operation that takes place within the sharding group.

In effect, sharded data parallelism introduces a tradeoff between the communication overhead and GPU memory efficiency. Using sharded data parallelism increases the communication cost, but the memory footprint per GPU (excluding the memory usage due to activations) is divided by the sharded data parallelism degree, thus larger models can be fit in the GPU cluster.

The selected sharded data parallelism degree must evenly divide the data parallelism degree. For example, for an 8-way data parallelism job, choose 2, 4, or 8 for the sharded data parallelism degree. While choosing the sharded data parallelism degree, we recommend that you start with a small number, and gradually increase it until the model fits in the memory together with the desired batch size.

**Topics**

- How to Apply Sharded Data Parallelism to Your Training Job (p. 2481)
- Mixed Precision Training with Sharded Data Parallelism (p. 2482)
- Tips and Considerations for Using Sharded Data Parallelism (p. 2483)

**How to Apply Sharded Data Parallelism to Your Training Job**

To use sharded data parallelism, apply the following modifications to your training script and estimator.

**Adapt your PyTorch training script**

Follow the instructions at Step 1: Modify a PyTorch Training Script (p. 2449) to wrap the model and optimizer objects with the \texttt{smdistributed.modelparallel.torch} wrappers of the \texttt{torch.nn.parallel} and \texttt{torch.distributed} modules.

**Configure a SageMaker PyTorch estimator**

As part of configuring a SageMaker PyTorch estimator in the section called “Step 2: Launch a Training Job” (p. 2455), add the parameters for sharded data parallelism.

To turn on sharded data parallelism, add the \texttt{sharded_data_parallel_degree} parameter to the SageMaker PyTorch Estimator. This parameter specifies the number of GPUs over which the training state is sharded. The value for \texttt{sharded_data_parallel_degree} must be an integer between one and the data parallelism degree and must evenly divide the data parallelism degree. Note that the library automatically detects the number of GPUs so thus the data parallel degree. The following additional parameters are available for configuring sharded data parallelism.

- **"sdp\_reduce\_bucket\_size"** \texttt{(int, default: 5e8)} – Specifies the size of PyTorch DDP gradient buckets in number of elements of the default dtype.
- **"sdp\_param\_persistence\_threshold"** \texttt{(int, default: 1e6)} – Specifies the size of a parameter tensor in number of elements that can persist at each GPU. Sharded data parallelism splits each parameter tensor across GPUs of a data parallel group. If the number of elements in the parameter tensor is smaller than this threshold, the parameter tensor is not split; this helps reduce communication overhead because the parameter tensor is replicated across data-parallel GPUs.
- **"sdp\_max\_live\_parameters"** \texttt{(int, default: 1e9)} – Specifies the maximum number of parameters that can simultaneously be in a recomposed training state during the forward and backward pass. Parameter fetching with the \texttt{AllGather} operation pauses when the number of active parameters reaches the given threshold. Note that increasing this parameter increases the memory footprint.
• "sdp_hierarchical_allgather" (bool, default: True) – If set to True, the AllGather operation runs hierarchically: it runs within each node first, and then runs across nodes. For multi-node distributed training jobs, the hierarchical AllGather operation is automatically activated.

• "sdp_gradient_clipping" (float, default: 1.0) – Specifies a threshold for gradient clipping the L2 norm of the gradients before propagating them backward through the model parameters. When sharded data parallelism is activated, gradient clipping is also activated. The default threshold is 1.0. Adjust this parameter if you have the exploding gradients problem.

The following code shows an example of how to configure sharded data parallelism.

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters": {
        # "pipeline_parallel_degree": 1,    # Optional, default is 1
        # "tensor_parallel_degree": 1,      # Optional, default is 1
        "ddp": True,
        # parameters for sharded data parallelism
        "sharded_data_parallel_degree": 2,  # Add this to activate sharded data parallelism
        "sdp_reduce_bucket_size": int(5e8),  # Optional
        "sdp_param_persistence_threshold": int(1e6),  # Optional
        "sdp_max_live_parameters": int(1e9),  # Optional
        "sdp_hierarchical_allgather": True,  # Optional
        "sdp_gradient_clipping": 1.0  # Optional
    }
}

mpi_options = {
    "enabled": True,  # Required
    "processes_per_host": 8  # Required
}

smp_estimator = PyTorch(
    entry_point="your_training_script.py",  # Specify your train script
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='1.12.0',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        " mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-job"
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

Mixed Precision Training with Sharded Data Parallelism

To further save GPU memory with half-precision floating point numbers and sharded data parallelism, you can activate 16-bit floating point format (FP16) or Brain floating point format (BF16) by adding one additional parameter to the distributed training configuration.

**Note**

You can't activate both data types in one training job, and the fp16 and bf16 parameters are mutually exclusive.

**For FP16 Training with Sharded Data Parallelism**
To run FP16 training with sharded data parallelism, add "fp16": True to the smp_options configuration dictionary. In your training script, you can choose between the static and dynamic loss scaling options through the smp.DistributedOptimizer module. For more information, see the section called “FP16 Training with Model Parallelism” (p. 2477).

```python
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
        "fp16": True
    }
}
```

For BF16 Training with Sharded Data Parallelism

The sharded data parallelism feature of SageMaker supports training in BF16 data type. The BF16 data type uses 8 bits to represent the exponent of a floating point number, while the FP16 data type uses 5 bits. Preserving the 8 bits for the exponent allows to keep the same representation of the exponent of a 32-bit single precision floating point (FP32) number. This makes the conversion between FP32 and BF16 simpler and significantly less prone to cause overflow and underflow issues that arise often in FP16 training, especially when training larger models. While both data types use 16 bits in total, this increased representation range for the exponent in the BF16 format comes at the expense of reduced precision. For training large models, this reduced precision is often considered an acceptable trade-off for the range and training stability.

**Note**
Currently, BF16 training works only when sharded data parallelism is activated.

To run BF16 training with sharded data parallelism, add "bf16": True to the smp_options configuration dictionary.

```python
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
        "bf16": True
    }
}
```

Tips and Considerations for Using Sharded Data Parallelism

Consider the following when using the SageMaker model parallel library's sharded data parallelism.

- Sharded data parallelism is compatible with FP16 training. To run FP16 training, see the section called “FP16 Training with Model Parallelism” (p. 2477).
- Sharded data parallelism currently is not compatible with tensor parallelism (p. 2462), pipeline parallelism (p. 2430), and optimizer state sharding (p. 2472). To activate sharded data parallelism, set tensor and pipeline parallelism degrees to 1, and turn off optimizer state sharding.

The activation checkpointing (p. 2473) and activation offloading (p. 2474) features are compatible with sharded data parallelism.

- To use sharded data parallelism with gradient accumulation, set the backward_passes_per_step argument to the number of accumulation steps while wrapping your model with the smdistributed.modelparallel.torch.DistributedModel module. This ensures that the gradient AllReduce operation across the model replication groups (sharding groups) takes place at the boundary of gradient accumulation.
• You can checkpoint your models trained with sharded data parallelism using the library's checkpointing APIs, `smp.save_checkpoint` and `smp.resume_from_checkpoint`. For more information, see the section called “Checkpointing Distributed Models and Optimizer States” (p. 2479).

• The behavior of the `delayed_parameter_initialization` configuration parameter changes under sharded data parallelism. When these two features are simultaneously turned on, parameters are immediately initialized upon model creation in a sharded manner instead of delaying the parameter initialization, so that each rank initializes and stores its own shard of parameters.

• When sharded data parallelism is activated, the library performs gradient clipping internally when the `optimizer.step()` call runs. You don't need to use utility APIs for gradient clipping, such as `torch.nn.utils.clip_grad_norm_()`. To adjust the threshold value for gradient clipping, you can set it through the `sdp_gradient_clipping` parameter for the distribution parameter configuration when you construct the SageMaker PyTorch estimator, as shown in the section called “How to Apply Sharded Data Parallelism to Your Training Job” (p. 2481) section.

SageMaker Distributed Model Parallel Best Practices

Use the following guidelines when you run a distributed training job with the SageMaker model parallel library.

Setting Up the Right Configuration for a Given Model

When scaling up a model, we recommend you to go over the following list in order. Each list item discusses the advantage of using the library's techniques along with the tradeoffs that might arise.

**Tip**
If a model can fit well using a subset of the library's features, adding more model parallelism or memory saving features does not usually improve performance.

Using large GPU instance types

• In the realm of model parallelism, it is best to use powerful instances with large GPU memories to handle overhead from model parallelism operations such as partitioning models across multiple GPUs. We recommend using `ml.p4d` or `ml.p3dn` instances for training large DL models. These instances are also equipped with Elastic Fabric Adapter (EFA), which provides higher network bandwidth and enables large-scale training with model parallelism.

Sharding optimizer state

• The impact of sharding optimizer state depends on the number of data parallel ranks. Typically, a higher degree of data parallelism (proportional to the size of compute node) can improve the efficiency of memory usage.

When you want to downsize a cluster, make sure you check the optimizer state sharding configuration. For example, a large DL model with optimizer state sharding that fits on a node with 16 GPUs won't fit on a node with 8 GPUs because there are simply not enough GPUs across which to shard the optimizer state.

For more information, see Optimizer State Sharding (p. 2472).

Activation checkpointing

• Memory efficiency can be improved by using activation checkpointing for a group of modules. The more you group the modules, the more efficient the memory usage. When checkpointing sequential modules for layers, the `strategy` argument of the `smp.set_activation_checkpointing` function
groups the layers together for checkpointing. For example, grouping two or more layers together for checkpointing is more memory efficient than checkpointing one layer at a time, and this trades extra computation time for reduced memory usage.

For more information, see Activation Checkpointing (p. 2473).

**Tensor parallelism**

- The degree of tensor parallelism should be a power of two (2, 4, 8, ..., $2^n$), where the maximum degree must be equal to the number of GPUs per node. For example, if you use a node with 8 GPUs, possible numbers for the degree of tensor parallelism are 2, 4, and 8. We don't recommend arbitrary numbers (such as 3, 5, 6, and 7) for the degree of tensor parallelism. When you use multiple nodes, misconfiguring the degree of tensor parallelism might result in running tensor parallelism across the nodes; this adds significant overhead from communication of activations across the nodes and can become computationally expensive.

For more information, see Tensor Parallelism (p. 2462).

**Pipeline parallelism across nodes**

- You can run pipeline parallelism both within a single node and across multiple nodes. When you use pipeline parallelism in combination with tensor parallelism, we recommend running pipeline parallelism across multiple nodes and keeping tensor parallelism within individual nodes.
- Pipeline parallelism comes with the following three knobs: `microbatches`, `active_microbatches`, and `prescaled_batch`.
- When you use tensor parallelism with pipeline parallelism, we recommend activating `prescaled_batch` so that the batch size per model parallel group can be increased for efficient pipelining. With `prescaled_batch` activated, the batch size set in the training script becomes `tp_size` times the batch size set for each rank without `prescaled_batch`.
- Increasing the number of `microbatches` helps achieve efficient pipelining and better performance. Note that the effective microbatch size is the batch size divided by number of microbatches. If you increase the number of microbatches while keeping batch size constant, each microbatch processes fewer samples.
- The number of `active_microbatches` is the maximum number of microbatches that are simultaneously in process during pipelining. For each active microbatch in process, its activations and gradients take up GPU memory. Therefore, increasing `active_microbatches` takes up more GPU memory.
- If both GPU and GPU memory are underutilized, increase `active_microbatches` for better parallelization during pipelining.
- For more information about how to use tensor parallelism with pipeline parallelism, see Tensor parallelism combined with pipeline parallelism (p. 2466).
- To find descriptions of the aforementioned parameters, see Parameters for `smdistributed` in the SageMaker Python SDK documentation.

**Offloading activations to CPU**

- Make sure that this is used in combination with activation checkpointing and pipeline parallelism. To ensure that the offloading and preloading happen in the background, specify a value greater than 1 to the `microbatches` parameter.
- When offloading activations, you might be able to increase `active_microbatches` and sometimes match with the total number of microbatches. This depends on which modules are checkpointed and how the model is partitioned.

For more information, see Activation Offloading (p. 2474).
Reference configurations

The SageMaker distributed model parallel training team provides the following reference points based on experiments with the GPT-2 model, the sequence length of 512, and the vocabulary size of 50,000.

<table>
<thead>
<tr>
<th>The number of model parameters</th>
<th>Instance type</th>
<th>Pipeline parallelism</th>
<th>Tensor parallelism</th>
<th>Optimizer state sharding</th>
<th>Activation checkpoint</th>
<th>Prescaled batch</th>
<th>Batch size</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 billion</td>
<td>16 ml.p4d.24xlarge</td>
<td>1</td>
<td>4</td>
<td>True</td>
<td>Each transformer layer</td>
<td>True</td>
<td>batch_size=40</td>
</tr>
<tr>
<td>30 billion</td>
<td>16 ml.p4d.24xlarge</td>
<td>1</td>
<td>8</td>
<td>True</td>
<td>Each transformer layer</td>
<td>True</td>
<td>batch_size=32</td>
</tr>
<tr>
<td>60 billion</td>
<td>32 ml.p4d.24xlarge</td>
<td>2</td>
<td>8</td>
<td>True</td>
<td>Each transformer layer</td>
<td>True</td>
<td>batch_size=56, microbatches=4, active_microbatches</td>
</tr>
</tbody>
</table>

You can extrapolate from the preceding configurations to estimate GPU memory usage for your model configuration. For example, if you increase the sequence length for a 10-billion-parameter model or increase the size of the model to 20 billion, you might want to lower batch size first. If the model still doesn’t fit, try increasing the degree of tensor parallelism.

Modifying Your Training Script

- Before you use the SageMaker model parallel library’s features in your training script, review SageMaker Distributed Model Parallel Configuration Tips and Pitfalls (p. 2487).
- To launch a training job faster, use the SageMaker local mode. This helps you quickly run a training job locally on a SageMaker notebook instance. Depending on the scale of the ML instance on which your SageMaker notebook instance is running, you might need to adjust the size of your model by changing the model configurations, such as the hidden width, number of transformer layers, and attention heads. Validate if the reduced model runs well on the notebook instance before using a large cluster for training the full model.

Monitoring and Logging a Training Job Using the SageMaker Console and Amazon CloudWatch

To monitor system-level metrics such as CPU memory utilization, GPU memory utilization, and GPU utilization, use visualization provided through the SageMaker console.

1. In the left navigation pane, choose **Training**.
2. Choose **Training jobs**.
3. In the main pane, choose the training job name for which you want to see more details.
4. Browse the main pane and find the **Monitor** section to see the automated visualization.
5. To see training job logs, choose **View logs** in the **Monitor** section. You can access the distributed training job logs of the training job in CloudWatch. If you launched multi-node distributed training, you should see multiple log streams with tags in the format of algo-n-1234567890. The algo-1 log stream tracks training logs from the main (0th) node.
For more information, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics (p. 2612).

Permissions

To run a SageMaker training job with model parallelism or the SageMaker distributed training example notebooks, make sure you have the right permissions in your IAM role, such as the following:

- To use FSx for Lustre, add AmazonFSxFullAccess.
- To use Amazon S3 as a data channel, add AmazonS3FullAccess.
- To use Docker, build your own container, and push it to Amazon ECR, add AmazonEC2ContainerRegistryFullAccess.
- To have a full access to use the entire suite of SageMaker features, add AmazonSageMakerFullAccess.

SageMaker Distributed Model Parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using Amazon SageMaker's distributed model parallel library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see Modify a TensorFlow Training Script (p. 2444) and Modify a PyTorch Training Script (p. 2449), respectively.

Batch Size and Number of Microbatches

- The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.
- Choosing a number of microbatches that is too small or too large can lower performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.
- Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it is not, you can set drop_remainder=True in the tf.Dataset.batch() call (in TensorFlow), or set drop_last=True in DataLoader (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

Manual Partitioning

- If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.
Data Preparation

- If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with `smp.dp_rank()`. If the dataset is being deterministically sharded across data parallel devices, make sure that the shard is indexed by `smp.dp_rank()`. This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

Returning Tensors from `smp.DistributedModel`

- Any tensor that is returned from the `smp.DistributedModel.call` (for TensorFlow) or `smp.DistributedModel.forward` (for PyTorch) function is broadcast to all other ranks, from the rank that computed that particular tensor. As a result, any tensor that is not needed outside the call and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

The `@smp.step` Decorator

- If an `smp.step`-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the `non_split_inputs` list when calling `smp.step`. This prevents the library from attempting to split the tensor into microbatches. For more information see `smp.step` in the API documentation.

Delaying Parameter Initialization

For very large models over 100 billion parameters, weight initialization through the CPU memory might result in an out-of-memory error. To get around this, the library offers `smp.delay_param_initialization` context manager. This delays the physical allocation of parameters until they move to GPU during the first execution of a `smp.step`-decorated function. This avoids unnecessary memory usage of the CPU during the initialization of training. Use the context manager when you create a model object as shown in the following code.

```python
with smp.delay_param_initialization(enabled=True):
    model = MyModel()
```

Tensor Parallelism for PyTorch

- If you are using a seed for deterministic results, set the seed based on `smp.dp_rank()` (for example, `torch.manual_seed(42 + smp.dp_rank())`). If you do not do this, different partitions of an `nn.Parameter` are initialized in the same way, impacting convergence.

- SageMaker’s model parallelism library uses NCCL to implement collectives needed for the distribution of the modules. Especially for smaller models, if too many NCCL calls are scheduled on the GPU at the same time, memory usage might increase because of additional space used by NCCL. To counteract this, `smp` throttles the NCCL calls so that the number of ongoing NCCL operations at any given time is less than or equal to a given limit. The default limit is 8, but this can be adjusted using the environment variable `SMP_NCCL_THROTTLE_LIMIT`. If you observe more memory usage than you expect while using tensor parallelism, you can try reducing this limit. However, choosing a limit that is too small might cause throughput loss. To disable throttling altogether, you can set `SMP_NCCL_THROTTLE_LIMIT=-1`.

- The following identity, which holds when the degree of tensor parallelism is 1, does not hold when the degree of tensor parallelism is greater than 1: `smp.mp_size() * smp.dp_size() == smp.size()`. This is because the tensor parallel group is part of both the model parallelism group and the data parallelism group. If your code has existing references to `mp_rank`, `mp_size`, `MP_GROUP`, and so on, and if you want to work with only the pipeline parallel group, you might need to replace the references with `smp.pp_size()`. The following identities are always true:
• \( \text{smp.mp\_size()} \times \text{smp.rdp\_size()} = \text{smp.size()} \)

• \( \text{smp.pp\_size()} \times \text{smp.dp\_size()} = \text{smp.size()} \)

• \( \text{smp.pp\_size()} \times \text{smp.tp\_size()} \times \text{smp.rdp\_size()} = \text{smp.size()} \)

Since the \text{smp.DistributedModel} wrapper modifies the model parameters when tensor parallelism is enabled, the optimizer should be created after calling \text{smp.DistributedModel}, with the distributed parameters. For example, the following does not work:

```
## WRONG
model = MyModel()
optimizer = SomeOptimizer(model.parameters())
model = smp.DistributedModel(model)  # optimizer now has outdated parameters!
```

Instead, the optimizer should be created with the parameters of the \text{smp.DistributedModel} as follows:

```
## CORRECT
model = smp.DistributedModel(MyModel())
optimizer = SomeOptimizer(model.optimizers())
```

• When a module is replaced with its distributed counterpart through tensor parallelism, the distributed module does not inherit its weights from the original module, and initializes new weights. This means that, for instance, if the weights need to be initialized in a particular call (for example, through a \text{load\_state\_dict} call), this needs to happen after the \text{smp.DistributedModel} call, once the module distribution takes place.

• When accessing the parameters of distributed modules directly, note that the weight does not have the same shape as the original module. For instance,

```
with smp.tensor\_parallelism():
    linear = nn.Linear(60, 60)

# will pass
assert tuple(linear.weight.shape) == (60, 60)

distributed_linear = smp.DistributedModel(linear)

# will fail. the number of input channels will have been divided by smp.tp\_size()
assert tuple(distributed_linear.module.weight.shape) == (60, 60)
```

• Using \text{torch.utils.data.distributed.DistributedSampler} is strongly recommended for tensor parallelism. This ensures that every data parallel rank receives the same number of data samples, which prevents hangs that might result from different \text{dp\_ranks} taking a different number of steps.

• If you use the \text{join} API of PyTorch's \text{DistributedDataParallel} class to handle cases in which different data parallel ranks have different numbers of batches, you still need to make sure that ranks that are in the same \text{TP\_GROUP} have the same number of batches; otherwise the communication collectives used in distributed execution of modules may hang. Ranks that are in different \text{TP\_GROUPs} can have different numbers of batches, as long as \text{join} API is used.

• If you want to checkpoint your model and use tensor parallelism, consider the following:
  • To avoid stalling and race conditions while saving and loading models when you use tensor parallelism, make sure you call appropriate functions from the following model and optimizer states inside a reduced-data parallelism rank.
  • If you are transitioning an existing pipeline parallel script and enabling tensor parallel for the script, ensure that you modify any \text{if smp.dp\_rank()} == 0 block used for saving and loading with \text{if smp.rdp\_rank()} == 0 blocks. Otherwise, it might cause your training job to stall.
  • Full checkpointing of optimizer states is currently not supported with tensor parallelism. If you want to resume training from a checkpoint, use partial checkpointing instead.
Model Parallel Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact AWS Support.

Topics
- Considerations for Using SageMaker Debugger with SageMaker Distributed Model Parallel (p. 2490)
- Saving Checkpoints (p. 2490)
- Convergence Using Model Parallel and TensorFlow (p. 2492)
- Stalling or Crashing Distributed Training Jobs (p. 2492)
- NCCL error (p. 2493)

Considerations for Using SageMaker Debugger with SageMaker Distributed Model Parallel

SageMaker Debugger is not available for SageMaker distributed model parallel. Debugger is enabled by default for all SageMaker TensorFlow and PyTorch training jobs, and you might see an error that looks like the following:

```
FileNotFoundError: [Errno 2] No such file or directory: '/opt/ml/checkpoints/metadata.json.sagemaker-uploading
```

To fix this issue, disable Debugger by passing `debugger_hook_config=False` when creating a framework estimator as shown in the following example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)

estimator = TensorFlow(...

distribution={"smdistributed": {"modelparallel": { "enabled": True }},
checkpoint_s3_uri=checkpoint_s3_bucket,
checkpoint_local_path="/opt/ml/checkpoints",
debugger_hook_config=False
}
```

Saving Checkpoints

You might run into the following error when saving checkpoints of a large model on SageMaker:

```
InternalServerError: We encountered an internal error. Please try again
```

This could be caused by a SageMaker limitation while uploading the local checkpoint to Amazon S3 during training. To disable checkpointing in SageMaker, use the following example to explicitly upload the checkpoints.
If you run into the preceding error, do not use checkpoint_s3_uri with the SageMaker estimator call. While saving checkpoints for larger models, we recommend saving checkpoints to a custom directory and passing the same to the helper function (as a local_path argument).

```python
import os

def aws_s3_sync(source, destination):
    """aws s3 sync in quiet mode and time profile""
    import time, subprocess

```
Use `aws_s3_sync(s3_uri, local_path)` return

Usage of helper functions:

```python
#base_s3_uri - user input s3 uri or save to model directory (default)
#curr_host - to save checkpoints of current host
#iteration - current step/epoch during which checkpoint is saved

def sync_local_checkpoints_to_s3(local_path=checkpoint_dir, s3_uri=full_s3_uri):
    if smp.local_rank() == 0:
        base_s3_uri = os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))
        curr_host = os.environ['SM_CURRENT_HOST']
        full_s3_uri = f'{base_s3_uri}/checkpoints/{curr_host}/{iteration}'
        sync_local_checkpoints_to_s3(local_path=checkpoint_dir, s3_uri=full_s3_uri)
```

### Convergence Using Model Parallel and TensorFlow

When you use SageMaker multi-node training with TensorFlow and distributed model parallel, the loss may not converge as expected because the order of training input files may be different on each node. This may cause different ranks in the same model parallel group to work on different input files, causing inconsistencies. To prevent this, ensure the input files are ordered the same way in all the ranks before they get converted to TensorFlow datasets. One way to achieve this is to sort the input file names in the training script.

### Stalling or Crashing Distributed Training Jobs

If your training job has stalling, crashing, or not responding issues, read the following troubleshooting items to identify what's the cause of the issue. If you need any further support, reach out to the SageMaker distributed training team through AWS Support.

- If you see a **distributed training job stalling at the NCCL initialization step**, consider the following:
  - If you are using one of the EFA-enabled instances (ml.p4d or ml.p3dn instances) with a custom VPC and its subnet, ensure that the security group used has inbound and outbound connections for all ports to and from the same SG. You also generally need outbound connections to any IP as a separate rule (for internet access). To find instructions on how to add inbound and outbound rules for EFA communication, refer to SageMaker Distributed Training Job Stalling During Initialization (p. 2427).

- If you see a **distributed training job stalling when checkpointing** the full model, this might be because the `state_dict()` call on the model or optimizer was not made on all ranks with `rdp_rank()==0` (when using tensor parallelism) or `dp_rank()==0` (when using only pipeline parallelism). These ranks need to communicate to construct the checkpoint to be saved. Similar stalling issues can also happen when checkpointing partial optimizer if `shard_optimizer_state` is enabled.

  For more information about checkpointing a model with model parallelism, see General Instruction for Saving and Loading and Instructions for Checkpointing with Tensor Parallelism (p. 2468).

- If the training job crashes with a **CUDA Out of Memory error**, this means that the distributed training configuration needs to be adjusted to fit the model on the GPU cluster. For more information and best practices, see Setting Up the Right Configuration for a Given Model (p. 2484).

- If the training job crashes with an **uncorrectable ECC error**, this means that one of the GPUs in the cluster has gone bad. If you need technical support, share the job ARN with the AWS team and restart your training job from a checkpoint if possible.

- In rare cases, a job configuration that worked previously but is close to the limits of GPU memory might fail later with a different cluster due to a **CUDA Out of Memory error**. This could be because some GPU has lower available memory than usual due to ECC errors.
Network timeout crash might happen when running a multinode job which doesn’t use all GPUs in the node. To get around this, use all GPUs on the node by ensuring that the `processes_per_host` parameter is set to the number of GPUs in each instance. For example, this is `processes_per_host=8` for `ml.p3.16xlarge`, `ml.p3dn.24xlarge`, and `ml.p4d.24xlarge` instances.

If you find that your training job takes a long time during the data downloading stage, make sure the Amazon S3 path you provided to `checkpoint_s3_uri` for the SageMaker `Estimator` class is unique for the current training job. If this path is reused across multiple training jobs running simultaneously, all those checkpoints are uploaded and downloaded to the same Amazon S3 path and might significantly increase checkpoint loading time.

Use FSx for Lustre when you deal with large data and models.

- If your dataset is large and fetching it takes a long time, we recommend keeping your dataset in FSx for Lustre.
- When training models are beyond 10 billion parameters, we recommend using FSx for Lustre for checkpointing.
- After you create a file system, make sure to wait for the status to become available before starting a training job using it.

NCCL error

If you encountered the following error, it might be due to a process running out of GPU memory.

```
NCCL error in: ../torch/lib/c10d/ProcessGroupNCCL.cpp:825, unhandled system error, NCCL version 2.7.8
ncclSystemError: System call (socket, malloc, munmap, etc) failed.
```

You can resolve this by reducing the batch size or `active_microbatches`. If auto partitioning is not resulting in a well-balanced partitioning, you might have to consider manual partitioning. For more information, see Pipeline parallelism across nodes (p. 2485).

Amazon SageMaker Distributed Training Notebook Examples

The following case studies and notebooks provide examples of implementing the SageMaker distributed training libraries for the supported deep learning frameworks (PyTorch, TensorFlow, and HuggingFace) and models, such as CNN and MaskRCNN for vision, and BERT for natural language processing.

These notebooks are provided in the SageMaker examples GitHub repository. You can also browse them on the SageMaker examples website.

The examples are set up to use `p3.16xlarge` instances for the worker nodes, but you may choose `ml.p3dn.24xlarge` or `ml.p4d.24xlarge` instance types for which the SageMaker distributed training libraries are optimized. You can test the notebooks using a cluster of a single node; however, to see a performance improvement as shown in the Training Benchmarks section, use a cluster of multiple nodes (two or more). The examples call out the section in which you modify this configuration.

Blogs and Case Studies

The following blogs discuss case studies about using the SageMaker distributed training libraries.

SageMaker Distributed Data Parallel

How to Access or Download the SageMaker Distributed Training Notebook Examples

Follow instructions to access or download the SageMaker distributed training example notebooks.

Option 1: Use a SageMaker notebook instance

To use the aforementioned examples, we recommend that you use an Amazon SageMaker notebook instance. A notebook instance runs Jupyter Notebook and JupyterServer apps on Amazon EC2 instances, which are optimized for machine learning. If you do not have an active notebook instance, follow the instructions in Create a Notebook Instance (p. 287) in the SageMaker developer guide to create one.

After you have created an instance, in the Notebook instances page of the SageMaker console, do the following:

1. Open JupyterLab.
2. Select the examples icon ( ) in the left tray.
3. Browse the examples for Training and look for notebooks titled Distributed Data Parallel or Distributed Model Parallel.

Option 2: Clone the SageMaker example repository to SageMaker Studio or notebook instance

To download and use the aforementioned example notebooks, do the following to clone the example GitHub repositories:

1. Open a terminal.
2. In the command line, navigate to the SageMaker folder.
   
   ```
   cd SageMaker
   ```
3. Clone the SageMaker examples GitHub repository.
   
   ```
   git clone https://github.com/aws/amazon-sagemaker-examples.git
   ```

   **Note**
   To download the HuggingFace example notebooks (p. 2494), clone the HuggingFace notebooks GitHub repository:

   ```
   git clone https://github.com/huggingface/notebooks huggingface-notebooks
   ```
4. In the JupyterLab interface, navigate into the amazon-sagemaker-examples folder.
5. In the training/distributed_training folder, there are folders for frameworks, and in each of these, there are folders for data_parallel and model_parallel. Choose the example of your choice and follow the instructions to launch distributed training with an SageMaker distributed training library.

Amazon SageMaker Training Compiler

Use Amazon SageMaker Training Compiler to train deep learning (DL) models faster on scalable GPU instances managed by SageMaker.
What Is SageMaker Training Compiler?

State-of-the-art deep learning (DL) models consist of complex multi-layered neural networks with billions of parameters that can take thousands of GPU hours to train. Optimizing such models on training infrastructure requires extensive knowledge of DL and systems engineering; this is challenging even for narrow use cases. Although there are open-source implementations of compilers that optimize the DL training process, they can lack the flexibility to integrate DL frameworks with some hardware such as GPU instances.

SageMaker Training Compiler is a capability of SageMaker that makes these hard-to-implement optimizations to reduce training time on GPU instances. The compiler optimizes DL models to accelerate training by more efficiently using SageMaker machine learning (ML) GPU instances. SageMaker Training Compiler is available at no additional charge within SageMaker and can help reduce total billable time as it accelerates training.

SageMaker Training Compiler is integrated into the AWS Deep Learning Containers (DLCs). Using the SageMaker Training Compiler–enabled AWS DLCs, you can compile and optimize training jobs on GPU instances with minimal changes to your code. Bring your deep learning models to SageMaker and enable SageMaker Training Compiler to accelerate the speed of your training job on SageMaker ML instances for accelerated computing.

How It Works

SageMaker Training Compiler converts DL models from their high-level language representation to hardware-optimized instructions. Specifically, SageMaker Training Compiler applies graph-level optimization, dataflow-level optimizations, and backend optimizations to produce an optimized model that efficiently uses hardware resources. As a result, you can train your models faster than when you train them without compilation.

It is a two-step process to activate SageMaker Training Compiler for your training job:

1. Bring your own DL script and, if needed, adapt to compile and train with SageMaker Training Compiler. To learn more, see Bring Your Own Deep Learning Model (p. 2506).
2. Create a SageMaker estimator object with the compiler configuration parameter using the SageMaker Python SDK.
   a. Enable SageMaker Training Compiler by adding `compiler_config=TrainingCompilerConfig()` to the SageMaker estimator class.
   b. Adjust hyperparameters (`batch_size` and `learning_rate`) to maximize the benefit that SageMaker Training Compiler provides. SageMaker Training Compiler reduces the memory footprint of your model during training, which typically allows you to fit a larger `batch_size` in the GPU memory. Using a larger `batch_size` results in a better GPU utilization and reduces...
the total training time. For reference of batch_size tested for popular models, see Tested Models (p. 2499).

When you adjust the batch size, you also have to adjust the learning_rate appropriately. For best practices of adjusting the learning rate along with the change in batch size, see the section called “Best Practices and Considerations” (p. 2526).

c. By running the estimator.fit() class method, SageMaker compiles your model and starts the training job.

For instructions on how to launch a training job, see Enable SageMaker Training Compiler (p. 2513).

SageMaker Training Compiler does not alter the final trained model, while allowing you to accelerate the training job by more efficiently using the GPU memory and fitting a larger batch size per iteration. The final trained model from the compiler-accelerated training job is identical to the one from the ordinary training job.

Tip
SageMaker Training Compiler only compiles DL models for training on supported GPU instances managed by SageMaker. To compile your model for inference and deploy it to run anywhere in the cloud and at the edge, use SageMaker Neo compiler.

**Supported Frameworks, AWS Regions, Instance Types, and Tested Models**

Before using SageMaker Training Compiler, check if your framework of choice is supported, the instance types are available in your AWS account, and your AWS account is in one of the supported AWS Regions.

**Note**
SageMaker Training Compiler is available in the SageMaker Python SDK v2.70.0 or later.

**Supported Frameworks**

SageMaker Training Compiler supports the following deep learning frameworks and is available through AWS Deep Learning Containers.

**Topics**

For more information, see Available Images in the AWS Deep Learning Containers GitHub repository.
AWS Regions

The SageMaker Training Compiler Containers are available in the AWS Regions where AWS Deep Learning Containers are in service except the China regions.

Supported Instance Types

SageMaker Training Compiler is tested on and supports the following ML instance types.

- P4 instances
- P3 instances
- G4dn instances
- G5 instances

For specs of the instance types, see the Accelerated Computing section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge for training job usage' is 0 Instances, with current utilization of 0 Instances and a request delta of 1 Instances. Please contact AWS support to request an increase for this limit.
```

Tested Models

The following table includes a list of the models that have been tested with SageMaker Training Compiler. For reference, the largest batch size that is able to fit into memory is also included alongside other training parameters. SageMaker Training Compiler can change the memory footprint of the model training process; as a result, a larger batch size can often be used during the training process, further decreasing total training time. You must retune your model with the compiler enabled to find this increased batch size. To save time, use the reference table to pick up the largest batch sizes that can be used with the tested models.

**Note**
The batch sizes are local batch size that fit into each individual GPU of an instance type. You should also adjust the learning rate when changing the batch size.

Bring Your Own Deep Learning Model

This guide walks you through how to adapt your training script for a compiler-accelerated training job. The preparation of your training script depends on the following:

- Training settings such as single-core or distributed training.
- Frameworks and libraries that you use to create the training script.

Choose one of the following topics depending on the framework you use.

Topics
- PyTorch (p. 2506)
- TensorFlow (p. 2511)

Note
After you finish preparing your training script, you can run a SageMaker training job using the SageMaker framework estimator classes. For more information, see the previous topic at Enable SageMaker Training Compiler (p. 2513).

PyTorch

Bring your own PyTorch model to SageMaker, and run the training job with SageMaker Training Compiler.

PyTorch Models with Hugging Face Transformers

PyTorch models with Hugging Face Transformers are based on PyTorch's `torch.nn.Module` API. Hugging Face Transformers also provides `Trainer` and pretrained model classes for PyTorch to help reduce the effort for configuring natural language processing (NLP) models. After creating your own training script using the Transformers library, you'll run the training script using the SageMaker HuggingFace estimator with the SageMaker Training Compiler configuration class as shown in the previous topic at Enable SageMaker Training Compiler (p. 2513).

Tip
When you create a tokenizer for an NLP model using Transformers in your training script, make sure that you use a static input tensor shape by specifying `padding='max_length'`. Do not use `padding='longest'` because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can trigger recompilation of the model and might increase total training time. For more information about padding options

---

of the Transformers tokenizers, see Padding and truncation in the Hugging Face Transformers documentation.

Topics

- Using the Hugging Face Transformers Trainer API (p. 2507)
- Using PyTorch (without the Hugging Face Transformers Trainer API) (p. 2507)
- Best Practices to Enable SageMaker Training Compiler for PyTorch without the Hugging Face Trainer API (p. 2510)

Using the Hugging Face Transformers Trainer API

If you use the transformers library's Trainer class, you don't need to make any additional changes to your training script. SageMaker Training Compiler automatically compiles your Trainer model if you enable it through the estimator class. The following code shows the basic form of a PyTorch training script with Hugging Face Trainer API.

```python
from transformers import Trainer, TrainingArguments
training_args=TrainingArguments(**kwargs)
trainer=Trainer(args=training_args, **kwargs)
```

For single GPU training

You don't need to change your code when you use the Transformers Trainer API.

For distributed training

For Transformers v4.21.1 with PyTorch v1.11.0

To run distributed training with SageMaker Training Compiler, you must add the following `_mp_fn()` function in your training script and wrap the `main()` function. It redirects the `_mp_fn(index)` function calls from the SageMaker distributed runtime for PyTorch (pytorchxla) to the `main()` function of your training script.

```python
def _mp_fn(index):
    main()
```

This function accepts the `index` argument to indicate the rank of the current GPU in the cluster for distributed training. To find more example scripts, see the Hugging Face Transformers language modeling example scripts.

For Transformers v4.17 and before with PyTorch v1.10.2 and before

SageMaker Training Compiler uses an alternate mechanism for launching a distributed training job, and you don't need to make any modification in your training script. Instead, SageMaker Training Compiler requires you to pass a SageMaker distributed training launcher script to the `entry_point` argument and pass your training script to the `hyperparameters` argument in the SageMaker Hugging Face estimator.

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 2514).

Using PyTorch (without the Hugging Face Transformers Trainer API)

If you have a training script that uses PyTorch directly, you need to make additional changes to your PyTorch training script. Follow the instructions to modify your script using PyTorch/XLA.
Topics

- For single GPU training (p. 2508)
- For distributed training (p. 2508)

For single GPU training

1. Import the optimization libraries.

```python
import torch_xla
import torch_xla.core.xla_model as xm
```

2. Change the target device to be XLA instead of `torch.device("cuda")`

```python
device=xm.xla_device()
```

3. If you're using PyTorch's Automatic Mixed Precision (AMP), do the following:
   a. Replace `torch.cuda.amp` with the following:

   ```python
   import torch_xla.amp
   ```

   b. Replace `torch.optim.SGD` and `torch.optim.Adam` with the following:

   ```python
   import torch_xla.amp.syncfree.Adam as adam
   import torch_xla.amp.syncfree.SGD as SGD
   ```

   c. Replace `torch.cuda.amp.GradScaler` with the following:

   ```python
   import torch_xla.amp.GradScaler as grad_scaler
   ```

4. If you're not using AMP, replace `optimizer.step()` with the following:

```python
xm.optimizer_step(optimizer)
```

5. If you're using a distributed dataloader, wrap your dataloader in the PyTorch/XLA's `ParallelLoader` class:

```python
import torch_xla.distributed.parallel_loader as pl
parallel_loader=pl.ParallelLoader(dataloader, [device]).per_device_loader(device)
```

6. Add `mark_step` at the end of the training loop when you're not using `parallel_loader`:

```python
xm.mark_step()
```

7. To checkpoint your training, use the PyTorch/XLA's model checkpoint method:

```python
xm.save(model.state_dict(), path_to_save)
```

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 2514).

For distributed training

In addition to the changes listed in the previous For single GPU training (p. 2508) section, add the following changes to properly distribute workload across GPUs.
1. If you're using AMP, add all_reduce after scaler.scale(loss).backward():

```python
gradients=xm._fetch_gradients(optimizer)
xm.all_reduce('sum', gradients, scale=1.0/xm.xrt_world_size())
```

2. If you need to set variables for local_ranks and world_size, use similar code to the following:

```python
local_rank=xm.get_local_ordinal()
world_size=xm.xrt_world_size()
```

3. For any world_size (num_gpus_per_node*num_nodes) greater than 1, you must define a train sampler which should look similar to the following:

```python
import torch_xla.core.xla_model as xm
if xm.xrt_world_size() > 1:
    train_sampler=torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=xm.xrt_world_size(),
        rank=xm.get_ordinal(),
        shuffle=True
    )
train_loader=torch.utils.data.DataLoader(
    train_dataset,
    batch_size=args.batch_size,
    sampler=train_sampler,
    drop_last=args.drop_last,
    shuffle=False if train_sampler else True,
    num_workers=args.num_workers
)
```

4. Make the following changes to make sure you use the parallel_loader provided by the torch_xla distributed module.

```python
import torch_xla.distributed.parallel_loader as pl
train_device_loader=pl.MpDeviceLoader(train_loader, device)
```

The `train_device_loader` functions like a regular PyTorch loader as follows:

```python
for step, (data, target) in enumerate(train_device_loader):
    optimizer.zero_grad()
    output=model(data)
    loss=torch.nn.NLLLoss(output, target)
    loss.backward()
```

With all of these changes, you should be able to launch distributed training with any PyTorch model without the Transformer Trainer API. Note that these instructions can be used for both single-node multi-GPU and multi-node multi-GPU.

5. For Transformers v4.21.1 with PyTorch v1.11.0

To run distributed training with SageMaker Training Compiler, you must add the following `_mp_fn()` function in your training script and wrap the `main()` function. It redirects the `_mp_fn(index)` function calls from the SageMaker distributed runtime for PyTorch (pytorchxla) to the `main()` function of your training script.

```python
def _mp_fn(index):
    main()
```
This function accepts the `index` argument to indicate the rank of the current GPU in the cluster for distributed training. To find more example scripts, see the Hugging Face Transformers language modeling example scripts.

**For Transformers v4.17 and before with PyTorch v1.10.2 and before**

SageMaker Training Compiler uses an alternate mechanism for launching a distributed training job and requires you to pass a SageMaker distributed training launcher script to the `entry_point` argument and pass your training script to the `hyperparameters` argument in the SageMaker Hugging Face estimator.

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 2514).

**Best Practices to Enable SageMaker Training Compiler for PyTorch without the Hugging Face Trainer API**

If you want to leverage the SageMaker Training Compiler on your native PyTorch training script, you may want to first get familiar with PyTorch on XLA devices. The following sections list some best practices to enable XLA for PyTorch.

**Note**

This guide assumes that you use the following Python modules:

```python
import torch_xla.core.xla_model as xm
import torch_xla.distributed.parallel_loader as pl
```

**Understand the lazy mode in PyTorch/XLA**

One significant difference between PyTorch/XLA and native PyTorch is that the PyTorch/XLA system runs in lazy mode while the native PyTorch runs in eager mode. Tensors in lazy mode are placeholders for building the computational graph until they are materialized after the compilation and evaluation are complete. The PyTorch/XLA system builds the computational graph on the fly when you call PyTorch APIs to build the computation using tensors and operators. The computational graph gets compiled and executed when `xm.mark_step()` is called explicitly or implicitly by `pl.MpDeviceLoader/pl.ParallelLoader`, or when you explicitly request the value of a tensor such as by calling `loss.item()` or `print(loss)`.

**Minimize the number of compilation-and-executions using pl.MpDeviceLoader/pl.ParallelLoader and xm.step_closure**

For best performance, you should keep in mind the possible ways to initiate compilation-and-executions as described in Understand the lazy mode in PyTorch/XLA (p. 2510) and should try to minimize the number of compilation-and-executions. Ideally, only one compilation-and-execution is necessary per training iteration and is initiated automatically by `pl.MpDeviceLoader/pl.ParallelLoader`. The `MpDeviceLoader` is optimized for XLA and should always be used if possible for best performance. During training, you might want to examine some intermediate results such as loss values. In such case, the printing of lazy tensors should be wrapped using `xm.add_step_closure()` to avoid unnecessary compilation-and-executions.

**Use AMP and syncfree optimizers**

Training in Automatic Mixed Precision (AMP) mode significantly accelerates your training speed by leveraging the Tensor cores of NVIDIA GPUs. SageMaker Training Compiler provides syncfree optimizers that are optimized for XLA to improve AMP performance. Currently, the following three syncfree optimizers are available and should be used if possible for best performance.
torch_xla.amp.syncfree.SGD
torch_xla.amp.syncfree.Adam
torch_xla.amp.syncfree.AdamW

These syncfree optimizers should be paired with torch_xla.amp.GradScaler for gradient scaling/unscaling.

### TensorFlow

Bring your own TensorFlow model to SageMaker, and run the training job with SageMaker Training Compiler.

#### TensorFlow Models

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API.

**Tip**
For preprocessing your input dataset, ensure that you use a static input shape. Dynamic input shape can initiate recompilation of the model and might increase total training time.

#### Using Keras (Recommended)

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras (tf.keras.Model).

**For single GPU training**

There's no additional change you need to make in the training script.

#### Without Keras

SageMaker Training Compiler does not support eager execution in TensorFlow. Accordingly, you should wrap your model and training loops with the TensorFlow function decorator (@tf.function) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.

**For single GPU training**

TensorFlow 2.0 or later has the eager execution on by default, so you should add the @tf.function decorator in front of every function that you use for constructing a TensorFlow model.

#### TensorFlow Models with Hugging Face Transformers

TensorFlow models with Hugging Face Transformers are based on TensorFlow's tf.keras.Model API. Hugging Face Transformers also provides pretrained model classes for TensorFlow to help reduce the effort for configuring natural language processing (NLP) models. After creating your own training script using the Transformers library, you can run the training script using the SageMaker HuggingFace estimator with the SageMaker Training Compiler configuration class as shown in the previous topic at Run TensorFlow Training Jobs with SageMaker Training Compiler (p. 2519).

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API, such as the TensorFlow transformer models.

**Tip**
When you create a tokenizer for an NLP model using Transformers in your training script, make sure that you use a static input tensor shape by specifying padding='max_length'. Do not use padding='longest' because padding to the longest sequence in the batch can change
the tensor shape for each training batch. The dynamic input shape can initiate recompilation of
the model and might increase total training time. For more information about padding options
of the Transformers tokenizers, see Padding and truncation in the Hugging Face Transformers
documentation.

Topics

- Using Keras (p. 2512)
- Without Keras (p. 2513)

Using Keras

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras
tf.keras.Model. As noted in the Quick tour page in the Hugging Face Transformers documentation, you
can use the models as regular TensorFlow Keras models.

For single GPU training

There’s no additional change you need to make in the training script.

For distributed training

SageMaker Training Compiler acceleration works transparently for multi-GPU workloads when the model
is constructed and trained using Keras APIs within the scope of tf.distribute.Strategy.scope() call.

1. Choose the right distributed training strategy.
   a. For single-node multi-GPU, use tf.distribute.MirroredStrategy to set the strategy.

   ```python
   strategy = tf.distribute.MirroredStrategy()
   ```

   b. For multi-node multi-GPU, add the following code to properly set the TensorFlow distributed
      training configuration before creating the strategy.

   ```python
   def set_sm_dist_config():
       DEFAULT_PORT = '8890'
       DEFAULT_CONFIG_FILE = '/opt/ml/input/config/resourceconfig.json'
       with open(DEFAULT_CONFIG_FILE) as f:
           config = json.loads(f.read())
       current_host = config['current_host']
       tf_config = {
           'cluster': {
               'worker': []
           },
           'task': {'type': 'worker', 'index': -1}
       }
       for i, host in enumerate(config['hosts']):
           tf_config['cluster']['worker'].append("%s:%s" % (host, DEFAULT_PORT))
           if current_host == host:
               tf_config['task']['index'] = i
       os.environ['TF_CONFIG'] = json.dumps(tf_config)
   set_sm_dist_config()

   Use tf.distribute.MultiWorkerMirroredStrategy to set the strategy.

   ```python
   strategy = tf.distribute.MultiWorkerMirroredStrategy()
   ```

2. Using the strategy of your choice, wrap the model.
Without Keras

If you want to bring custom models with custom training loops using TensorFlow without Keras, you should wrap the model and the training loop with the TensorFlow function decorator (@tf.function) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.

For single GPU training

TensorFlow 2.0 or later has the eager execution on by default, so you should add the @tf.function decorator in front of every function that you use for constructing a TensorFlow model.

For distributed training

In addition to the changes needed for Using Keras for distributed training, you need to ensure that functions to be run on each GPU are annotated with @tf.function, while cross-GPU communication functions are not annotated. An example training code should look like the following:

```python
@tf.function()
def compiled_step(inputs, outputs):
    with tf.GradientTape() as tape:
        pred=model(inputs, training=True)
        total_loss=loss_object(outputs, pred)/args.batch_size
        gradients=tape.gradient(total_loss, model.trainable_variables)
        return total_loss, pred, gradients

def train_step(inputs, outputs):
    total_loss, pred, gradients=compiled_step(inputs, outputs)
    if args.weight_decay > 0.:
        gradients=[g+v*args.weight_decay for g,v in zip(gradients, model.trainable_variables)]
        optimizer.apply_gradients(zip(gradients, model.trainable_variables))
    train_loss.update_state(total_loss)
    train_accuracy.update_state(outputs, pred)

@tf.function()
def train_step_dist(inputs, outputs):
    strategy.run(train_step, args= (inputs, outputs))
```

Note that this instruction can be used for both single-node multi-GPU and multi-node multi-GPU.

Enable SageMaker Training Compiler

SageMaker Training Compiler is built into the SageMaker Python SDK and AWS Deep Learning Containers so that you don't need to change your workflows to enable Training Compiler. Choose one of the following topics that matches with your use case.

**Topics**
- Run PyTorch Training Jobs with SageMaker Training Compiler (p. 2514)
Run TensorFlow Training Jobs with SageMaker Training Compiler (p. 2519)

Run PyTorch Training Jobs with SageMaker Training Compiler

You can use any of the SageMaker interfaces to run a training job with SageMaker Training Compiler: Amazon SageMaker Studio, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface.

Topics
- Using the SageMaker Python SDK (p. 2514)
- Using the SageMaker CreateTrainingJob API Operation (p. 2519)

Using the SageMaker Python SDK

To turn on SageMaker Training Compiler, add the compiler_config parameter to the SageMaker Hugging Face estimator. Import the TrainingCompilerConfig class and pass an instance of it to the compiler_config parameter. The following code examples show the structure of SageMaker estimator classes with SageMaker Training Compiler turned on.

Tip
To get started with prebuilt models provided by the Transformers library, try using the batch sizes provided in the reference table at Tested Models (p. 2499).

Note
SageMaker Training Compiler for PyTorch is currently available through the SageMaker Hugging Face framework estimator.

For information that fits your use case, see one of the following options.

For single GPU training

Hugging Face Transformers with PyTorch

To compile and train a transformer model with PyTorch, configure a SageMaker Hugging Face estimator with SageMaker Training Compiler as shown in the following code example.

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
  "n_gpus": 1,
  "batch_size": batch_size,
  "learning_rate": learning_rate
}

pytorch_huggingface_estimator=HuggingFace(
  entry_point='train.py',
  instance_count=1,
  instance_type='ml.p3.2xlarge',
  transformers_version='4.21.1',
  hyperparameters=hyperparameters,
  training_compiler_config=TrainingCompilerConfig(compile=True, core_num=1024))
```
To prepare your training script, see the following pages.

- For single GPU training (p. 2507) of a PyTorch model using Hugging Face Transformers' Trainer API
- For single GPU training (p. 2508) of a PyTorch model without Hugging Face Transformers' Trainer API

To find end-to-end examples, see the following notebooks:

- Compile and Train a Hugging Face Transformers Trainer Model for Question and Answering with the SQuAD dataset
- Compile and Train a Hugging Face Transformer BERT Model with the SST Dataset using SageMaker Training Compiler
- Compile and Train a Binary Classification Trainer Model with the SST2 Dataset for Single-Node Single-GPU Training

For distributed training

For Transformers v4.21 with PyTorch v1.11 and later

For PyTorch v1.11 and later, SageMaker Training Compiler is available for distributed training with the `pytorch_xla` option specified to the `distribution` parameter.
entry_point='your_training_script.py',
instance_count=instance_count,
instance_type=instance_type,
transformers_version='4.21.1',
pytorch_version='1.11.0',
hyperparameters=hyperparameters,
compiler_config=TrainingCompilerConfig(),
distribution ={'pytorchxla': { 'enabled': True }},
disable_profiler=True,
debugger_hook_config=False
)

pytorch_huggingface_estimtor.fit()

Tip
To prepare your training script, see the following pages.

- For distributed training (p. 2507) of a PyTorch model using Hugging Face Transformers' Trainer API
- For distributed training (p. 2508) of a PyTorch model without Hugging Face Transformers' Trainer API

For Transformers v4.17 with PyTorch v1.10.2 and before

For the supported version of PyTorch v1.10.2 and before, SageMaker Training Compiler requires an alternate mechanism for launching a distributed training job. To run distributed training, SageMaker Training Compiler requires you to pass a SageMaker distributed training launcher script to the entry_point argument, and pass your training script to the hyperparameters argument. The following code example shows how to configure a SageMaker Hugging Face estimator applying the required changes.

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, # and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

training_script="your_training_script.py"

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate,
    "training_script": training_script  # Specify the file name of your training script.
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='distributed_training_launcher.py',  # Specify the distributed training launcher script.
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.21.1',
    pytorch_version='1.11.0',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    distribution ={'pytorchxla': { 'enabled': True }},
    disable_profiler=True,
    debugger_hook_config=False
)
instance_count=instance_count,
instance_type=instance_type,
transformers_version='4.17.0',
pytorch_version='1.10.2',
hyperparameters=hyperparameters,
compiler_config=TrainingCompilerConfig(),
disable_profiler=True,
debugger_hook_config=False
)
}
pytorch_huggingface_estimator.fit()

The launcher script should look like the following. It wraps your training script and configures the distributed training environment depending on the size of the training instance of your choice.

```
# distributed_training_launcher.py
#!/bin/python
import subprocess
import sys
if __name__ == '__main__':
    arguments_command = ' '.join([arg for arg in sys.argv[1:]])

    """
The following line takes care of setting up an inter-node communication as well as managing intra-node workers for each GPU.
    """
    subprocess.check_call("python -m torch_xla.distributed.sm_dist " +
        arguments_command, shell=True)
```

**Tip**
To prepare your training script, see the following pages.

- For distributed training (p. 2507) of a PyTorch model using Hugging Face Transformers' Trainer API
- For distributed training (p. 2508) of a PyTorch model without Hugging Face Transformers' Trainer API

**Tip**
To find end-to-end examples, see the following notebooks:

- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

The following list is the minimal set of parameters required to run a SageMaker training job with the compiler.

**Note**
When using the SageMaker Hugging Face estimator, you must specify the transformers_version, pytorch_version, hyperparameters, and compiler_config parameters to enable SageMaker Training Compiler. You cannot use image_uri to manually specify the Training Compiler integrated Deep Learning Containers that are listed at Supported Frameworks (p. 2497).

- entry_point (str) – Required. Specify the file name of your training script.
Enable Training Compiler

**Note**
To run a distributed training with SageMaker Training Compiler and PyTorch v1.10.2 and before, specify the file name of a launcher script to this parameter. The launcher script should be prepared to wrap your training script and configure the distributed training environment. For more information, see the following example notebooks:

- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

- `instance_count` (int) – Required. Specify the number of instances.
- `instance_type` (str) – Required. Specify the instance type.
- `transformers_version` (str) – Required only when using the SageMaker Hugging Face estimator. Specify the Hugging Face Transformers library version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 2497).
- `framework_version` or `pytorch_version` (str) – Required. Specify the PyTorch version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 2497).

**Note**
When using the SageMaker Hugging Face estimator, you must specify both `transformers_version` and `pytorch_version`.

- `hyperparameters` (dict) – Optional. Specify hyperparameters for the training job, such as `n_gpus`, `batch_size`, and `learning_rate`. When you enable SageMaker Training Compiler, try larger batch sizes and adjust the learning rate accordingly. To find case studies of using the compiler and adjusted batch sizes to improve training speed, see the section called “Tested Models” (p. 2499) and SageMaker Training Compiler Example Notebooks and Blogs (p. 2525).

**Note**
To run a distributed training with SageMaker Training Compiler and PyTorch v1.10.2 and before, you need to add an additional parameter, "training_script", to specify your training script, as shown in the preceding code example.

- `compiler_config` (TrainingCompilerConfig object) – Required to activate SageMaker Training Compiler. Include this parameter to turn on SageMaker Training Compiler. The following are parameters for the TrainingCompilerConfig class.
  - `enabled` (bool) – Optional. Specify True or False to turn on or turn off SageMaker Training Compiler. The default value is True.
  - `debug` (bool) – Optional. To receive more detailed training logs from your compiler-accelerated training jobs, change it to True. However, the additional logging might add overhead and slow down the compiled training job. The default value is False.

- `distribution` (dict) – Optional. To run a distributed training job with SageMaker Training Compiler, add `distribution = { 'pytorchxla' : { 'enabled': True } }.`

**Warning**
If you turn on SageMaker Debugger, it might impact the performance of SageMaker Training Compiler. We recommend that you turn off Debugger when running SageMaker Training Compiler to make sure there's no impact on performance. For more information, see the section called “Performance Considerations” (p. 2527). To turn the Debugger functionalities off, add the following two arguments to the estimator:

```python
disable_profiler=True,
d debugger_hook_config=False
```

If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:
Enable Training Compiler

- With `TrainingCompilerConfig(debug=False)`

    Found configuration for Training Compiler
    Configuring SM Training Compiler...

- With `TrainingCompilerConfig(debug=True)`

    Found configuration for Training Compiler
    Configuring SM Training Compiler...
    Training Compiler set to debug mode

Using the SageMaker `CreateTrainingJob` API Operation

SageMaker Training Compiler configuration options must be specified through the `AlgorithmSpecification` and `HyperParameters` field in the request syntax for the `CreateTrainingJob` API operation.

```
"AlgorithmSpecification": {
    "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>",

"HyperParameters": {
    "sagemaker_training_compiler_enabled": "true",
    "sagemaker_training_compiler_debug_mode": "false",
    "sagemaker_pytorch_xla_multi_worker_enabled": "false"  // set to "true" for distributed training
}
```

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler implemented, see Supported Frameworks (p. 2497).

Run TensorFlow Training Jobs with SageMaker Training Compiler

You can use any of the SageMaker interfaces to run a training job with SageMaker Training Compiler: Amazon SageMaker Studio, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface.

Topics
- Using the SageMaker Python SDK (p. 2519)
- Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 2523)
- Enable SageMaker Training Compiler Using the SageMaker `CreateTrainingJob` API Operation (p. 2525)

Using the SageMaker Python SDK

To turn on SageMaker Training Compiler, add the `compiler_config` parameter to the SageMaker TensorFlow or Hugging Face estimator. Import the `TrainingCompilerConfig` class and pass an instance of it to the `compiler_config` parameter. The following code examples show the structure of the SageMaker estimator classes with SageMaker Training Compiler turned on.

Tip
- To get started with prebuilt models provided by the TensorFlow and Transformers libraries, try using the batch sizes provided in the reference table at Tested Models (p. 2499).
Note
SageMaker Training Compiler for TensorFlow is available through the SageMaker TensorFlow and Hugging Face framework estimators.

For information that fits your use case, see one of the following options.

For single GPU training

TensorFlow

```python
from sagemaker.tensorflow import TensorFlow, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

tensorflow_estimator=TensorFlow(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    framework_version='2.9.1',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

tensorflow_estimator.fit()
```

To prepare your training script, see the following pages.

- For single GPU training (p. 2511) of a model constructed using TensorFlow Keras (tf.keras.*).
- For single GPU training (p. 2511) of a model constructed using TensorFlow modules (tf.* excluding the TensorFlow Keras modules).

Hugging Face Estimator with TensorFlow

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
```
Enable Training Compiler

```
"n_gpus": 1,
"batch_size": batch_size,
"learning_rate": learning_rate
}

tensorflow_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    transformers_version='4.21.1',
    tensorflow_version='2.6.3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

tensorflow_huggingface_estimator.fit()
```

To prepare your training script, see the following pages.

- For single GPU training (p. 2512) of a TensorFlow Keras model with Hugging Face Transformers
- For single GPU training (p. 2513) of a TensorFlow model with Hugging Face Transformers

For distributed training

Hugging Face Estimator with TensorFlow

```
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use,
# and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

hyperparameters={

    "batch_size": batch_size,
    "learning_rate": learning_rate
}

tensorflow_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.21.1',
    tensorflow_version='2.6.3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)
```

2521
tensorflow_huggingface_estimator.fit()

Tip
To prepare your training script, see the following pages.
- For distributed training (p. 2512) of a TensorFlow Keras model with Hugging Face Transformers
- For distributed training (p. 2513) of a TensorFlow model with Hugging Face Transformers

The following list is the minimal set of parameters required to run a SageMaker training job with the compiler.

Note
When using the SageMaker Hugging Face estimator, you must specify the transformers_version, tensorflow_version, hyperparameters, and compiler_config parameters to enable SageMaker Training Compiler. You cannot use image_uri to manually specify the Training Compiler integrated Deep Learning Containers that are listed at Supported Frameworks (p. 2497).

- entry_point (str) – Required. Specify the file name of your training script.
- instance_count (int) – Required. Specify the number of instances.
- instance_type (str) – Required. Specify the instance type.
- transformers_version (str) – Required only when using the SageMaker Hugging Face estimator. Specify the Hugging Face Transformers library version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 2497).
- framework_version or tensorflow_version (str) – Required. Specify the TensorFlow version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 2497).

Note
When using the SageMaker TensorFlow estimator, you must specify framework_version. When using the SageMaker Hugging Face estimator, you must specify both transformers_version and tensorflow_version.

- hyperparameters (dict) – Optional. Specify hyperparameters for the training job, such as n_gpus, batch_size, and learning_rate. When you enable SageMaker Training Compiler, try larger batch sizes and adjust the learning rate accordingly. To find case studies of using the compiler and adjusted batch sizes to improve training speed, see the section called “Tested Models” (p. 2499) and SageMaker Training Compiler Example Notebooks and Blogs (p. 2525).
- compiler_config (TrainingCompilerConfig object) – Required. Include this parameter to turn on SageMaker Training Compiler. The following are parameters for the TrainingCompilerConfig class.
  - enabled (bool) – Optional. Specify True or False to turn on or turn off SageMaker Training Compiler. The default value is True.
  - debug (bool) – Optional. To receive more detailed training logs from your compiler-accelerated training jobs, change it to True. However, the additional logging might add overhead and slow down the compiled training job. The default value is False.

Warning
If you turn on SageMaker Debugger, it might impact the performance of SageMaker Training Compiler. We recommend that you turn off Debugger when running SageMaker Training Compiler to make sure there's no impact on performance. For more information, see the section called “Performance Considerations” (p. 2527). To turn the Debugger functionalities off, add the following two arguments to the estimator:

disable_profiler=True,
debugger_hook_config=False

If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:

- With TrainingCompilerConfig(debug=False)

  Found configuration for Training Compiler
  Configuring SM Training Compiler...

- With TrainingCompilerConfig(debug=True)

  Found configuration for Training Compiler
  Configuring SM Training Compiler...
  Training Compiler set to debug mode

**Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers**

AWS Deep Learning Containers (DLC) for TensorFlow use adapted versions of TensorFlow that include changes on top of the open-source TensorFlow framework. The SageMaker Framework Deep Learning Containers are optimized for the underlying AWS infrastructure and Amazon SageMaker. With the advantage of using the DLCs, SageMaker Training Compiler integration adds more performance improvements over the native TensorFlow. Furthermore, you can create a custom training container by extending the DLC image.

**Note**

This Docker customization feature is currently available only for TensorFlow.

To extend and customize the SageMaker TensorFlow DLCs for your use-case, use the following instructions.

**Create a Dockerfile**

Use the following Dockerfile template to extend the SageMaker TensorFlow DLC. You must use the SageMaker TensorFlow DLC image as the base image of your Docker container. To find the SageMaker TensorFlow DLC image URIs, see Supported Frameworks.

```bash
# SageMaker TensorFlow Deep Learning Container image
FROM 763104351884.dkr.ecr.<aws-region>.amazonaws.com/tensorflow-training:<image-tag>

ENV PATH="/opt/ml/code:${PATH}"
# This environment variable is used by the SageMaker container
# to determine user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
# Add more code lines to customize for your use-case
...
```

For more information, see Step 2: Create and upload the Dockerfile and Python training scripts.

Consider the following pitfalls when extending SageMaker Framework DLCs:

- Do not explicitly uninstall or change the version of TensorFlow packages in SageMaker containers. Doing so causes the AWS optimized TensorFlow packages to be overwritten by open-source TensorFlow packages, which might result in performance degradation.
- Watch out for packages that have a particular TensorFlow version or flavor as a dependency. These packages might implicitly uninstall the AWS optimized TensorFlow and install open-source TensorFlow packages.

For example, there’s a known issue that the tensorflow/models and tensorflow/text libraries always attempt to reinstall open source TensorFlow. If you need to install these libraries to choose a specific version for your use case, we recommend that you look into the SageMaker TensorFlow DLC Dockerfiles for v2.9 or later. The paths to the Dockerfiles are typically in the following format: tensorflow/training/docker/<tensorflow-version>/py3/<cuda-version>/Dockerfile.gpu. In the Dockerfiles, you should find the code lines to reinstall AWS managed TensorFlow binary (specified to the TF_URL environment variable) and other dependencies in order. The reinstallation section should look like the following example:

```bash
# tf-models does not respect existing installations of TensorFlow
# and always installs open source TensorFlow
RUN pip3 install --no-cache-dir -U \   
tf-models-official==x.y.z

RUN pip3 uninstall -y tensorflow tensorflow-gpu \   
; pip3 install --no-cache-dir -U \   
${TF_URL} \   
tensorflow-io==x.y.z \   
tensorflow-datasets==x.y.z
```

### Build and push to ECR

To build and push your Docker container to Amazon ECR, follow the instructions in the following links:

- **Step 3: Build the container**
- **Step 4: Test the container**
- **Step 5: Push the container to Amazon ECR**

### Run using the SageMaker Python SDK Estimator

Use the SageMaker TensorFlow framework estimator as usual. You must specify image_uri to use the new container you hosted in Amazon ECR.

```python
import sagemaker, boto3
from sagemaker import get_execution_role
from sagemaker.tensorflow import TensorFlow, TrainingCompilerConfig

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'tf-custom-container-test'
tag = ':latest'
region = boto3.session.Session().region_name
uri_suffix = 'amazonaws.com'

byoc_image_uri = '{}/{}.dkr.ecr.{}.{}'.format(  
    account_id, region, uri_suffix, ecr_repository + tag  
)

byoc_image_uri
# This should return something like
# 111122223333.dkr.ecr.us-east-2.amazonaws.com/tf-custom-container-test:latest
```
estimator = TensorFlow(
    image_uri=image_uri,
    role=get_execution_role(),
    base_job_name='tf-custom-container-test-job',
    instance_count=1,
    instance_type='ml.p3.8xlarge',
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

# Start training
estimator.fit()

Enable SageMaker Training Compiler Using the SageMaker CreateTrainingJob API Operation

SageMaker Training Compiler configuration options must be specified through the AlgorithmSpecification and HyperParameters field in the request syntax for the CreateTrainingJob API operation.

"AlgorithmSpecification": {
    "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>"
},

"HyperParameters": {
    "sagemaker_training_compiler_enabled": "true",
    "sagemaker_training_compiler_debug_mode": "false"
}

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler implemented, see Supported Frameworks (p. 2497).

SageMaker Training Compiler Example Notebooks and Blogs

The following blogs, case studies, and notebooks provide examples of how to implement SageMaker Training Compiler.

Example notebooks are provided in the SageMaker examples GitHub repository, and you can also browse them on the SageMaker examples website.

Blogs and Case Studies

The following blogs discuss case studies about using SageMaker Training Compiler.

- New – Introducing SageMaker Training Compiler
- Hugging Face Transformers BERT fine-tuning using Amazon SageMaker Training Compiler
- Speed up Hugging Face Training Jobs on AWS by Up to 50% with SageMaker Training Compiler

Examples Notebooks

To find examples of using SageMaker Training Compiler, see the Training Compiler page in the Amazon SageMaker Example Read the Docs website.
SageMaker Training Compiler Best Practices and Considerations

Review the following best practices and considerations when using SageMaker Training Compiler.

Best Practices

Use the following guidelines to achieve the best results when you run training jobs with SageMaker Training Compiler.

General Best Practices

- Make sure that you use one of the Supported Instance Types (p. 2499) and Tested Models (p. 2499).
- When you create a tokenizer for an NLP model using the Hugging Face Transformers library in your training script, make sure that you use a static input tensor shape by specifying `padding='max_length'`. Do not use `padding='longest'` because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can initiate recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the Hugging Face Transformers documentation.
- Measure GPU memory utilization to make sure that you use the maximum batch size that can fit into the GPU memory. Amazon SageMaker Training Compiler reduces the memory footprint of your model during training, which typically allows you to fit a larger `batch_size` in the GPU memory. Using a larger `batch_size` results in a better GPU utilization and reduces the total training time. When you adjust the batch size, you also have to adjust the `learning_rate` appropriately. For example, if you increased the batch size by a factor of \( k \), you need to adjust `learning_rate` linearly (simple multiplication by \( k \)) or multiply by the square root of \( k \). This is to achieve the same or similar convergence behavior in the reduced training time. For reference of `batch_size` tested for popular models, see Tested Models (p. 2499).
- To debug the compiler-accelerated training job, enable the `debug` flag in the `compiler_config` parameter. This enables SageMaker to put the debugging logs into SageMaker training job logs.

```python
huggingface_estimator=HuggingFace(
    ...
    compiler_config=TrainingCompilerConfig(debug=True)
)
```

Note that if you enable full debugging of the training job with the compiler, this might add some overhead.

Best Practices for PyTorch

- If you bring a PyTorch model and want to checkpoint it, make sure you use PyTorch/XLA's model save function to properly checkpoint your model. For more information about the function, see `torch_xla.core.xla_model.save` in the PyTorch on XLA Devices documentation.

To learn how to add the modifications to your PyTorch script, see Using PyTorch (without the Hugging Face Transformers Trainer API) (p. 2507).

For more information about the actual application of using the model save function, see Checkpoint Writing and Loading in the Hugging Face on PyTorch/XLA TPUs: Faster and cheaper training blog.
- To achieve the most optimal training time for distributed training, consider the following.
• Use instances with multiple GPUs instead of using single-gpu instances. For example, a single ml.p3dn.24xlarge instance has faster training time compared to 8 x ml.p3.2xlarge instances.
• Use instances with EFA support such as ml.p3dn.24xlarge and ml.p4d.24xlarge. These instance types have accelerated networking speed and reduce training time.
• Tune the preprocessing_num_workers parameter for datasets, so that model training is not delayed by slow preprocessing.

Performance Considerations

Consider the following when using SageMaker Training Compiler.

• Avoid logging, checkpointing, and profiling model tensors that lead to explicit evaluations. To understand what an explicit evaluation is, consider the following code compiling example.

```python
a = b+c
e = a+d
```

A compiler interprets the code as follows and reduces the memory footprint for the variable `a`:

```python
e = b+c+d
```

Now consider the following case in which the code is changed to add a print function for the variable `a`.

```python
a = b+c
e = a+d
print(a)
```

The compiler makes an explicit evaluation of the variable `a` as follows.

```python
e = b+c+d
a = b+c      # Explicit evaluation
print(a)
```

In PyTorch, for example, avoid using `torch.tensor.items()`, which might introduce explicit evaluations. In deep learning, such explicit evaluations can cause overhead because they break fused operations in a compilation graph of a model and lead to recomputation of the tensors.

If you still want to periodically evaluate the model during training while using SageMaker Training Compiler, we recommend logging and checkpointing at a lower frequency to reduce overhead due to explicit evaluations. For example, log every 10 epochs instead of every epoch.

• Graph compilation runs during the first few steps of training. As a result, the first few steps are expected to be exceptionally slow. However, this is a one-time compilation cost and can be amortized by training for a longer duration because compilation makes future steps much faster. The initial compilation overhead depends on the size of the model, the size of the input tensors, and the distribution of input tensor shapes.

SageMaker Training Compiler FAQ

Use the following FAQ items to find answers to commonly asked questions about SageMaker Training Compiler.

Q. How do I know SageMaker Training Compiler is working?
If you successfully launched your training job with SageMaker Training Compiler, you receive the following log messages:

- With `TrainingCompilerConfig(debug=False)`
  
  Found configuration for Training Compiler
  Configuring SM Training Compiler...

- With `TrainingCompilerConfig(debug=True)`
  
  Found configuration for Training Compiler
  Configuring SM Training Compiler...
  Training Compiler set to debug mode

**Q. Which models does SageMaker Training Compiler accelerate?**

SageMaker Training Compiler supports the most popular deep learning models from the Hugging Face transformers library. With most of the operators that the compiler supports, these models can be trained faster with SageMaker Training Compiler. Compilable models include but are not limited to the following: `bert-base-cased`, `bert-base-chinese`, `bert-base-uncased`, `distilbert-base-uncased`, `distilbert-base-uncased-finetuned-sst-2-english`, `gpt2`, `roberta-base`, `roberta-large`, `t5-base`, and `xlm-roberta-base`. The compiler works with most DL operators and data structures and can accelerate many other DL models beyond those that have been tested.

**Q. What happens if I enable SageMaker Training Compiler with a model that isn’t tested?**

For an untested model, you might need to first modify the training script to be compatible with SageMaker Training Compiler. For more information, see Bring Your Own Deep Learning Model (p. 2506) and follow the instructions on how to prepare your training script.

Once you have updated your training script, you can start the training job. The compiler proceeds to compile the model. However, training speed may not increase and might even decrease relative to the baseline with an untested model. You might need to retune training parameters such as `batch_size` and `learning_rate` to achieve any speedup benefits.

If compilation of the untested model fails, the compiler returns an error. See SageMaker Training Compiler Troubleshooting (p. 2529) for detailed information about the failure types and error messages.

**Q. Will I always get a faster training job with SageMaker Training Compiler?**

No, not necessarily. First, SageMaker Training Compiler adds some compilation overhead before the ongoing training process can be accelerated. The optimized training job must run sufficiently long to amortize and make up for this incremental compilation overhead at the beginning of the training job.

Additionally, as with any model training process, training with suboptimal parameters can increase training time. SageMaker Training Compiler can change the characteristics of the training job by, for example, changing the memory footprint of the job. Because of these differences, you might need to retune your training job parameters to speed up training. A reference table specifying the best performing parameters for training jobs with different instance types and models can be found at Tested Models (p. 2499).

Finally, some code in a training script might add additional overhead or disrupt the compiled computation graph and slow training. If working with a customized or untested model, see the instructions at Best Practices to Enable SageMaker Training Compiler for PyTorch without the Hugging Face Trainer API (p. 2510).

**Q. Can I always use a larger batch size with SageMaker Training Compiler?**
Batch size increases in most, but not all, cases. The optimizations made by SageMaker Training Compiler can change the characteristics of your training job, such as the memory footprint. Typically, a Training Compiler job occupies less memory than an uncompiled training job with the native framework, which allows for a larger batch size during training. A larger batch size, and a corresponding adjustment to the learning rate, increases training throughput and can decrease total training time.

However, there could be cases where SageMaker Training Compiler might actually increase memory footprint based on its optimization scheme. The compiler uses an analytical cost model to predict the execution schedule with the lowest cost of execution for any compute-intensive operator. This model could find an optimal schedule that increases memory use. In this case, you won't be able to increase batch sizes, but your sample throughput is still higher.

Q. Does SageMaker Training Compiler work with other SageMaker training features, such as the SageMaker distributed training libraries and SageMaker Debugger?

SageMaker Training Compiler is currently not compatible with SageMaker's distributed training libraries.

SageMaker Training Compiler is compatible with SageMaker Debugger, but Debugger might degrade computational performance by adding overhead.

Q. Does SageMaker Training Compiler support custom containers (bring your own container)?

SageMaker Training Compiler is provided through AWS Deep Learning Containers, and you can extend a subset of the containers to customize for your use-case. Containers that are extended from AWS DLCs are supported by SageMaker Training Compiler. For more information, see Supported Frameworks and Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 2523). If you need further support, reach out to the SageMaker team through AWS Support or AWS Developer Forums for Amazon SageMaker.

SageMaker Training Compiler Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If you need further support, reach out to the SageMaker team through AWS Support or AWS Developer Forums for Amazon SageMaker.

Training Job Fails Due to Missing XLA Configuration

If a training job fails with the Missing XLA configuration error message, it might be due to a misconfiguration in the number of GPUs per instance that you use.

XLA requires additional environment variables to compile the training job. The most common missing environment variable is GPU_NUM_DEVICES. For the compiler to work properly, you must set this environment variable equal to the number of GPUs per instance.

There are three approaches to set the GPU_NUM_DEVICES environment variable:

- **Approach 1** – Use the environment argument of the SageMaker estimator class. For example, if you use an ml.p3.8xlarge instance that has four GPUs, do the following:

```python
# Using the SageMaker Python SDK's HuggingFace estimator
hf_estimator=HuggingFace(
    ...
    instance_type="ml.p3.8xlarge",
    hyperparameters={...},
    environment={
        ...
        "GPU_NUM_DEVICES": "4" # corresponds to number of GPUs on the specified instance
    },
)```

2529
• **Approach 2** – Use the `hyperparameters` argument of the SageMaker estimator class and parse it in your training script.

1. To specify the number of GPUs, add a key-value pair to the `hyperparameters` argument.

   For example, if you use an `ml.p3.8xlarge` instance that has four GPUs, do the following:

   ```python
   # Using the SageMaker Python SDK's HuggingFace estimator
   hf_estimator = HuggingFace(
       ...
       entry_point = "train.py",
       instance_type= "ml.p3.8xlarge",
       hyperparameters = {
           ...
           "n_gpus": 4  # corresponds to number of GPUs on specified instance
       }
   )
   hf_estimator.fit()
   ```

2. In your training script, parse the `n_gpus` hyperparameter and specify it as an input for the `GPU_NUM_DEVICES` environment variable.

   ```python
   # train.py
   import os, argparse
   if __name__ == "__main__":
       parser = argparse.ArgumentParser()
       ...
       # Data, model, and output directories
       parser.add_argument("--output_data_dir", type=str,
                           default=os.environ["SM_OUTPUT_DATA_DIR"])
       parser.add_argument("--model_dir", type=str, default=os.environ["SM_MODEL_DIR"])
       parser.add_argument("--training_dir", type=str,
                           default=os.environ["SM_CHANNEL_TRAIN"])
       parser.add_argument("--test_dir", type=str, default=os.environ["SM_CHANNEL_TEST"])
       parser.add_argument("--n_gpus", type=str, default=os.environ["SM_NUM_GPUS"])
       args, _ = parser.parse_known_args()
       os.environ["GPU_NUM_DEVICES"] = args.n_gpus
   ```

• **Approach 3** – Hard-code the `GPU_NUM_DEVICES` environment variable in your training script. For example, add the following to your script if you use an instance that has four GPUs.

   ```python
   # train.py
   import os
   os.environ["GPU_NUM_DEVICES"] = 4
   ```

**Tip**
To find the number of GPU devices on machine learning instances that you want to use, see Accelerated Computing in the Amazon EC2 Instance Types page.

**Incorrect API Uses for PyTorch without Hugging Face Trainer API**

PyTorch/XLA defines a set of APIs to replace some of the existing PyTorch training APIs. Failing to use them properly leads PyTorch training to fail.
• One of the most typical errors when compiling a PyTorch model is due to a wrong device type for operators and tensors. To properly compile a PyTorch model, make sure you use XLA devices (`xm.xla_device()`) instead of using CUDA or mixing CUDA devices and XLA devices.

• `mark_step()` is a barrier just for XLA. Failing to set it correctly causes a training job to stall.

• PyTorch/XLA provides additional distributed training APIs. Failing to program the APIs properly causes gradients to be collected incorrectly, which causes a training convergence failure.

To properly set up your PyTorch script and avoid the aforementioned incorrect API uses, see Using PyTorch (without the Hugging Face Transformers Trainer API) (p. 2507) and Best Practices to Enable SageMaker Training Compiler for PyTorch without the Hugging Face Trainer API (p. 2510).

**SageMaker Training Compiler Does Not Reduce the Total Training Time**

If the total training time does not decrease with SageMaker Training Compiler, we highly recommend you to go over the SageMaker Training Compiler Best Practices and Considerations (p. 2526) page to check your training configuration, padding strategy for the input tensor shape, and hyperparameters.

**Amazon SageMaker Training Compiler Release Notes**

See the following release notes to track the latest updates for Amazon SageMaker Training Compiler.

**SageMaker Training Compiler Release Notes: September 1, 2022**

**Currency Updates**

• Added support for Hugging Face Transformers v4.21.1 with PyTorch v1.11.0.

**Improvements**

• Implemented a new distributed training launcher mechanism to activate SageMaker Training Compiler for Hugging Face Transformer models with PyTorch. To learn more, see Run PyTorch Training Jobs with SageMaker Training Compiler for Distributed Training (p. 2515).

• Integrated with EFA to improve the collective communication in distributed training.

• Added support for G5 instances for PyTorch training jobs. For more information, see the section called “Supported Frameworks, AWS Regions, Instance Types, and Tested Models” (p. 2497).

**Migration to AWS Deep Learning Containers**

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

• HuggingFace v4.21.1 with PyTorch v1.11.0

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 2497).
SageMaker Training Compiler Release Notes: June 14, 2022

**New Features**

- Added support for TensorFlow v2.9.1. SageMaker Training Compiler fully supports compiling TensorFlow modules (tf.*) and TensorFlow Keras modules (tf.keras.*).
- Added support for custom containers created by extending AWS Deep Learning Containers for TensorFlow. For more information, see Enable SageMaker Training Compiler Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 2523).
- Added support for G5 instances for TensorFlow training jobs.

**Migration to AWS Deep Learning Containers**

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- TensorFlow 2.9.1

To find a complete list of the pre-built containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 2497).

SageMaker Training Compiler Release Notes: April 26, 2022

**Improvements**

- Added support for all of the AWS Regions where AWS Deep Learning Containers are in service except the China regions.

SageMaker Training Compiler Release Notes: April 12, 2022

**Currency Updates**

- Added support for Hugging Face Transformers v4.17.0 with TensorFlow v2.6.3 and PyTorch v1.10.2.

SageMaker Training Compiler Release Notes: February 21, 2022

**Improvements**

- Completed benchmark test and confirmed training speed-ups on the ml.g4dn instance types. To find a complete list of tested ml instances, see Supported Instance Types (p. 2499).

SageMaker Training Compiler Release Notes: December 01, 2021

**New Features**

Migration to AWS Deep Learning Containers

- Amazon SageMaker Training Compiler passed benchmark testing and is migrated to AWS Deep Learning Containers. To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 2497).

Amazon SageMaker Clarify Bias Detection and Model Explainability

This topic describes how to configure an Amazon SageMaker Clarify processing job capable of computing bias metrics and feature attributions for explainability. It is implemented using a specialized SageMaker Clarify container image. Instructions are provided for how to locate and download one of these container images. A brief overview of how SageMaker Clarify works is sketched. The parameters needed to configure the processing job and type of analysis are described. Prerequisites are outlined and some advice about compute resources consumed by SageMaker Clarify processing job is provided.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection and model explainability:

- **Amazon SageMaker Clarify Processing** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSON Lines data formats, bringing your own container, and running processing jobs with Spark.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 132). If you're prompted to choose a kernel, choose Python 3 (Data Science).

Topics

- Prerequisites (p. 2533)
- How SageMaker Clarify Processing Jobs Work (p. 2534)
- Get Started with a SageMaker Clarify Container (p. 2534)
- Configure a SageMaker Clarify Processing Job Container’s Input and Output Parameters (p. 2536)
- Configure the Analysis (p. 2537)
- Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability (p. 2544)
- Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify (p. 2547)
- Amazon SageMaker Clarify Model Explainability (p. 2569)
- Troubleshoot SageMaker Clarify Processing Jobs (p. 2577)

Prerequisites

Before you begin, you need to meet the following prerequisites:

- You need to provide an input dataset as tabular files in CSV or JSON Lines format. The input dataset must include a label column for bias analysis. The dataset should be prepared for machine learning with any pre-processing needed, such as data cleaning or feature engineering, already completed.
• You need to provide a model artifact that supports either the CSV or JSON Lines file format as one of its content type inputs. For posttraining bias metrics and explainability, we use the dataset to make inferences with the model artifact. Each row minus the label column must be ready to be used as payload for inferences.
• When creating processing jobs with the SageMaker container image, you need the following:
  • Network isolation must be disabled for the processing job.
  • If the model is in a VPC, the processing job must be in the same VPC as the model.
  • The IAM user/role of the caller must have permissions for SageMaker APIs. We recommend that you use the "arn:aws:iam::aws:policy/AmazonSageMakerFullAccess" managed policy.

How SageMaker Clarify Processing Jobs Work

A SageMaker processing job uses the SageMaker Clarify container at several stages in the lifecycle of the machine learning workflow. You can use the SageMaker Clarify container with your datasets and models to compute the following types of analysis:

• pretraining bias metrics
• posttraining bias metrics
• SHAP values for explainability
• Partial dependence plots (PDP)

You can control which of these analyses are computed when you configure the processing job. For pretraining bias metrics, you need to provide the dataset. You can compute posttraining bias metrics and explainability after your model has been trained by providing the dataset and model name. You must configure the necessary parameters in the form of a JSON configuration file and provide this as an input to the processing job.

After the processing job completes, the result of the analyses is saved in the output location specified in the `ProcessingOutput` parameters of the processing job. You can then download it from there and view the outputs or you can view the results in Studio if you have run a notebook there.

In order to compute posttraining bias metrics and SHAP values, the computation needs to get inferences for the model name provided. To accomplish this, the processing job creates an ephemeral endpoint with the model name, known as a shadow endpoint. The processing job deletes the shadow endpoint after the computations are completed.

At a high level, the processing job completes the following steps:

1. Validate inputs and parameters.
2. Create the shadow endpoint.
3. Compute pretraining bias metrics.
5. Compute local and global feature attributions.
6. Delete shadow endpoint.
7. Generate output files.

Get Started with a SageMaker Clarify Container

Amazon SageMaker provides prebuilt SageMaker Clarify container images that include the libraries and other dependencies needed to compute bias metrics and feature attributions for explainability. This image has been enabled to run SageMaker Process Data (p. 976) in your account.
The image URIs for the containers are in the following form:

<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-clarify-processing:1.0

For example:

205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0

The following table lists the addresses by AWS Region.

Configure a SageMaker Clarify Processing Job
Container's Input and Output Parameters

The Processing Job requires that you specify the following input parameters: a dataset files with input name "dataset" as Amazon S3 object or prefix, and an analysis configuration file with input name "analysis_config" as an Amazon S3 object. The job also requires an output parameter: the output location as an Amazon S3 prefix.

You can create and run a processing job with SageMaker `CreateProcessingJob` API using the AWS SDK or CLI or SageMaker Python SDK.

Using SageMaker Python SDK, create a `Processor` using the SageMaker Clarify container image URI:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor( role=role,
    instance_count=1,
    instance_type='ml.c5.xlarge',
    max_runtime_in_seconds=1200,
    volume_size_in_gb=100)
```

After you finish creating the Clarify processor, you need to set up the input and output object for the processor.

**Note**
If you provide the "dataset_uri" through the "analysis_config.json" (see the following topic at Configure the Analysis (p. 2537)), you don't need to create the `dataset_input` object.

```python
dataset_path = "s3://my_bucket/my_folder/train.csv"
analysis_config_path = "s3://my_bucket/my_folder/analysis_config.json"
analysis_result_path = "s3://my_bucket/my_folder/output"

analysis_config_input = ProcessingInput(
```
Configure the Analysis

The inputs for the analysis are configured by the parameters of the ProcessingInput API. The "analysis_config" value of the input_name specifies the JSON file named `analysis_config.json` that contains the configuration values. The path to the JSON file is provided in the source parameter of ProcessingInput. Examples of analysis configuration JSON files are provided for JSON files for CSV, JSON Lines, image, and text datasets following the parameter descriptions.

Topics
- Parameters for JSON configuration files (p. 2537)
- Example JSON configuration files (p. 2540)

Parameters for JSON configuration files

In the JSON configuration file, you can specify the following parameters.

- "version" – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.
- "dataset_type" – (Required) Format of the dataset. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable computer vision explainability. For more information see Common Data Formats for Inference.
- "dataset_uri" – (Optional) Dataset S3 prefix/object URI (if not given as ProcessingInput). If it is a prefix, the processing job recursively collects all S3 files under the prefix. For computer vision, the URI is required and it can either be a path to the image manifest file, or to the bucket of images to be explained.
- "headers" – (Optional) A list of column names in the dataset. If the dataset type is "application/jsonlines" and "label" is specified, then the last header shall be the header of label column.
- "label" – (Optional) Target attribute for the model to be used for bias metrics. Specified as a column name, or as index if the dataset format is CSV, or as JSONPath if the dataset format is JSON Lines.
- "probability_threshold" – (Optional) A float value to indicate the threshold to select the binary label in the case of binary classification. This parameter is used in object detection to filter out objects detected with confidence scores lower than the probability_threshold value. The default value is 0.5.
- "features" – (Optional) JSONPath for locating the feature columns for bias metrics, if the dataset format is JSON Lines.
- "label_values_or_threshold" – (Optional) List of label values or threshold. Indicates positive outcome used for bias metrics.

- "facet" – (Optional) A list of features that are sensitive attributes, referred to as facets. Facets are used for bias metrics in the form of pairs, and include the following:
  - "name_or_index" – Facet column name or index.
  - "value_or_threshold" – (Optional) List of values or threshold that the facet column can take. Indicates the sensitive group, such as the group that is used to measure bias against. If not provided, bias metrics are computed as one group for every unique value (rather than all values). If the facet column is numeric, this threshold value is applied as the lower bound to select the sensitive group.

- "group_variable" – (Optional) A column name or index to indicate the group variable to be used for the bias metric Conditional Demographic Disparity.

- "joinsource_name_or_index" – (Optional) The name or index of the column in the dataset that acts as an identifier column, for example, while performing a join. This column is only used as an identifier, and not used for any other computations. This is an optional field in all cases except when the dataset contains more than one file, and "save_local_shap_values" is set to true.

- "methods" – A list of methods and their parameters for the analyses and reports. If any section is omitted, then it is not computed.
  - "pre_training_bias" – (Optional) Section on pretraining bias metrics.
    - "methods" – A list of pretraining metrics to be computed.
  - "post_training_bias" – (Optional) Section on posttraining bias metrics.
    - "methods" – A list of posttraining metrics to be computed.
  - "shap" – (Optional) Section on SHAP value computation.
    - "agg_method" – Aggregation method for global SHAP values. Valid values are as follows:
      - "mean_abs" – Mean of absolute SHAP values for all instances.
      - "median" – Median of SHAP values for all instances.
      - "mean_sq" – Mean of squared SHAP values for all instances.
    - "baseline" – (Optional) A list of rows (at least one), or an S3 object URI. To be used as the baseline dataset (also known as a background dataset) in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns (or values) and omit any column that must be excluded before being sent to the model. This includes label column, joinsource column, and columns included in the "exclude_column" field.
      - For Computer Vision, a path to the baseline image that is used to mask out features from the input image. Default: RGB Noise mask.
      - For natural language processing (NLP) of text columns, the baseline value should be the value used to replace the unit of text specified by the granularity in the "text_config". Valid values for the unit of text are token, sentence, and paragraph.
    - "num_clusters" – (Optional) If "baseline" is not provided, Clarify attempts to compute a baseline by clustering the dataset. The "num_clusters" determines the number of clusters that the dataset is clustered into. Each cluster contributes to a baseline, so the number of clusters directly affects the runtime of SHAP explanations.
    - "num_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
    - "seed" – (Optional) Seed value for the random number generator to obtain a deterministic SHAP result.
  - "text_config" – (Required) The configuration that specifies the natural language processing (NLP) features. If this config is provided, text features are treated as text and explanations are provided for individual units of text. The unit of text is specified by the "granularity".
    - "granularity" – (Required) For NLP, determines the unit of granularity for the analysis of text features. Valid values are "token", "sentence", or "paragraph". Each of these units is considered a feature, and SHAP values are computed for the feature specified.

• "use_logit" – (Optional) Boolean value to indicate if the logit function is to be applied to the model predictions. If "use_logit" is true, then the SHAP values have log-odds units. The default value is false.

• "image_config" – (Optional) Section for configuring SHAP configuration parameters for computer vision explainability.
  • "model_type" – Either an object detection model or an image classification model.
  • "num_segments" – (Optional) Determines the approximate number of segments to be labeled in the input image. The default is 20.
  • "segment_compactness" – (Optional) Determines the shape and size of the image segments generated by SKLearn's slic method. For more details, see scikit-image slic documentation. The default is 5.
  • "max_objects" – (Optional) Used to filter objects detected by the computer vision model by top confidence score. The default is 3.
  • "iou_threshold" – (Optional) Minimum intersection over union (IOU) metric for evaluating predictions against the original detections. Used because detection boxes will shift during masking. The default value is 0.5.
  • "context" – (Optional) Masks the area around the bounding box of the detected object when running SHAP. Valid values are 0 to mask everything, or 1 to mask nothing. The default value is 1.
  • "save_local_shap_values" – (Optional) Boolean value to indicate if local SHAP values are to be saved in the output location. Use true to save them; false to not save them. The default is false.

• "pdp" – (Optional) Section for configuring partial dependence plots (PDP). Shows the dependence of the target response on a set of input features of interest. Marginalizes over the values of all other input features.
  • "features": ["pdp_feature_1", "pdp_feature_2"] – (Optional) The list of feature names or indices for which partial dependence plots are to be computed and plotted. If SHAP is not requested, the features must be provided.
  • "grid_resolution" – (Required) Used for numerical features. Represents that number of buckets into which the range of numerical values is divided. This specifies the granularity of the grid for the PDP plot.
  • "top_k_features" – (Optional) If the features parameter is not provided, and shap is provided, Clarify chooses the top k features based on SHAP attributions. You can set this value to specify how many of the top features must be used for PDP plots. The default is 10.

• "predictor" – (Optional) Section on model parameters, required if "shap" and "post_training_bias" sections are present.
  • "model_name" – Model name created by CreateModel API, with container mode as SingleModel.
  • "instance_type" – Instance type for the shadow endpoint.
  • "initial_instance_count" – Instance count for the shadow endpoint.
• "content_type" – (Optional) The model input format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable Computer Vision explainability. The default value is the same as the dataset_type format.

• "accept_type" – (Optional) The model output format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable Computer Vision explainability. The default value is the same as content_type.

• "accelerator_type" – (Optional) The type of Elastic Inference (EI) accelerator to attach to the instance. Example: ml.eia1.medium. For more information, see Use Amazon SageMaker Elastic Inference (EI) (p. 2979).

• "custom_attributes" – (Optional) Provides additional information about a request for an inference that is submitted to a model hosted on an Amazon SageMaker endpoint. The information is an opaque value that is forwarded verbatim. You can use this value, for example, to provide an ID that tracks a request. You can also use this value to provide metadata that a service endpoint was programmed to process. The value must consist of no more than 1024 visible US-ASCII characters, as specified in Section 3.3.6. Field Value Components of the Hypertext Transfer Protocol (HTTP/1.1).

• "label" – (Optional) Index or JSONPath location in the model output for the target attribute that is used by the bias metrics. If the label is not provided in the CSV accept_type case, then Clarify assumes that the model output is a single numeric value corresponding to the score or probability.

• "probability" – (Optional) Index or JSONPath location in the model output for probabilities or scores to be used for explainability. If the model output is JSON Lines with a list of labels and probabilities, for example, then the label that corresponds to the maximum probability is selected for bias computations. For explainability method, currently all probabilities are explained.

• "endpoint_name-prefix" – (Optional) Provides a custom prefix to the name of the temporary endpoint.

• "endpoint_name" – (Optional) Specifies an existing endpoint to use for getting predictions. Using an existing endpoint reduces the bootstrap time, but can cause a significant load increase for existing endpoints. Be cautious when specifying an existing production endpoint.

• "target_model" – (Optional) Sets the target model name when using a multi-model endpoint. For more information about multi-model endpoints, see Request Syntax.

• "label_headers" – (Optional) A list of values that the "label" takes in the dataset. Associates the scores returned by the model endpoint with their corresponding label values. Used to extract the label value with the highest score as the predicted label.

• "content_template" – (Optional) A template string used to construct the model input from dataset instances. It is only used when "content_type" is "application/jsonlines". The template should have only one placeholder, $features, which is replaced by the features list at runtime. For example, given "content_template":"{"myfeatures":$features}", if an instance (no label) is 1,2,3, then model input becomes JSON Line '{"myfeatures":[1,2,3]}'.

• "report" – (Optional) Section on report parameters. A report is generated if this section is present.

• "name" – (Optional) Filename prefix for the report notebook and PDF file. The default name is "report".

• "title" – (Optional) Title string for the report notebook and PDF file. The default title is "SageMaker Analysis Report".

**Example JSON configuration files**

Here are examples of analysis configuration JSON files for CSV, JSON Lines, image, and text datasets.

**Topics**

- Analysis configuration JSON file for a CSV dataset (p. 2541)
- Analysis configuration JSON file for a JSON Lines dataset (p. 2542)
Analysis configuration JSON file for a CSV dataset

The following code sample shows how to configure an analysis for a CSV dataset.

```json
{
   "dataset_type": "text/csv",
   "headers": ["feature_0", "feature_1", "feature_2", "feature_3", "target"],
   "label": "target",
   "label_values_or_threshold": [1],
   "probability_threshold": 0.7,
   "facet": [
      {
         "name_or_index": "feature_1",
         "value_or_threshold": [1]
      },
      {
         "name_or_index": "feature_2",
         "value_or_threshold": [0.7]
      }
   ],
   "group_variable": "feature_3",
   "joinsource_name_or_index": 'column_name',
   "methods": {
      "shap": {
         "baseline": [
            "yes",
            3,
            0.9,
            1
         ],
         "num_samples": 1000,
         "agg_method": "mean",
         "use_logit": true,
         "save_local_shap_values": true,
         "num_clusters": 5,
         "seed": 1234
      },
      "pre_training_bias": {
         "methods": "all"
      },
      "post_training_bias": {
         "methods": "all"
      },
      "report": {
         "name": "report",
         "title": "Analysis Report"
      }
   },
   "predictor": {
      "model_name": "my_model",
      "instance_type": "ml.m5.xlarge",
      "initial_instance_count": 1,
   }
}
```
Model output as CSV is as follows:

```
Current,[0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860035]
```

Corresponding predictor configuration is as follows:

```
"predictor": {
  ...
  "accept_type": "text/csv",
  "label": 0,
  "probability": 1,
  ...
}
```

### Analysis configuration JSON file for a JSON Lines dataset

The following code sample shows how to configure an analysis for a JSON Lines dataset.

```json
{
  "dataset_type": "application/jsonlines",
  "dataset_uri": "s3://my_bucket/my_folder/dataset.jsonl",
  "headers": ["Label", "Feature1", "Feature2"],
  "label": "data.label",
  "features": "data.features.values",
  "facet": [{
    "name_or_index": "Feature1",
    "value_or_threshold": [1,5]
  }, {
    "name_or_index": "Feature2",
    "value_or_threshold": [2,6]
  }],
  "methods": {
    "shap": {
      "baseline": [
        {"data":{"features":{"values":[9,10]},"label":0}},
        {"data":{"features":{"values":[11,12]},"label":1}}
      ]
    }
  },
  "predictor": {
    "model_name": "my_jsonl_model",
    "instance_type": "ml.m5.xlarge",
    "initial_instance_count": 1
  }
}
```
Dataset as S3 prefix is as follows:

```
"dataset_uri": "s3://my_bucket/my_folder"
```

Dataset as S3 object is as follows:

```
"dataset_uri": "s3://my_bucket/my_folder/train.csv"
```

Baseline as S3 object is as follows:

```
"baseline": "s3://my_bucket/my_folder/baseline.csv"
```

Model output as JSON Lines is as follows:

```
{"predicted_label": "Current", "score": [0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860035]}
```

Corresponding predictor configuration is as follows:

```
"predictor": {
  ...
  "accept_type": "application/jsonlines",
  "label": "predicted_label",
  "probability": "score",
  ...
}
```

**Analysis configuration JSON file for an image dataset**

The following code sample shows how to configure an analysis for object detection with Computer Vision.

```
"dataset_type": "application/x-image",
"dataset_uri": "s3://<BUCKET/KEY>",
"probability_threshold": 0.7,
"methods": {
  "shap": {
    "num_samples": 500,
    "baseline": "s3://path/to/baseline/image/noise_rgb.png",
    "image_config": {
      "model_type": "OBJECT_DETECTION|IMAGE_CLASSIFICATION",
      "num_segments": 20,
      "segment_compactness": (5|10|100),
      "max_objects": 3,
      "overlap": 0.5,
      "context": 1.0
    }
  }
},

"predictor": {
  "endpoint_name": "sagemaker-endpoint-name",
  "content_type": "(image/jpeg | image/png | application/x-npy)",
  "label_headers": [...] # Required for CV
}
```
NLP analysis configuration JSON file for a text dataset

The following code sample shows how to configure an analysis for natural processing.

```json
{
    "dataset_type":...

    "methods": {
        "shap": {
            "baseline": "...
            "num_samples": 100
            "text_config": {
                "granularity": "(token|sentence|paragraph)"
            }
        }
    }
}
```

Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability

You use SageMaker Clarify processing jobs to analyze potential sources of bias in your training data and to check your trained model for bias. For the procedure to analyze the data in SageMaker Studio, see Generate Reports for Bias in Pretraining Data in SageMaker Studio (p. 787). The focus here is on posttraining bias metric and SHAP values for explainability. Model predictions can be a source of bias (for example, if they make predictions that more frequently produce a negative result for one group than another). SageMaker Clarify is integrated with SageMaker Experiments so that after a model has been trained, you can identify attributes you would like to check for bias (for example, income). SageMaker runs a set of algorithms to check the trained model and provides you with a visual report on the different types of bias for each attribute, such as whether high-income earners receive more positive predictions compared to low-income earners.

Topics

- Compute Resources Required for SageMaker Clarify Processing Jobs (p. 2544)
- Run the Clarify Processing Job (p. 2545)
- Run the Clarify Processing Job with Spark (p. 2546)
- Get the Analysis Results (p. 2546)

Compute Resources Required for SageMaker Clarify Processing Jobs

Take the following into consideration when determining the compute resources you need to run SageMaker Clarify processing jobs:

- Processing jobs can take several minutes or more to complete.
- Computing explanations can be more time intensive than the actual inference. This includes the time to launch compute resources.
- Computing explanations can be more compute intensive than the actual inference. Review and monitor the charges you may incur from using SageMaker resources. For more information, see Amazon SageMaker Pricing.
Run the Clarify Processing Job

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio to detect posttraining model bias, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 132). The following code samples are taken from the example notebook listed previously.

After you have trained your model, instantiate the SageMaker Clarify processor using the following command:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role,
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=session)
```

Next, configure the input dataset, where to store the output, the label column targeted with a `DataConfig` object, specify information about your trained model with `ModelConfig`, and provide information about the formats of your predictions with `ModelPredictedLabelConfig`.

```python
bias_report_output_path = 's3://{}/clarify-bias'.format(bucket, prefix)
bias_data_config = clarify.DataConfig(
    s3_data_input_path=train_uri,
    s3_output_path=bias_report_output_path,
    label='Target',
    headers=training_data.columns.to_list(),
    dataset_type='text/csv')
model_config = clarify.ModelConfig(
    model_name=model_name,
    instance_type='ml.c5.xlarge',
    instance_count=1,
    accept_type='text/csv')
predictions_config = clarify.ModelPredictedLabelConfig(probability_threshold=0.8)
```

Use `BiasConfig` to provide information on which columns contain the facets (sensitive groups, `Sex`), what the sensitive features (`facet_values_or_threshold`) might be, and what the desirable outcomes are (`label_values_or_threshold`).

```python
bias_config = clarify.BiasConfig(
    label_values_or_threshold=[1],
    facet_name='Sex',
    facet_values_or_threshold=[0])
```

You can run both the pretraining and posttraining analysis in the processing job at the same time with `run_bias()`.

```python
clarify_processor.run_bias(
    data_config=bias_data_config,
    bias_config=bias_config,
    model_config=model_config,
    model_predicted_label_config=predictions_config,
    pre_training_methods='all',
    post_training_methods='all')
```
Run the Clarify Processing Job with Spark

Apache Spark is a unified analytics engine for large-scale data processing. When working with large datasets, you can use the Spark processing capabilities of SageMaker Clarify to enable your Clarify processing jobs to run faster. To use Spark processing for Clarify jobs, set the instance count to a number greater than one. Clarify uses Spark distributed computing when there is more than once instance per Clarify processor.

The following example shows how to use SageMakerClarifyProcessor to create a Clarify processor with 5 instances.

```
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role,
    instance_count=5,
    instance_type='ml.c5.xlarge',
    max_runtime_in_seconds=1200,
    volume_size_in_gb=100)
```

If you configure a Clarify job to save local SHAP values in the SHAPConfig class, Spark saves the local SHAP value as multiple part files in parallel.

If you add more instances, we recommend that you also increase the number of instances in the model configuration ModelConfig for the shadow endpoint. This is to prevent the processing instances from being bottlenecked by the shadow endpoint. Specifically, we recommend that you use a one-to-one ratio of endpoint to processing instances.

Get the Analysis Results

After the processing job is finished, you can download the output files to inspect or visualize the results in Studio. The output directory contains the following files:

- analysis.json – Bias metrics and SHAP values in JSON format.
- report.ipynb – Static notebook to visualize the bias metrics and SHAP values.
- explanations_shap/out.csv – Local (per-instance) SHAP values for each row in the dataset in the same format as input dataset. On each row, the output file contains SHAP values for each feature and the predicted label.

In the analysis JSON file, the bias metrics and SHAP values are organized into three separate sections.

```
{
    "explanations": { . . . }
    "pre_training_bias_metrics": { . . . }
    "post_training_bias_metrics": { . . . }
}
```

SHAP values are in the “explanations” section. Values correspond to the global SHAP value for each feature column.

```
"explanations": {
    "kernel_shap": {
        "label0": {
```
The bias metrics are in the pretraining and posttraining bias metrics sections.

```
{
  "post_training_bias_metrics": {
    "label": "target",
    "label_value_or_threshold": "1",
    "facets": {
      "feature_2": [
        {
          "value_or_threshold": "1",
          "metrics": [
            {
              "name": "DI",
              "description": "Disparate Impact (DI)",
              "value": 0.711340206185567
            },
            {
              "name": "DCR",
              "description": "Difference in Conditional Rejections (DCR)",
              "value": -0.3478260869565218
            }
          ]
        }
      ]
    }
  }
}
```

For more information on bias metrics and SHAP values and how to interpret them, see the Amazon AI Fairness and Explainability Whitepaper.

A bar chart of top SHAP values and tables with the bias metrics are provided in the report notebook.

## Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify

Posttraining bias analysis can help reveal biases that might have emanated from biases in the data, or from biases introduced by the classification and prediction algorithms. These analyses take into consideration the data, including the labels, and the predictions of a model. You assess performance by analyzing predicted labels or by comparing the predictions with the observed target values in the data with respect to groups with different attributes. There are different notions of fairness, each requiring different bias metrics to measure.

There are legal concepts of fairness that might not be easy to capture because they are hard to detect. For example, the US concept of disparate impact that occurs when a group, referred to as a less favored facet, experiences an adverse effect even when the approach taken appears to be fair. This type of bias might not be due to a machine learning model, but might still be detectable by posttraining bias analysis.
Amazon SageMaker Clarify tries to ensure a consistent use of terminology. For a list of terms and their definitions, see Amazon SageMaker Clarify Terms for Bias and Fairness (p. 776).

For additional information about posttraining bias metrics, see Fairness Measures for Machine Learning in Finance.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection:

- Amazon SageMaker Clarify Processing – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSON Lines data formats, bringing your own container, and running processing jobs with Spark.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 132). If you’re prompted to choose a kernel, choose Python 3 (Data Science).

Measure Posttraining Data and Model Bias

Amazon SageMaker Clarify provides eleven posttraining data and model bias metrics to help quantify various conceptions of fairness. These concepts cannot all be satisfied simultaneously and the selection depends on specifics of the cases involving potential bias being analyzed. Most of these metrics are a combination of the numbers taken from the binary classification confusion matrices for the different demographic groups. Because fairness and bias can be defined by a wide range of metrics, human judgment is required to understand and choose which metrics are relevant to the individual use case, and customers should consult with appropriate stakeholders to determine the appropriate measure of fairness for their application.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multicategory classification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet \(a\) and for a disfavored facet \(d\). These labels \(y\) are referred to as observed labels to distinguish them from the predicted labels \(y'\) that are assigned by a machine learning model during the training or inference stages of the ML life cycle. These labels are used to define probability distributions \(P_a(y)\) and \(P_d(y)\) for their respective facet outcomes.

- labels:
  - \(y\) represents the \(n\) observed labels for event outcomes in a training dataset.
  - \(y'\) represents the predicted labels for the \(n\) observed labels in the dataset by a trained model.
- outcomes:
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
    - \(n^{(1)}\) is the number of observed labels for positive outcomes (acceptances).
    - \(n'^{(1)}\) is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
    - \(n^{(0)}\) is the number of observed labels for negative outcomes (rejections).
    - \(n'^{(0)}\) is the number of predicted labels for negative outcomes (rejections).
- facet values:
  - facet \(a\) – The feature value that defines a demographic that bias favors.
    - \(n_a\) is the number of observed labels for the favored facet value: \(n_a = n_a^{(1)} + n_a^{(0)}\) the sum of the positive and negative observed labels for the value facet \(a\).
- $n'_a$ is the number of predicted labels for the favored facet value: $n'_a = n'_a(1) + n'_a(0)$ the sum of the positive and negative predicted outcome labels for the facet value $a$. Note that $n'_a = n_a$.

- facet $d$ – The feature value that defines a demographic that bias disfavors.

- $n_d$ is the number of observed labels for the disfavored facet value: $n_d = n_d(1) + n_d(0)$ the sum of the positive and negative observed labels for the facet value $d$.

- $n'_d$ is the number of predicted labels for the disfavored facet value: $n'_d = n'_d(1) + n'_d(0)$ the sum of the positive and negative predicted labels for the facet value $d$. Note that $n'_d = n_d$.

- probability distributions for outcomes of the labeled facet data outcomes:
  - $P_a(y)$ is the probability distribution of the observed labels for facet $a$. For binary labeled data, this distribution is given by the ratio of the number of samples in facet $a$ labeled with positive outcomes to the total number, $P_a(y^1) = n_a(1) / n_a$, and the ratio of the number of samples with negative outcomes to the total number, $P_a(y^0) = n_a(0) / n_a$.
  - $P_d(y)$ is the probability distribution of the observed labels for facet $d$. For binary labeled data, this distribution is given by the number of samples in facet $d$ labeled with positive outcomes to the total number, $P_d(y^1) = n_d(1) / n_d$, and the ratio of the number of samples with negative outcomes to the total number, $P_d(y^0) = n_d(0) / n_d$.

The following table contains a cheat sheet for quick guidance and links to the posttraining bias metrics.

</tbody>
</table>

Interpretation:
- Values less than 1 indicate the favored facet $a$ has a higher proportion of predicted positive outcomes.
- A value of 1 indicates that we have demographic parity.
- Values greater than 1 indicate the disfavored facet $d$ has a higher proportion of predicted positive outcomes.

**Conditional Demographic Disparity in Predicted Labels (CDDPL) (p. 2567)**

Measures the disparity of predicted labels between the facets as a whole, but also by subgroups.

Do some demographic groups have a larger proportion of rejections for loan application outcomes than their proportion of acceptances?

The range of CDDPL values for binary, multicategory, and continuous outcomes: $[-1, +1]$.

- Positive values indicate outcomes where facet $d$ is rejected more than accepted.
- Near zero indicates no demographic disparity on average.
- Negative values indicate outcomes where facet $a$ is rejected more than accepted.

| Difference in Rejection Rates (DRR) (p. 2564) | Measures the difference in the ratios of the observed negative outcomes (TN) to the predicted negatives (TN + FN) between the disfavored and favored facets. | Does the model have equal precision when predicting loan rejections for unqualified applicants across all age groups? | The range for binary, multicategory facet, and continuous labels is $[-1, +1]$.  
- Positive values indicate a possible bias caused by the occurrence of relatively more false negatives in the favored facet $a$.  
- Values near zero indicate that negative outcomes (rejections) are being predicted with equal precision for both facets.  
- Negative values indicate a possible bias caused by the occurrence of relatively more false negatives in the disfavored facet $d$. |
| Treatment Equality (TE) (p. 2566) | Measures the difference in the ratio of false positives to false negatives between the favored and disfavored facets. | In loan applications, is the relative ratio of false positives to false negatives the same across all age demographics? | The range for binary and multicategory facet labels: $(-\infty, +\infty)$.  
- Positive values occur when the ratio of false positives to false negatives for facet $a$ is greater than that for facet $d$.  
- Values near zero occur when the ratio of false positives to false negatives for facet $a$ is similar to that for facet $d$.  
- Negative values occur when the ratio of false positives to false negatives for facet $a$ is less than that for facet $d$. |
Detect Posttraining Data and Model Bias

### Posttraining bias metric | Description | Example question | Interpreting metric values
--- | --- | --- | ---
Generalized entropy (GE) (p. 2569) | Measures the inequality in benefits assigned to each input by the model predictions. | Of two candidate models for loan application classification, does one lead to a more uneven distribution of desired outcomes than the other? | The range for binary and multiclass labels: (0, 0.5). GE is undefined when the model predicts only false negatives.  
- Zero values occur when all predictions are correct or all predictions are false positives.  
- Positive values indicate inequality in benefits; 0.5 corresponds to the largest inequality. |

For additional information about posttraining bias metrics, see [A Family of Fairness Measures for Machine Learning in Finance](#).

**Topics**

- Counterfactual Fliptest (FT) (p. 2568)
- Generalized entropy (GE) (p. 2569)

**Difference in Positive Proportions in Predicted Labels (DPPL)**

The difference in positive proportions in predicted labels (DPPL) metric determines whether the model predicts outcomes differently for each facet. It is defined as the difference between the proportion of positive predictions \( y' = 1 \) for facet \( a \) and the proportion of positive predictions \( y' = 1 \) for facet \( d \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% of other age groups (facet \( d \)), it might be biased against facet \( d \). In this example, you need to determine whether the 10% difference is material to a case for bias. A comparison of DPL with DPPL assesses whether bias initially present in the dataset increases or decreases in the model predictions after training.

The formula for the difference in proportions of predicted labels:

\[
DPPL = q'_{a} - q'_{d}
\]
Detect Posttraining Data and Model Bias

Where:

- \( q_a = \frac{n_a^{(1)}}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n_a^{(1)} \) represents the number of members of facet \( a \) who get a positive predicted outcome of value 1 and \( n_a \) the is number of members of facet \( a \).

- \( q_d = \frac{n_d^{(1)}}{n_d} \) is the predicted proportion of facet \( d \) who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n_d^{(1)} \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

If DPPL is close enough to 0, it means that postraining demographic parity has been achieved.

For binary and multicategory facet labels, the normalized DPL values range over the interval \([-1, 1]\). For continuous labels, the values vary over the interval \((0, +0)\).
- Positive DPPL values indicate that facet \( a \) has a higher proportion of predicted positive outcomes when compared with facet \( d \).
  - This is referred to as positive bias.
- Values of DPPL near zero indicate a more equal proportion of predicted positive outcomes between facets \( a \) and \( d \) and a value of zero indicates perfect demographic parity.
- Negative DPPL values indicate that facet \( d \) has a higher proportion of predicted positive outcomes when compared with facet \( a \). This is referred to as negative bias.

**Disparate Impact (DI)**

The difference in positive proportions in the predicted labels metric can be assessed in the form of a ratio.

The comparison of positive proportions in predicted labels metric can be assessed in the form of a ratio instead of as a difference, as it is with the Difference in Positive Proportions in Predicted Labels (DPPL) (p. 2557). The disparate impact (DI) metric is defined as the ratio of the proportion of positive predictions \((y' = 1)\) for facet \( d \) over the proportion of positive predictions \((y' = 1)\) for facet \( a \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% other age groups (facet \( d \)), then \( DI = \frac{0.6}{0.5} = 0.8 \), which indicates a positive bias and an adverse impact on the other aged group represented by facet \( d \).

The formula for the ratio of proportions of the predicted labels:

\[
DI = \frac{q_d}{q_a}
\]

Where:

- \( q_a = \frac{n_a^{(1)}}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n_a^{(1)} \) represents the number of members of facet \( a \) who get a positive predicted outcome and \( n_a \) the is number of members of facet \( a \).

- \( q_d = \frac{n_d^{(1)}}{n_d} \) is the predicted proportion of facet \( d \) a who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n_d^{(1)} \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

For binary, multicategory facet, and continuous labels, the DI values range over the interval \([0, \infty)\).
• Values less than 1 indicate that facet $a$ has a higher proportion of predicted positive outcomes than facet $d$. This is referred to as positive bias.
• A value of 1 indicates demographic parity.
• Values greater than 1 indicate that facet $d$ has a higher proportion of predicted positive outcomes than facet $a$. This is referred to as negative bias.

### Difference in Conditional Acceptance (DCAcc)

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for predicted positive outcomes. This metric comes close to mimicking human bias in that it quantifies how many more positive outcomes a model predicted (labels $y'$) for a certain facet as compared to what was observed in the training dataset (labels $y$). For example, if there were more acceptances (a positive outcome) observed in the training dataset for loan applications for a middle-aged group (facet $a$) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet $d$), this might indicate potential bias in the way loans were approved favoring the middle-aged group.

The formula for the difference in conditional acceptance:

$$\text{DCAcc} = c_a - c_d$$

Where:

- $c_a = n_a^{(1)}/n_a^{(1)}$ is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet $a$ to the predicted number of positive outcome (acceptances) for facet $a$.
- $c_d = n_d^{(1)}/n_d^{(1)}$ is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet $d$ to the predicted number of predicted positive outcomes (acceptances) for facet $d$.

The DCAcc metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan acceptances.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 70 from facet $a$ and 20 from facet $d$ were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested (70/60 = 1.17) and granted loans to 33% more from other age groups than the observed labels suggested (20/30 = 0.67). The calculation of the DCAcc value gives the following:

$$\text{DCAcc} = 70/60 - 20/30 = 1/2$$

The positive value indicates that there is a potential bias against the middle-aged facet $a$ with a lower acceptance rate as compared with the other facet $d$ than the observed data (taken as unbiased) indicate is the case.

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 50 from facet $a$ and 40 from facet $d$ were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested (50/60 = 0.83), and granted loans to 33% more from other age groups than the observed labels suggested (40/30 = 1.33). The calculation of the DCAcc value gives the following:
The negative value indicates that there is a potential bias against facet \( d \) with a lower acceptance rate as compared with the middle-aged facet \( a \) than the observed data (taken as unbiased) indicate is the case.

Note that you can use DCAcc to help you detect potential (unintentional) biases by humans overseeing the model predictions in a human-in-the-loop setting. Assume, for example, that the predictions \( y' \) by the model were unbiased, but the eventual decision is made by a human (possibly with access to additional features) who can alter the model predictions to generate a new and final version of \( y' \). The additional processing by the human may unintentionally deny loans to a disproportionate number from one facet. DCAcc can help detect such potential biases.

The range of values for differences in conditional acceptance for binary, multicategory facet, and continuous labels is \((-\infty, +\infty)\).

- Positive values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet \( a \) is higher than the same ratio for facet \( d \). These values indicate a possible bias against the qualified applicants from facet \( a \). The larger the difference of the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet \( a \) is the similar to the ratio for facet \( d \). These values indicate that predicted acceptance rates are consistent with the observed values in the labeled data and that qualified applicants from both facets are being accepted in a similar way.
- Negative values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet \( a \) is less than that ratio for facet \( d \). These values indicate a possible bias against the qualified applicants from facet \( d \). The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Conditional Rejection (DCR)**

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for negative outcomes (rejections). This metric comes close to mimicking human bias, in that it quantifies how many more negative outcomes a model granted (predicted labels \( y' \)) to a certain facet as compared to what was suggested by the labels in the training dataset (observed labels \( y \)). For example, if there were more observed rejections (a negative outcome) for loan applications for a middle-aged group (facet \( a \)) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet \( d \)), this might indicate potential bias in the way loans were rejected that favored the middle-aged group over other groups.

The formula for the difference in conditional acceptance:

\[
DCR = r_d - r_a
\]

Where:

- \( r_d = \frac{n_d^{(0)}}{n_d^{(0)}} \) is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet \( d \) to the predicted number of negative outcome (rejections) for facet \( d \).
- \( r_a = \frac{n_a^{(0)}}{n_a^{(0)}} \) is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet \( a \) to the predicted number of negative outcome of value 0 (rejections) for facet \( a \).

The DCR metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan rejections.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet \( a \)) and 50 people from other age groups (facet \( d \)) who applied for loans, where the model recommended that 60 from facet \( a \) and 30 from facet
$d$ be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 50 from facet $a$ and 40 from facet $d$ were rejected. In other words, the model rejected 17% more loans from the middle aged facet than the observed labels in the training data suggested ($50/60 = 0.83$), and rejected 33% fewer loans from other age groups than the observed labels suggested ($40/30 = 1.33$). The DCR value quantifies this difference in the ratio of observed to predicted rejection rates between the facets. The positive value indicates that there is a potential bias favoring the middle aged group with lower rejection rates as compared with other groups than the observed data (taken as unbiased) indicate is the case.

$$DCR = 40/30 - 50/60 = 1/2$$

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 70 from facet $a$ and 20 from facet $d$ were rejected. In other words, the model rejected 17% fewer loans from the middle aged facet than the observed labels in the training data suggested ($70/60 = 1.17$), and rejected 33% more loans from other age groups than the observed labels suggested ($20/30 = 0.67$). The negative value indicates that there is a potential bias favoring facet $a$ with lower rejection rates as compared with the middle-aged facet $a$ than the observed data (taken as unbiased) indicate is the case.

$$DCR = 20/30 - 70/60 = -1/2$$

The range of values for differences in conditional rejection for binary, multicategory facet, and continuous labels is $(-\infty, +\infty)$.

- **Positive values** occur when the ratio of the observed number of rejections compared to predicted rejections for facet $d$ is greater than that ratio for facet $a$. These values indicate a possible bias against the qualified applicants from facet $a$. The larger the value of DCR metric, the more extreme the apparent bias.
- **Values near zero** occur when the ratio of the observed number of rejections compared to predicted acceptances for facet $a$ is similar to the ratio for facet $d$. These values indicate that predicted rejections rates are consistent with the observed values in the labeled data and that the qualified applicants from both facets are being rejected in a similar way.
- **Negative values** occur when the ratio of the observed number of rejections compared to predicted rejections for facet $d$ is less than that ratio facet $a$. These values indicate a possible bias against the qualified applicants from facet $d$. The larger magnitude of the negative DCR metric, the more extreme the apparent bias.

### Specificity difference (SD)

The specificity difference (SD) is the difference in specificity between the favored facet $a$ and disfavored facet $d$. Specificity measures how often the model correctly predicts a negative outcome ($y'=0$). Any difference in these specificities is a potential form of bias.

Specificity is perfect for a facet if all of the $y=0$ cases are correctly predicted for that facet. Specificity is greater when the model minimizes false positives, known as a Type I error. For example, the difference between a low specificity for lending to facet $a$, and high specificity for lending to facet $d$, is a measure of bias against facet $d$.

The following formula is for the difference in the specificity for facets $a$ and $d$.

$$SD = \frac{TN_d}{(TN_a + FP_d)} - \frac{TN_a}{(TN_d + FP_a)} = TNR_d - TNR_a$$

The following variables used to calculated SD are defined as follows:
- TN<sub>d</sub> are the true negatives predicted for facet <i>d</i>.
- FP<sub>d</sub> are the false positives predicted for facet <i>d</i>.
- TN<sub>a</sub> are the true negatives predicted for facet <i>a</i>.
- FP<sub>a</sub> are the false positives predicted for facet <i>a</i>.
- TNR<sub>a</sub> = TN<sub>a</sub>/(TN<sub>a</sub> + FP<sub>a</sub>) is the true negative rate, also known as the specificity, for facet <i>a</i>.
- TNR<sub>d</sub> = TN<sub>d</sub>/(TN<sub>d</sub> + FP<sub>d</sub>) is the true negative rate, also known as the specificity, for facet <i>d</i>.

For example, consider the following confusion matrices for facets <i>a</i> and <i>d</i>.

### Confusion matrix for the favored facet <i>a</i>

<table>
<thead>
<tr>
<th>Class a predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

### Confusion matrix for the disfavored facet <i>d</i>

<table>
<thead>
<tr>
<th>Class d predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the specificity difference is SD = 18/(18+5) − 20/(20+10) = 0.7826 − 0.6667 = 0.1159, which indicates a bias against facet <i>d</i>.

The range of values for the specificity difference between facets <i>a</i> and <i>d</i> for binary and multcategory classification is [−1, +1]. This metric is not available for the case of continuous labels. Here is what different values of SD imply:

- Positive values are obtained when there is higher specificity for facet <i>d</i> than for facet <i>a</i>. This suggests that the model finds less false positives for facet <i>d</i> than for facet <i>a</i>. A positive value indicates bias against facet <i>d</i>.
- Values near zero indicate that the specificity for facets that are being compared is similar. This suggests that the model finds a similar number of false positives in both of these facets and is not biased.
- Negative values are obtained when there is higher specificity for facet <i>a</i> than for facet <i>d</i>. This suggests that the model finds more false positives for facet <i>a</i> than for facet <i>d</i>. A negative value indicates bias against facet <i>a</i>.

### Recall Difference (RD)

The recall difference (RD) metric is the difference in recall of the model between the favored facet <i>a</i> and disfavored facet <i>d</i>. Any difference in these recalls is a potential form of bias. Recall is the true positive rate (TPR), which measures how often the model correctly predicts the cases that should receive a positive outcome. Recall is perfect for a facet if all of the y=1 cases are correctly predicted as y′=1 for that facet. Recall is greater when the model minimizes false negatives known as the Type II error. For example, how many of the people in two different groups (facets <i>a</i> and <i>d</i>) that should qualify for loans...
are detected correctly by the model? If the recall rate is high for lending to facet $a$, but low for lending to facet $d$, the difference provides a measure of this bias against the group belonging to facet $d$.

The formula for difference in the recall rates for facets $a$ and $d$:

$$RD = \frac{TP_a}{TP_a + FN_a} - \frac{TP_d}{TP_d + FN_d} = TPR_a - TPR_d$$

Where:

- $TP_a$ are the true positives predicted for facet $a$.
- $FN_a$ are the false negatives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TPR_a = \frac{TP_a}{TP_a + FN_a}$ is the recall for facet $a$ or its true positive rate.
- $TPR_d = \frac{TP_d}{TP_d + FN_d}$ is the recall for facet $d$ or its true positive rate.

For example, consider the following confusion matrices for facets $a$ and $d$.

### Confusion Matrix for the FavoredFacet a

<table>
<thead>
<tr>
<th>Class a predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

### Confusion Matrix for the Disfavored Facet d

<table>
<thead>
<tr>
<th>Class d predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the recall difference is $RD = 65/70 - 20/27 = 0.93 - 0.74 = 0.19$ which indicates a bias against facet $d$.

The range of values for the recall difference between facets $a$ and $d$ for binary and multicategory classification is $[-1, +1]$. This metric is not available for the case of continuous labels.

- Positive values are obtained when there is higher recall for facet $a$ than for facet $d$. This suggests that the model finds more of the true positives for facet $a$ than for facet $d$, which is a form of bias.
- Values near zero indicate that the recall for facets being compared is similar. This suggests that the model finds about the same number of true positives in both of these facets and is not biased.
- Negative values are obtained when there is higher recall for facet $d$ than for facet $a$. This suggests that the model finds more of the true positives for facet $d$ than for facet $a$, which is a form of bias.

### Difference in Acceptance Rates (DAR)

The difference in acceptance rates (DAR) metric is the difference in the ratios of the true positive (TP) predictions to the observed positives (TP + FP) for facets $a$ and $d$. This metric measures the difference
in the precision of the model for predicting acceptances from these two facets. Precision measures the fraction of qualified candidates from the pool of qualified candidates that are identified as such by the model. If the model precision for predicting qualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DAR.

The formula for difference in acceptance rates between facets $a$ and $d$:

$$DAR = \frac{TP_a}{TP_a + FP_a} - \frac{TP_d}{TP_d + FP_d}$$

Where:

- $TP_a$ are the true positives predicted for facet $a$.
- $FP_a$ are the false positives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FP_d$ are the false positives predicted for facet $d$.

For example, suppose the model accepts 70 middle-aged applicants (facet $a$) for a loan (predicted positive labels) of whom only 35 are actually accepted (observed positive labels). Also suppose the model accepts 100 applicants from other age demographics (facet $d$) for a loan (predicted positive labels) of whom only 40 are actually accepted (observed positive labels). Then $DAR = 35/70 - 40/100 = 0.10$, which indicates a potential bias against qualified people from the second age group (facet $d$).

The range of values for DAR for binary, multicategory facet, and continuous labels is $[-1, +1]$. 

- Positive values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet $a$ is larger than the same ratio for facet $d$. These values indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false positives in facet $d$. The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facets $a$ and $d$ have similar values indicating the observed labels for positive outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet $d$ is larger than the ratio facet $a$. These values indicate a possible bias against the favored facet $a$ caused by the occurrence of relatively more false positives in facet $a$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Rejection Rates (DRR)**

The difference in rejection rates (DRR) metric is the difference in the ratios of the true negative (TN) predictions to the observed negatives (TN + FN) for facets $a$ and $d$. This metric measures the difference in the precision of the model for predicting rejections from these two facets. Precision measures the fraction of unqualified candidates from the pool of unqualified candidates that are identified as such by the model. If the model precision for predicting unqualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DRR.

The formula for difference in rejection rates between facets $a$ and $d$:

$$DRR = \frac{TN_d}{TN_d + FN_d} - \frac{TN_a}{TN_a + FN_a}$$

Where:

- $TN_d$ are the true negatives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TP_a$ are the true negatives predicted for facet $a$. 

2564
Detect Posttraining Data and Model Bias

- FN_a are the false negatives predicted for facet a.

For example, suppose the model rejects 100 middle-aged applicants (facet a) for a loan (predicted negative labels) of whom 80 are actually unqualified (observed negative labels). Also suppose the model rejects 50 applicants from other age demographics (facet d) for a loan (predicted negative labels) of whom only 40 are actually unqualified (observed negative labels). Then DRR = 40/50 - 80/100 = 0, so no bias is indicated.

The range of values for DRR for binary, multicategory facet, and continuous labels is [-1, +1].

- Positive values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet d is larger than the same ratio for facet a. These values indicate a possible bias against the favored facet a caused by the occurrence of relatively more false negatives in facet a. The larger the difference in the ratios, the more extreme the apparent bias.

- Values near zero occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facets a and d have similar values, indicating the observed labels for negative outcomes are being predicted with equal precision by the model.

- Negative values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet a is larger than the ratio facet d. These values indicate a possible bias against the disfavored facet d caused by the occurrence of relatively more false positives in facet d. The more negative the difference in the ratios, the more extreme the apparent bias.

### Accuracy Difference (AD)

Accuracy difference (AD) metric is the difference between the prediction accuracy for different facets. This metric determines whether the classification by the model is more accurate for one facet than the other. AD indicates whether one facet incurs a greater proportion of Type I and Type II errors. But it cannot differentiate between Type I and Type II errors. For example, the model may have equal accuracy for different age demographics, but the errors may be mostly false positives (Type I errors) for one age-based group and mostly false negatives (Type II errors) for the other.

Also, if loan approvals are made with much higher accuracy for a middle-aged demographic (facet a) than for another age-based demographic (facet d), either a greater proportion of qualified applicants in the second group are denied a loan (FN) or a greater proportion of unqualified applicants from that group get a loan (FP) or both. This can lead to within group unfairness for the second group, even if the proportion of loans granted is nearly the same for both age-based groups, which is indicated by a DPPL value that is close to zero.

The formula for AD metric is the difference between the prediction accuracy for facet a, ACC_a, minus that for facet d, ACC_d:

\[ AD = ACC_a - ACC_d \]

Where:

- ACC_a = (TP_a + TN_a)/(TP_a + TN_a + FP_a + FN_a)
  - TP_a are the true positives predicted for facet a
  - TN_a are the true negatives predicted for facet a
  - FP_a are the false positives predicted for facet a
  - FN_a are the false negatives predicted for facet a
- ACC_d = (TP_d + TN_d)/(TP_d + TN_d + FP_d + FN_d)
  - TP_d are the true positives predicted for facet d
  - TN_d are the true negatives predicted for facet d
  - FP_d are the false positives predicted for facet d
• FN_d are the false negatives predicted for facet d

For example, suppose a model approves loans to 70 applicants from facet a of 100 and rejected the other 30. 10 should not have been offered the loan (FP_a) and 60 were approved that should have been (TP_a). 20 of the rejections should have been approved (FN_a) and 10 were correctly rejected (TN_a). The accuracy for facet a is as follows:

$$ACC_a = \frac{60 + 10}{60 + 10 + 20 + 10} = 0.7$$

Next, suppose a model approves loans to 50 applicants from facet d of 100 and rejected the other 50. 10 should not have been offered the loan (FP_d) and 40 were approved that should have been (TP_d). 40 of the rejections should have been approved (FN_d) and 10 were correctly rejected (TN_d). The accuracy for facet d is determined as follows:

$$ACC_d = \frac{40 + 10}{40 + 10 + 40 + 10} = 0.5$$

The accuracy difference is thus AD = ACC_a - ACC_d = 0.7 - 0.5 = 0.2. This indicates there is a bias against facet d as the metric is positive.

The range of values for AD for binary and multicategory facet labels is [-1, +1].

• Positive values occur when the prediction accuracy for facet a is greater than that for facet d. It means that facet d suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet d.

• Values near zero occur when the prediction accuracy for facet a is similar to that for facet d.

• Negative values occur when the prediction accuracy for facet d is greater than that for facet a. It means that facet a suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a bias against the favored facet a.

**Treatment Equality (TE)**

The treatment equality (TE) is the difference in the ratio of false negatives to false positives between facets a and d. The main idea of this metric is to assess whether, even if the accuracy across groups is the same, is it the case that errors are more harmful to one group than another? Error rate comes from the total of false positives and false negatives, but the breakdown of these two maybe very different across facets. TE measures whether errors are compensating in the similar or different ways across facets.

The formula for the treatment equality:

$$TE = \frac{FN_d}{FP_d} - \frac{FN_a}{FP_a}$$

Where:

• FN_d are the false negatives predicted for facet d.
• FP_d are the false positives predicted for facet d.
• FN_a are the false negatives predicted for facet a.
• FP_a are the false positives predicted for facet a.

Note the metric becomes unbounded if FP_a or FP_d is zero.

For example, suppose that there are 100 loan applicants from facet a and 50 from facet d. For facet a, 8 were wrongly denied a loan (FN_a) and another 6 were wrongly approved (FP_a). The remaining predictions were true, so TP_a + TN_a = 86. For facet d, 5 were wrongly denied (FN_d) and 2 were wrongly approved (FP_d). The remaining predictions were true, so TP_d + TN_d = 43. The ratio of false negatives to false
positives equals 8/6 = 1.33 for facet \( a \) and 5/2 = 2.5 for facet \( d \). Hence \( TE = 2.5 - 1.33 = 1.167 \), even though both facets have the same accuracy:

\[
\text{ACC}_a = \frac{86}{86 + 8 + 6} = 0.86 \\
\text{ACC}_d = \frac{43}{43 + 5 + 2} = 0.86
\]

The range of values for differences in conditional rejection for binary and multicategory facet labels is \((-\infty, +\infty)\). The TE metric is not defined for continuous labels. The interpretation of this metric depends on the relative important of false positives (Type I error) and false negatives (Type II error).

- Positive values occur when the ratio of false negatives to false positives for facet \( d \) is greater than that for facet \( a \).
- Values near zero occur when the ratio of false negatives to false positives for facet \( a \) is similar to that for facet \( d \).
- Negative values occur when the ratio of false negatives to false positives for facet \( d \) is less than that for facet \( a \).

**Note**

A previous version stated that the Treatment Equality metric is computed as \( \frac{\text{FP}_a}{\text{FN}_a} - \frac{\text{FP}_d}{\text{FN}_d} \) instead of \( \frac{\text{FN}_d}{\text{FP}_d} - \frac{\text{FN}_a}{\text{FP}_a} \). While either of the versions can be used. For more information, see Fairness measures for Machine Learning in Finance.

**Conditional Demographic Disparity in Predicted Labels (CDDPL)**

The demographic disparity metric (DDPL) determines whether facet \( d \) has a larger proportion of the predicted rejected labels than that of the predicted accepted labels. It enables a comparison of difference in predicted rejection proportion and predicted acceptance proportion across facets. This metric is exactly the same as the pretraining CDD metric except that it is computed off the predicted labels instead of the observed ones. This metric lies in the range \((-1, +1)\).

The formula for the demographic disparity predictions for labels of facet \( d \) is as follows:

\[
\text{DDPL}_d = \frac{n'_d(0)}{n'_d(0) + n'_d(1)} - \frac{n'_a(1)}{n'_a(1) + n'_a(0)} = P_d^R(y'_0) - P_a^A(y'_1)
\]

Where:

- \( n'_d(0) = n'_a(0) + n'_d(0) \) is the number of predicted rejected labels for facets \( a \) and \( d \).
- \( n'_d(1) = n'_a(1) + n'_d(1) \) is the number of predicted accepted labels for facets \( a \) and \( d \).
- \( P_d^R(y'_0) \) is the proportion of predicted rejected labels (value 0) in facet \( d \).
- \( P_d^A(y'_1) \) is the proportion of predicted accepted labels (value 1) in facet \( d \).

A conditional demographic disparity in predicted labels (CDDPL) metric that conditions DDPL on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson’s paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. But when departmental subgroups were examined, women were shown to have higher admission rates than men by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgroup acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDDPL metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities in predicted labels (DDPL) for each of the subgroups, with each subgroup disparity weighted
in proportion to the number of observations in contains. The formula for the conditional demographic
disparity in predicted labels is as follows:

\[
\text{CDDPL} = \frac{1}{n} \sum n_i \cdot \text{DDPL}_i
\]

Where:
- \( \sum n_i = n \) is the total number of observations and \( n_i \) is the number of observations for each subgroup.
- \( \text{DDPL}_i = n_i^{(0)}/n^{(0)} - n_i^{(1)}/n^{(1)} = p_i^R(y^{(0)}) - p_i^A(y^{(1)}) \) is the demographic disparity in predicted labels for the subgroup.

So the demographic disparity for a subgroup in predicted labels (DDPL) are the difference between
the proportion of predicted rejected labels and the proportion of predicted accepted labels for each
subgroup.

The range of DDPL values for binary, multicategory, and continuous outcomes is \([-1,+1]\).
- +1: when there are no predicted rejection labels for facet \( a \) or subgroup and no predicted acceptances
  for facet \( d \) or subgroup.
- Positive values indicate there is a demographic disparity in predicted labels as facet \( d \) or subgroup has
  a larger proportion of the predicted rejected labels than of the predicted accepted labels. The higher
  the value the greater the disparity.
- Values near zero indicate there is no demographic disparity on average.
- Negative values indicate there is a demographic disparity in predicted labels as facet \( a \) or subgroup has
  a larger proportion of the predicted rejected labels than of the predicted accepted labels. The lower
  the value the greater the disparity.
- -1: when there are no predicted rejection labels for facet \( d \) or subgroup and no predicted acceptances
  for facet \( a \) or subgroup.

Counterfactual Flippert (FT)

The flippert is an approach that looks at each member of facet \( d \) and assesses whether similar members
of facet \( a \) have different model predictions. The members of facet \( a \) are chosen to be k-nearest neighbors
of the observation from facet \( d \). We assess how many nearest neighbors of the opposite group receive a
different prediction, where the flipped prediction can go from positive to negative and vice versa.

The formula for the counterfactual flippert is the difference in the cardinality of two sets divided by the
number of members of facet \( d \):

\[
\text{FT} = (F^+ - F^-)/n_d
\]

Where:
- \( F^+ \) is the number of disfavored facet \( d \) members with an unfavorable outcome whose nearest
  neighbors in favored facet \( a \) received a favorable outcome.
- \( F^- \) is the number of disfavored facet \( d \) members with a favorable outcome whose nearest neighbors
  in favored facet \( a \) received an unfavorable outcome.
- \( n_d \) is the sample size of facet \( d \).

The range of values for the counterfactual flippert for binary and multicategory facet labels is \([-1, +1]\).
For continuous labels, we set a threshold to collapse the labels to binary.
- Positive values occur when the number of unfavorable counterfactual flippert decisions for the
  disfavored facet \( d \) exceeds the favorable ones.
• Values near zero occur when the number of unfavorable and favorable counterfactual flip test decisions balance out.
• Negative values occur when the number of unfavorable counterfactual flip test decisions for the disfavored facet \( d \) is less than the favorable ones.

**Generalized entropy (GE)**

The generalized entropy index (GE) measures the inequality in benefit \( b \) for the predicted label compared to the observed label. A benefit occurs when a false positive is predicted. A false positive occurs when a negative observation \((y=0)\) has a positive prediction \((y'=1)\). A benefit also occurs when the observed and predicted labels are the same, also known as a true positive and true negative. No benefit occurs when a false negative is predicted. A false negative occurs when a positive observation \((y=1)\) is predicted to have a negative outcome \((y'=0)\). The benefit \( b \) is defined, as follows.

\[
b = y' - y + 1
\]

Using this definition, a false positive receives a benefit \( b \) of 2, and a false negative receives a benefit of 0. Both a true positive and a true negative receive a benefit of 1.

The GE metric is computed following the Generalized Entropy Index (GE) with the weight \( \alpha \) set to 2. This weight controls the sensitivity to different benefit values. A smaller \( \alpha \) means an increased sensitivity to smaller values.

\[
GE = \frac{1}{2n} \sum_{i=1}^{n} \left[ \left( \frac{b_i}{b'} \right)^2 - 1 \right]
\]

The following variables used to calculate GE are defined as follows:

- \( b_i \) is the benefit received by the \( i^{th} \) data point.
- \( b' \) is the mean of all benefits.

GE can range from 0 to 0.5, where values of zero indicate no inequality in benefits across all data points. This occurs either when all inputs are correctly predicted or when all the predictions are false positives. GE is undefined when all predictions are false negatives.

**Note**
The metric GE does not depend on a facet value being either favored or disfavored.

**Amazon SageMaker Clarify Model Explainability**

Amazon SageMaker Clarify provides tools to help explain how machine learning (ML) models make predictions. These tools can help ML modelers and developers and other internal stakeholders understand model characteristics as a whole prior to deployment and to debug predictions provided by the model after it's deployed. Transparency about how ML models arrive at their predictions is also critical to consumers and regulators. They need to trust the model predictions if they are going to accept the decisions based on them. SageMaker Clarify uses a model-agnostic feature attribution approach. You can use this to understand why a model made a prediction after training, and to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of SHAP. This is based on the concept of a Shapley value, from the field of cooperative game theory, that assigns each feature an importance value for a particular prediction.

Clarify produces partial dependence plots (PDPs) that show the marginal effect features have on the predicted outcome of a machine learning model. Partial dependence helps explain target response given a set of input features. It also supports both computer vision (CV) and natural language processing (NLP) explainability using the same Shapley Values (SHAP) algorithm as used for tabular data explanations.
What is the function of an explanation in the machine learning context? An explanation can be thought of as the answer to a Why question that helps humans understand the cause of a prediction. In the context of an ML model, you might be interested in answering questions such as:

- Why did the model predict a negative outcome such as a loan rejection for a given applicant?
- How does the model make predictions?
- Why did the model make an incorrect prediction?
- Which features have the largest influence on the behavior of the model?

You can use explanations for auditing and meeting regulatory requirements, building trust in the model and supporting human decision-making, and debugging and improving model performance.

The need to satisfy the demands for human understanding about the nature and outcomes of ML inference is key to the sort of explanation needed. Research from philosophy and cognitive science disciplines has shown that people care especially about contrastive explanations, or explanations of why an event X happened instead of some other event Y that did not occur. Here, X could be an unexpected or surprising event that happened and Y corresponds to an expectation based on their existing mental model referred to as a baseline. Note that for the same event X, different people might seek different explanations depending on their point of view or mental model Y. In the context of explainable AI, you can think of X as the example being explained and Y as a baseline that is typically chosen to represent an uninformative or average example in the dataset. Sometimes, for example in the case of ML modeling of images, the baseline might be implicit, where an image whose pixels are all the same color can serve as a baseline.

**Sample Notebooks**

Amazon SageMaker Clarify provides the following sample notebook for model explainability:

- **Amazon SageMaker Clarify Processing** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSONLines data formats, bringing your own container, and running processing jobs with Spark.
- **Explaining Image Classification with SageMaker Clarify** – SageMaker Clarify provides you with insights into how your computer vision models classify images.
- **Explaining object detection models with SageMaker Clarify** – SageMaker Clarify provides you with insights into how your computer vision models detect objects.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 132). If you’re prompted to choose a kernel, choose Python 3 (Data Science).

**Topics**

- Feature Attributions that Use Shapley Values (p. 2570)
- SHAP Baselines for Explainability (p. 2571)
- Partial Dependence Plots: Analysis Configuration and Output (p. 2572)
- SageMaker Clarify Computer Vision (p. 2574)
- Create Feature Attribute Baselines and Explainability Reports (p. 2575)
- Explainability Reports for NLP Models (p. 2576)

**Feature Attributions that Use Shapley Values**

SageMaker Clarify provides feature attributions based on the concept of Shapley value. You can use Shapley values to determine the contribution that each feature made to model predictions. These
attributions can be provided for specific predictions and at a global level for the model as a whole. For example, if you used an ML model for college admissions, the explanations could help determine whether the GPA or the SAT score was the feature most responsible for the model’s predictions, and then you can determine how responsible each feature was for determining an admission decision about a particular student.

SageMaker Clarify has taken the concept of Shapley values from game theory and deployed it in a machine learning context. The Shapley value provides a way to quantify the contribution of each player to a game, and hence the means to distribute the total gain generated by a game to its players based on their contributions. In this machine learning context, SageMaker Clarify treats the prediction of the model on a given instance as the game and the features included in the model as the players. For a first approximation, you might be tempted to determine the marginal contribution or effect of each feature by quantifying the result of either dropping that feature from the model or dropping all other features from the model. However, this approach does not take into account that features included in a model are often not independent from each other. For example, if two features are highly correlated, dropping either one of the features might not alter the model prediction significantly.

To address these potential dependencies, the Shapley value requires that the outcome of each possible combination (or coalition) of features must be considered to determine the importance of each feature. Given $d$ features, there are $2^d$ such possible feature combinations, each corresponding to a potential model. To determine the attribution for a given feature $f$, consider the marginal contribution of including $f$ in all feature combinations (and associated models) that do not contain $f$, and take the average. It can be shown that Shapley value is the unique way of assigning the contribution or importance of each feature that satisfies certain desirable properties. In particular, the sum of Shapley values of each feature corresponds to the difference between the predictions of the model and a dummy model with no features. However, even for reasonable values of $d$, say 50 features, it is computationally prohibitive and impractical to train $2^d$ possible models. As a result, SageMaker Clarify needs to make use of various approximation techniques. For this purpose, SageMaker Clarify uses SHapley Additive exPlanations (SHAP), which incorporates such approximations and devised a scalable and efficient implementation of the Kernel SHAP algorithm through additional optimizations.

For additional information on Shapley values, see A Unified Approach to Interpreting Model Predictions.

**SHAP Baselines for Explainability**

Explanations are typically contrastive (that is, they account for deviations from a baseline). As a result, for the same model prediction, you can expect to get different explanations with respect to different baselines. Therefore, your choice of a baseline is crucial. In an ML context, the baseline corresponds to a hypothetical instance that can be either uninformative or informative. During the computation of Shapley values, SageMaker Clarify generates several new instances between the baseline and the given instance, in which the absence of a feature, is modeled by setting the feature value to that of the baseline and the presence of a feature is modeled by setting the feature value to that of the given instance. Thus, the absence of all features corresponds to the baseline and the presence of all features corresponds to the given instance.

How can you choose good baselines? Often it is desirable to select a baseline with very low information content. For example, you can construct an average instance from the training dataset by taking either the median or average for numerical features and the mode for categorical features. For the college admissions example, you might be interested in explaining why a particular applicant was accepted as compared to a baseline acceptances based on an average applicant. If not provided, a baseline is calculated automatically by SageMaker Clarify using K-means or K-prototypes in the input dataset. Alternatively, you can choose to generate explanations with respect to informative baselines. For the college admissions scenario, you might want to explain why a particular applicant was rejected when compared with other applicants from similar demographic backgrounds. In this case, you can choose a baseline that represents the applicants of interest, namely those from a similar demographic background. Thus, you can use informative baselines to concentrate the analysis on the specific aspects
of a particular model prediction. You can isolate the features for assessment by setting demographic attributes and other features that you can't act on to the same value as in the given instance.

**Partial Dependence Plots: Analysis Configuration and Output**

Partial dependence plots (PDP) show the dependence of the predicted target response on a set of input features of interest. These are marginalized over the values of all other input features and are referred to as the *complement features*. Intuitively, you can interpret the partial dependence as the target response, which is expected as a function of each input feature of interest.

**Topics**
- Partial dependence plots analysis configuration (p. 2572)
- Partial dependence plots analysis output (p. 2572)

**Partial dependence plots analysis configuration**

To create a partial dependence plot (PDP), Amazon SageMaker Clarify initially looks for the feature columns specified in a JSON array of the `analysis_config.json`. The other parameters that configure the analysis of a processing job must be provided in this JSON file. For more information about configuring PDPs and other aspects of an analysis, see Configure the Analysis (p. 2537).

The following code contains an example of a JSON "pdp" object in the "methods" object of an analysis_config.json configuration file.

```json
{
    "dataset_type":...
    "baseline": [[..]]
    ...
    "methods": {
        "shap": {
            "baseline": ".."
            "num_samples": 100
        },
        "pdp": {
            "features": ["Age", "MaturityMonths"] // The features for which we need to plot PDP.
            "grid_resolution": 20, //Required for numerical columns only.
            //The number of buckets into which the range of values is divided.
            "top_k_features": 10, //Specifies how many of the top features must be used for PDP plots. The default is 10.
        }
    }
}
```

**Note**

If "features" is not mentioned in the "pdp" object but "shap" config is provided, SageMaker Clarify takes top ten features from the global SHAP results to plot the PDP visualizations.

**Partial dependence plots analysis output**

The following code shows an example of the partial dependence plot (PDP) schema returned in the analysis.json result file. The "pdp" section in this analysis output file contains the information required
to generate the PDP plots. Each dictionary in the list contains the specification for the PDP of the feature specified by the feature_name.

The data_type indicates whether the data is numerical or categorical. The feature_values field contains the values present in the feature. If the data_type inferred by Clarify is categorical, feature_values contain all the unique values that the feature could assume. If the data_type inferred by Clarify is numerical, it contains a list of the central values of each of the grid_resolution number of buckets generated by Clarify.

If the partial dependence plots are computed for a particular feature, the feature_values, model_predictions, and data_distributions fields are replaced by the error field which contains an error message.

```json
{
    "version": "1.0",
    "explanations":{
        "kernel_shap":{
            
        },
        "pdp": [
            {
                "feature_name": "Age",
                "data_type": "numerical",
                "feature_values": [
                    20.4,
                    23.2,
                    26.0,
                    28.799999999999997,
                    31.599999999999998,
                    34.4,
                    70.8,
                    73.6
                ],
                "model_predictions": [
                    0.6830344458296895,
                    0.6812452118471265,
                    0.6908621763065458,
                    0.7008252082392573,
                    0.733054383918643,
                    0.7352442337572574,
                    0.7337257475033403,
                    0.7395857129991055
                ],
                "data_distribution": [
                    0.13,
                    0.25,
                    0.15,
                    0.35,
                    0.17
                ]
            },
            {
                "feature_name": "text_column",
                "data_type": "free_text",
                "error": "Detected data type is not supported for PDP. PDP can only be computed for numerical or categorical columns"
            }
        ]
    }
}
```
This PDP schema generates the following partial dependence plot for the Age feature. The PDP plots the `feature_values` along the x-axis. The y-axis contains the values in `model_predictions` field. Each list in the `model_predictions` field corresponds to one class in the output from the model.

![Partial Dependence Plots](image)

You can view the plot in the report.pdf file in the analysis output path that you provided.

**SageMaker Clarify Computer Vision**

Amazon SageMaker Clarify generates heat maps for images that highlight features under analysis. In particular, the heat maps provide insights into how your computer vision models classify the images and how they detect objects in those images.

**Topics**
- Explain Image Classification with Amazon SageMaker Clarify (p. 2574)
- Explain Object Detection with Amazon SageMaker Clarify (p. 2575)

**Explain Image Classification with Amazon SageMaker Clarify**

SageMaker Clarify processing jobs provides support for explaining images using the KernelSHAP algorithm. This algorithm treats the image as a collection of super pixels. Given a dataset consisting of images, the processing job outputs a dataset of images where each image shows the heat map of the relevant super pixels.

For a sample notebook that uses SageMaker Clarify to classify images and explain its classification, see Explaining Image Classification with SageMaker Clarify.
Explain Object Detection with Amazon SageMaker Clarify

Amazon SageMaker Clarify can detect and classify objects in an image and then provide an explanation for the detection predicted. The objects are first categorized into one of the classes in a specified collection. SageMaker Clarify produces a confidence score for each object that it belongs to the class and the coordinates of a bounding box that delimits the object. For each detected object identified with sufficient probability, SageMaker Clarify extracts features using the Simple Linear Iterative Clustering (SLIC) method from scikit-learn library for image segmentation.

SageMaker Clarify can then provide an explanation for the detection of an object in the image scene. It uses Shapley values to determine the contribution that each feature has made to a model prediction. It produces a heat map that shows how important each of the features in the image scene were for its detection of the object. The context of an object is often very important for the correct identification of an object, so it is important not to just use the cropped image for classification.

For a sample notebook that uses SageMaker Clarify to detect objects in an image and explain its predictions, see Explaining object detection models with Amazon SageMaker Clarify.

Create Feature Attribute Baselines and Explainability Reports

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio that creates explanations for its predictions relative to a baseline, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 132). The following code examples are taken from the example notebook listed previously. This section discusses the code related to the use of Shapley values to provide reports that compare the relative contributions each feature made the predictions.

Use `SHAPConfig` to create the baseline. In this example, the `mean_abs` is the mean of absolute SHAP values for all instances, specified as the baseline. You use `DataConfig` to configure the target variable, data input and output paths, and their formats.

```python
shap_config = clarify.SHAPConfig(baseline=test_features.iloc[0].values.tolist(),
                                  num_samples=15,
                                  agg_method='mean_abs')

explainability_output_path = 's3://{}/clarify-explainability'.format(bucket, prefix)
explainability_data_config = clarify.DataConfig(s3_data_input_path=train_uri,
                                                 s3_output_path=explainability_output_path,
                                                 label='Target',
                                                 headers=training_data.columns.to_list(),
                                                 dataset_type='text/csv')
```

**Note**

Kernel SHAP in SageMaker Clarify supports omitting the “baseline” parameter. In this case, a baseline based on clustering the input dataset is generated automatically.

Then run the explainability job.

```python
clarify_processor.run_explainability(data_config=explainability_data_config,
                                      model_config=model_config,
                                      explainability_config=shap_config)
```

To view Partial Dependence plots (PDP), use `explainability_config=PDP_config`.

You can select both types of reports with `explainability_config=[PDP_config,shap_config]`. 
View the results in Studio or download them from the `explainability_output_path` S3 bucket.

**Explainability Reports for NLP Models**

Amazon SageMaker Clarify supports explanations for natural language processing (NLP) models. NLP models help you understand which sections of text are most important for the predictions made by your model. This functionality can be used to explain either an individual local prediction or the model's expected predictions for overall global explanations. You can define the length of the text segment (tokens, phrases, sentences, paragraphs) to understand and visualize a model's behavior at multiple levels of granularity.

SageMaker Clarify NLP explainability is compatible with classification and regression models. You can also use Clarify to explain your model's behavior on multi-modal datasets that contain text, categorical, or numerical features. NLP explainability for multi-modal datasets can help you understand how important each feature is to the model's output. SageMaker Clarify supports 62 languages and can handle text which includes multiple languages.

To obtain feature importance for parts of an input text, create a `TextConfig` specifying the granularity of the parts of the text and the language. Clarify then breaks the text down into tokens, sentences, or paragraphs depending on your choice of granularity. It replaces subsets of these parts with the values from the baseline. The baseline defaults to empty strings, meaning SageMaker Clarify drops parts of the input text. SageMaker Clarify then replaces tokens (sentences and paragraphs, respectively) to determine how these replacements affect the model's prediction, in order to assess their importance.

```python
from sagemaker import clarify
text_config = clarify.TextConfig(
    # Specify the language of your text or use "multi-language" for multi-language.
    language=\"english\",
    # Choose the granularity of your explanations as tokens, sentences or paragraphs.
    granularity=\"token\"
)
shap_config = clarify.SHAPConfig(
    # For now, we don't support global aggregation, so make sure you retrieve local explanations.
    save_local_shap_values=True,
    text_config=text_config,
    # Determine with what to replace tokens/sentences/paragraphs (based on your choice of granularity) with.
    baseline=[\"<UNK>\"])
```

The remainder of the explainability job is coded as usual.

```python
explainability_output_path = \'s3:///{}/clarify-explainability\'.format(bucket, prefix)
explainability_data_config = clarify.DataConfig(
    s3_data_input_path=train_uri,
    s3_output_path=explainability_output_path,
    # With text data sometimes detection of headers fails, so we recommend explicitly setting it in the config.
    headers=[\"text\"],
    dataset_type=\"text/csv\")
model_config = clarify.ModelConfig(
    model_name=model_name,
    # Specialized hardware is well-suited for NLP models.
    instance_type=\"ml.p2.xlarge\",
    instance_count=1
)
```
clarify_processor = clarify.SageMakerClarifyProcessor(  
    role=role, instance_count=1, instance_type="ml.m5.xlarge", sagemaker_session=session  
)
clarify_processor.run_explainability(  
    data_config=explainability_data_config,  
    model_config=model_config,  
    explainability_config=shap_config)  

View the local explanations in the explainability_output_path S3 bucket. SageMaker Clarify does not aggregate the importance of individual tokens/sentences/paragraphs.

Extensions:

- **Multi-modal data** - If your data contains more than text, such as categorical or numeric features, you can add more columns in your header and baseline to accommodate those features.
- **JSON** - If the model input or output data is in JSON Lines format, specify the dataset_type in the DataConfig or the accept_type and content_type in the ModelConfig.
- **Multi-class model output** - If your model does multi-class or multi-label predictions, SageMaker Clarify computes the importance for each class.
- **Model output** - Some model outputs contain more than a single score. A prediction of three examples returns a matrix of shape [3, 1] such as [[0.1], [-1.1], [10.2], [0.0], [3.2]]. You can specify model_scores in run_explainability. For example, if your model predicts probabilities of five classes and additionally outputs the winning class, ["c1", [0.1, 0.4, 0.3, 0.2]], then you can set model_scores=1.

Tips for fast results:

- During the development phase, work with a small subset of examples for quick iterations.
- To scale up for deployment, increase the instance_count for the processing job and the predictor. This instructs SageMaker Clarify to partition the data and work with multiple machines in parallel. For parallel processing, we recommend using the parquet data format because Spark can struggle with special characters in CSV files.
- Choose an appropriate instance_type for your model. GPU instances are often suitable for NLP models.
- To save unnecessary computation, consider truncating your text. Many models work with a maximum text length. By applying the truncation in a preprocessing step, SageMaker Clarify does not waste resources determining the feature importance for the parts of text that are disregarded by the model.

**Troubleshoot SageMaker Clarify Processing Jobs**

If you encounter failures with SageMaker Clarify processing jobs, consult the following scenarios to help identify the issue.

**Note**

The failure reason and exit message are intended to contain descriptive messages and exceptions, if encountered, during the run. One common reason is invalid or missing parameters. If you encounter unclear, confusing, or misleading messages or are unable to find a solution, submit feedback.

**Topics**

- Processing job fails to finish (p. 2578)
- Processing job finishes without results and you get a CloudWatch warning message (p. 2578)
- Error message for invalid analysis configuration (p. 2578)
- Bias metric computation fails for several or all metrics (p. 2578)
Troubleshoot Jobs

- Mismatch between analysis config and dataset/model input/output (p. 2579)
- Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error (p. 2579)
- Execution role is invalid (p. 2579)
- Failed to download data (p. 2579)
- Could not connect to SageMaker (p. 2579)

Processing job fails to finish

If the processing job fails to finish, you can try the following:

- Inspect the job logs directly in the notebook where you ran the job in. The job logs are located in the output of the notebook cell where you initiated the run.
- Inspect the job logs in CloudWatch.
- Add the following line in your notebook to describe the last processing job and look for the failure reason and exit message:
  ```python
  clarify_processor.jobs[-1].describe()
  ```
- Execute the following AWS CLI command to describe the processing job and look for the failure reason and exit message:
  ```bash
  aws sagemaker describe-processing-job --processing-job-name <processing-job-id>
  ```

Processing job finishes without results and you get a CloudWatch warning message

If the processing job finishes but no results are found and a warning message is found in the CloudWatch logs that says “Signal 15 received, cleaning up”, this is an indication that the job was stopped either due to a customer request that called the StopProcessingJob API or that the job ran out of time allotted for its completion. In the later case, check the maximum runtime in the job configuration (max_runtime_in_seconds) and increase it as needed.

Error message for invalid analysis configuration

- If you get the error message "Unable to load analysis configuration as JSON.", this means that the analysis configuration input file for the processing job does not contain a valid JSON object. Check the validity of the JSON object using a JSON linter.
- If you get the error message "Analysis configuration schema validation error.", this means that the analysis configuration input file for the processing job contains unknown fields or invalid types for some field values. Review the configuration parameters in the file and cross-check them with the parameters listed in the configuration specification file.

Bias metric computation fails for several or all metrics

If your receive one of the following error messages "No Label values are present in the predicted Label Column, Positive Predicted Index Series contains all False values." or "Predicted Label Column series data type is not the same as Label Column series.", try the following:

- Check that the correct dataset is being used.
- Check whether the dataset size is too small; whether, for example, it contains only a few rows. This may cause the model outputs to have the same value or the data type is inferred incorrectly.
• Check if the label or facet is treated as continuous or categorical. SageMaker Clarify uses heuristics to determine the `DataType`. For post-training bias metrics, the data type returned by the model may not match what is in the dataset or SageMaker Clarify may not be able to transform it correctly.
  • In the bias report, you should see a single value for categorical columns or an interval for continuous columns.
  • For example, if a column has values 0.0 and 1.0 as floats, it will be treated as continuous even if there are too few unique values.

Mismatch between analysis config and dataset/model input/output

• Check that the baseline format in the analysis config is the same as dataset format.
• If you receive the error message "Could not convert string to float.", check that the format is correctly specified. It could also indicate that the model predictions have a different format than the label column or it could indicate that the configuration for the label or probabilities is incorrect.
• If you receive the error message "Unable to locate the facet." or "Headers must contain label." or "Headers in config do not match with the number of columns in the dataset." or "Feature names not found.", check that the headers match the columns.
• If you receive the error message "Data must contain features.", check the content template for JSON Lines and compare it with the dataset sample if available.

Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error

If you receive the error message "Fallback to per-record prediction because of model error.", this could indicate that model cannot handle the batch size, or be throttled, or just does not accept the input passed by the container due to serialization problems. You should review the CloudWatch logs for the SageMaker endpoint and look for error messages or tracebacks. For model throttling cases, it may help to use a different instance type or increasing the number of instances for the endpoint.

Execution role is invalid

This indicates that the role provided is incorrect or missing required permissions. Check the role and its permissions that were used to configure the processing job and verify the permission and trust policy for the role.

Failed to download data

This indicates that job inputs could not be downloaded for the job to start. Check the bucket name and permissions for the dataset and the configuration inputs.

Could not connect to SageMaker

This indicates that the job could not reach SageMaker service endpoints. Check the network configuration settings for the processing job and verify VPC configuration.

Train Using a Heterogeneous Cluster

Using the heterogeneous cluster feature of SageMaker Training, you can run a training job with multiple types of ML instances for a better resource scaling and utilization for different ML training tasks and
purposes. For example, if your training job on a cluster with GPU instances suffers low GPU utilization and CPU bottleneck problems due to CPU-intensive tasks, using a heterogeneous cluster can help offload CPU-intensive tasks by adding more cost-efficient CPU instance groups, resolve such bottleneck problems, and achieve a better GPU utilization.

**Note**
This feature is available in the SageMaker Python SDK v2.98.0 and later.

**Note**
This feature is available through the SageMaker PyTorch and TensorFlow framework estimator classes. Supported frameworks are PyTorch v1.11 or later and TensorFlow v2.6 or later.

**Topics**
- How to Configure a Heterogeneous Cluster (p. 2580)
- Distributed Training with a Heterogeneous Cluster (p. 2583)
- Modify Your Training Script to Assign Instance Groups (p. 2585)
- Considerations (p. 2587)

### How to Configure a Heterogeneous Cluster

This section provides instructions on how to run a training job using a heterogeneous cluster that consists of multiple instance types.

**Topics**
- Using the SageMaker Python SDK (p. 2580)
- Using the Low-Level SageMaker APIs (p. 2583)

### Using the SageMaker Python SDK

Follow instructions on how to configure instance groups for a heterogeneous cluster using the SageMaker Python SDK.

1. To configure instance groups of a heterogeneous cluster for a training job, use the `sagemaker.instance_group.InstanceGroup` class. You can specify a custom name for each instance group, the instance type, and the number of instances for each instance group. For more information, see `sagemaker.instance_group.InstanceGroup` in the *SageMaker Python SDK documentation*.

   **Note**
   For more information about available instance types and the maximum number of instance groups that you can configure in a heterogeneous cluster, see the `InstanceGroup` API reference.

The following code example shows how to set up two instance groups that consists of two `ml.c5.18xlarge` CPU-only instances named `instance_group_1` and one `ml.p3dn.24xlarge` GPU instance named `instance_group_2`, as shown in the following diagram.
The preceding diagram shows a conceptual example of how pre-training processes, such as data preprocessing, can be assigned to the CPU instance group and stream the preprocessed data to the GPU instance group.

```python
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup(
    "instance_group_1", "ml.c5.18xlarge", 2
)

instance_group_2 = InstanceGroup(
    "instance_group_2", "ml.p3dn.24xlarge", 1
)
```

2. Using the instance group objects, set up training input channels and assign instance groups to the channels through the `instance_group_names` argument of the `sagemaker.inputs.TrainingInput` class. The `instance_group_names` argument accepts a list of strings of instance group names.
The following example shows how to set two training input channels and assign the instance groups created in the example of the previous step. You can also specify Amazon S3 bucket paths to the s3_data argument for the instance groups to process data for your usage purposes.

```python
from sagemaker.inputs import TrainingInput

training_input_channel_1 = TrainingInput(
    s3_data_type='S3Prefix',  # Available Options: S3Prefix | ManifestFile | AugmentedManifestFile
    s3_data='s3://your-training-data-storage/folder1',
    distribution='FullyReplicated',  # Available Options: FullyReplicated | ShardedByS3Key
    input_mode='File',  # Available Options: File | Pipe | FastFile
    instance_group_names=['instance_group_1'],
)

training_input_channel_2 = TrainingInput(
    s3_data_type='S3Prefix',
    s3_data='s3://your-training-data-storage/folder2',
    distribution='FullyReplicated',
    input_mode='File',
    instance_group_names=['instance_group_2'],
)
```

For more information about the arguments of TrainingInput, see the following links.

- The `sagemaker.inputs.TrainingInput` class in the SageMaker Python SDK documentation
- The `S3DataSource` API in the SageMaker API Reference

3. Configure a SageMaker estimator with the instance_groups argument as shown in the following code example. The instance_groups argument accepts a list of InstanceGroup objects.

**PyTorch**

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    entry_point='my-training-script.py',
    framework_version='x.y.z',  # 1.10.0 or later
    py_version='pyxy',
    job_name='my-training-job-with-heterogeneous-cluster',
    instance_groups=[instance_group_1, instance_group_2]
)
```

**TensorFlow**

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    entry_point='my-training-script.py',
    framework_version='x.y.z',  # 2.6.0 or later
    py_version='pyxy',
    job_name='my-training-job-with-heterogeneous-cluster',
    instance_groups=[instance_group_1, instance_group_2]
)
```

**Note**
The instance_type and instance_count argument pair and the instance_groups argument of the SageMaker estimator class are mutually exclusive. For homogeneous cluster
Distributed Training with a Heterogeneous Cluster

Through the `distribution` argument of the SageMaker estimator class, you can assign a specific instance group to run distributed training. For example, assume that you have the following two instance groups and want to run multi-GPU training on one of them.

```python
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup("instance_group_1", "ml.c5.18xlarge", 1)
instance_group_2 = InstanceGroup("instance_group_2", "ml.p3dn.24xlarge", 2)
```

You can set the distributed training configuration for one of the instance groups. For example, the following code examples show how to assign `training_group_2` with two `ml.p3dn.24xlarge` instances to the distributed training configuration.

**Note**
Currently, only one instance group of a heterogeneous cluster can be specified to the distribution configuration.

**With MPI**

**PyTorch**

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
```
...  
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
      "mpi": {
        "enabled": True, "processes_per_host": 8
      },
      "instance_groups": [instance_group_2]
    })
)

TensorFlow

from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
...  
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
      "mpi": {
        "enabled": True, "processes_per_host": 8
      },
      "instance_groups": [instance_group_2]
    }
)

With the SageMaker data parallel library

PyTorch

from sagemaker.pytorch import PyTorch

estimator = PyTorch(
...  
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
      "smdistributed": {
        "dataparallel": {
          "enabled": True
        }
      },
      "instance_groups": [instance_group_2]
    }
)

TensorFlow

from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
...  
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
      "smdistributed": {
        "dataparallel": {
          "enabled": True
        }
      },
      "instance_groups": [instance_group_2]
    }
)
Note
When using the SageMaker data parallel library, make sure the instance group consists of the supported instance types by the library.

For more information about the SageMaker data parallel library, see SageMaker Data Parallel Training.

With the SageMaker model parallel library

PyTorch

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {

                    # SageMaker model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

TensorFlow

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {

                    # SageMaker model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

For more information about the SageMaker model parallel library, see SageMaker Model Parallel Training.

Modify Your Training Script to Assign Instance Groups

With the heterogeneous cluster configuration in the previous sections, you have prepared the SageMaker training environment and instances for your training job. To further assign the instance groups to certain training and data processing tasks, the next step is to modify your training script. By default, the training job simply makes training script replicas for all nodes regardless the size of the instance, and this might lead to performance loss.
For example, if you mix CPU instances and GPU instances in a heterogeneous cluster while passing a deep neural network training script to the `entry_point` argument of the SageMaker estimator, the `entry_point` script is replicated to each instance. This means that, without proper task assignments, CPU instances also run the entire script and start the training job that’s designed for distributed training on GPU instances. Therefore, you must make changes in specific processing functions that you want to offload and run on the CPU instances. You can use the SageMaker environment variables to retrieve the information of the heterogeneous cluster and let specific processes to run accordingly.

**Query instance group information during the initialization phase of a SageMaker training job**

When your training job starts, your training script reads SageMaker training environment information that includes heterogeneous cluster configuration. The configuration contains information such as the current instance groups, the current hosts in each group, and in which group the current host resides.

You can retrieve instance group information in the following ways.

**(Recommended) Reading instance group information with the SageMaker training toolkit**

Use the environment Python module that the [SageMaker training toolkit library](https://docs.aws.amazon.com/sagemaker/latest/dg/instances-groups.html) provides. The toolkit library is preinstalled in the [SageMaker framework containers](https://docs.aws.amazon.com/sagemaker/latest/dg/containers.html) for TensorFlow and PyTorch, so you don’t need an additional installation step when using the prebuilt containers. This is the recommended way to retrieve the SageMaker environment variables with fewer code changes in your training script.

```python
from sagemaker_training import environment
env = environment.Environment()
```

Environment variables related to general SageMaker training and heterogeneous clusters:

- `env.is_hetero` – Returns a Boolean result whether a heterogeneous cluster is configured or not.
- `env.current_host` – Returns the current host.
- `env.current_instance_type` – Returns the type of instance of the current host.
- `env.current_instance_group` – Returns the name of the current instance group.
- `env.current_instance_group_hosts` – Returns a list of hosts in current instance group.
- `env.instance_groups` – Returns a list of instance group names used for training.
- `env.instance_groups_dict` – Returns the entire heterogeneous cluster configuration of the training job.
- `env.distribution_instance_groups` – Returns a list of instance groups assigned to the `distribution` parameter of the SageMaker estimator class.
- `env.distribution_hosts` – Returns a list of hosts belonging to the instance groups assigned to the `distribution` parameter of the SageMaker estimator class.

For example, consider the following example of a heterogeneous cluster that consists of two instance groups.

```python
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup(
    "instance_group_1", "ml.c5.18xlarge", 1)
instance_group_2 = InstanceGroup(
    "instance_group_2", "ml.p3dn.24xlarge", 2)
```
The output of `env.instance_groups_dict` of the example heterogeneous cluster should be similar to the following:

```json
{
    "instance_group_1": {
        "hosts": ["algo-2"],
        "instance_group_name": "instance_group_1",
        "instance_type": "ml.c5.18xlarge"
    },
    "instance_group_2": {
        "hosts": ["algo-3", "algo-1"],
        "instance_group_name": "instance_group_2",
        "instance_type": "ml.p3dn.24xlarge"
    }
}
```

(Optional) Reading instance group information from the resource configuration JSON file

If you prefer to retrieve the environment variables in JSON format, you can directly use the resource configuration JSON file. The JSON file in a SageMaker training instance is located at `/opt/ml/input/config/resourceconfig.json` by default.

```python
file_path = '/opt/ml/input/config/resourceconfig.json'
config = read_file_as_json(file_path)
print(json.dumps(config, indent=4, sort_keys=True))
```

Considerations

Consider the following items when using the heterogeneous cluster feature.

- All instance groups share the same Docker image and training script. Therefore, your training script should be modified to detect which instance group it belongs to and fork execution accordingly.
- The heterogeneous cluster feature is not supported in SageMaker local mode.
- The Amazon CloudWatch log streams of a heterogeneous cluster training job are not grouped by instance groups. You need to figure out from the logs which nodes are in which group.
- The heterogeneous cluster feature is available through the SageMaker PyTorch and TensorFlow framework estimator classes. Supported frameworks are PyTorch v1.10 or later and TensorFlow v2.6 or later. To find a complete list of available framework containers, framework versions, and Python versions, see SageMaker Framework Containers in the AWS Deep Learning Container GitHub repository.
- A distributed training strategy can be applied only to one instance group.

Incremental Training in Amazon SageMaker

Over time, you might find that a model generates inference that are not as good as they were in the past. With incremental training, you can use the artifacts from an existing model and use an expanded dataset to train a new model. Incremental training saves both time and resources.

Use incremental training to:
Perform Incremental Training (Console)

To complete this procedure, you need:

- The Amazon Simple Storage Service (Amazon S3) bucket URI where you've stored the training data.
- The S3 bucket URI where you want to store the output of the job.
- The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code (p. 1060).
- The URL of the S3 bucket where you've stored the model artifacts that you want to use in incremental training. To find the URL for the model artifacts, see the details page of the training job used to create the model. To find the details page, in the SageMaker console, choose Inference, choose Models, and then choose the model.

To restart a stopped training job, use the URL to the model artifacts that are stored in the details page as you would with a model or a completed training job.

**To perform incremental training (console)**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. The training job name must have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1051).
6. (Optional) For Resource configuration, either leave the default values or increase the resource consumption to reduce computation time.
   a. (Optional) For Instance type, choose the ML compute instance type that you want to use. In most cases, ml.m4.xlarge is sufficient.
Perform Incremental Training (Console)

b. For **Instance count**, use the default, 1.

c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.

7. Provide information about the input data for the training dataset.

   a. For **Channel name**, either leave the default (`train`) or enter a more meaningful name for the training dataset, such as `expanded-training-dataset`.

   b. For **InputMode**, choose **File**. For incremental training, you need to use file input mode.

   c. For **S3 data distribution type**, choose **FullyReplicated**. This causes each ML compute instance to use a full replicate of the expanded dataset when training incrementally.

   d. If the expanded dataset is uncompressed, set the **Compression type** to **None**. If the expanded dataset is compressed using Gzip, set it to **Gzip**.

   e. (Optional) If you are using **File** input mode, leave **Content type** empty. For **Pipe** input mode, specify the appropriate MIME type. **Content type** is the multipurpose internet mail extension (MIME) type of the data.

   f. For **Record wrapper**, if the dataset is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO formatted file, choose **None**.

   g. For **S3 data type**, if the dataset is stored as a single file, choose **S3Prefix**. If the dataset is stored as several files in a folder, choose **Manifest**.

   h. For **S3 location**, provide the URL to the path where you stored the expanded dataset.

   i. Choose **Done**.

8. To use model artifacts in a training job, you need to add a new channel and provide the needed information about the model artifacts.

   a. For **Input data configuration**, choose **Add channel**.

   b. For **Channel name**, enter **model** to identify this channel as the source of the model artifacts.

   c. For **InputMode**, choose **File**. Model artifacts are stored as files.

   d. For **S3 data distribution type**, choose **FullyReplicated**. This indicates that each ML compute instance should use all of the model artifacts for training.

   e. For **Compression type**, choose **None** because we are using a model for the channel.

   f. Leave **Content type** empty. Content type is the multipurpose internet mail extension (MIME) type of the data. For model artifacts, we leave it empty.

   g. Set **Record wrapper** to **None** because model artifacts are not stored in RecordIO format.

   h. For **S3 data type**, if you are using a built-in algorithm or an algorithm that stores the model as a single file, choose **S3Prefix**. If you are using an algorithm that stores the model as several files, choose **Manifest**.

   i. For **S3 location**, provide the URL to the path where you stored the model artifacts. Typically, the model is stored with the name `model.tar.gz`. To find the URL for the model artifacts, in the navigation pane, choose **Inference**, then choose **Models**. From the list of models, choose a model to display its details page. The URL for the model artifacts is listed under **Primary container**.

   j. Choose **Done**.

9. For **Output data configuration**, provide the following information:

   a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.

   b. (Optional) For **Encryption key**, you can add your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. Provide the key ID or its Amazon Resource Number (ARN). For more information, see KMS-Managed Encryption Keys.

10. (Optional) For **Tags**, add one or more tags to the training job. A tag is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs.
tag consists of a key and a value, which you define. For example, you might want to create a tag with Project as a key and a value referring to a project that is related to the training job, such as Home value forecasts.

11. Choose Create training job. SageMaker creates and runs training job.

After the training job has completed, the newly trained model artifacts are stored under the S3 output path that you provided in the Output data configuration field. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 84).

Perform Incremental Training (API)

This example shows how to use SageMaker APIs to train a model using the SageMaker image classification algorithm and the Caltech 256 Image Dataset, then train a new model using the first one. It uses Amazon S3 for input and output sources. Please see the incremental training sample notebook for more details on using incremental training.

Note
In this example we used the original datasets in the incremental training, however you can use different datasets, such as ones that contain newly added samples. Upload the new datasets to S3 and make adjustments to the data_channels variable used to train the new model.

Get an AWS Identity and Access Management (IAM) role that grants required permissions and initialize environment variables:

```python
import sagemaker
from sagemaker import get_execution_role

role = get_execution_role()
print(role)
sess = sagemaker.Session()
bucket = sess.default_bucket()
print(bucket)
prefix = 'ic-inr-training'
```

Get the training image for the image classification algorithm:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri

training_image = get_image_uri(sess.boto_region_name, 'image-classification', repo_version="latest")
#Display the training image
print (training_image)
```

Download the training and validation datasets, then upload them to Amazon Simple Storage Service (Amazon S3):

```python
import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split("/")[~1]
    if not os.path.exists(filename):
        urllib.request.urlretrieve(url, filename)
```

```python
import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split("/")[~1]
    if not os.path.exists(filename):
        urllib.request.urlretrieve(url, filename)
```
# Download the caltech-256 training and validation datasets
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-train.rec')
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-val.rec')

# Create four channels: train, validation, train_lst, and validation_lst
s3train = 's3:///{}/train/'.format(bucket, prefix)
s3validation = 's3:///{}/validation/'.format(bucket, prefix)

# Upload the first files to the train and validation channels
!aws s3 cp caltech-256-60-train.rec $s3train --quiet
!aws s3 cp caltech-256-60-val.rec $s3validation --quiet

Define the training hyperparameters:

# Define hyperparameters for the estimator
hyperparams = {
    "num_layers": "18",
    "resize": "32",
    "num_training_samples": "50000",
    "num_classes": "10",
    "image_shape": "3,28,28",
    "mini_batch_size": "128",
    "epochs": "3",
    "learning_rate": "0.1",
    "lr_scheduler_step": "2,3",
    "lr_scheduler_factor": "0.1",
    "augmentation_type": "crop_color",
    "optimizer": "sgd",
    "momentum": "0.9",
    "weight_decay": "0.0001",
    "beta_1": "0.9",
    "beta_2": "0.999",
    "gamma": "0.9",
    "eps": "1e-8",
    "top_k": "5",
    "checkpoint_frequency": "1",
    "use_pretrained_model": "0",
    "model_prefix": ""}

Create an estimator object and train the first model using the training and validation datasets:

# Fit the base estimator
s3_output_location = 's3:///{}/output'.format(bucket, prefix)
ic = sagemaker.estimator.Estimator(training_image,
    role,
    instance_count=1,
    instance_type='ml.p2.xlarge',
    volume_size=50,
    max_run=360000,
    input_mode='File',
    output_path=s3_output_location,
    sagemaker_session=sess,
    hyperparameters=hyperparams)

train_data = sagemaker.inputs.TrainingInput(s3train, distribution='FullyReplicated',
                                            content_type='application/x-recordio',
                                            s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3validation,
                                                distribution='FullyReplicated',
                                                content_type='application/x-recordio',
                                                s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}
ic.fit(inputs=data_channels, logs=True)

To use the model to incrementally train another model, create a new estimator object and use the model artifacts (ic.model_data, in this example) for the model_uri input argument:

```python
# Given the base estimator, create a new one for incremental training
incr_ic = sagemaker.estimator.Estimator(training_image,
    role,
    instance_count=1,
    instance_type='ml.p2.xlarge',
    volume_size=50,
    max_run=360000,
    input_mode='File',
    output_path=s3_output_location,
    sagemaker_session=sess,
    hyperparameters=hyperparams,
    model_uri=ic.model_data) # This parameter will
    ingest the previous job's model as a new channel
incr_ic.fit(inputs=data_channels, logs=True)
```

After the training job has completed, the newly trained model artifacts are stored under the S3 output path that you provided in Output_path. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 84).

Amazon SageMaker Training Storage Folders for Training Datasets, Checkpoints, Model Artifacts, and Outputs

This page provides a high-level summary of how the SageMaker training platform manages storage paths for training datasets, model artifacts, checkpoints, and outputs between AWS cloud storage and training jobs in SageMaker. Throughout this guide, you learn to identify the default paths set by the SageMaker platform and how the data channels can be streamlined with your data sources in Amazon S3, FSx for Lustre, and Amazon EFS. For more information about various data channel input modes and storage options, see Access Training Data (p. 2596).

Topics
- Overview (p. 2592)
- SageMaker Environment Variables and Default Paths for Training Storage Folders (p. 2594)
- Tips and Considerations for Setting Up Storage Paths (p. 2595)

Overview

The following diagram shows the simplest example of how SageMaker manages input and output folders when you run a training job using the SageMaker Python SDK Estimator class and its fit method. It's based on using file mode as the data access strategy and Amazon S3 as the data source for the training input channels.
s3://bucket-data1/
This figure shows an overview of how SageMaker pairs storage paths between an Amazon S3 bucket as the data source and the SageMaker training instance based on how the paths are specified in a SageMaker estimator class. More information about the paths, how they read from or write to the paths, and purposes of the paths are described in the following section the section called “SageMaker Environment Variables and Default Paths for Training Storage Folders” (p. 2594).

For more information and examples of how SageMaker manages data source, input modes, and local paths in SageMaker training instances, see Access Training Data.

SageMaker Environment Variables and Default Paths for Training Storage Folders

The following table summarizes input and output paths for training datasets, checkpoints, model artifacts, and outputs, managed by the SageMaker training platform.

<table>
<thead>
<tr>
<th>Local path in SageMaker training instance</th>
<th>SageMaker environment variable</th>
<th>Purpose</th>
<th>Read from S3 during start</th>
<th>Read from S3 during Spot-restart</th>
<th>Writes to S3 during training</th>
<th>Writes to S3 when job is terminated</th>
</tr>
</thead>
<tbody>
<tr>
<td>/opt/ml/input/data/channel_name¹</td>
<td>SM_CHANNEL_CHANNEL_NAME</td>
<td>Reading training data from the input channels specified through the SageMaker Python SDK Estimator class or the CreateTrainingJob API operation. For more information about how to specify it in your training script using the SageMaker Python SDK, see Prepare a Training script.</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>/opt/ml/output²</td>
<td>SM_OUTPUT_DIR</td>
<td>Saving outputs such as loss, accuracy, intermediate layers, weights, gradients, bias, and TensorBoard-compatible outputs. You can also save any arbitrary output you’d like using this path. Note that this is a different path from the one for storing the final model artifact /opt/ml/model/.</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>/opt/ml/model³</td>
<td>SM_MODEL_DIR</td>
<td>Storing the final model artifact. This is also the path from where the model artifact is deployed for Real-time</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

¹ The SageMaker environment variable `SM_CHANNEL_NAME` is used to specify input channels in the SageMaker estimator class.

² The SageMaker environment variable `SM_OUTPUT_DIR` is used to specify the output directory where various outputs such as loss, accuracy, intermediate layers, weights, gradients, bias, and TensorBoard-compatible outputs are saved. This path is different from the one used for storing the final model artifact.

³ The SageMaker environment variable `SM_MODEL_DIR` is used to specify the path where the final model artifact is stored. This is also the path from which the model artifact is deployed for Real-time inference.
### Tips and Considerations for Setting Up Storage Paths

Consider the following items when setting up storage paths for training jobs in SageMaker.

- If you want to store training artifacts for distributed training in the `/opt/ml/output/` directory, you must properly assign subfolders or unique file names for the artifacts through your model definition or training script. If the subfolders and file names are not properly configured, all of the distributed training workers might write outputs to the same file name in the same output folder in Amazon S3.

- If you use a custom training container, make sure you install the SageMaker Training Toolkit that helps set up the environment for SageMaker training jobs. Otherwise, you must specify the environment variables explicitly in your Dockerfile. For more information, see Create a container with your own algorithms and models.

1. `channel_name` is the place to specify user-defined channel names for training data inputs. Each training job can contain several data input channels. You can specify up to 20 training input channels per training job. Note that the data downloading time from the data channels is counted to the billable time. For more information about data input paths, see How Amazon SageMaker Provides Training Information. Also, there are three types of data input modes that SageMaker supports: file, FastFile, and pipe mode. To learn more about the data input modes for training in SageMaker, see Access Training Data.

2. SageMaker compresses and writes training artifacts to TAR files (`tar.gz`). Compression and uploading time is counted to the billable time. For more information, see How Amazon SageMaker Processes Training Output.

3. SageMaker compresses and writes the final model artifact to a TAR file (`tar.gz`). Compression and uploading time is counted to the billable time. For more information, see How Amazon SageMaker Processes Training Output.

4. Sync with Amazon S3 during training. Write as is without compressing to TAR files. For more information, see Use Checkpoints in Amazon SageMaker.
• When using an ML instance with NVMe SSD volumes, SageMaker doesn’t provision Amazon EBS gp2 storage. Available storage is fixed to the NVMe-type instance's storage capacity. SageMaker configures storage paths for training datasets, checkpoints, model artifacts, and outputs to use the entire capacity of the instance storage. For example, ML instance families with the NVMe-type instance storage include ml.p4d, ml.g4dn, and ml.g5. When using an ML instance with the EBS-only storage option and without instance storage, you must define the size of EBS volume through the volume_size parameter in the SageMaker estimator class (or VolumeSizeInGB if you are using the ResourceConfig API). For example, ML instance families that use EBS volumes include ml.c5 and ml.p2. To look up instance types and their instance storage types and volumes, see Amazon EC2 Instance Types.

• The default paths for SageMaker training jobs are mounted to Amazon EBS volumes or NVMe SSD volumes of the ML instance. When you adapt your training script to SageMaker, make sure that you use the default paths listed in the previous topic about the section called “SageMaker Environment Variables and Default Paths for Training Storage Folders” (p. 2594). We recommend that you use the /tmp directory as a scratch space for temporarily storing any large objects during training. This means that you must not use directories that are mounted to small disk space allocated for system, such as /user and /home, to avoid out-of-space errors.

To learn more, see the AWS machine learning blog Choose the best data source for your Amazon SageMaker training job that further discusses case studies and performance benchmarks of data sources and input modes.

Access Training Data

When you create a training job, you specify the location of a training dataset and an input mode for accessing the dataset. For data location, Amazon SageMaker supports Amazon Simple Storage Service (Amazon S3), Amazon Elastic File System (Amazon EFS), and Amazon FSx for Lustre. The input modes determine whether to stream data files of the dataset in real time or download the whole dataset at the start of the training job.

SageMaker Input Modes and AWS Cloud Storage

This section summarizes SageMaker input modes for Amazon S3 and file systems in Amazon EFS and Amazon FSx for Lustre.
• **File mode** presents a file system view of the dataset to the training container. This is the default input mode if you don’t explicitly specify one of the other two options. If you use file mode, SageMaker downloads the training data from the storage location to a local directory in the Docker container. Training starts after the full dataset has been downloaded. In file mode, the training instance must have enough storage space to fit the entire dataset. File mode download speed depends on the size of dataset, the average size of files, and the number of files. You can configure the dataset for file mode by providing either an Amazon S3 prefix, manifest file, or augmented manifest file. You should use an S3 prefix when all your dataset files are located within a common S3 prefix. File mode is compatible with SageMaker local mode (starting a SageMaker training container interactively in seconds). For distributed training, you can shard the dataset across multiple instances with the `ShardedByS3Key` option.

• **Fast file mode** provides file system access to an Amazon S3 data source while leveraging the performance advantage of pipe mode. At the start of training, fast file mode identifies the data files but does not download them. Training can start without waiting for the entire dataset to download. This means that the training startup takes less time when there are fewer files in the Amazon S3 prefix provided.

  In contrast to pipe mode, fast file mode works with random access to the data. However, it works best when data is read sequentially. Fast file mode doesn’t support augmented manifest files.

  Fast file mode exposes S3 objects using a POSIX-compliant file system interface, as if the files are available on the local disk of your training instance. It streams S3 content on demand as your training script consumes data. This means that your dataset no longer needs to fit into the training instance storage space as a whole, and you don’t need to wait for the dataset to be downloaded to the training instance before training starts. Fast file currently supports S3 prefixes only (it does not support manifest and augmented manifest). Fast file mode is compatible with SageMaker local mode.

• **Pipe mode** streams data directly from an Amazon S3 data source. Streaming can provide faster start times and better throughput than file mode.

  When you stream the data directly, you can reduce the size of the Amazon EBS volumes used by the training instance. Pipe mode needs only enough disk space to store the final model artifacts.

  It is another streaming mode that is largely replaced by the newer and simpler-to-use fast file mode. In pipe mode, data is pre-fetched from Amazon S3 at high concurrency and throughput, and streamed into a named pipe, which also known as a First-In-First-Out (FIFO) pipe for its behavior. Each pipe may only be read by a single process. A SageMaker specific extension to TensorFlow conveniently integrates Pipe mode into the native TensorFlow data loader for streaming text, TFRecords, or RecordIO file formats. Pipe mode also supports managed sharding and shuffling of data.

• **Amazon FSx for Lustre** – FSx for Lustre can scale to hundreds of gigabytes of throughput and millions of IOPS with low-latency file retrieval. When starting a training job, SageMaker mounts the FSx for Lustre file system to the training instance file system, then starts your training script. Mounting itself is a relatively fast operation that doesn’t depend on the size of the dataset stored in FSx for Lustre.

  To access FSx for Lustre, your training job must connect to an Amazon Virtual Private Cloud (VPC), which requires DevOps setup and involvement. To avoid data transfer costs, the file system uses a single Availability Zone, and you need to specify a VPC subnet which maps to this Availability Zone ID when running the training job.

• **Amazon EFS** – To use Amazon EFS as a data source, the data must already reside in Amazon EFS prior to training. SageMaker mounts the specified Amazon EFS file system to the training instance, then starts your training script. Your training job must connect to a VPC to access Amazon EFS.

  **Tip**
  To learn more about how to specify your VPC configuration to SageMaker estimators, see Use File Systems as Training Inputs in the SageMaker Python SDK documentation.
Choosing Data Input Mode Using the SageMaker Python SDK

SageMaker Python SDK provides the generic Estimator class and its variations for ML frameworks for launching training jobs. You can specify one of the data input modes while configuring the SageMaker Estimator class or the Estimator.fit method. The following code templates show the two ways to specify input modes.

**To specify the input mode using the Estimator class**

```python
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

estimator = Estimator(
    checkpoint_s3_uri='s3://my-bucket/checkpoint-destination/',
    output_path='s3://my-bucket/output-path/",
    base_job_name='job-name',
    input_mode='File'  # Available options: File | Pipe | FastFile
    ...
)

# Run the training job
estimator.fit(
    inputs=TrainingInput(s3_data="s3://my-bucket/my-data/train")
)
```

For more information, see the sagemaker.estimator.Estimator class in the SageMaker Python SDK documentation.

**To specify the input mode through the Estimator fit method**

```python
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

estimator = Estimator(
    checkpoint_s3_uri='s3://my-bucket/checkpoint-destination/',
    output_path='s3://my-bucket/output-path/',
    base_job_name='job-name',
    ...
)

# Run the training job
estimator.fit(
    inputs=TrainingInput(
        s3_data="s3://my-bucket/my-data/train",
        input_mode='File'  # Available options: File | Pipe | FastFile
    )
)
```

For more information, see the sagemaker.estimator.Estimator.fit class method and the sagemaker.inputs.TrainingInput class in the SageMaker Python SDK documentation.

**Tip**

To learn more about how to configure Amazon FSx for Lustre or Amazon EFS with your VPC configuration using the SageMaker Python SDK estimators, see Use File Systems as Training Inputs in the SageMaker Python SDK documentation.

**Tip**
The data input mode integrations with Amazon S3, Amazon EFS, and FSx for Lustre are recommended ways to optimally configure data source for the best practices. You can
strategically improve data loading performance using the SageMaker managed storage options and input modes, but it's not strictly constrained. You can write your own data reading logic directly in your training container. For example, you can set to read from a different data source, write your own S3 data loader class, or use third-party frameworks' data loading functions within your training script. However, you must make sure that you specify the right paths that SageMaker can recognize.

**Tip**
If you use a custom training container, make sure you install the SageMaker training toolkit that helps set up the environment for SageMaker training jobs. Otherwise, you must specify the environment variables explicitly in your Dockerfile. For more information, see Create a container with your own algorithms and models.

For more information about how to set the data input modes using the low-level SageMaker APIs, see How Amazon SageMaker Provides Training Information (p. 3032), the CreateTrainingJob API, and the TrainingInputMode in AlgorithmSpecification.

### Best Practices for Choosing Data Source and Input Mode

The best data source for your training job depends on workload characteristics such as the size of the dataset, the file format, the average size of files, the training duration, a sequential or random data loader read pattern, and how fast your model can consume the training data. The following best practices provide guidelines to get started with the most suitable input mode and data storage for your use case.
Best Practices for Choosing Data Source and Input Mode

1. Where is the dataset stored?
   - EFS
     - Try Amazon EFS
     - EFS
       - Good enough performance?
         - Yes
           - Try Amazon FSx for Lustre
         - No
           - How big is the dataset?
             - Less than 50GB-100GB
               - Less than 50MB
                 - Can you concatenate files?
                   - Yes
                     - Try FastFile mode
                   - No
                     - Try File mode
             - More than 50GB-100GB
               - How big are your files?
                 - More than 50MB
                   - Try File mode
                 - Less than 50GB-100GB
                   - Try FastFile mode
       - S3
         - How big is the dataset?
           - Less than 50GB-100GB
             - Try File mode
           - More than 50GB-100GB
             - How big are your files?
               - More than 50MB
                 - Try File mode
               - Less than 50GB-100GB
                 - Try FastFile mode

2. end
This flowchart summarizes and visualizes best practices of choosing the best storage as the data source and input file mode. All of the cases in the flowchart are described in the following sections.

**When to use Amazon EFS**

If your dataset is stored in Amazon Elastic File System, you might have a preprocessing or annotations application that uses Amazon EFS for storage. You can run a training job configured with a data channel that points to the Amazon EFS file system. For more information, see Speed up training on Amazon SageMaker using Amazon FSx for Lustre and Amazon EFS file systems. If you cannot achieve better performance, check your optimization options following the Amazon Elastic File System performance guide or consider using different input modes or data storage.

**Use file mode for small datasets**

If the dataset is stored in Amazon Simple Storage Service and its overall volume is relatively small (for example, less than 50-100 GB), try using file mode. The overhead of downloading a 50 GB dataset can vary based on the total number of files. For example, it takes about 5 minutes if a dataset is chunked into 100 MB shards. Whether this startup overhead is acceptable primarily depends on the overall duration of your training job, because a longer training phase means a proportionally smaller download phase.

**Serializing many small files**

If your dataset size is small (less than 50-100 GB), but is made up of many small files (less than 50 MB per file), the file mode download overhead grows, because each file needs to be downloaded individually from Amazon Simple Storage Service to the training instance volume. To reduce this overhead and data traversal time in general, consider serializing groups of such small files into fewer larger file containers (such as 150 MB per file) by using file formats, such as TFRecord for TensorFlow, WebDataset for PyTorch, and RecordIO for MXNet.

**When to use fast file mode**

For larger datasets with larger files (more than 50 MB per file), the first option is to try fast file mode, which is more straightforward to use than FSx for Lustre because it doesn't require creating a file system, or connecting to a VPC. Fast file mode is ideal for large file containers (more than 150 MB), and might also do well with files more than 50 MB. Because fast file mode provides a POSIX interface, it supports random reads (reading non-sequential byte-ranges). However, this is not the ideal use case, and your throughput might be lower than with the sequential reads. However, if you have a relatively large and computationally intensive ML model, fast file mode might still be able to saturate the effective bandwidth of the training pipeline and not result in an IO bottleneck. You'll need to experiment and see. To switch from file mode to fast file mode (and back), just add (or remove) the input_mode='FastFile' parameter while defining your input channel using the SageMaker Python SDK:

```python
sagemaker.inputs.TrainingInput(S3_INPUT_FOLDER, input_mode = 'FastFile')
```

**When to use Amazon FSx for Lustre**

If your dataset is too large for file mode, has many small files that you can't serialize easily, or uses a random read access pattern, FSx for Lustre is a good option to consider. Its file system scales to hundreds of gigabytes per second (GB/s) of throughput and millions of IOPS, which is ideal when you have many small files. However, note that there might be the cold start issue due to lazy loading and the overhead of setting up and initializing the FSx for Lustre file system.
Managed Spot Training in Amazon SageMaker

Amazon SageMaker makes it easy to train machine learning models using managed Amazon EC2 Spot instances. Managed spot training can optimize the cost of training models up to 90% over on-demand instances. SageMaker manages the Spot interruptions on your behalf.

Managed Spot Training uses Amazon EC2 Spot instance to run training jobs instead of on-demand instances. You can specify which training jobs use spot instances and a stopping condition that specifies how long SageMaker waits for a job to run using Amazon EC2 Spot instances. Metrics and logs generated during training runs are available in CloudWatch.

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, can use managed spot training. For more information on automatic model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2360).

Spot instances can be interrupted, causing jobs to take longer to start or finish. You can configure your managed spot training job to use checkpoints. SageMaker copies checkpoint data from a local path to Amazon S3. When the job is restarted, SageMaker copies the data from Amazon S3 back into the local path. The training job can then resume from the last checkpoint instead of restarting. For more information about checkpointing, see Use Checkpoints in Amazon SageMaker (p. 2604).

Tip
To learn more, see Choose the best data source for your Amazon SageMaker training job. This AWS machine learning blog further discusses case studies and performance benchmark of data sources and input modes.

Note
Unless your training job will complete quickly, we recommend you use checkpointing with managed spot training. SageMaker built-in algorithms and marketplace algorithms that do not checkpoint are currently limited to a MaxWaitTimeInSeconds of 3600 seconds (60 minutes).

Using Managed Spot Training

To use managed spot training, create a training job. Set EnableManagedSpotTraining to True and specify the MaxWaitTimeInSeconds. MaxWaitTimeInSeconds must be larger than MaxRuntimeInSeconds. For more information about creating a training job, see DescribeTrainingJob.

You can calculate the savings from using managed spot training using the formula (1 - (BillableTimeInSeconds / TrainingTimeInSeconds)) * 100. For example, if BillableTimeInSeconds is 100 and TrainingTimeInSeconds is 500, the savings is 80%.

To learn how to run training jobs on Amazon SageMaker spot instances and how managed spot training works and reduces the billable time, see the following example notebooks:

- Managed Spot Training with TensorFlow
- Managed Spot Training with XGBoost
- Managed Spot Training with MXNet
- Amazon SageMaker Managed Spot Training Examples GitHub repository
Managed Spot Training Lifecycle

You can monitor a training job using TrainingJobStatus and SecondaryStatus returned by DescribeTrainingJob. The list below shows how TrainingJobStatus and SecondaryStatus values change depending on the training scenario:

- **Spot instances acquired with no interruption during training**
  1. InProgress: Starting ↞ Downloading ↞ Training ↞ Uploading

- **Spot instances interrupted once. Later, enough spot instances were acquired to finish the training job.**
  1. InProgress: Starting ↞ Downloading ↞ Training ↞ Interrupted ↞ Starting ↞ Downloading ↞ Training ↞ Uploading

- **Spot instances interrupted twice and MaxWaitTimeInSeconds exceeded.**
  1. InProgress: Starting ↞ Downloading ↞ Training ↞ Interrupted ↞ Starting ↞ Downloading ↞ Training ↞ Interrupted ↞ Downloading ↞ Training
  2. Stopping: Stopping
  3. Stopped: MaxWaitTimeExceeded

- **Spot instances were never launched.**
  1. InProgress: Starting
  2. Stopping: Stopping
  3. Stopped: MaxWaitTimeExceeded

Use Checkpoints in Amazon SageMaker

Use checkpoints in Amazon SageMaker to save the state of machine learning (ML) models during training. Checkpoints are snapshots of the model and can be configured by the callback functions of ML frameworks. You can use the saved checkpoints to restart a training job from the last saved checkpoint.

The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers. SageMaker provides functionality to copy the checkpoints from the local path to Amazon S3.

The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers (default is /opt/ml/checkpoints). SageMaker automatically syncs the checkpoints in that directory with Amazon S3. Existing checkpoints in S3 are written to the SageMaker container at the start of the job, enabling jobs to resume from a checkpoint. Checkpoints added to the S3 folder after the job has started are not copied to the training container. SageMaker also writes new checkpoints from the container to S3 during training. If a checkpoint is deleted in the SageMaker container, it will also be deleted in the S3 folder.

Using checkpoints, you can do the following:

- Save your model snapshots under training due to an unexpected interruption to the training job or instance.
- Resume training the model in the future from a checkpoint.
- Analyze the model at intermediate stages of training.
- Use checkpoints with SageMaker managed spot training to save on training costs.

If you are using checkpoints with SageMaker managed spot training, SageMaker manages checkpointing your model training on a spot instance and resuming the training job on the next spot instance. With
SageMaker managed spot training, you can significantly reduce the billable time for training ML models. For more information, see Managed Spot Training in Amazon SageMaker (p. 2603).

Checkpoints for Frameworks and Algorithms in SageMaker

Use checkpoints to save snapshots of ML models built on your preferred frameworks within SageMaker.

SageMaker frameworks and algorithms that support checkpointing

SageMaker supports checkpointing for AWS Deep Learning Containers and a subset of built-in algorithms without requiring training script changes. SageMaker saves the checkpoints to the default local path '/opt/ml/checkpoints' and copies them to Amazon S3.

- Deep Learning Containers: TensorFlow, PyTorch, MXNet, and HuggingFace
  
  **Note**
  
  If you are using the HuggingFace framework estimator, you need to specify a checkpoint output path through hyperparameters. For more information, see Run training on Amazon SageMaker in the HuggingFace documentation.

- Built-in algorithms: Image Classification, Object Detection, Semantic Segmentation, and XGBoost (0.90-1 or later)
  
  **Note**
  
  If you are using the XGBoost algorithm in framework mode (script mode), you need to bring an XGBoost training script with checkpointing that's manually configured. For more information about the XGBoost training methods to save model snapshots, see Training XGBoost in the XGBoost Python SDK documentation.

If a pre-built algorithm that does not support checkpointing is used in a managed spot training job, SageMaker does not allow a maximum wait time greater than an hour for the job in order to limit wasted training time from interrupts.

For custom training containers and other frameworks

If you are using your own training containers, training scripts, or other frameworks not listed in the previous section, you must properly set up your training script using callbacks or training APIs to save checkpoints to the local path ('/opt/ml/checkpoints') and load from the local path in your training script. SageMaker estimators can sync up with the local path and save the checkpoints to Amazon S3.

Enable Checkpointing

After you enable checkpointing, SageMaker saves checkpoints to Amazon S3 and syncs your training job with the checkpoint S3 bucket.
The following example shows how to configure checkpoint paths when you construct a SageMaker estimator. To enable checkpointing, add the `checkpoint_s3_uri` and `checkpoint_local_path` parameters to your estimator.

The following example template shows how to create a generic SageMaker estimator and enable checkpointing. You can use this template for the supported algorithms by specifying the `image_uri` parameter. To find Docker image URIs for algorithms with checkpointing supported by SageMaker, see Docker Registry Paths and Example Code (p. 1060). You can also replace `estimator` and `Estimator` with other SageMaker frameworks' estimator parent classes and estimator classes, such as TensorFlow, PyTorch, MXNet, HuggingFace and XGBoost.

```python
import sagemaker
from sagemaker.estimator import Estimator

bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)

# The local path where the model will save its checkpoints in the training container
checkpoint_local_path="/opt/ml/checkpoints"

estimator = Estimator(
    ...
    image_uri="<ecr_path>/<algorithm-name>:<tag>" # Specify to use built-in algorithms
    output_path=bucket,
    base_job_name=base_job_name,

    # Parameters required to enable checkpointing
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path=checkpoint_local_path
)
```

The following two parameters specify paths for checkpointing:

- `checkpoint_local_path` — Specify the local path where the model saves the checkpoints periodically in a training container. The default path is set to ‘/opt/ml/checkpoints’. If you are using other frameworks or bringing your own training container, ensure that your training script's checkpoint configuration specifies the path to ‘/opt/ml/checkpoints’.

Note
We recommend specifying the local paths as ‘/opt/ml/checkpoints’ to be consistent with the default SageMaker checkpoint settings. If you prefer to specify your own local
Browse Checkpoint Files

Locate checkpoint files using the SageMaker Python SDK and the Amazon S3 console.

**To find the checkpoint files programmatically**

To retrieve the S3 bucket URI where the checkpoints are saved, check the following estimator attribute:

```
estimator.checkpoint_s3_uri
```

This returns the Amazon S3 output path for checkpoints configured while requesting the `CreateTrainingJob` request. To find the saved checkpoint files using the Amazon S3 console, use the following procedure.

**To find the checkpoint files from the Amazon S3 console**

2. In the left navigation pane, choose Training jobs.
3. Choose the link to the training job with checkpointing enabled to open Job settings.
4. On the Job settings page of the training job, locate the Checkpoint configuration section.

   ![Checkpoint configuration table](image)

   - **S3 output path**: `s3://path-to-your-checkpoint`
   - **Local path**: `/opt/ml/checkpoints/`

5. Use the link to the S3 bucket to access the checkpoint files.

**Resume Training From a Checkpoint**

To resume a training job from a checkpoint, run a new estimator with the same `checkpoint_s3_uri` that you created in the Enable Checkpointing (p. 2605) section. Once the training has resumed, the checkpoints from this S3 bucket are restored to `checkpoint_local_path` in each instance of the new training job. Ensure that the S3 bucket is in the same Region as that of the current SageMaker session.
Considerations for Checkpointing

Consider the following when using checkpoints in SageMaker.

- To avoid overwrites in distributed training with multiple instances, you must manually configure the checkpoint file names and paths in your training script. The high-level SageMaker checkpoint configuration specifies a single Amazon S3 location without additional suffixes or prefixes to tag checkpoints from multiple instances.
- The SageMaker Python SDK does not support high-level configuration for checkpointing frequency. To control the checkpointing frequency, modify your training script using the framework's model save functions or checkpoint callbacks.
- If you use SageMaker checkpoints with SageMaker Debugger and SageMaker distributed and are facing issues, see the following pages for troubleshooting and considerations.
  - Considerations for Amazon SageMaker Debugger (p. 2356)
  - Data Parallel Troubleshooting (p. 2426)
  - Model Parallel Troubleshooting (p. 2490)

Provide Dataset Metadata to Training Jobs with an Augmented Manifest File

To include metadata with your dataset in a training job, use an augmented manifest file. When using an augmented manifest file, your dataset must be stored in Amazon Simple Storage Service (Amazon S3), and you must configure your training job to use the dataset stored there. You specify the location and format of this dataset for one or more Channel. Augmented manifests can only support Pipe input mode. See the section, InputMode in Channel to learn more about pipe input mode.

When specifying a channel's parameters, you specify a path to the file, called a S3Uri. Amazon SageMaker interprets this URI based on the specified S3DataType in S3DataSource. The AugmentedManifestFile option defines a manifest format that includes metadata with the input data. Using an augmented manifest file is an alternative to preprocessing when you have labeled data. For training jobs using labeled data, you typically need to preprocess the dataset to combine input data with metadata before training. If your training dataset is large, preprocessing can be time consuming and expensive.

Augmented Manifest File Format

An augmented manifest file must be formatted in JSON Lines format. In JSON Lines format, each line in the file is a complete JSON object followed by a newline separator.
During training, SageMaker parses each JSON line and sends some or all of its attributes on to the training algorithm. You specify which attribute contents to pass and the order in which to pass them with the AttributeNames parameter of the CreateTrainingJob API. The AttributeNames parameter is an ordered list of attribute names that SageMaker looks for in the JSON object to use as training input.

For example, if you list ['"line"', "book"] for AttributeNames, the input data must include the attribute names of line and book in the specified order. For this example, the following augmented manifest file content is valid:

```
{"author": "Herman Melville", "line": "Call me Ishmael", "book": "Moby Dick"}
{"line": "It was love at first sight.", "author": "Joseph Heller", "book": "Catch-22"}
```

SageMaker ignores unlisted attribute names even if they precede, follow, or are in between listed attributes.

When using augmented manifest files, observe the following guidelines:

- The order of the attributes listed in the AttributeNames parameter determines the order of the attributes passed to the algorithm in the training job.
- The listed AttributeNames can be a subset of all of the attributes in the JSON line. SageMaker ignores unlisted attributes in the file.
- You can specify any type of data allowed by the JSON format in AttributeNames, including text, numerical, data arrays, or objects.
- To include an S3 URI as an attribute name, add the suffix -ref to it.

If an attribute name contains the suffix -ref, the attribute's value must be an S3 URI to a data file that is accessible to the training job. For example, if AttributeNames contains ["image-ref", "is-a-cat"], the following example shows a valid augmented manifest file:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "is-a-cat": 1}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "is-a-cat": 0}
```

In case of the first JSON line of this manifest file, SageMaker retrieves the image1.jpg file from s3://mybucket/sample01/ and the string representation of the is-a-cat attribute "1" for image classification.

**Tip**
To create an augmented manifest file, use Amazon SageMaker Ground Truth and create a labeling job. For more information about the output from a labeling job, see Output Data (p. 591).

## Stream Augmented Manifest File Data

Augmented manifest format enables you to do training in Pipe mode using files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Augmented manifest files are supported only for channels using Pipe input mode. For each channel, the data is extracted from its augmented manifest file and streamed (in order) to the algorithm through the channel's named pipe. Pipe mode uses the first in first out (FIFO) method, so records are processed in the order in which they are queued. For information about Pipe input mode, see Input Mode.

Attribute names with a -ref suffix point to preformatted binary data. In some cases, the algorithm knows how to parse the data. In other cases, you might need to wrap the data so that records are delimited for the algorithm. If the algorithm is compatible with RecordIO-formatted data, specifying
RecordIO for RecordWrapperType solves this issue. If the algorithm is not compatible with RecordIO format, specify None for RecordWrapperType and make sure that your data is parsed correctly for your algorithm.

Using the ["image-ref", "is-a-cat"] example, if you use RecordIO wrapping, the following stream of data is sent to the queue:

```
recordio_formatted(s3://mybucket/foo/image1.jpg)recordio_formatted("1")recordio_formatted(s3://mybucket/bar/image2.jpg)recordio_formatted("0")
```

Images that are not wrapped with RecordIO format, are streamed with the corresponding is-a-cat attribute value as one record. This can cause a problem because the algorithm might not delimit the images and attributes correctly. For more information about using augmented manifest files for image classification, see Train with Augmented Manifest Image Format.

With augmented manifest files and Pipe mode in general, size limits of the EBS volume do not apply. This includes settings that otherwise must be within the EBS volume size limit such as S3DataDistributionType. For more information about Pipe mode and how to use it, see Using Your Own Training Algorithms - Input Data Configuration.

**Use an Augmented Manifest File (Console)**

To complete this procedure, you need:

- The URL of the S3 bucket where you've stored the augmented manifest file.
- To store the data that is listed in the augmented manifest file in an S3 bucket.
- The URL of the S3 bucket where you want to store the output of the job.

**To use an augmented manifest file in a training job (console)**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. It can have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and .: + = @ % - (hyphen).
5. Choose the algorithm that you want to use. For information about supported built-in algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1051). If you want to use a custom algorithm, make sure that it is compatible with Pipe mode.
6. (Optional) For Resource configuration, either accept the default values or, to reduce computation time, increase the resource consumption.
   a. (Optional) For Instance type, choose the ML compute instance type that you want to use. In most cases, ml.m4.xlarge is sufficient.
   b. For Instance count, use the default, 1.
   c. (Optional) For Additional volume per instance (GB), choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
   a. For Channel name, either accept the default (train) or enter a more meaningful name, such as training-augmented-manifest-file.
   b. For InputMode, choose Pipe.
Use an Augmented Manifest File (API)

The following shows how to train a model with an augmented manifest file using the SageMaker high-level Python library:

```python
import sagemaker

# Create a model object set to using "Pipe" mode.
model = sagemaker.estimator.Estimator(
    training_image,  # Training image
    role,            # Role
    instance_count=1,  # Number of instances
    instance_type='ml.p3.2xlarge',  # Instance type
    volume_size = 50,  # Volume size
    max_run = 360000,  # Maximum run time
)...  # Additional arguments

# Use the AugmentedManifestFile mode
model.set_hyperparameters(...)

# Use the AugmentedManifestFile mode
model.fit(S3_data_distribution_type='FullyReplicated')
```

After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for `S3_output_path` in the `Output data configuration` field. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 84).
Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics

An Amazon SageMaker training job is an iterative process that teaches a model to make predictions by presenting examples from a training dataset. Typically, a training algorithm computes several metrics, such as training error and prediction accuracy. These metrics help diagnose whether the model is learning well and will generalize well for making predictions on unseen data. The training algorithm writes the values of these metrics to logs, which SageMaker monitors and sends to Amazon CloudWatch in real time. To analyze the performance of your training job, you can view graphs of these metrics in CloudWatch. When a training job has completed, you can also get a list of the metric values that it computes in its final iteration by calling the `DescribeTrainingJob` operation.

Note
Amazon CloudWatch supports **high-resolution custom metrics**, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see `GetMetricStatistics` in the Amazon CloudWatch API Reference.

Tip
If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker Debugger also provides visualizations through Studio and its profiling report. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

**Monitor and Analyze Using CloudWatch Metrics**

```python
input_mode = 'Pipe',
output_path=s3_output_location,
sagemaker_session=session
)

# Create a train data channel with S3_data_type as 'AugmentedManifestFile' and attribute names.
train_data = sagemaker.inputs.TrainingInput(  
    your_augmented_manifest_file,
    distribution='FullyReplicated',  
    content_type='application/x-recordio',
    s3_data_type='AugmentedManifestFile',
    attribute_names=['source-ref', 'annotations'],
    input_mode='Pipe',
    record_wrapping='RecordIO'
)

data_channels = {'train': train_data}

# Train a model.
model.fit(inputs=data_channels, logs=True)
```

After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 84).
Defining Training Metrics

SageMaker automatically parses training job logs and sends training metrics to CloudWatch. By default, SageMaker sends system resource utilization metrics listed in SageMaker Jobs and Endpoint Metrics. If you want SageMaker to parse logs and send custom metrics from a training job of your own algorithm to CloudWatch, you need to specify metrics definitions by passing the name of metrics and regular expressions when you configure a SageMaker training job request.

You can specify the metrics that you want to track using the SageMaker console, the SageMaker Python SDK, or the low-level SageMaker API.

If you are using your own algorithm, do the following:

- Make sure that the algorithm writes the metrics that you want to capture to logs.
- Define a regular expression that accurately searches the logs to capture the values of the metrics that you want to send to CloudWatch.

For example, suppose your algorithm emits the following metrics for training error and validation error:

```
Train_error=0.138318; Valid_error=0.324557;
```

If you want to monitor both of those metrics in CloudWatch, the dictionary for the metric definitions should look like the following example:

```
[
  {
    "Name": "train:error",
    "Regex": "Train_error=(.*?);"
  },
  {
    "Name": "validation:error",
    "Regex": "Valid_error=(.*?);"
  }
]
```

In the regex for the `train:error` metric defined in the preceding example, the first part of the regex finds the exact text "Train_error=", and the expression `(.*?);` captures any characters until the first semicolon character appears. In this expression, the parenthesis tell the regex to capture what is inside them, `.` means any character, `*` means zero or more, and `?` means capture only until the first instance of the `;` character.

Define Metrics Using the SageMaker Python SDK

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions as the `metric_definitions` argument when you initialize an `Estimator` object. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `Estimator` initialization would look like the following example:

```python
import sagemaker
```
from sagemaker.estimator import Estimator

estimator = Estimator(
    image_uri="your-own-image-uri",
    role=sagemaker.get_execution_role(),
    sagemaker_session=sagemaker.Session(),
    instance_count=1,
    instance_type='ml.c4.xlarge',
    metric_definitions=[
        {'Name': 'train:error', 'Regex': 'Train_error=(.*?);'},
        {'Name': 'validation:error', 'Regex': 'Valid_error=(.*?);'}
    ]
)

For more information about training by using Amazon SageMaker Python SDK estimators, see Sagemaker Python SDK on GitHub.

Define Metrics Using the SageMaker Console

If you choose the Your own algorithm container in ECR option as your algorithm source in the SageMaker console when you create a training job, add the metric definitions in the Metrics section. The following screenshot shows how it should look after you add the example metric names and the corresponding regular expressions.

Algorithm options
Use an Amazon SageMaker built-in algorithm, your own algorithm, or a third-party algorithm from AWS Marketplace.

Algorithm source
- Amazon SageMaker built-in algorithm Learn more
- Your own algorithm resource
- Your own algorithm container in ECR Learn more
- An algorithm subscription from AWS Marketplace

Provide container ECR path

Container
The registry path where the training image is stored in Amazon ECR. Learn more

Input mode
You can provide your training data as a file or pipe.

File

Metrics
Define the metrics you want to emit to CloudWatch metrics.

Metric name | Regex
---|---
train/error | Train_error=(.*?);
validation/error | Valid_error=(.*?);

Add metric

Define Metrics Using the Low-level SageMaker API

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions in the MetricDefinitions field of the AlgorithmSpecification input parameter.
that you pass to the `CreateTrainingJob` operation. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `AlgorithmSpecification` would look like the following example:

```
"AlgorithmSpecification": {
    "TrainingImage": "your-own-image-uri",
    "TrainingInputMode": "File",
    "MetricDefinitions": [
        { "Name": "train:error", "Regex": "Train_error=(.*?);" },
        { "Name": "validation:error", "Regex": "Valid_error=(.*?);" }
    ]
}
```

For more information about defining and running a training job by using the low-level SageMaker API, see `CreateTrainingJob`.

### Monitoring Training Job Metrics (CloudWatch Console)

You can monitor the metrics that a training job emits in real time in the CloudWatch console.

**To monitor training job metrics (CloudWatch console)**

2. Choose **Metrics**, then choose `/aws/sagemaker/TrainingJobs`.
3. Choose **TrainingJobName**.
4. On the **All metrics** tab, choose the names of the training metrics that you want to monitor.
5. On the **Graphed metrics** tab, configure the graph options. For more information about using CloudWatch graphs, see **Graph Metrics** in the *Amazon CloudWatch User Guide*.

### Monitoring Training Job Metrics (SageMaker Console)

You can monitor the metrics that a training job emits in real time by using the SageMaker console.

**To monitor training job metrics (SageMaker console)**

2. Choose **Training jobs**, then choose the training job whose metrics you want to see.
3. Choose **TrainingJobName**.
4. In the **Monitor** section, you can review the graphs of instance utilization and algorithm metrics.
Example: Viewing a Training and Validation Curve

Typically, you split the data on which you train your model into training and validation datasets. You use the training set to train the model parameters that are used to make predictions on the training dataset. Then you test how well the model makes predictions by calculating predictions for the validation set. To analyze the performance of a training job, you commonly plot a training curve against a validation curve.

Viewing a graph that shows the accuracy for both the training and validation sets over time can help you to improve the performance of your model. For example, if training accuracy continues to increase over time, but, at some point, validation accuracy starts to decrease, you are likely overfitting your model. To address this, you can make adjustments to your model, such as increasing regularization.

For this example, you can use the Image-classification-full-training example in the Example notebooks section of your SageMaker notebook instance. If you don't have a SageMaker notebook instance, create one by following the instructions at Step 1: Create an Amazon SageMaker Notebook Instance (p. 74). If you prefer, you can follow along with the End-to-End Multiclass Image Classification Example in the example notebook on GitHub. You also need an Amazon S3 bucket to store the training data and for the model output.

To view training and validation error curves

2. Choose Notebooks, and then choose Notebook instances.
3. Choose the notebook instance that you want to use, and then choose Open.
4. On the dashboard for your notebook instance, choose SageMaker Examples.
5. Expand the Introduction to Amazon Algorithms section, and then choose Use next to Image-classification-fulltraining.ipynb.
7. Run all of the cells in the notebook up to the Inference section. You don't need to deploy an endpoint or get inference for this example.
8. After the training job starts, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch.
9. Choose Metrics, then choose /aws/sagemaker/TrainingJobs.
10. Choose TrainingJobName.
11. On the All metrics tab, choose the train:accuracy and validation:accuracy metrics for the training job that you created in the notebook.
12. On the graph, choose an area that the metric's values to zoom in. You should see something like the following example.
Example: Viewing a Training and Validation Curve
Deploy Models for Inference

After you build and train your models, you can deploy them to get predictions in one of two ways:

- To set up a persistent endpoint to get predictions from your models, use Amazon SageMaker hosting services. For an example of how to deploy a model to the SageMaker hosting service, see Create your endpoint and deploy your model (p. 2642).

Or, if you prefer, watch the following video tutorial:

Deploy Your ML Models to Production at Scale with Amazon SageMaker

- To get predictions for an entire dataset, use SageMaker batch transform. For an overview on deploying a model with SageMaker batch transform, see Use Batch Transform (p. 2807).

For an example of how to deploy a model with batch transform, see (Optional) Make Prediction with Batch Transform (p. 85).

Or, if you prefer, watch the following video tutorial:

Deploy Your ML Models to Production at Scale with Amazon SageMaker

Prerequisites

These topics assume that you have built and trained one or more machine learning models and are ready to deploy them. If you are new to SageMaker and have not completed these prerequisite tasks, work through the steps in the Get Started with Amazon SageMaker (p. 33) tutorial to familiarize yourself with an example of how SageMaker manages the data science process and how it handles model deployment. For more information about training a model, see Train Models (p. 1046).

What do you want to do?

SageMaker provides features to manage resources and optimize inference performance when deploying machine learning models. For guidance on using inference pipelines, compiling and deploying models with Neo, Elastic Inference, and automatic model scaling, see the following topics.

- To manage data processing and real-time predictions or to process batch transforms in a pipeline, see Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2674).

- If you want to deploy a model on inf1 instances, see Optimize model performance using Neo (p. 2913).

- To train TensorFlow, Apache MXNet, PyTorch, ONNX, and XGBoost models once and optimize them to deploy on ARM, Intel, and Nvidia processors, see Optimize model performance using Neo (p. 2913).

- To preprocess entire datasets quickly or to get inferences from a trained model for large datasets when you don't need a persistent endpoint, see Use Batch Transform (p. 2807).

- To speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as SageMaker hosted models using a GPU instance for your endpoint, see Use Amazon SageMaker Elastic Inference (EI) (p. 2979).

- To dynamically adjust the number of instances provisioned in response to changes in your workload, see Automatically Scale Amazon SageMaker Models (p. 2688).

- To create an endpoint that can host multiple models using a shared serving container, see Host multiple models in one container behind one endpoint (p. 2652).
Manage Model Deployments

For guidance on managing model deployments, including monitoring, troubleshooting, and best practices, and for information on storage associated with inference hosting instances:

- For tools that can be used to monitor model deployments, see Monitor Amazon SageMaker (p. 3498).
- For troubleshooting model deployments, see Troubleshoot Amazon SageMaker model deployments (p. 2714).
- For model deployment best practices, see Best practices (p. 2711).
- For information about the size of storage volumes provided for different sizes of hosting instances, see Host instance storage volumes (p. 2703).

Deploy Your Own Inference Code

For developers that need more advanced guidance on how to run your own inference code:

- To run your own inference code hosting services, see Use Your Own Inference Code with Hosting Services (p. 3038).
- To run your own inference code for batch transforms, see Use Your Own Inference Code with Batch Transform (p. 3043).

Amazon SageMaker Inference Recommender

Amazon SageMaker Inference Recommender is a new capability of Amazon SageMaker that reduces the time required to get machine learning (ML) models in production by automating load testing and model tuning across SageMaker ML instances. You can use Inference Recommender to deploy your model to a real-time inference endpoint that delivers the best performance at the lowest cost. Inference Recommender helps you select the best instance type and configuration (such as instance count, container parameters, and model optimizations) for your ML models and workloads.

Amazon SageMaker Inference Recommender only charges you for the instances used while your jobs are executing.

How it Works

To use Amazon SageMaker Inference Recommender, you must first register a model to SageMaker model registry with your model artifact and container, use AWS SDK for Python (Boto3) to benchmark different SageMaker endpoint configurations, collect metrics, and visualize metrics across performance and resource utilization to help you decide on which instance type to choose.

How to Get Started

If you are a first-time user of Amazon SageMaker Inference Recommender, we recommend that you do the following:

1. Read through the Prerequisites (p. 2621) section to make sure you have satisfied the requirements to use Amazon SageMaker Inference Recommender.
2. Read through the Recommendation jobs (p. 2627) section to launch your first Inference Recommender recommendation jobs.
3. Explore the Amazon SageMaker Inference Recommender Jupyter notebook example.

Prerequisites

To use Amazon SageMaker Inference Recommender, first make sure you have met the prerequisites listed below. As an example, we show how to use a PyTorch (v1.7.1) ResNet-18 pre-trained model for both types of Amazon SageMaker Inference Recommender recommendation jobs.

**Note**

- The following code examples use Python. Remove the `!` prefix character if you run any of the following code samples in your terminal or AWS CLI.
- This example uses the `conda_pytorch_p36_latest` kernel within an Amazon SageMaker Notebook instance. This kernel is provided by SageMaker and uses Python 3.6 and PyTorch 1.7.1. For more information about SageMaker Notebooks, see Use Amazon SageMaker Notebook Instances (p. 283).

1. **Create an IAM role for Amazon SageMaker.**

   Create an IAM Role for Amazon SageMaker that has the `AmazonSageMakerFullAccess` IAM managed policy attached.

2. **(Optional) Review existing models benchmarked by Inference Recommender.**

   Inference Recommender benchmarks models from popular model zoos. Inference Recommender supports your model even if it is not already benchmarked.

   Use `ListModelMetadata` to get a response object that lists the domain, framework, task, and model name of machine learning models found in common model zoos.

   You use the domain, framework, framework version, task, and model name in later steps to both select an inference Docker image and register your model with SageMaker Model Registry. The following demonstrates how to list model metadata with SDK for Python (Boto3):

   ```python
   import boto3
   aws_region="<INSERT>"
   sagemaker_client = boto3.client("sagemaker", aws_region)
   list_model_metadata_response=sagemaker_client.list_model_metadata()
   ```

   The output includes model summaries (`ModelMetadataSummaries`) and response metadata (`ResponseMetadata`) similar to the following:

   ```json
   {   'ModelMetadataSummaries': [{   'Domain': 'NATURAL_LANGUAGE_PROCESSING',
   'Framework': 'PYTORCH:1.6.0',
   'Model': 'bert-base-cased',
   'Task': 'FILL_MASK'
   },
   {   'Domain': 'NATURAL_LANGUAGE_PROCESSING',
   'Framework': 'PYTORCH:1.6.0',
   'Model': 'bert-base-uncased',
   'Task': 'FILL_MASK'
   },
   {   'Domain': 'COMPUTER_VISION',
   'Framework': 'MXNET:1.8.0',
   ```
For this demo, we use a PyTorch (v1.7.1) ResNet-18 model to perform image classification. The following Python code sample stores the framework, framework version, domain, and task into variables for later use:

```python
# ML framework details
framework = 'PYTORCH'
framework_version = '1.7.1'

# ML model details
ml_domain = 'COMPUTER_VISION'
ml_task = 'IMAGE_CLASSIFICATION'
```

3. **Upload your machine learning model to Amazon S3.**

Use this PyTorch (v1.7.1) ResNet-18 model if you do not have a pre-trained machine learning model:

```python
# Optional: Download a sample PyTorch model
import torch
from torchvision import models, transforms, datasets

# Create an example input for tracing
image = torch.zeros([1, 3, 256, 256], dtype=torch.float32)

# Load a pretrained resnet18 model from TorchHub
model = models.resnet18(pretrained=True)

# Tell the model we are using it for evaluation (not training). Note this is required for Inferentia compilation.
model.eval()
model_trace = torch.jit.trace(model, image)

# Save your traced model
model_trace.save('model.pth')
```

Download a sample inference script `inference.py`. Create a code directory and move the inference script to the code directory:

```bash
# Download the inference script
```

2622
# move it into a code/ directory
!mkdir code
!mv inference.py code/

Amazon SageMaker requires pre-trained machine learning models be packaged as a compressed TAR file (*tar.gz*). Compress your model to satisfy this requirement:

```
!tar -czf test.tar.gz model.pth resnet18.py
```

When your endpoint is provisioned, the files in the archive are extracted to `/opt/ml/model/` on the endpoint.

After you compress your model and model artifacts as a `.tar.gz` file, upload them to your Amazon S3 bucket. The following demonstrates how to upload your model to Amazon S3 using the AWS CLI:

```
!aws s3 cp test.tar.gz s3://{your-bucket}/models/
```

4. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**

SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see [Available Deep Learning Containers Images](#).

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, create a new Docker image. See [Use Your Own Inference Code (p. 3037)](#) for information about how to create your Docker image.

The following demonstrates how to retrieve a PyTorch version 1.7.1 inference image using the SageMaker Python SDK:

```python
from sagemaker import image_uris

aws_region="<aws_region>"

## Uncomment and replace with your own values if you did not define
## these variables a previous step.
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# Note: you can use any CPU-based instance here,
# this is just to set the arch as CPU for the Docker image
instance_type = 'ml.m5.2xlarge'

image_uri = image_uris.retrieve(framework, 
    region=aws_region, 
    version=framework_version, 
    py_version='py3', 
    instance_type=instance_type, 
    image_scope='inference')
```

For a list of available SageMaker Instances, see [Amazon SageMaker Pricing](#).

5. **Create a sample payload archive.**

Create an archive that contains individual files that the load testing tool can send to your SageMaker endpoints. Your inference code must be able to read the file formats from the sample payload.

The following downloads a .jpg image that this example uses in a later step for the ResNet-18 model.

```
from sagemaker import image_uris

aws_region="<aws_region>"

## Uncomment and replace with your own values if you did not define
## these variables a previous step.
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# Note: you can use any CPU-based instance here,
# this is just to set the arch as CPU for the Docker image
instance_type = 'ml.m5.2xlarge'

image_uri = image_uris.retrieve(framework, 
    region=aws_region, 
    version=framework_version, 
    py_version='py3', 
    instance_type=instance_type, 
    image_scope='inference')
```
6. **Register your model in the model registry**

With SageMaker Model Registry, you can catalog models for production, manage model versions, associate metadata (such as training metrics) with a model, manage the approval status of a model, deploy models to production, and automate model deployment with CI/CD.

When you use SageMaker Model Registry to track and manage your models, they are represented as a versioned model package within model package groups. Unversioned model packages are not part of a model group. Model package groups hold multiple versions or iterations of a model. Though it is not required to create them for every model in the registry, they help organize various models that all have the same purpose and provide automatic versioning.

To use Amazon SageMaker Inference Recommender, you must have a versioned model package. You can create a versioned model package programmatically with the AWS SDK for Python (Boto3) or with Amazon SageMaker Studio. To create a versioned model package programmatically, first create a model package group with the CreateModelPackageGroup API. Next, create a model package using the CreateModelPackage API. Calling this method makes a versioned model package.

See Create a Model Group (p. 2835) and Register a Model Version (p. 2840) for detailed instructions about how to programmatically and interactively create a model package group and how to create a versioned model package, respectively, with the AWS SDK for Python (Boto3) and Amazon SageMaker Studio.

The following code sample demonstrates how to create a versioned model package using the AWS SDK for Python (Boto3).

**Note**

Note: You do not need to approve the model package to create an Inference Recommender job.

a. **Create a model package group**

Create a model package group with the CreateModelPackageGroup API. Provide a name to the model package group for the ModelPackageGroupName and optionally provide a description of the model package in the ModelPackageGroupDescription field.
model_package_group_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageGroupDescription" : model_package_group_description,
}

model_package_group_response = sagemaker_client.create_model_package_group(**model_package_group_input_dict)

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to CreateModelPackageGroup.

Create a Model Package by specifying a Docker image that runs your inference code and the Amazon S3 location of your model artifacts and provide values for InferenceSpecification. InferenceSpecification should contain information about inference jobs that can be run with models based on this Model Package, including the following:

- The Amazon ECR paths of images that run your inference code.
- (Optional) The instance types that the Model Package supports for transform jobs and real-time endpoints used for inference.
- The input and output content formats that the Model Package supports for inference.

In addition, you must specify the following parameters when you create a model package:

- **Domain**: The machine learning domain of your model package and its components. Common machine learning domains include computer vision and natural language processing.
- **Task**: The machine learning task your model package accomplishes. Common machine learning tasks include object detection and image classification. Specify "OTHER" if none of the tasks listed in the API Reference Guide satisfy your use case. See the Task API field descriptions for a list of supported machine learning tasks.
- **SamplePayloadUrl**: The Amazon Simple Storage Service (Amazon S3) path where the sample payload are stored. This path must point to a single gzip compressed tar archive (.tar.gz suffix).
- **Framework**: The machine learning framework of the model package container image.
- **FrameworkVersion**: The framework version of the Model Package Container Image.

If you provide an allow list of instance types to use to generate inferences in real-time for the SupportedRealtimeInferencelInstanceTypes, Inference Recommender will limit the search space for instance types during a Default job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.

In a previous step we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called models. We retrieved a PyTorch (v1.7.1) Deep Learning Container inference image and stored the URI in a variable called image_uri. We use those variables in the following code sample where we define a dictionary used as input to the CreateModelPackage API.

```python
# Provide the Amazon S3 URI of your compressed tarfile
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
model_s3_key = f"{bucket_prefix}/test.tar.gz"
model_url= f"s3://{bucket}/{model_s3_key}"

# Similar open source model to the packaged model
# The name of the ML model as standardized by common model zoos
```

2625
nearest_model_name = 'resnet18'

# The supported MIME types for input and output data. In this example,  
# we are using images as input.  
input_content_type='image/jpeg'

# Optional - provide a description of your model.  
model_package_description = '<INSERT>'

## Uncomment if you did not store the domain and task in an earlier  
## step  
#ml_domain = 'COMPUTER_VISION'  
#ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version  
## in a previous step.  
#framework = 'PYTORCH'  
#framework_version = '1.7.1'

# Optional: Used for optimizing your model using SageMaker Neo  
# PyTorch uses NCHW format for images  
data_input_configuration = "[[1,3,256,256]]"

# Create a dictionary to use as input for creating a model package group  
model_package_input_dict = {  
    "ModelPackageGroupName" : model_package_group_name,  
    "ModelPackageDescription" : model_package_description,  
    "Domain" : ml_domain,  
    "Task" : ml_task,  
    "SamplePayloadUrl" : sample_payload_url,  
    "InferenceSpecification" : {  
        "Containers" : [  
            {  
                "Image" : image_uri,  
                "ModelDataUrl" : model_url,  
                "Framework" : framework.upper(),  
                "FrameworkVersion" : framework_version,  
                "NearestModelName" : nearest_model_name,  
                "ModelInput" : {"DataInputConfig" : data_input_configuration}  
            }  
        ],  
        "SupportedContentTypes" : [input_content_type]  
    }  
}

b. Create a Model Package

Use the CreateModelPackage API to create a Model Package. Pass the input dictionary  
defined in the previous step:

model_package_response =  
sagemaker_client.create_model_package(**model_package_input_dict)

You need the model package ARN to use Amazon SageMaker Inference Recommender. Note the  
ARN of the model package or store it in a variable:

model_package_arn = model_package_response["ModelPackageArn"]

print('ModelPackage Version ARN : {}'.format(model_package_arn))
Recommendation jobs

Amazon SageMaker Inference Recommender can make two types of recommendations:

1. Instance recommendations (Default job type) run a set of load tests on recommended instance types. You only need to provide a model package Amazon Resource Name (ARN) to launch this type of recommendation job. Instance recommendation jobs complete within 45 minutes.

2. Endpoint recommendations (Advanced job type) are based on a custom load test where you select ML instances, provide a custom traffic pattern, and provide requirements for latency and throughput based on your production requirements. This job takes an average of 2 hours to complete depending on the job duration set and the total number of instance configurations tested.

Both types of recommendations use the same APIs to create, describe, and stop jobs. The output is a list of instance configuration recommendations with associated environment variables, cost, throughput, and latency metrics. Endpoint recommendations also provide an initial instance count which you can use to configure an autoscaling policy. To differentiate between the two types of jobs, specify Default to create preliminary endpoint recommendations and Advanced for custom load testing and endpoint recommendations.

Note
- You do not need to do both types of recommendation jobs in your own workflow. You can do either independently of each other.

Topics
- Get an instance recommendation (p. 2627)
- Run a custom load test (p. 2634)

Get an instance recommendation

Instance recommendation jobs run a set of load tests on recommended instance types. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

Note
- Before you create an Inference Recommender recommendation job, make sure you have satisfied the Prerequisites (p. 2621).

The following demonstrates how to use Amazon SageMaker Inference Recommender to create an instance recommendation based on your model type using the AWS SDK for Python (Boto3), AWS CLI, and Amazon SageMaker Studio.

Create an instance recommendation

Create an instance recommendation programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using Studio. Specify a job name for your instance recommendation, an AWS IAM role ARN, an input configuration, and your model package ARN when you registered your model with the model registry.

AWS SDK for Python (Boto3)

Use the CreateInferenceRecommendationsJob API to get an instance endpoint recommendation. Set the JobType field to ‘Default’ for instance endpoint recommendation jobs. In addition, provide the following:
• The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.

• The ARN of the versioned model package you created when you registered your model with the model registry. Define this for `ModelPackageVersionArn` in the `InputConfig` field.

• Provide a name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

Import the AWS SDK for Python (Boto3) package and create a SageMaker client object using the `client` class. If you followed the steps in the Prerequisites section, the model package group ARN was stored in a variable named `model_package_arn`.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region = '<INSERT>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<INSERT>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<INSERT>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = 'arn:aws:iam::<account>::role/*'

sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
    RoleArn = role_arn,
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn
    }
)
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

AWS CLI

Use the `create-inference-recommendations-job` API to get an instance endpoint recommendation. Set the `job-type` field to 'Default' for instance endpoint recommendation jobs. In addition, provide the following:

• The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the `role-arn` field.

• The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for `ModelPackageVersionArn` in the `input-config` field.

• Provide a name for your Inference Recommender recommendation job for the `job-name` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

```bash
aws sagemaker create-inference-recommendations-job
```
Recommendation jobs

```
--region <region> \
--job-name <job_name> \
--job-type Default \
--role-arn arn:aws:iam::<account:role/*> \
--input-config "{
    }"
```

Amazon SageMaker Studio

Create an instance recommendation job in Studio.

1. In the left sidebar of Amazon SageMaker, choose the **Components and registries** icon.
2. Select **Model Registry** from the dropdown list to display models you have registered with the model registry.
   
The left panel displays a list of model groups. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio.
3. Select the name of your model group. When you select your model group, the right pane of Studio displays column heads such as **Versions** and **Setting**.
   
   If you have one or more model packages within your model group, you will see a list of those model packages within the **Versions** column.
4. Choose the **Inference recommender** column.
5. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the **AmazonSageMakerFullAccess** IAM managed policy to accomplish this. Or you can let Studio create a role for you.
6. Choose **Get recommendations**.
   
The instance recommendation can take up to 45 minutes.
   
   **Warning**
   
   Do not close this tab. If you close this tab, you cancel the instance recommendation job.

Get Your Instance Recommendation Job Results

Collect the results of your instance recommendation job programmatically with AWS SDK for Python (Boto3), the AWS CLI, or Studio.

**AWS SDK for Python (Boto3)**

Once an instance recommendation is complete, you can use `DescribeInferenceRecommendationsJob` to get the job details and recommended instance types. Provide the job name that you used when you created the instance recommendation job.

```python
job_name='<INSERT>'
response = sagemaker_client.describe_inference_recommendations_job(
    JobName=job_name)

print(response['Status'])
```

This returns a JSON response similar to the following:

```
{
```
'JobName': 'job-name',
'JobDescription': 'job-description',
'JobType': 'Default',
'Status': 'COMPLETED',
'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000, tzinfo=tzlocal()),
'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 25, 1, 997000, tzinfo=tzlocal()),
'InputConfig': {
'JobDurationInSeconds': 0
},
'InferenceRecommendations': [{
'Metrics': {
'CostPerHour': 0.20399999618530273,
'CostPerInference': 5.246913588052848e-06,
'MaximumInvocations': 648,
'ModelLatency': 263596
},
'EndpointConfiguration': {
'EndpointName': 'endpoint-name',
'VariantName': 'variant-name',
'InstanceType': 'ml.c5.xlarge',
'InitialInstanceCount': 1
},
'ModelConfiguration': {
'Compiled': False,
'EnvironmentParameters': []
}
},
{
'Metrics': {
'CostPerHour': 0.11500000208616257,
'CostPerInference': 2.92620870823157e-06,

'ModelLatency': 1085446
},
'EndpointConfiguration': {
'EndpointName': 'endpoint-name',
'VariantName': 'variant-name',
'InstanceType': 'ml.m5.large',
'InitialInstanceCount': 1
},
'ModelConfiguration': {
'Compiled': False,
The first few lines provide information about the instance recommendation job itself. This includes the job name, role ARN, and creation and deletion times.

The InferenceRecommendations dictionary contains a list of Inference Recommender instance recommendations.

The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) that was used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498) for more information.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) in US dollars for your real-time endpoint, the expected maximum number of InvokeEndpoint requests per minute sent to the endpoint (MaxInvocations), and the model latency (ModelLatency), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

AWS CLI

Once an instance recommendation is complete, you can use describe-inference-recommendations-job to get the job details and recommended instance types. Provide the job name that you used when you created the instance recommendation job.

```
aws sagemaker describe-inference-recommendations-job
  --job-name <job-name>
  --region <aws-region>
```

The JSON response similar should resemble the following:

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Default',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000, tzinfo=tzlocal()),
    'InputConfig': {
```
'JobDurationInSeconds': 0,
}
,'InferenceRecommendations': [{
'Metrics': {
'CostPerHour': 0.20399999618530273,

'date': 'Tue, 26 Oct 2021 20:31:10 GMT'
}
The first few lines provide information about the instance recommendation job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender instance recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498) for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

Amazon SageMaker Studio

The instance recommendations populate in a new `Inference recommendations` tab within Studio. It can take up to 45 minutes for the results to show up. This tab contains `Results` and `Details` column headings.

The `Details` column provides information about the instance recommendation job, such as the name of the instance recommendation, when the job was created (`Creation time`), and more. It also provides `Settings` information, such as the maximum number of invocations that occurred per minute and information about the Amazon Resource Names used.

The `Results` column provides a `Deployment goals` and `SageMaker recommendations` window in which you can adjust the order that the results are displayed based on deployment importance. There are three dropdown menus that you can use to provide the level of importance of the `Cost`, `Latency`, and `Throughput` for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: `Lowest Importance`, `Low Importance`, `Moderate importance`, `High importance`, or `Highest importance`.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the `SageMaker recommendation` field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances.

In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the `All runs` section.

**Stop Your Instance Endpoint Recommendation**

Stop your Inference Recommender instance recommendation jobs programmatically with the `StopInferenceRecommendationsJob` API or with Studio.

**AWS SDK for Python (Boto3)**

Specify the name of the instance recommendation job for the `JobName` field:
Recommendation jobs

AWS CLI

Specify the job name of the instance recommendation job for the job-name flag:

```bash
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

Amazon SageMaker Studio

Close the tab in which you initiated the instance recommendation to stop your Inference Recommender instance recommendation.

Run a custom load test

Amazon SageMaker Inference Recommender load tests conduct extensive benchmarks based on production requirements for latency and throughput, custom traffic patterns, and instances (up to 10) that you select.

The following sections demonstrate how to create, describe, and stop a load test programmaticially using AWS SDK for Python (Boto3) and the AWS CLI, and interactively using Amazon SageMaker Studio.

Create a Load Test Job

Create a load test programmaticially using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using Studio. As with Inference Recommender instance recommendations, specify a job name for your load test, an AWS IAM role ARN, an input configuration, and your model package ARN when you registered your model with the model registry. Load tests require that you also specify a traffic pattern and stopping conditions.

AWS SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to create an Inference Recommender load test. Specify `Advanced` for the `JobType` field and provide:

- A job name for your load test (`JobName`). The job name must be unique within your AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- A traffic pattern of the load test (`TrafficPattern`).
- An endpoint configuration dictionary (`InputConfig`) where you specify an AWS instance type against which to run benchmarks.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region='INSERT'
sagemaker_client=boto3.client('sagemaker', region=aws_region)

# Provide a name to your recommendation based on load testing
load_test_job_name='INSERT'

# Provide the name of the sagemaker instance type
instance_type='INSERT'

# Provide the IAM Role that gives SageMaker permission to access AWS services
```
# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn='arn:aws:sagemaker:<region>:<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
    JobName=load_test_job_name,
    JobType="Advanced",
    RoleArn=role_arn,
    InputConfig={
        'ModelPackageVersionArn': model_package_arn,
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES',
            'Phases': [
                {'InitialNumberOfUsers': 1,
                 'SpawnRate': 1,
                 'DurationInSeconds': 120},
                {'InitialNumberOfUsers': 1,
                 'SpawnRate': 1,
                 'DurationInSeconds': 120}
            ]
        },
        'ResourceLimit': {
            'MaxNumberOfTests': 10,
            'MaxParallelOfTests': 3
        },
        'EndpointConfigurations': [[
            'InstanceType': 'ml.c5.xlarge'
        ],
        {'InstanceType': 'ml.m5.xlarge'
        ],
        {'InstanceType': 'ml.r5.xlarge'
        ]}
    },
    StoppingConditions={
        'MaxInvocations': 1000,
        'ModelLatencyThresholds': [{'Percentile': 'P95',
                                     'ValueInMilliseconds': 100}
    ]
)

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to CreateInferenceRecommendationsJob.

AWS CLI

Use the create-inference-recommendations-job API to create an Inference Recommender load test. Specify Advanced for the JobType field and provide:

- A job name for your load test (job-name). The job name must be unique within your AWS region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the role-arn field.
- A traffic pattern of the load test (TrafficPattern).
• An endpoint configuration dictionary (input-config) where you specify an AWS instance type for running benchmarks against.

```bash
aws sagemaker create-inference-recommendations-job
   --region <region>
   --job-name <job-name>
   --job-type ADVANCED
   --role-arn arn:aws:iam::<account>:role/*
   --input-config "{
       "JobDurationInSeconds": 7200,
       "TrafficPattern": { 
           "TrafficType": "PHASES",
           "Phases": [
               { 
                   "InitialNumberOfUsers": 1,
                   "SpawnRate": 60,
                   "DurationInSeconds": 300
               }
           ],
       },
       "ResourceLimit": { 
           "MaxNumberOfTests": 10,
           "MaxParallelOfTests": 3
       },
       "EndpointConfigurations": [
           { 
               "InstanceType": "ml.c5.xlarge"
           },
           { 
               "InstanceType": "ml.m5.xlarge"
           },
           { 'InstanceType': 'ml.r5.xlarge' 
           }
       ]
   }"
   --stopping-conditions "{
       "MaxInvocations": 1000,
       "ModelLatencyThresholds": [ 
           { 
               "Percentile": "P95",
               "ValueInMilliseconds": 100
           }
       ]
   }"
```

Amazon SageMaker Studio

Create a load test with Studio.

1. In the left sidebar of Studio, choose the Components and registries icon.
2. Select Inference Recommender Jobs from the dropdown list. A new tab titled Create inference recommender job opens in the right pane.
3. Select the name of your model group from the dropdown Model group field. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio.
4. Select a model version from the dropdown Model version field.
5. Choose Continue.
6. Provide a name for the job in the Name field.
7. (Optional) Provide a description of your job in the Description field.

8. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the AmazonSageMakerFullAccess IAM managed policy to accomplish this, or you can let Studio create a role for you.

9. Choose Stopping Conditions to expand the available input fields. Provide a set of conditions for stopping a deployment recommendation.
   a. Specify the maximum number of requests per minute expected for the endpoint in the Max Invocations Per Minute field.
   b. Specify the model latency threshold in microseconds in the Model Latency Threshold field. The Model Latency Threshold depicts the interval of time taken by a model to respond as viewed from Inference Recommender. The interval includes the local communication time taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

10. Choose Traffic Pattern to expand the available input fields.
    a. Set the initial number of virtual users by specifying an integer in the Initial Number of Users field.
    b. Provide an integer number for the Spawn Rate field. The spawn rate sets the number of users created per second.
    c. Set the duration for the phase in seconds by specifying an integer in the Duration field.
    d. (Optional) Add additional traffic patterns. To do so, choose Add.

11. Choose the Additional setting to reveal the Max test duration field. Specify, in seconds, the maximum time a test can take during a job. New jobs are not scheduled after the defined duration. This helps ensure jobs that are in progress are not stopped and that you only view completed jobs.

12. Choose Continue.

13. Choose Selected Instances.

14. In the Instances for benchmarking field, choose Add instances to test. Select up to 10 instances for Inference Recommender to use for load testing.

15. Choose Additional settings.
    a. Provide an integer that sets an upper limit on the number of tests a job can make for the Max number of tests field. Note that each endpoint configuration results in a new load test.
    b. Provide an integer for the Max parallel test field. This setting defines an upper limit on the number of load tests that can run in parallel.

16. Choose Submit.

   The load test can take up to 2 hours.

   Warning
   Do not close this tab. If you close this tab, you cancel the Inference Recommender load test job.

Get Your Load Test Results

You can collect metrics across all load tests once the load tests are done programatically with AWS SDK for Python (Boto3), the AWS CLI, or Studio.

AWS SDK for Python (Boto3)

Collect metrics with the DescribeInferenceRecommendationsJob API. Specify the job name of the load test for the JobName field:
load_test_response = sagemaker_client.describe_inference_recommendations_job(
    JobName=load_test_job_name
)

Print the response object.

load_test_response['Status']

This returns a JSON response similar to the following:

```json
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 399000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES'
        },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
            'MaxParallelOfTests': 100
        },
        'EndpointConfigurations': [{
            'InstanceType': 'ml.c5d.xlarge'
        }]
    },
    'StoppingConditions': {
        'MaxInvocations': 1000,
        'ModelLatencyThresholds': [{
            'Percentile': 'P95',
            'ValueInMilliseconds': 100
        }],
    'InferenceRecommendations': [{
        'Metrics': {
            'CostPerHour': 0.6899999976158142,
            'CostPerInference': 1.0332434612791985e-05,
            'MaximumInvocations': 1113,
            'ModelLatency': 100000
        },
        'EndpointConfiguration': {
            'EndpointName': 'endpoint-name',
            'VariantName': 'variant-name',
            'InstanceType': 'ml.c5d.xlarge',
            'InitialInstanceCount': 3
        },
        'ModelConfiguration': {
            'Compiled': False,
            'EnvironmentParameters': []
        }
    }],
    'ResponseMetadata': {
        'RequestId': 'request-id',
        'HTTPStatusCode': 200
    }
}
```
The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The InferenceRecommendations dictionary contains a list of Inference Recommender instance recommendations.

The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498) for more information.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) for your real-time endpoint, the maximum number of InvokeEndpoint requests sent to the endpoint, and the model latency (ModelLatency), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

AWS CLI

Collect metrics with the describe-inference-recommendations-job API. Specify the job name of the load test for the job-name flag:

```
aws sagemaker describe-inference-recommendations-job --job-name <job-name>
```

This returns a response similar to the following:

```
{
    'JobName': '<job-name>',
    'JobDescription': '<job-description>',
    'JobType': 'Advanced',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 399000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES'
        },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
            'MaxParallelOfTests': 100
        },
        'EndpointConfigurations': [{
            'InstanceType': 'ml.c5d.xlarge'
        }],
    }
}
```
The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender instance recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498) for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) for your real-time endpoint, the maximum number of `InvokeEndpoint` requests sent to the endpoint, and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

Amazon SageMaker Studio

The recommendations populate in a new tab called `Inference recommendations` within Studio. It can take up to 2 hours for the results to show up. This tab contains `Results` and `Details` columns.
The **Details** column provides information about the load test job, such as the name given to the load test job, when the job was created (**Creation time**), and more. It also contains **Settings** information, such as the maximum number of invocation that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides **Deployment goals** and **SageMaker recommendations** windows in which you can adjust the order in which results are displayed based on deployment importance. There are three dropdown menus in which you can provide the level of importance of the **Cost**, **Latency**, and **Throughput** for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: **Lowest Importance**, **Low Importance**, **Moderate importance**, **High importance**, or **Highest importance**.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances.

In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the **All runs** section.

### Stop Your Load Test

Stop your load test jobs programmatically with the `StopInferenceRecommendationsJob` API or with Studio.

**AWS SDK for Python (Boto3)**

Specify the job name of the load test for the `JobName` field:

```python
sagemaker_client.stop_inference_recommendations_job(
    JobName='<INSERT>'
)
```

**AWS CLI**

Specify the job name of the load test for the `--job-name` flag:

```
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

**Amazon SageMaker Studio**

Close the tab where you initiated your custom load job to stop your Inference Recommender load test.

### Real-time inference

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. You can deploy your model to SageMaker hosting services and get an endpoint that can be used for inference. These endpoints are fully managed and support autoscaling (see [Automatically Scale Amazon SageMaker Models](p. 2688)).

**Topics**

- Hosting options (p. 2642)
Hosting options

The following topics describe available SageMaker realtime hosting options along with how to set up, invoke, and delete each hosting option.

Topics

- Host a single model (p. 2642)
- Host multiple models in one container behind one endpoint (p. 2652)
- Host multiple models which use different containers behind one endpoint (p. 2667)
- Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2674)

Host a single model

Create, update, and delete real-time inference endpoints that host a single model with the AWS SDK for Python (Boto3), the SageMaker Python SDK, the SageMaker console, or the AWS CLI.

Topics

- Create your endpoint and deploy your model (p. 2642)
- Delete Endpoints and Resources (p. 2648)

Create your endpoint and deploy your model

There are several options to deploy a model using SageMaker hosting services. You can programmatically deploy a model using an AWS SDK (for example, the SDK for Python (Boto3)), the SageMaker Python SDK, the AWS CLI, or you can interactively deploy a model with the SageMaker console. The AWS SDK is a low-level API and supports Java, C++, Go, JavaScript, Node.js, PHP, Ruby, and Python whereas the SageMaker Python SDK is a high-level Python API. The following documentation demonstrates how to deploy a model using the AWS SDK for Python (Boto3) and the SageMaker Python SDK.

Deploying a model using SageMaker hosting services is a three-step process if you use AWS SDK for Python (Boto3), the AWS CLI, or the SageMaker console:

2. Create an endpoint configuration for an HTTPS endpoint.
3. Create an HTTPS endpoint.

Deploying a model using the SageMaker Python SDK does not require that you create an endpoint configuration. It is therefore a two-step process:

1. Create a model object from the `Model` Class that can be deployed to an HTTPS endpoint.
2. Create an HTTPS endpoint with the Model object’s pre-built `deploy()` method.

To use the proceeding code snippets, replace the italicized placeholder text in the example code with your own information.

**Note**

- SageMaker supports running (a) multiple models, (b) multiple variants of a model, or (c) combinations of models and variants on the same endpoint. Model variants can reference the same model inference container (i.e. run the same algorithm), but use different model artifacts (e.g., different model weight values based on other hyper-parameter configurations). In contrast, two different models may use the same algorithm, but focus on different business problems or underlying goals and may operate on different data sets.

- When you create an endpoint, SageMaker attaches an Amazon EBS storage volume to each ML compute instance that hosts the endpoint. The size of the storage volume depends on the instance type. For a list of instance types that SageMaker hosting service supports, see AWS Service Limits. For a list of the sizes of the storage volumes that SageMaker attaches to each instance, see Host instance storage volumes (p. 2703).

- Endpoints are scoped to an individual AWS account, and are not public. The URL does not contain the account ID, but SageMaker determines the account ID from the authentication token that is supplied by the caller.

For an example of how to use Amazon API Gateway and AWS Lambda to set up and deploy a web service that you can call from a client application that is not within the scope of your account, see Call a SageMaker model endpoint using Amazon API Gateway and AWS Lambda in the AWS Machine Learning Blog.

Before you begin

Before you create and deploy a SageMaker model, locate and make note of the:

- AWS region where your Amazon S3 bucket is located
- Amazon S3 URI path where the model artifacts are stored
- IAM role for SageMaker
- Docker Amazon ECR URI registry path for the custom image that contains the inference code, or the framework and version of a built-in Docker image that is supported and by AWS.

For a list of AWS Services available in each AWS Region, see Region Maps and Edge Networks. See Creating IAM roles for information on how to create an IAM role.

**Important**

The Amazon S3 bucket where the model artifacts are stored must be in the same region as the model that you are creating.

The following demonstrates how to define the aforementioned parameters programmatically.

AWS SDK for Python (Boto3)

Import `boto3`. Define your AWS region. Next, initialize a low-level SageMaker service client object using the `Client` class. This will make it easy to send and receive requests to AWS services. In addition, define the AWS role that gives SageMaker permission to access AWS services on your behalf:

```python
import boto3
```
The first few lines define:

- `sagemaker_client`: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.

Import the `image_uris` module from the SageMaker Python SDK. Use the `retrieve()` function to retrieve the Amazon ECR URI for the Docker image matching the given arguments. Provide both the name of the framework or algorithm (`framework` field) along with the version of the framework or algorithm (`version` field). For a list of built-in Docker images provided by AWS, see Available Deep Learning Containers Images. For more information on how to bring your own image, see Use Your Own Inference Code (p. 3037).

Next, provide the Amazon S3 URI of the pre-trained model. This model will be used to create a SageMaker Python SDK `Model` object in the next step. In this example, the full Amazon S3 URI is stored in a string variable `model_url`:
SageMaker Python SDK

Define your AWS region. In addition, define the AWS role that gives SageMaker permission to access AWS services on your behalf:

```python
# Specify your AWS Region
aws_region='<aws_region>'

# Role to give SageMaker permission to access AWS services.
sagemaker_role= "arn:aws:iam::<region>::<account>::role/*"'
```

The first few lines define:
- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.

Import the `image_uris` module from the SageMaker Python SDK. Use the `retrieve()` function to retrieve the Amazon ECR URI for the Docker image matching the given arguments. Provide both the name of the framework or algorithm (`framework` field) along with the version of the framework or algorithm (`version` field). For a list of built-in Docker images provided by AWS, see Available Deep Learning Containers Images. For more information on how to bring your own image, see Use Your Own Inference Code (p. 3037).

```python
from sagemaker import image_uris

# Name of the framework or algorithm
framework='<framework>'
#framework='xgboost' # Example

# Version of the framework or algorithm
version = '<version-number>'
#version = '0.90-1' # Example

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region,
                                 framework=framework,
                                 version=version)
```

Next, provide the Amazon S3 URI of the pre-trained model. This model will be used to create a SageMaker Python SDK `Model.model` object in the next step. In this example, the full Amazon S3 URI is stored in a string variable `model_url`:

```python
# Create a variable w/ the model S3 URI
# First, provide the name of your S3 bucket
s3_bucket = '<your-bucket-name>'

# Specify what directory within your S3 bucket your model is stored in
bucket_prefix = '<directory-name>'

# Replace with the name of your model artifact
model_filename = '<model-name>.tar.gz'

# Relative S3 path
model_s3_key = f'{bucket_prefix}/{model_filename}

# Combine bucket name, model file name, and relate S3 path to create S3 model URI
model_url = f's3://{s3_bucket}/{model_s3_key}'
```
Create a Model

By creating a model, you tell SageMaker where it can find the model components.

AWS SDK for Python (Boto3)

Create a model in SageMaker with CreateModel. Specify the following:

- **ModelName**: A name for your model (in this example it is stored as a string variable called `model_name`).
- **ExecutionRoleArn**: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- **PrimaryContainer**: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

For the primary container, specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

```python
model_name = '<The_name_of_the_model>'

# Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    })
```

See [CreateModel](https://docs.aws.amazon.com/sagemaker/latest/dg/API_CreateModel.html) description in the SageMaker API Reference Guide for a full list of API parameters.

SageMaker Python SDK

Create a model object from the SageMaker Python SDK [Model](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#Model) Class. You will use this object to deploy your model to an endpoint in a later step.

```python
from sagemaker.model import Model

model = Model(image_uri=container,
               model_data=model_url,
               role=sagemaker_role)
```

Create an Endpoint Configuration

Create an endpoint configuration for an HTTPS endpoint. Specify the name of one or more models in production (variants) and the ML compute instances that you want SageMaker to launch to host each production variant.

**Note**
Skip this section if you are exclusively using the SageMaker Python SDK.

When hosting models in production, you can configure the endpoint to elastically scale the deployed ML compute instances. For each production variant, you specify the number of ML compute instances that you want to deploy. When you specify two or more instances, SageMaker launches them in multiple Availability Zones. This ensures continuous availability. SageMaker manages deploying the instances.
AWS SDK for Python (Boto3)

Create an endpoint configuration with `CreateEndpointConfig`. Amazon SageMaker hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using with `CreateModel`, to deploy the resources that you want Amazon SageMaker to provision.

The following example shows how to create an endpoint configuration using AWS SDK for Python (Boto3):

```python
import datetime
from time import gmtime, strftime

# Create an endpoint config name. Here we create one based on the date
# so it we can search endpoints based on creation time.
endpoint_config_name = '<endpoint-config-name>'

# The name of the model that you want to host. This is the name that you specified when creating the model.
model_name = '<The_name_of_your_model>'

instance_type = '<instance-type>'
# instance_type='ml.m5.xlarge' # Example

endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name, # You will specify this name in a CreateEndpoint request.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": instance_type, # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ]
)

print(f"Created EndpointConfig: {endpoint_config_response['EndpointConfigArn']}")
```

In the aforementioned example, you specify the following keys for the `ProductionVariants` field:

- **VariantName**: The name of the production variant.
- **ModelName**: The name of the model that you want to host. This is the name that you specified when creating the model.
- **InstanceType**: The compute instance type. See the `InstanceType` field in [https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html](https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html) and [SageMaker Pricing](https://aws.amazon.com/sagemaker/pricing) for a list of supported compute instance types and pricing for each instance type.

SageMaker Python SDK

You do not need to define an endpoint configuration for real-time endpoints if you use the SageMaker Python SDK `Model` Class.

**Deploy your model**

Deploy your model and create an HTTPS endpoint.
AWS SDK for Python (Boto3)

Provide the endpoint configuration to SageMaker. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the `CreateEndpoint` API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name = '<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
```

For more information, see the `CreateEndpoint` API.

SageMaker Python SDK

Define a name for your endpoint. This step is optional. If you do not provide one, SageMaker will create a unique name for you:

```python
from datetime import datetime

endpoint_name = f"DEMO-{datetime.utcnow():%Y-%m-%d-%H%M}"  # Example
print("EndpointName =", endpoint_name)
```

Deploy your model to a real-time, HTTPS endpoint with the Model object's built-in `deploy()` method. Provide the name of the Amazon EC2 instance type to deploy this model to in the `instance_type` field along with the initial number of instances to run the endpoint on for the `initial_instance_count` field:

```python
initial_instance_count=<integer>  # Example
instance_type='<instance-type>'
model.deploy(
    initial_instance_count=initial_instance_count,
    instance_type=instance_type,
    endpoint_name=endpoint_name
)
```

Delete Endpoints and Resources

Delete endpoints to stop incurring charges.

Delete Endpoint

Delete your endpoint programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console.
Amazon SageMaker Developer Guide
Hosting options

SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting an endpoint will not delete the endpoint configuration or the SageMaker model. See Delete Endpoint Configuration (p. 2649) and Delete Model (p. 2651) for information on how to delete your endpoint configuration and SageMaker model.

AWS SDK for Python (Boto3)

Use the `DeleteEndpoint` API to delete your endpoint. Specify the name of your endpoint for the `EndpointName` field.

```python
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint
sagemaker_client.delete_endpoint(EndpointName=endpoint_name)
```

AWS CLI

Use the `delete-endpoint` command to delete your endpoint. Specify the name of your endpoint for the `endpoint-name` flag.

```
aws sagemaker delete-endpoint --endpoint-name <endpoint-name>
```

SageMaker Console

Delete your endpoint interactively with the SageMaker console.

2. Choose Endpoints from the drop down menu. A list of endpoints created in you AWS account will appear by name, Amazon Resource Name (ARN), creation time, status, and a time stamp of when the endpoint was last updated.
3. Select the endpoint you want to delete.
4. Select the Actions dropdown button in the top right corner.
5. Choose Delete.

Delete Endpoint Configuration

Delete your endpoint configuration programmaticially using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console. Deleting an endpoint configuration does not delete endpoints created using this configuration. See Delete Endpoint (p. 2648) for information on how to delete your endpoint.

Do not delete an endpoint configuration in use by an endpoint that is live or while the endpoint is being updated or created. You might lose visibility into the instance type the endpoint is using if you delete the endpoint configuration of an endpoint that is active or being created or updated.

AWS SDK for Python (Boto3)

Use the `DeleteEndpointConfig` API to delete your endpoint. Specify the name of your endpoint configuration for the `EndpointConfigName` field.
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint configuration
endpoint_config_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)

You can optionally use the DescribeEndpointConfig API to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the EndpointConfigName field.

# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the next step.
response = sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
endpoint_config_name = response['ProductionVariants'][0]['EndpointConfigName']

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)

For more information about other response elements returned by DescribeEndpointConfig, see DescribeEndpointConfig in the SageMaker API Reference guide.

AWS CLI

Use the delete-endpoint-config command to delete your endpoint configuration. Specify the name of your endpoint configuration for the endpoint-config-name flag.

```
aws sagemaker delete-endpoint-config \
    --endpoint-config-name <endpoint-config-name>
```

You can optionally use the describe-endpoint-config command to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the endpoint-config-name flag.

```
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the endpoint configuration name associated with that endpoint.
**SageMaker Console**

Delete your endpoint configuration interactively with the SageMaker console.

1. In the SageMaker console at https://console.aws.amazon.com/sagemaker/ navigation menu, choose **Inference**.
2. Choose **Endpoint configurations** from the dropdown menu. A list of endpoint configurations created in your AWS account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the endpoint configuration you want to delete.
4. Select the **Actions** dropdown button in the top right corner.
5. Choose **Delete**.

**Delete Model**

Delete your SageMaker model programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console. Deleting a SageMaker model only deletes the model entry that was created in SageMaker. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

**AWS SDK for Python (Boto3)**

Use the **DeleteModel** API to delete your SageMaker model. Specify the name of your model for the **ModelName** field.

```python
import boto3

# Specify your AWS Region
aws_region= '<aws_region>'

# Specify the name of your endpoint configuration
model_name= '<model_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete model
sagemaker_client.delete_model(ModelName=model_name)
```

You can optionally use the **DescribeEndpointConfig** API to return information about the name of the deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the **EndpointConfigName** field.

```python
# Specify the name of your endpoint
endpoint_name= '<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the next
# step.
response = sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
model_name = response['ProductionVariants'][0]['ModelName']
sagemaker_client.delete_model(ModelName=model_name)
```
For more information about other response elements returned by DescribeEndpointConfig, see DescribeEndpointConfig in the SageMaker API Reference guide.

AWS CLI

Use the delete-model command to delete your SageMaker model. Specify the name of your model for the model-name flag.

```
aws sagemaker delete-model \
  --model-name <model-name>
```

You can optionally use the describe-endpoint-config command to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the endpoint-config-name flag.

```
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the name of the model associated with that endpoint.

SageMaker Console

Delete your SageMaker model interactively with the SageMaker console.

2. Choose Models from the dropdown menu. A list of models created in you AWS account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the model you want to delete.
4. Select the Actions dropdown button in the top right corner.
5. Choose Delete.

Host multiple models in one container behind one endpoint

To create an endpoint that can host multiple models, use multi-model endpoints. Multi-model endpoints provide a scalable and cost-effective solution to deploying large numbers of models. They use a shared serving container that is enabled to host multiple models. This reduces hosting costs by improving endpoint utilization compared with using single-model endpoints. It also reduces deployment overhead because Amazon SageMaker manages loading models in memory and scaling them based on the traffic patterns to them.

Multi-model endpoints also enable time-sharing of memory resources across your models. This works best when the models are fairly similar in size and invocation latency. When this is the case, multi-model endpoints can effectively use instances across all models. If you have models that have significantly higher transactions per second (TPS) or latency requirements, we recommend hosting them on dedicated endpoints. Multi-model endpoints are also well suited to scenarios that can tolerate occasional cold-start-related latency penalties that occur when invoking infrequently used models.

Multi-model endpoints support A/B testing. They work with Auto Scaling and AWS PrivateLink. You can use multi-model-enabled containers with serial inference pipelines, but only one multi-model-enabled container can be included in an inference pipeline. You can't use multi-model-enabled containers with Amazon Elastic Inference.

You can use the AWS SDK for Python (Boto) or the SageMaker console to create a multi-model endpoint. You can use multi-model endpoints with custom-built containers by integrating the Multi Model Server library.

Supported Algorithms and Frameworks

The inference containers for the following algorithms and frameworks support multi-model endpoints:

• XGBoost Algorithm (p. 1990)
• K-Nearest Neighbors (k-NN) Algorithm (p. 1948)
• Linear Learner Algorithm (p. 1966)
• Random Cut Forest (RCF) Algorithm (p. 2104)
• Use TensorFlow with Amazon SageMaker (p. 30)
• Use Scikit-learn with Amazon SageMaker (p. 29)
• Use Apache MXNet with Amazon SageMaker (p. 14)
• Use PyTorch with Amazon SageMaker (p. 26)

To use any other framework or algorithm, use the SageMaker inference toolkit to build a container that supports multi-model endpoints. For information, see Build Your Own Container with Multi Model Server (p. 2661).

Sample Notebooks for Multi-Model Endpoints

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see the Multi-Model Endpoint XGBoost Sample Notebook. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the Multi-Model Endpoint BYOC Sample Notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you've created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. The Multi-Model Endpoint notebook is located in the ADVANCED FUNCTIONALITY section. To open a notebook, choose its Use tab and choose Create copy.

How Multi-Model Endpoints Work

SageMaker manages the lifecycle of models hosted on multi-model endpoints in the container’s memory. Instead of downloading all of the models from an Amazon S3 bucket to the container when you create the endpoint, SageMaker dynamically loads them when you invoke them. When SageMaker receives an invocation request for a particular model, it does the following:

1. Routes the request to an instance behind the endpoint.
2. Downloads the model from the S3 bucket to that instance's storage volume.
3. Loads the model to the container's memory on that instance. If the model is already loaded in the container's memory, invocation is faster because SageMaker doesn't need to download and load it.

SageMaker continues to route requests for a model to the instance where the model is already loaded. However, if the model receives many invocation requests, and there are additional instances for the multi-model endpoint, SageMaker routes some requests to another instance to accommodate the traffic. If the model isn't already loaded on the second instance, the model is downloaded to that instance's storage volume and loaded into the container's memory.

When an instance's memory utilization is high and SageMaker needs to load another model into memory, it unloads unused models from that instance's container to ensure that there is enough memory to load the model. Models that are unloaded remain on the instance's storage volume and can be loaded into the container's memory later without being downloaded again from the S3 bucket. If the instance's storage volume reaches its capacity, SageMaker deletes any unused models from the storage volume.

To delete a model, stop sending requests and delete it from the S3 bucket. SageMaker provides multi-model endpoint capability in a serving container. Adding models to, and deleting them from, a multi-model endpoint doesn't require updating the endpoint itself. To add a model, you upload it to the S3 bucket and invoke it. You don't need code changes to use it.

When you update a multi-model endpoint, invocation requests on the endpoint might experience higher latencies as traffic is directed to the instances in the updated endpoint.

**Setting SageMaker Multi-Model Endpoint Model Caching Behavior**

By default, multi-model endpoints cache frequently used models in memory and on disk to provide low latency inference. The cached models are unloaded and/or deleted from disk only when a container runs out of memory or disk space to accommodate a newly targeted model.

You can change the caching behavior of a multi-model endpoint and explicitly enable or disable model caching by setting the parameter `ModelCacheSetting` when you call `create_model`.

We recommend setting the value of the `ModelCacheSetting` parameter to `Disabled` for use cases that do not benefit from model caching. For example, when a large number of models need to be served from the endpoint but each model is invoked only once (or very infrequently). For such use cases, setting the value of the `ModelCacheSetting` parameter to `Disabled` allows higher transactions per second (TPS) for `invoke_endpoint` requests compared to the default caching mode. Higher TPS in these use cases is because SageMaker does the following after the `invoke_endpoint` request:

- Asynchronously unloads the model from memory and deletes it from disk immediately after it is invoked.
- Provides higher concurrency for downloading and loading models in the inference container. The concurrency is a factor of the number of vCPUs of the container instance.

For guidelines on choosing a SageMaker ML instance type for a multi-model endpoint, see Instance Recommendations for Multi-Model Endpoint Deployments (p. 2654).

**Instance Recommendations for Multi-Model Endpoint Deployments**

There are several items to consider when selecting a SageMaker ML instance type for a multi-model endpoint. Provision sufficient Amazon Elastic Block Store (Amazon EBS) capacity for all of the models that need to be served. Balance performance (minimize cold starts) and cost (don't over-provision instance capacity). For information about the size of the storage volume that SageMaker attaches for each instance type for an endpoint and for a multi-model endpoint, see Host instance storage volumes (p. 2703). For a container configured to run in **MultiModel** mode, the storage volume
provisioned for its instances has more memory. This allows more models to be cached on the instance storage volume.

When choosing a SageMaker ML instance type, consider the following:

- Multi-model endpoints are not supported on GPU instance types.
- The traffic distribution (access patterns) to the models that you want to host behind the multi-model endpoint, along with the model size (how many models could be loaded in memory on the instance);
- Think of the amount of memory on an instance as the cache space for models to be loaded. Think of the number of vCPUs as the concurrency limit to perform inference on the loaded models (assuming that invoking a model is bound to CPU).
- A higher amount of instance memory enables you to have more models loaded and ready to serve inference requests. You don’t need to waste time loading the model.
- A higher amount of vCPUs enables you to invoke more unique models concurrently (again assuming that inference is bound to CPU).
- Have some “slack” memory available so that unused models can be unloaded, and especially for multi-model endpoints with multiple instances. If an instance or an Availability Zone fails, the models on those instances will be rerouted to other instances behind the endpoint.
- Tolerance to loading/downloading times:
  - d instance type families (for example, m5d, c5d, or r5d) come with an NVMe (non-volatile memory express) SSD, which offers high I/O performance and might reduce the time it takes to download models to the storage volume and for the container to load the model from the storage volume.
  - Because d instance types come with an NVMe SSD storage, SageMaker does not attach an Amazon EBS storage volume to these ML compute instances that hosts the multi-model endpoint. Auto scaling works best when the models are similarly sized and homogenous, that is when they have similar inference latency and resource requirements.

In some cases, you might opt to reduce costs by choosing an instance type that can't hold all of the targeted models in memory at once. SageMaker dynamically unloads models when it runs out of memory to make room for a newly targeted model. For infrequently requested models, you are going to pay a price with the dynamic load latency. In cases with more stringent latency needs, you might opt for larger instance types or more instances. Investing time up front for proper performance testing and analysis will pay great dividends in successful production deployments.

You can use the Average statistic of the ModelCacheHit metric to monitor the ratio of requests where the model is already loaded. You can use the SampleCount statistic for the ModelUnloadingTime metric to monitor the number of unload requests sent to the container during a time period. If models are unloaded too frequently (an indicator of thrashing, where models are being unloaded and loaded again because there is insufficient cache space for the working set of models), consider using a larger instance type with more memory or increasing the number of instances behind the multi-model endpoint. For multi-model endpoints with multiple instances, be aware that a model might be loaded on more than 1 instance.

SageMaker multi-model endpoints fully supports Auto Scaling, which manages replicas of models to ensure models scale based on traffic patterns. We recommend that you configure your multi-model endpoint and the size of your instances by considering all of the above and also set up auto scaling for your endpoint. The invocation rates used to trigger an auto-scale event is based on the aggregate set of predictions across the full set of models served by the endpoint.

Create a Multi-Model Endpoint

You can use AWS SDK for Python (Boto) or Amazon SageMaker to create a multi-model endpoint.

Topics

- Create a Multi-Model Endpoint (Console) (p. 2656)
- Create a Multi-Model Endpoint AWS SDK for Python (Boto3) (p. 2658)

Create a Multi-Model Endpoint (Console)

To create a multi-model endpoint (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Model, and then from the Inference group, choose Create model.
3. For Model name, enter a name.
4. For IAM role, choose or create an IAM role that has the AmazonSageMakerFullAccess IAM policy attached.
5. In the Container definition section, for Provide model artifacts and inference image options choose Use multiple models.
Create model

To deploy a model to Amazon SageMaker, first create the model by providing the location of the inference code. See Deploying a Model on Amazon SageMaker Hosting Services [Learn More]

Model settings

Model name

mml-test-model

Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique in your account in an AWS Region.

IAM role

Amazon SageMaker requires permissions to call other services on your behalf. Choose a role or let SageMaker create a role that has the AmazonSageMakerFullAccess IAM policy attached.

AmazonSageMaker-ExecutionRole- XXXXXXXXXXXXXXXXXXX

Container definition 1

Container input options

Provide model artifacts and inference image location

Provide model artifacts and inference image options

Use a single model

Use this to host a single model in this container.

Use multiple models

Use this to host multiple models in this container.

Location of inference code image

Type the registry path where the inference code image is stored in Amazon ECR.

123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage:mytag

Location of model artifacts

Type the URL where model artifacts are stored in S3.

s3://my-bucket/path/to/artifacts/
Choose **Create model**.

7. Deploy your multi-model endpoint as you would a single model endpoint. For instructions, see *Deploy the Model to SageMaker Hosting Services (p. 84)*.

### Create a Multi-Model Endpoint AWS SDK for Python (Boto3)

You create a multi-model endpoint using the Amazon SageMaker `create_model`, `create_endpoint_config`, and `create_endpoint` APIs just as you would create a single model endpoint, but with two changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model.

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see *Multi-Model Endpoint XGBoost Sample Notebook*.

The following procedure outlines the key steps used in that sample to create a multi-model endpoint.

**To deploy the model (AWS SDK for Python (Boto 3))**

1. Get a container with an image that supports deploying multi-model endpoints. For a list of built-in algorithms and framework containers that support multi-model endpoints, see *Supported Algorithms and Frameworks (p. 2653)*. For this example, we use the K-Nearest Neighbors (k-NN) Algorithm built-in algorithm. We call the SageMaker Python SDK utility function `image_uris.retrieve()` to get the address for the K-Nearest Neighbors built-in algorithm image.

   ```python
   import sagemaker
   region = sagemaker_session.boto_region_name
   image = sagemaker.image_uris.retrieve("knn", region=region)
   container = {
       'Image':        image,  
       'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',  
       'Mode':         'MultiModel'
    }
   ```

2. Get a Boto 3 SageMaker client and create the model that uses this container.

   ```python
   import boto3
   sagemaker_client = boto3.client('sagemaker')
   response = sagemaker_client.create_model(
       ModelName        = '<MODEL_NAME>',  
       ExecutionRoleArn = role,  
       Containers       = [container])
   ```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of `CreateModel`:

   ```python
   preprocessor_container = {
       'Image':  
       '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>:<TAG>'
    }
   
   multi_model_container = {
       'Image':  
       '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',  
       'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',  
       'Mode':         'MultiModel'
    }
   ```
response = sagemaker_client.create_model(
    ModelName = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers = [preprocessor_container, multi_model_container]
)

4. (Optional) If your use case does not benefit from model caching, set the value of the ModelCacheSetting field of the MultiModelConfig parameter to Disabled, and include it in the Container argument of the call to create_model. The value of the ModelCacheSetting field is Enabled by default.

    container = {
        'Image': image,
        'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
        'Mode': 'MultiModel'
        'MultiModelConfig': {
            // Default value is 'Enabled'
            'ModelCacheSetting': 'Disabled'
        }
    }

    response = sagemaker_client.create_model(
        ModelName = '<MODEL_NAME>',
        ExecutionRoleArn = role,
        Containers = [container]
    )

5. Configure the multi-model endpoint for the model. We recommend configuring your endpoints with at least two instances. This allows SageMaker to provide a highly available set of predictions across multiple Availability Zones for the models.

    response = sagemaker_client.create_endpoint_config(
        EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
        ProductionVariants=[
            {
                'InstanceType': 'ml.m4.xlarge',
                'InitialInstanceCount': 2,
                'InitialVariantWeight': 1,
                'ModelName': '<MODEL_NAME>',
                'VariantName': 'AllTraffic'
            }
        ]
    )

**Note**
You can use only one multi-model-enabled endpoint in a serial inference pipeline.

6. Create the multi-model endpoint using the EndpointName and EndpointConfigName parameters.

    response = sagemaker_client.create_endpoint(
        EndpointName = '<ENDPOINT_NAME>',
        EndpointConfigName = '<ENDPOINT_CONFIG_NAME>'
    )

**Invoke a Multi-Model Endpoint**

To invoke a multi-model endpoint, use the `invoke_endpoint` from the SageMaker Runtime just as you would invoke a single model endpoint, with one change. Pass a new TargetModel parameter that specifies which of the models at the endpoint to target. The SageMaker Runtime `InvokeEndpoint` request supports X-Amzn-SageMaker-Target-Model as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by
combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

AWS SDK for Python (Boto 3)

The following example prediction request uses the AWS SDK for Python (Boto 3) in the sample notebook.

```python
response = runtime_sagemaker_client.invoke_endpoint(
    EndpointName = "<ENDPOINT_NAME>",
    ContentType  = "text/csv",
    TargetModel  = "<MODEL_FILENAME>.tar.gz",
    Body         = body)
```

AWS CLI

The following example shows how to make a CSV request with two rows using the AWS Command Line Interface (AWS CLI):

```bash
aws sagemaker-runtime invoke-endpoint \
 --endpoint-name "<ENDPOINT_NAME>" \
 --body "1.0,2.0,5.0"$'
'n"2.0,3.0,4.0" \
 --content-type "text/csv" \
 --target-model "<MODEL_NAME>.tar.gz" \
 output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful. For more examples on how to make predictions with the AWS CLI, see Making predictions with the AWS CLI in the SageMaker Python SDK documentation.

The multi-model endpoint dynamically loads target models as needed. You can observe this when running the MME Sample Notebook as it iterates through random invocations against multiple target models hosted behind a single endpoint. The first request against a given model takes longer because the model has to be downloaded from Amazon Simple Storage Service (Amazon S3) and loaded into memory. (This is called a cold start.) Subsequent calls finish faster because there’s no additional overhead after the model has loaded.

**Retry Requests on ModelNotReadyException Errors**

The first time you call `invoke_endpoint` for a model, the model is downloaded from Amazon Simple Storage Service and loaded into the inference container. This makes the first call take longer to return. Subsequent calls to the same model finish faster, because the model is already loaded.

SageMaker returns a response for a call to `invoke_endpoint` within 60 seconds. Some models are too large to download within 60 seconds. If the model does not finish loading before the 60 second timeout limit, the request to `invoke_endpoint` returns with the error code `ModelNotReadyException`, and the model continues to download and load into the inference container for up to 360 seconds. If you get a `ModelNotReadyException` error code for an `invoke_endpoint` request, retry the request. By default, the AWS SDKs for Python (Boto 3) (using `Legacy retry mode`) and Java retry `invoke_endpoint` requests that result in `ModelNotReadyException` errors. You can configure the retry strategy to continue retrying the request for up to 360 seconds. If you expect your model to take longer than 60 seconds to download and load into the container, set the SDK socket timeout to 70 seconds. For more information about configuring the retry strategy for Boto 3, see Configuring a retry mode. The following code shows an example that configures the retry strategy to retry calls to `invoke_endpoint` for up to 180 seconds.

```python
import boto3
from botocore.config import Config
```
Add or Remove Models

You can deploy additional models to a multi-model endpoint and invoke them through that endpoint immediately. When adding a new model, you don't need to update or bring down the endpoint, so you avoid the cost of creating and running a separate endpoint for each new model.

SageMaker unloads unused models from the container when the instance is reaching memory capacity and more models need to be downloaded into the container. SageMaker also deletes unused model artifacts from the instance storage volume when the volume is reaching capacity and new models need to be downloaded. The first invocation to a newly added model takes longer because the endpoint takes time to download the model from S3 to the container's memory in instance hosting the endpoint.

With the endpoint already running, copy a new set of model artifacts to the Amazon S3 location where you store your models.

```python
# Add an AdditionalModel to the endpoint and exercise it
aws s3 cp AdditionalModel.tar.gz s3://my-bucket/path/to/artifacts/
```

**Important**

To update a model, proceed as you would when adding a new model. Use a new and unique name. Don't overwrite model artifacts in Amazon S3 because the old version of the model might still be loaded in the containers or on the storage volume of the instances on the endpoint. Invocations to the new model could then invoke the old version of the model.

Client applications can request predictions from the additional target model as soon as it is stored in S3.

```python
response = runtime_sagemaker_client.invoke_endpoint(
    EndpointName='<ENDPOINT_NAME>',
    ContentType='text/csv',
    TargetModel='AdditionalModel.tar.gz',
    Body=body)
```

To delete a model from a multi-model endpoint, stop invoking the model from the clients and remove it from the S3 location where model artifacts are stored.

**Build Your Own Container with Multi Model Server**

Custom Elastic Container Registry (ECR) images deployed in Amazon SageMaker are expected to adhere to the basic contract described in Use Your Own Inference Code with Hosting Services (p. 3038) that govern how SageMaker interacts with a Docker container that runs your own inference code. For a container to be capable of loading and serving multiple models concurrently, there are additional APIs and behaviors that must be followed. This additional contract includes new APIs to load, list, get, and unload models, and a different API to invoke models. There are also different behaviors for error scenarios that the APIs need to abide by. To indicate that the container complies with the additional requirements, you can add the following command to your Docker file:

```bash
LABEL com.amazonaws.sagemaker.capabilities.multi-models=true
```
SageMaker also injects an environment variable into the container

```
SAGEMAKER_MULTI_MODEL=true
```

If you are creating a multi-model endpoint for a serial inference pipeline, your Docker file must have the required labels for both multi-models and serial inference pipelines. For more information about serial information pipelines, see Run Real-time Predictions with an Inference Pipeline (p. 2678).

To help you implement these requirements for a custom container, two libraries are available:

- **Multi Model Server** is an open source framework for serving machine learning models that can be installed in containers to provide the front end that fulfills the requirements for the new multi-model endpoint container APIs. It provides the HTTP front end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and performs inference on a specified loaded model. It also provides a pluggable backend that supports a pluggable custom backend handler where you can implement your own algorithm.

- **SageMaker Inference Toolkit** is a library that bootstraps Multi Model Server with a configuration and settings that make it compatible with SageMaker multi-model endpoints. It also allows you to tweak important performance parameters, such as the number of workers per model, depending on the needs of your scenario.

**Use the SageMaker Inference Toolkit**

Pre-built containers that support multi-model endpoints are listed in Supported Algorithms and Frameworks (p. 2653). If you want to use any other framework or algorithm, you need to build a container. The easiest way to do this is to use the SageMaker Inference Toolkit to extend an existing pre-built container. The SageMaker inference toolkit is an implementation for the multi-model server (MMS) that creates endpoints that can be deployed in SageMaker. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the Multi-Model Endpoint BYOC Sample Notebook.

**Note**

The SageMaker inference toolkit supports only Python model handlers. If you want to implement your handler in any other language, you must build your own container that implements the additional multi-model endpoint APIs. For information, see Contract for Custom Containers to Serve Multiple Models (p. 2664).

**To extend a container by using the SageMaker inference toolkit**

1. Create a model handler. MMS expects a model handler, which is a Python file that implements functions to pre-process, get predictions from the model, and process the output in a model handler. For an example of a model handler, see model_handler.py from the sample notebook.

2. Import the inference toolkit and use its `model_server.start_model_server` function to start MMS. The following example is from the dockerd-entrypoint.py file from the sample notebook. Notice that the call to `model_server.start_model_server` passes the model handler described in the previous step:

```python
import subprocess
import sys
import shlex
import os
from retrying import retry
from subprocess import CalledProcessError
from sagemaker_inference import model_server

def _retry_if_error(exception):
    return isinstance(exception, CalledProcessError or OSError)
```

---

2662
@retry(stop_max_delay=1000 * 50,
    retry_on_exception=_retry_if_error)
def _start_mms():
    # by default the number of workers per model is 1, but we can configure it through
    # the
    # environment variable below if desired.
    # os.environ[‘SAGEMAKER_MODEL_SERVER_WORKERS’] = ‘2’
    model_server.start_model_server(handler_service='/home/model-server/model_handler.py:handle')

def main():
    if sys.argv[1] == 'serve':
        _start_mms()
    else:
        subprocess.check_call(shlex.split(' '.join(sys.argv[1:])))
        # prevent docker exit
        subprocess.call(['tail', '-f', '/dev/null'])

main()

3. In your Dockerfile, copy the model handler from the first step and specify the Python file from
   the previous step as the entrypoint in your Dockerfile. The following lines are from the Dockerfile
   used in the sample notebook:

   # Copy the default custom service file to handle incoming data and inference requests
   COPY model_handler.py /home/model-server/model_handler.py

   # Define an entrypoint script for the docker image
   ENTRYPOINT ['python', '/usr/local/bin/dockerd-entrypoint.py']

4. Build and register your container. The following shell script from the sample notebook builds the
   container and uploads it to an Amazon Elastic Container Registry repository in your AWS account:

   # The name of our algorithm
   algorithm_name=demo-sagemaker-multimodel
   cd container
   account=$(aws sts get-caller-identity --query Account --output text)
   # Get the region defined in the current configuration (default to us-west-2 if none
   # defined)
   region=$(aws configure get region)
   region=${region:-us-west-2}
   fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"
   # If the repository doesn’t exist in ECR, create it.
   aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
   if [ $? -ne 0 ]
      then
      aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
   fi
   # Get the login command from ECR and execute it directly
   $(aws ecr get-login --region ${region} --no-include-email)
   # Build the docker image locally with the image name and then push it to ECR
   # with the full name.

2663
You can now use this container to deploy multi-model endpoints in SageMaker.

Topics
- Contract for Custom Containers to Serve Multiple Models (p. 2664)

Contract for Custom Containers to Serve Multiple Models

To handle multiple models, your container must support a set of APIs that enable Amazon SageMaker to communicate with the container for loading, listing, getting, and unloading models as required. The `model_name` is used in the new set of APIs as the key input parameter. The customer container is expected to keep track of the loaded models using `model_name` as the mapping key. Also, the `model_name` is an opaque identifier and is not necessarily the value of the `TargetModel` parameter passed into the `InvokeEndpoint` API. The original `TargetModel` value in the `InvokeEndpoint` request is passed to container in the APIs as a `X-Amzn-SageMaker-Target-Model` header that can be used for logging purposes.

Topics
- Load Model API (p. 2664)
- List Model API (p. 2664)
- Get Model API (p. 2665)
- Unload Model API (p. 2665)
- Invoke Model API (p. 2666)

Load Model API

Instructs the container to load a particular model present in the `url` field of the body into the memory of the customer container and to keep track of it with the assigned `model_name`. After a model is loaded, the container should be ready to serve inference requests using this `model_name`.

```json
POST /models HTTP/1.1
Content-Type: application/json
Accept: application/json

{
  "model_name" : "{model_name}",
  "url" : "/opt/ml/models/{model_name}/model",
}
```

**Note**

If `model_name` is already loaded, this API should return 409. Any time a model cannot be loaded due to lack of memory or to any other resource, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

List Model API

Returns the list of models loaded into the memory of the customer container.

```http
GET /models HTTP/1.1
Accept: application/json
```
Response =
{
    "models": [
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ....
    ]
}

This API also supports pagination.

GET /models HTTP/1.1
Accept: application/json
Response =
{
    "models": [
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ....
    ]
}

SageMaker can initially call the List Models API without providing a value for next_page_token. If a nextPageToken field is returned as part of the response, it will be provided as the value for next_page_token in a subsequent List Models call. If a nextPageToken is not returned, it means that there are no more models to return.

Get Model API

This is a simple read API on the model_name entity.

GET /models/{model_name} HTTP/1.1
Accept: application/json
{
    "modelName" : "{model_name}",
    "modelUrl" : "/opt/ml/models/{model_name}/model",
}

Note
If model_name is not loaded, this API should return 404.

Unload Model API

Instructs the SageMaker platform to instruct the customer container to unload a model from memory. This initiates the eviction of a candidate model as determined by the platform when starting the process
of loading a new model. The resources provisioned to `model_name` should be reclaimed by the container when this API returns a response.

```
DELETE /models/{model_name}
```

**Note**

If `model_name` is not loaded, this API should return 404.

### Invoke Model API

Makes a prediction request from the particular `model_name` supplied. The SageMaker Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

```
POST /models/{model_name}/invoke HTTP/1.1
Content-Type: ContentType
Accept: Accept
X-Amzn-SageMaker-Custom-Attributes: CustomAttributes
X-Amzn-SageMaker-Target-Model: [relativePath]/{artifactName}.tar.gz
```

**Note**

If `model_name` is not loaded, this API should return 404.

### Multi-Model Endpoint Security

Models and data in a multi-model endpoint are co-located on instance storage volume and in container memory. All instances for Amazon SageMaker endpoints run on a single tenant container that you own. Only your models can run on your multi-model endpoint. It's your responsibility to manage the mapping of requests to models and to provide access for users to the correct target models. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify allowed or denied actions and resources and the conditions under which actions are allowed or denied.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-model endpoint can invoke any model at the address of the S3 prefix defined in the `CreateModel` operation, provided that the IAM Execution Role defined in operation has permissions to download the model. If you need to restrict `InvokeEndpoint` access to a limited set of models in S3, you can do one of the following:

- Restrict `InvokeEndpoint` calls to specific models hosted at the endpoint by using the `sagemaker:TargetModel` IAM condition key. For example, the following policy allows `InvokeEndpoint` requests only when the value of the `TargetModel` field matches one of the specified regular expressions:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Resource": 
            "arn:aws:sagemaker:region:account-id:endpoint/endpoint_name",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetModel": ["company_a/*", "common/*"]
                }
            }
        }
    ]
}
```
For information about SageMaker condition keys, see Condition Keys for Amazon SageMaker in the AWS Identity and Access Management User Guide.

- Create multi-model endpoints with more restrictive S3 prefixes.

For more information about how SageMaker uses roles to manage access to endpoints and perform operations on your behalf, see SageMaker Roles (p. 3375). Your customers might also have certain data isolation requirements dictated by their own compliance requirements that can be satisfied using IAM identities.

### CloudWatch Metrics for Multi-Model Endpoint Deployments

Amazon SageMaker provides metrics for endpoints so you can monitor the cache hit rate, the number of models loaded, and the model wait times for loading, downloading, and uploading at a multi-model endpoint. For information, see Multi-Model Endpoint Model Loading Metrics and Multi-Model Endpoint Model Instance Metrics in Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498). Per-model metrics aren't supported.

### Host multiple models which use different containers behind one endpoint

SageMaker multi-container endpoints enable customers to deploy multiple containers, that use different models or frameworks, on a single SageMaker endpoint. The containers can be run in a sequence as an inference pipeline, or each container can be accessed individually by using direct invocation to improve endpoint utilization and optimize costs.

For information about invoking the containers in a multi-container endpoint in sequence, see Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2674).

For information about invoking a specific container in a multi-container endpoint, see Use a multi-container endpoint with direct invocation (p. 2668)

#### Topics

- Create a multi-container endpoint (Boto 3) (p. 2667)
- Update a multi-container endpoint (p. 2668)
- Delete a multi-container endpoint (p. 2668)
- Use a multi-container endpoint with direct invocation (p. 2668)

#### Create a multi-container endpoint (Boto 3)

Create a Multi-container endpoint by calling CreateModel, CreateEndpointConfig, and CreateEndpoint APIs as you would to create any other endpoints. You can run these containers sequentially as an inference pipeline, or run each individual container by using direct invocation. Multi-container endpoints have the following requirements when you call create_model:

- Use the Containers parameter instead of PrimaryContainer, and include more than one container in the Containers parameter.
- The ContainerHostname parameter is required for each container in a multi-container endpoint with direct invocation.
- Set the Mode parameter of the InferenceExecutionConfig field to Direct for direct invocation of each container, or Serial to use containers as an inference pipeline. The default mode is Serial.
Note
Currently there is a limit of up to 15 containers supported on a multi-container endpoint.

The following example creates a multi-container model for direct invocation.

1. Create container elements and InferenceExecutionConfig with direct invocation.

   ```python
   container1 = { 'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage1:mytag',
                 'ContainerHostname': 'firstContainer'}
   container2 = { 'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage2:mytag',
                 'ContainerHostname': 'secondContainer'}
   inferenceExecutionConfig = {'Mode': 'Direct'}
   ```

2. Create the model with the container elements and set the InferenceExecutionConfig field.

   ```python
   import boto3
   sm_client = boto3.Session().client('sagemaker')
   response = sm_client.create_model(
       ModelName='my-direct-mode-model-name',
       InferenceExecutionConfig=inferenceExecutionConfig,
       ExecutionRoleArn=role,
       Containers=[container1, container2])
   ```

To create an endpoint, you would then call `create_endpoint_config` and `create_endpoint` as you would to create any other endpoint.

**Update a multi-container endpoint**

To update a multi-container endpoint, complete the following steps.

1. Call `create_model` to create a new model with a new value for the `Mode` parameter in the InferenceExecutionConfig field.
2. Call `create_endpoint_config` to create a new endpoint config with a different name by using the new model you created in the previous step.
3. Call `update_endpoint` to update the endpoint with the new endpoint config you created in the previous step.

**Delete a multi-container endpoint**

To delete an endpoint, call `delete_endpoint`, and provide the name of the endpoint you want to delete as the EndpointName parameter.

**Use a multi-container endpoint with direct invocation**

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. You can host up to 15 different inference containers on a single endpoint. By using direct invocation, you can send a request to a specific inference container hosted on a multi-container endpoint.

**Topics**
- Invoke a multi-container endpoint with direct invocation (p. 2669)
Invoke a multi-container endpoint with direct invocation

To invoke a multi-container endpoint with direct invocation, call `invoke_endpoint` as you would invoke any other endpoint, and specify which container you want to invoke by using the `TargetContainerHostname` parameter.

The following example directly invokes the `secondContainer` of a multi-container endpoint to get a prediction.

```
import boto3
runtime_sm_client = boto3.Session().client('sagemaker-runtime')
response = runtime_sm_client.invoke_endpoint(
    EndpointName = 'my-endpoint',
    ContentType = 'text/csv',
    TargetContainerHostname='secondContainer',
    Body = body)
```

For each direct invocation request to a multi-container endpoint, only the container with the `TargetContainerHostname` processes the invocation request. You will get validation errors if you do any of the following:

- Specify a `TargetContainerHostname` that does not exist in the endpoint
- Do not specify a value for `TargetContainerHostname` in a request to an endpoint configured for direct invocation
- Specify a value for `TargetContainerHostname` in a request to an endpoint that is not configured for direct invocation.

Security with multi-container endpoints with direct invocation

For multi-container endpoints with direct invocation, there are multiple containers hosted in a single instance by sharing memory and a storage volume. It's your responsibility to use secure containers, maintain the correct mapping of requests to target containers, and provide users with the correct access to target containers. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify whether access to a resource is allowed or denied to that role, and under what conditions. For information about IAM roles, see IAM roles in the AWS Identity and Access Management User Guide. For information about identity-based policies, see Identity-based policies and resource-based policies.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-container endpoint with direct invocation can invoke any container inside the endpoint with the endpoint name that you specify when you call `invoke_endpoint`. If you need to restrict `invoke_endpoint` access to a limited set of containers inside a multi-container endpoint, use the `sagemaker:TargetContainerHostname` IAM condition key. The following policies show how to limit calls to specific containers within an endpoint.

The following policy allows `invoke_endpoint` requests only when the value of the `TargetContainerHostname` field matches one of the specified regular expressions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "sagemaker:InvokeEndpoint",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": [
                        "secondContainer",
                        "thirdContainer"
                    ]
                }
            }
        }
    ]
}
```
The following policy denies `invoke_endpoint` requests when the value of the `TargetContainerHostname` field matches one of the specified regular expressions in the Deny statement:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "sagemaker:InvokeEndpoint"
      ],
      "Effect": "Allow",
      "Condition": {
        "StringLike": {
          "sagemaker:TargetContainerHostname": ["customIps*", "common*"]
        }
      }
    },
    {
      "Action": [
        "sagemaker:InvokeEndpoint"
      ],
      "Effect": "Deny",
      "Condition": {
        "StringLike": {
          "sagemaker:TargetContainerHostname": ["special*"]
        }
      }
    }
  ]
}
```

For information about SageMaker condition keys, see Condition Keys for SageMaker in the AWS Identity and Access Management User Guide.

**Metrics for multi-container endpoints with direct invocation**

In addition to the endpoint metrics that are listed in Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498), SageMaker also provides per-container metrics.

Per-container metrics for multi-container endpoints with direct invocation are located in CloudWatch and categorized into two namespaces: AWS/SageMaker and aws/sagemaker/Endpoints. The AWS/SageMaker namespace includes invocation-related metrics, and the aws/sagemaker/Endpoints namespace includes memory and CPU utilization metrics.

The following table lists the per-container metrics for multi-container endpoints with direct invocation. All the metrics use the [EndpointName, VariantName, ContainerName] dimension, which filters
metrics at a specific endpoint, for a specific variant and corresponding to a specific container. These metrics share the same metric names as in those for inference pipelines, but at a per-container level [EndpointName, VariantName, ContainerName].

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Dimension</th>
<th>NameSpace</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocations</td>
<td>The number of InvokeEndpoint requests sent to a container inside an endpoint. To get the total number of requests sent to that container, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>Invocation4XX Errors</td>
<td>The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for on a specific container. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>Invocation5XX Errors</td>
<td>The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for on a specific container. For each 5xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>ContainerLatency</td>
<td>The time it took for the target container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Unit</td>
<td></td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
<td></td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead. OverheadLatency is measured from the time that SageMaker receives the request until it returns a response to the client, minus the ModelLatency. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: Average, Sum, Min, Max, <code>Sample Count</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU units that are used by each container running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For endpoints with direct invocation, the number of CPUUtilization metrics equals the number of containers in that endpoint. Units: Percent</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
MemoryUtilization  The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as CPUUtilization, in endpoints with direct invocation, the number of MemoryUtilization metrics equals the number of containers in that endpoint. Units: Percent

| EndpointName, VariantName, ContainerName | aws/sagemaker/Endpoints |

All the metrics in the previous table are specific to multi-container endpoints with direct invocation. Besides these special per-container metrics, there are also metrics at the variant level with dimension [EndpointName, VariantName] for all the metrics in the table expect ContainerLatency.

**Autoscale multi-container endpoints**

If you want to configure automatic scaling for a multi-container endpoint using the InvocationsPerInstance metric, we recommend that the model in each container exhibits similar CPU utilization and latency on each inference request. This is recommended because if traffic to the multi-container endpoint shifts from a low CPU utilization model to a high CPU utilization model, but the overall call volume remains the same, the endpoint does not scale out and there may not be enough instances to handle all the requests to the high CPU utilization model. For information about automatically scaling endpoints, see Automatically Scale Amazon SageMaker Models (p. 2688).

**Troubleshoot multi-container endpoints**

The following sections can help you troubleshoot errors with multi-container endpoints.

**Ping Health Check Errors**

With multiple containers, endpoint memory and CPU are under higher pressure during endpoint creation. Specifically, the MemoryUtilization and CPUUtilization metrics are higher than for single-container endpoints, because utilization pressure is proportional to the number of containers. Because of this, we recommend that you choose instance types with enough memory and CPU to ensure that there is enough memory on the instance to have all the models loaded (the same guidance applies to deploying an inference pipeline). Otherwise, your endpoint creation might fail with an error such as XXX did not pass the ping health check.

**Missing accept-bind-to-port=true Docker label**

The containers in a multi-container endpoints listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable instead of port 8080. When a container runs in a multi-container endpoint, SageMaker automatically provides this environment variable to the container. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

Otherwise, You will see an error message such as Your Ecr Image XXX does not contain required com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true Docker label(s).
If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format `XXXX-YYYY`, where XXXX and YYYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multi-container endpoint.

**Host models along with pre-processing logic as serial inference pipeline behind one endpoint**

An *inference pipeline* is a Amazon SageMaker model that is composed of a linear sequence of two to fifteen containers that process requests for inferences on data. You use an inference pipeline to define and deploy any combination of pretrained SageMaker built-in algorithms and your own custom algorithms packaged in Docker containers. You can use an inference pipeline to combine preprocessing, predictions, and post-processing data science tasks. Inference pipelines are fully managed.

You can add SageMaker Spark ML Serving and scikit-learn containers that reuse the data transformers developed for training models. The entire assembled inference pipeline can be considered as a SageMaker model that you can use to make either real-time predictions or to process batch transforms directly without any external preprocessing.

Within an inference pipeline model, SageMaker handles invocations as a sequence of HTTP requests. The first container in the pipeline handles the initial request, then the intermediate response is sent as a request to the second container, and so on, for each container in the pipeline. SageMaker returns the final response to the client.

When you deploy the pipeline model, SageMaker installs and runs all of the containers on each Amazon Elastic Compute Cloud (Amazon EC2) instance in the endpoint or transform job. Feature processing and inferences run with low latency because the containers are co-located on the same EC2 instances. You define the containers for a pipeline model using the `CreateModel` operation or from the console. Instead of setting one `PrimaryContainer`, you use the `Containers` parameter to set the containers that make up the pipeline. You also specify the order in which the containers are executed.

A pipeline model is immutable, but you can update an inference pipeline by deploying a new one using the `UpdateEndpoint` operation. This modularity supports greater flexibility during experimentation.

For information on how to create an inference pipeline with the SageMaker model registry, see [Register and Deploy Models with Model Registry](#).

There are no additional costs for using this feature. You pay only for the instances running on an endpoint.

- Feature Processing with Spark ML and Scikit-learn (p. 2675)
- Create a Pipeline Model (p. 2675)
- Run Real-time Predictions with an Inference Pipeline (p. 2678)
- Run Batch Transforms with Inference Pipelines (p. 2680)
- Inference Pipeline Logs and Metrics (p. 2681)
- Troubleshoot Inference Pipelines (p. 2686)

**Sample Notebooks for Inference Pipelines**

For an example that shows how to create and deploy inference pipelines, see the [Training using SparkML on EMR and hosting on SageMaker](#) sample notebook. For instructions on creating and accessing Jupyter
Hosting options

notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283).

To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the SageMaker Examples tab. There are three inference pipeline notebooks. The first two inference pipeline notebooks just described are located in the advanced_functionality folder and the third notebook is in the sagemaker-python-sdk folder. To open a notebook, choose its Use tab, then choose Create copy.

Feature Processing with Spark ML and Scikit-learn

Before training a model with either Amazon SageMaker built-in algorithms or custom algorithms, you can use Spark and scikit-learn preprocessors to transform your data and engineer features.

Feature Processing with Spark ML

You can run Spark ML jobs with AWS Glue, a serverless ETL (extract, transform, load) service, from your SageMaker notebook. You can also connect to existing EMR clusters to run Spark ML jobs with Amazon EMR. To do this, you need an AWS Identity and Access Management (IAM) role that grants permission for making calls from your SageMaker notebook to AWS Glue.

Note
To see which Python and Spark versions AWS Glue supports, refer to AWS Glue Release Notes.

After engineering features, you package and serialize Spark ML jobs with MLeap into MLeap containers that you can add to an inference pipeline. You don't need to use externally managed Spark clusters. With this approach, you can seamlessly scale from a sample of rows to terabytes of data. The same transformers work for both training and inference, so you don't need to duplicate preprocessing and feature engineering logic or develop a one-time solution to make the models persist. With inference pipelines, you don't need to maintain outside infrastructure, and you can make predictions directly from data inputs.

When you run a Spark ML job on AWS Glue, a Spark ML pipeline is serialized into MLeap format. Then, you can use the job with the SparkML Model Serving Container in a SageMaker Inference Pipeline. MLeap is a serialization format and execution engine for machine learning pipelines. It supports Spark, Scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

Feature Processing with Scikit-Learn

You can run and package scikit-learn jobs into containers directly in Amazon SageMaker. For an example of Python code for building a scikit-learn featurizer model that trains on Fisher's Iris flower data set and predicts the species of Iris based on morphological measurements, see IRIS Training and Prediction with Sagemaker Scikit-learn.

Create a Pipeline Model

To create a pipeline model that can be deployed to an endpoint or used for a batch transform job, use the Amazon SageMaker console or the CreateModel operation.

To create an inference pipeline (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Models, and then choose Create models from the Inference group.
3. On the Create model page, provide a model name, choose an IAM role, and, if you want to use a private VPC, specify VPC values.
4. To add information about the containers in the inference pipeline, choose Add container, then choose Next.

5. Complete the fields for each container in the order that you want to execute them, up to the maximum of fifteen. Complete the Container input options, Location of inference code image, and, optionally, Location of model artifacts, Container host name, and Environmental variables fields.
The **MyInferencePipelineModel** page summarizes the settings for the containers that provide input for the model. If you provided the environment variables in a corresponding container definition, SageMaker shows them in the **Environment variables** field.

### Run Real-time Predictions with an Inference Pipeline

You can use trained models in an inference pipeline to make real-time predictions directly without performing external preprocessing. When you configure the pipeline, you can choose to use the built-in feature transformers already available in Amazon SageMaker. Or, you can implement your own transformation logic using just a few lines of scikit-learn or Spark code.
MLeap, a serialization format and execution engine for machine learning pipelines, supports Spark, scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

The containers in a pipeline listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable (instead of 8080). When running in an inference pipeline, SageMaker automatically provides this environment variable to containers. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

If your container needs to listen on a second port, choose a port in the range specified by the SAGEMAKER_SAFE_PORT_RANGE environment variable. Specify the value as an inclusive range in the format "XXXX--YYYY", where XXXX and YYYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multicontainer pipeline.

**Note**
To use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (Amazon ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2686).

Create and Deploy an Inference Pipeline Endpoint

The following code creates and deploys a real-time inference pipeline model with SparkML and XGBoost models in series using the SageMaker SDK.

```python
from sagemaker.model import Model
from sagemaker.pipeline_model import PipelineModel
from sagemaker.sparkml.model import SparkMLModel

sparkml_data = 's3://{}/{}/{}'.format(s3_model_bucket, s3_model_key_prefix, 'model.tar.gz')
sparkml_model = SparkMLModel(model_data=sparkml_data)
xgb_model = Model(model_data=xgb_model.model_data, image=training_image)

model_name = 'serial-inference-' + timestamp_prefix
endpoint_name = 'serial-inference-ep-' + timestamp_prefix
sm_model = PipelineModel(name=model_name, role=role, models=[sparkml_model, xgb_model])
sm_model.deploy(initial_instance_count=1, instance_type='ml.c4.xlarge',
endpoint_name=endpoint_name)
```

Request Real-Time Inference from an Inference Pipeline Endpoint

The following example shows how to make real-time predictions by calling an inference endpoint and passing a request payload in JSON format:

```python
import sagemaker
from sagemaker.predictor import json_serializer, json_deserializer, Predictor

payload = {
    "input": [
        {
            "name": "Pclass",
            "type": "float",
            "val": 1.0
        },
        {
            "name": "Embarked",
            "type": "string",
```
predictor = Predictor(endpoint=endpoint_name, sagemaker_session=sagemaker.Session(),
serializer=json_serializer, content_type='text/csv', accept='application/json')

print(predictor.predict(payload))

The response you get from `predictor.predict(payload)` is the model's inference result.

**Realtime inference pipeline example**

You can run this example notebook using the SKLearn predictor that shows how to deploy an endpoint, run an inference request, then deserialize the response. Find this notebook and more examples in the Amazon SageMaker example GitHub repository.

**Run Batch Transforms with Inference Pipelines**

To get inferences on an entire dataset you run a batch transform on a trained model. To run inferences on a full dataset, you can use the same inference pipeline model created and deployed to an endpoint for real-time processing in a batch transform job. To run a batch transform job in a pipeline, you download the input data from Amazon S3 and send it in one or more HTTP requests to the inference pipeline model. For an example that shows how to prepare data for a batch transform, see "Section 2 - Preprocess the raw housing data using Scikit Learn" of the Amazon SageMaker Multi-Model Endpoints using Linear Learner sample notebook. For information about Amazon SageMaker batch transforms, see Use Batch Transform (p. 2807).

**Note**

To use custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2686).

The following example shows how to run a transform job using the Amazon SageMaker Python SDK. In this example, `model_name` is the inference pipeline that combines SparkML and XGBoost models.
Hosting options

(created in previous examples). The Amazon S3 location specified by `input_data_path` contains the input data, in CSV format, to be downloaded and sent to the Spark ML model. After the transform job has finished, the Amazon S3 location specified by `output_data_path` contains the output data returned by the XGBoost model in CSV format.

```python
import sagemaker
input_data_path = 's3://{}/{}{}'.format(default_bucket, 'key', 'file_name')
output_data_path = 's3://{}/{}'.format(default_bucket, 'key')
transform_job = sagemaker.transformer.Transformer(
    model_name = model_name,
    instance_count = 1,
    instance_type = 'ml.m4.xlarge',
    strategy = 'SingleRecord',
    assemble_with = 'Line',
    output_path = output_data_path,
    base_transform_job_name='inference-pipelines-batch',
    sagemaker_session=sagemaker.Session(),
    accept = CONTENT_TYPE_CSV)
transform_job.transform(data = input_data_path,
    content_type = CONTENT_TYPE_CSV,
    split_type = 'Line')
```

Inference Pipeline Logs and Metrics

Monitoring is important for maintaining the reliability, availability, and performance of Amazon SageMaker resources. To monitor and troubleshoot inference pipeline performance, use Amazon CloudWatch logs and error messages. For information about the monitoring tools that SageMaker provides, see Monitor Amazon SageMaker (p. 3498).

Use Metrics to Monitor Multi-container Models

To monitor the multi-container models in Inference Pipelines, use Amazon CloudWatch. CloudWatch collects raw data and processes it into readable, near real-time metrics. SageMaker training jobs and endpoints write CloudWatch metrics and logs in the `AWS/SageMaker` namespace.

The following tables list the metrics and dimensions for the following:

- Endpoint invocations
- Training jobs, batch transform jobs, and endpoint instances

A **dimension** is a name/value pair that uniquely identifies a metric. You can assign up to 10 dimensions to a metric. For more information on monitoring with CloudWatch, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498).

Endpoint Invocation Metrics

The `AWS/SageMaker` namespace includes the following request metrics from calls to `InvokeEndpoint`.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of <code>InvokeEndpoint</code> requests that the model returned a 4xx HTTP response code for. For each 4xx response, SageMaker sends a 1.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
</tbody>
</table>

2681
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Units</th>
<th>Valid statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation5XXErrors</td>
<td>The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for. For each 5xx response, SageMaker sends a 1.</td>
<td>None</td>
<td>Average, Sum</td>
</tr>
<tr>
<td>Invocations</td>
<td>The number of InvokeEndpoint requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the Sum statistic.</td>
<td>None</td>
<td>Sum, Sample Count</td>
</tr>
<tr>
<td>InvocationsPerInstance</td>
<td>The number of endpoint invocations sent to a model, normalized by InstanceCount in each ProductionVariant. SageMaker sends 1/numberOfInstances as the value for each request, where numberOfInstances is the number of active instances for the ProductionVariant at the endpoint at the time of the request.</td>
<td>None</td>
<td>Sum</td>
</tr>
<tr>
<td>ModelLatency</td>
<td>The time the model or models took to respond. This includes the time it took to send the request, to fetch the response from the model container, and to complete the inference in the container. ModelLatency is the total time taken by all containers in an inference pipeline.</td>
<td>Microseconds</td>
<td>Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead. OverheadLatency is measured from the time that SageMaker receives the request until it returns a response to the client, minus the ModelLatency. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors.</td>
<td>Microseconds</td>
<td>Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ContainerLatency</td>
<td>The time it took for an Inference Pipelines container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container.</td>
<td>Microseconds</td>
<td>Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

**Dimensions for Endpoint Invocation Metrics**
## Hosting options

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName, ContainerName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant at the specified endpoint and for the specified variant.</td>
</tr>
</tbody>
</table>

For an inference pipeline endpoint, CloudWatch lists per-container latency metrics in your account as **Endpoint Container Metrics** and **Endpoint Variant Metrics** in the **SageMaker** namespace, as follows. The **ContainerLatency** metric appears only for inferences pipelines.

![ContainerLatency Metrics](image)

For each endpoint and each container, latency metrics display names for the container, endpoint, variant, and metric.

![Container and Endpoint Metrics](image)

### Training Job, Batch Transform Job, and Endpoint Instance Metrics

The namespaces `/aws/sagemaker/TrainingJobs`, `/aws/sagemaker/TransformJobs`, and `/aws/sagemaker/Endpoints` include the following metrics for training jobs and endpoint instances.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU units that are used by the containers running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, CPUUtilization is the CPU utilization of the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, CPUUtilization is the CPU utilization of the transform container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For multi-container models, CPUUtilization is the sum of CPU utilization by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, CPUUtilization is the sum of CPU utilization by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>The percentage of memory that is used by the containers running on an instance. This value ranges from 0% to 100%. For training jobs, MemoryUtilization is the memory used by the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, MemoryUtilization is the memory used by the transform container running on the instance. For multi-container models, MemoryUtilization is the sum of memory used by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, MemoryUtilization is the sum of memory used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>GPUUtilization</td>
<td>The percentage of GPU units that are used by the containers running on an instance. GPUUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, GPUUtilization is the GPU used by the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, GPUUtilization is the GPU used by the transform container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For multi-container models, GPUUtilization is the sum of GPU used by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, GPUUtilization is the sum of GPU used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>GPUMemoryUtilization</td>
<td>The percentage of GPU memory used by the containers running on an instance. GPUMemoryUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUMemoryUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, GPUMemoryUtilization is the GPU memory used by the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, GPUMemoryUtilization is the GPU memory used by the transform container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For multi-container models, GPUMemoryUtilization is sum of GPU used by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, GPUMemoryUtilization is the sum of the GPU memory used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
</tbody>
</table>
### Hosting options

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DiskUtilization</td>
<td>The percentage of disk space used by the containers running on an instance. DiskUtilization ranges from 0% to 100%. This metric is not supported for batch transform jobs. For training jobs, DiskUtilization is the disk space used by the algorithm container running on the instance. For endpoint variants, DiskUtilization is the sum of the disk space used by all of the provided containers running on the instance. Units: Percent</td>
</tr>
</tbody>
</table>

### Dimensions for Training Job, Batch Transform Job, and Endpoint Instance Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>For training jobs, Host has the format [training-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the /aws/sagemaker/TrainingJobs namespace. For batch transform jobs, Host has the format [transform-job-name]/[instance-id]. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the /aws/sagemaker/TransformJobs namespace. For endpoints, Host has the format [endpoint-name]/[production-variant-name]/[instance-id]. Use this dimension to filter instance metrics for the specified endpoint, variant, and instance. This dimension format is present only in the /aws/sagemaker/Endpoints namespace.</td>
</tr>
</tbody>
</table>

To help you debug your training jobs, endpoints, and notebook instance lifecycle configurations, SageMaker also sends anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to stdout or stderr to Amazon CloudWatch Logs. You can use this information for debugging and to analyze progress.

**Use Logs to Monitor an Inference Pipeline**

The following table lists the log groups and log streams SageMaker sends to Amazon CloudWatch.

A **log stream** is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A **log group** is a group of log streams that share the same retention, monitoring, and access control settings.

**Logs**

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Stream Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/sagemaker/TrainingJobs</td>
<td>[training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]</td>
</tr>
<tr>
<td>/aws/sagemaker/Endpoints/ [EndpointName]</td>
<td>[production-variant-name]/[instance-id]</td>
</tr>
<tr>
<td>Log Group Name</td>
<td>Log Stream Name</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>/aws/sagemaker/NotebookInstances</td>
<td>[notebook-instance-name]/[LifecycleConfigHook]</td>
</tr>
<tr>
<td>/aws/sagemaker/TransformJobs</td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]</td>
</tr>
<tr>
<td></td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/data-log</td>
</tr>
<tr>
<td></td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in the SageMaker model] (For Inference Pipelines) For Inference Pipelines logs, if you don't provide container names, CloudWatch uses <strong>container-1, container-2</strong>, and so on, in the order that containers are provided in the model.</td>
</tr>
</tbody>
</table>

**Note**

SageMaker creates the /aws/sagemaker/NotebookInstances log group when you create a notebook instance with a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 291).

For more information about SageMaker logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3510).

**Troubleshoot Inference Pipelines**

To troubleshoot inference pipeline issues, use CloudWatch logs and error messages. If you are using custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you might also encounter permissions problems. To grant the required permissions, create an Amazon Elastic Container Registry (Amazon ECR) policy.

**Topics**

- Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2686)
- Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines (p. 2687)
- Use Error Messages to Troubleshoot Inference Pipelines (p. 2688)

**Troubleshoot Amazon ECR Permissions for Inference Pipelines**

When you use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon ECR policy. The policy allows your Amazon ECR repository to grant permission for SageMaker to pull the image. The policy must add the following permissions:

```json
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Sid": "allowSageMakerToPull",
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            }
        }
    ]
}
```
Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines

SageMaker publishes the container logs for endpoints that deploy an inference pipeline to Amazon CloudWatch at the following path for each container.

/aws/sagemaker/Endpoints/{EndpointName}/{Variant}/{InstanceId}/{ContainerHostname}

For example, logs for this endpoint are published to the following log groups and streams:

EndpointName: MyInferencePipelinesEndpoint
Variant: MyInferencePipelinesVariant
InstanceId: i-0179208609ff7e488
ContainerHostname: MyContainerName1 and MyContainerName2

clogGroup: /aws/sagemaker/Endpoints/MyInferencePipelinesEndpoint
clogStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName1
clogStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName2

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

To see the log groups and streams

2. In the navigation page, choose Logs.
3. In Log Groups, filter on MyInferencePipelinesEndpoint:

4. To see the log streams, on the CloudWatch Log Groups page, choose MyInferencePipelinesEndpoint, and then Search Log Group.
For a list of the logs that SageMaker publishes, see Inference Pipeline Logs and Metrics (p. 2681).

Use Error Messages to Troubleshoot Inference Pipelines

The inference pipeline error messages indicate which containers failed.

If an error occurs while SageMaker is invoking an endpoint, the service returns a ModelError (error code 424), which indicates which container failed. If the request payload (the response from the previous container) exceeds the limit of 5 MB, SageMaker provides a detailed error message, such as:

Received response from MyContainerName1 with status code 200. However, the request payload from MyContainerName1 to MyContainerName2 is 6000000 bytes, which has exceeded the maximum limit of 5 MB.

If a container fails the ping health check while SageMaker is creating an endpoint, it returns a ClientError and indicates all of the containers that failed the ping check in the last health check.

Automatically Scale Amazon SageMaker Models

Amazon SageMaker supports automatic scaling (autoscaling) for your hosted models. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances so that you don't pay for provisioned instances that you aren't using.

Topics

- Prerequisites (p. 2688)
- Configure model autoscaling with the console (p. 2691)
- Register a model (p. 2692)
- Define a scaling policy (p. 2693)
- Apply a scaling policy (p. 2695)
- Edit a scaling policy (p. 2696)
- Delete a scaling policy (p. 2698)
- Query Endpoint Autoscaling History (p. 2699)
- Update or delete endpoints that use automatic scaling (p. 2700)
- Load testing your autoscaling configuration (p. 2702)
- Use AWS CloudFormation to update autoscaling policies (p. 2703)

Prerequisites

Before you can use autoscaling, must have already created a Amazon SageMaker model deployment. Deployed models are referred to as a production variant. This includes information about the model and the resources used to host it.

For more information about deploying a model endpoint, see Deploy the Model to SageMaker Hosting Services (p. 84).

To enable autoscaling for a model, you can use the console, the AWS CLI, or the Application Auto Scaling API. It is recommended to try to Configure model autoscaling with the console (p. 2691) to get familiar with the requirements and to test your first autoscaling configuration. When using the AWS CLI or
Autoscaling policy overview

To use automatic scaling, you define and apply a scaling policy that uses Amazon CloudWatch metrics and target values that you assign. Automatic scaling uses the policy to increase or decrease the number of instances in response to actual workloads.

You can use the AWS Management Console to apply a scaling policy based on a predefined metric. A predefined metric is defined in an enumeration so that you can specify it by name in code or use it in the AWS Management Console. Alternatively, you can use either the AWS Command Line Interface (AWS CLI) or the Application Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

There are two types of supported scaling policies: target-tracking scaling and step scaling. It is recommended to use target-tracking scaling policies for your autoscaling configuration. You configure the target-tracking scaling policy by specifying a predefined or custom metric and a target value for the metric. For more information about using Application Auto Scaling target-tracking scaling policies, see Target Tracking Scaling Policies.

You can use step scaling when you require an advanced configuration, such as specifying how many instances to deploy under what conditions. Otherwise, using target-tracking scaling is preferred as it will be fully automated. For more information about using Application Auto Scaling step scaling policies, see Step Scaling Policies.

A scaling policy has the following components:

- A target metric—The Amazon CloudWatch metric that SageMaker automatic scaling uses to determine when and how much to scale.
- Minimum and maximum capacity—The minimum and maximum number of instances to use for scaling.
- A cool down period—The amount of time, in seconds, after a scale-in or scale-out activity completes before another scale-out activity can start.
- Required permissions—Permissions that are required to perform automatic scaling actions.
- A service-linked role—An AWS Identity and Access Management (IAM) role that is linked to a specific AWS service. A service-linked role includes all of the permissions that the service requires to call other AWS services on your behalf. SageMaker automatic scaling automatically generates this role, AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint, for you.

Target metric for autoscaling

Amazon CloudWatch alarms trigger the scaling policy, which calculate how to adjust scaling based on the metric and target value that you set. The scaling policy adds or removes endpoint instances as required to keep the metric at, or close to, the specified target value. In addition, a scaling policy also adjusts to fluctuations in the metric when a workload changes. The scaling policy minimizes rapid fluctuations in the number of available instances for your model.

For example, a scaling policy that uses the predefined InvocationsPerInstance metric with a target value of 70 can keep InvocationsPerInstance at, or close to 70.

Minimum and maximum capacity

You may specify the maximum number of endpoint instances for the model. The maximum value must be equal to or greater than the value specified for the minimum number of endpoint instances. SageMaker automatic scaling does not enforce a limit for this value.
You must also specify the minimum number of instances for the model. This value must be at least 1, and equal to or less than the value specified for the maximum number of endpoint instances.

To determine the minimum and maximum number of instances that you need for typical traffic, test your autoscaling configuration with the expected rate of traffic to your model.

**Important**

Scaling-in occurs when there is no traffic: if a variant’s traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

**Cooldown period**

Tune the responsiveness of your scaling policy by adding a cooldown period. A *cooldown period* controls when your model is scaled-in (by reducing instances) or scaled-out (by increasing instances). It does this by blocking subsequent scale-in or scale-out requests until the period expires. This slows the deletion of instances for scale-in requests, and the creation of instances for scale-out requests. A cooldown period helps to ensure that the scaling policy doesn’t launch or terminate additional instances before the previous scaling activity takes effect. After automatic scaling dynamically scales using a scaling policy, it waits for the cooldown period to complete before resuming scaling activities.

You configure the cooldown period in your automatic scaling policy. You can specify the following cooldown periods:

- A scale-in activity reduces the number of instances. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.
- A scale-out activity increases the number of instances. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

If you don’t specify a scale-in or a scale-out cooldown period automatic scaling use the default, which is 300 seconds for each.

If instances are being added or removed too quickly when you test your automatic scaling configuration, consider increasing this value. You can see this behavior if the traffic to your model has a lot of spikes, or if you have multiple automatic scaling policies defined for a variant.

If instances are not being added quickly enough to address increased traffic, consider decreasing this value.

**Permissions**

The `SagemakerFullAccessPolicy` IAM policy has all of the IAM permissions required to perform autoscaling. For more information about SageMaker IAM permissions, see [SageMaker Roles](p. 3375).

If you are using a custom permission policy, you must include the following permissions:

```json
{
   "Effect": "Allow",
   "Action": [
      "sagemaker:DescribeEndpoint",
      "sagemaker:DescribeEndpointConfig",
      "sagemaker:UpdateEndpointWeightsAndCapacities"
   ],
   "Resource": "*"
}
```
{ "Action": [ "application-autoscaling:*" ], "Effect": "Allow", "Resource": "*" }

### Service-linked role

Autoscaling uses the AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint service-linked role; it created for you automatically. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles are predefined by the service and include all of the permissions that the service requires to call other AWS services on your behalf. For more information, see Service-Linked Roles.

### Configure model autoscaling with the console

**To configure autoscaling for a model using the console**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Endpoints**.
3. Choose the endpoint that you want to configure.
4. For **Endpoint runtime settings**, choose the model variant that you want to configure.
5. For **Endpoint runtime settings**, choose **Configure autoscaling**.

   The Configure variant automatic scaling page appears.
6. For **Minimum capacity**, type the minimum number of instances that you want the scaling policy to maintain. At least 1 instance is required.
7. For **Maximum capacity**, type the maximum number of instances that you want the scaling policy to maintain.
8. For the **target value**, type the average number of invocations per instance per minute for the model. To determine this value, follow the guidelines in Load testing (p. 2702).

   Application Auto Scaling adds or removes instances to keep the metric close to the value that you specify.

9. For **Scale-in cool down (seconds)** and **Scale-out cool down (seconds)**, type the number seconds for each cool down period. Assuming that the order in the list is based on either most important to less important of first applied to last applied.

10. Select **Disable scale in** to prevent the scaling policy from deleting variant instances if you want to ensure that your variant scales out to address increased traffic, but are not concerned with removing instances to reduce costs when traffic decreases, disable scale-in activities.

    Scale-out activities are always enabled so that the scaling policy can create endpoint instances as needed.

11. Choose **Save**.

This procedure registers a model as a scalable target with Application Auto Scaling. When you register a model, Application Auto Scaling performs validation checks to ensure the following:

- The model exists
- The permissions are sufficient
- You aren't registering a variant with an instance that is a burstable performance instance such as T2

**Note**

SageMaker doesn't support autoscaling for burstable instances such as T2, because they already allow for increased capacity under increased workloads. For information about burstable performance instances, see [Amazon EC2 Instance Types](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-types.html).

**Register a model**

You can add autoscaling for a model with the AWS CLI or the Application Auto Scaling API. You first must register the model, then you must define an autoscaling policy.

**Register a model with the AWS CLI**

With the AWS CLI, you can configure autoscaling based on either a predefined or a custom metric.

To register your endpoint, use the `register-scalable-target` AWS CLI command with the following parameters:

- `--service-namespace=service-name`—Set this value to `sagemaker`.
- `--resource-id=resource-id`—The resource identifier for the model (specifically, the production variant). For this parameter, the resource type is `endpoint` and the unique identifier is the name of the production variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- `--scalable-dimension=dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--min-capacity=number`—The minimum number of instances that for this model. Set `min-capacity` to at least 1. It must be equal to or less than the value specified for `max-capacity`.
- `--max-capacity=number`—The maximum number of instances that Application Auto Scaling should manage. Set `max-capacity` to a minimum of 1, It must be equal to or greater than the value specified for `min-capacity`.

**Example**

The following example shows how to register a model named `MyVariant` that is dynamically scaled to have one to eight instances:

```bash
aws application-autoscaling register-scalable-target \    
    --service-namespace sagemaker \
```
Register a model with the Application Auto Scaling API

To define the scaling limits for the model, register your model with Application Auto Scaling. Application Auto Scaling dynamically scales the number of production variant instances.

To register your model with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API action with the following parameters:

- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceId**—The resource identifier for the production variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant, for example `endpoint/MyEndPoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- **MinCapacity**—The minimum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or less than the value specified for `MaxCapacity`.
- **MaxCapacity**—The maximum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or greater than the value specified for `MinCapacity`.

**Example**

The following example shows how to register a SageMaker production variant that is dynamically scaled to use one to eight instances:

```json
{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndPoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "MinCapacity": 1,
    "MaxCapacity": 8
}
```

Define a scaling policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see `TargetTrackingScalingPolicyConfiguration` in the *Application Auto Scaling API Reference*.

The following options are available for defining a target-tracking scaling policy configuration.
Use a predefined metric

To quickly define a target-tracking scaling policy for a variant, use the SageMakerVariantInvocationsPerInstance predefined metric. SageMakerVariantInvocationsPerInstance is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

Example

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the SageMakerVariantInvocationsPerInstance predefined metric to adjust the number of variant instances so that each instance has an InvocationsPerInstance metric of 70.

```json
{
  "TargetValue": 70.0,
  "PredefinedMetricSpecification":
  {
    "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
  }
}
```

Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

Important

Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

Example

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a variant named my-variant, a custom metric adjusts the variant based on an average CPU utilization of 50 percent across all instances.

```json
{
  "TargetValue": 50,
  "CustomizedMetricSpecification":
  {
    "MetricName": "CPUUtilization",
    "Namespace": "/aws/sagemaker/Endpoints",
    "Dimensions": [
      {
        "Name": "EndpointName", "Value": "my-endpoint"
      },
      {
        "Name": "VariantName", "Value": "my-variant"
      }
    ],
    "Statistic": "Average",
    "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
  }
}
```
Add a cooldown period

To add a cooldown period for scaling-out your model, specify a value, in seconds, for `ScaleOutCooldown`. Similarly, to add a cooldown period for scaling-in your model, add a value, in seconds, for `ScaleInCooldown`. For more information about `ScaleInCooldown` and `ScaleOutCooldown`, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

Example

The following is an example target-tracking configuration for a scaling policy. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric is used to adjust scaling based on an average of 70 across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```json
{
  "TargetValue": 70.0,
  "PredefinedMetricSpecification": {
    "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance",
    "ScaleInCooldown": 600,
    "ScaleOutCooldown": 300
  }
}
```

Apply a scaling policy

After registering your model and defining a scaling policy, apply the scaling policy to the registered model. To apply a scaling policy, you can use the AWS CLI or the Application Auto Scaling API.

Apply a scaling policy (AWS CLI)

To apply a scaling policy to your model, use the `put-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name`—The name of the scaling policy.
- `--policy-type`—Set this value to TargetTrackingScaling.
- `--resource-id`—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace`—Set this value to `sagemaker`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--target-tracking-scaling-policy-configuration`—The target-tracking scaling policy configuration to use for the model.

Example

The following example uses with Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a model (variant) named `myscalablevariant`. The policy configuration is saved in a file named `config.json`. 
Apply a scaling policy (Application Auto Scaling API)

To apply a scaling policy to a variant with the Application Auto Scaling API, use the `PutScalingPolicy` Application Auto Scaling API action with the following parameters:

- **PolicyName**—The name of the scaling policy.
- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceId**—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- **PolicyType**—Set this value to `TargetTrackingScaling`.
- **TargetTrackingScalingPolicyConfiguration**—The target-tracking scaling policy configuration to use for the variant.

Example

The following example uses Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a variant named `myscalablevariant`. It uses a policy configuration based on the `SageMakerVariantInvocationsPerInstance` predefined metric.

```plaintext
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 70.0,
        "PredefinedMetricSpecification": {
            "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
        }
    }
}
```

Edit a scaling policy

You can edit an autoscaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.
Scale-in

Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

Disable scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your variant by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting instances, while still allowing it to create them as needed.

To enable or disable scale-in activity for your model, specify a Boolean value for `DisableScaleIn`. For more information about `DisableScaleIn`, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

Example

The following is an example of a target-tracking configuration for a scaling policy where it will scale-out, but not scale-in. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric will scale-out based on an average of 70 invocations (inference requests) across all instances the model is on. The configuration also disables scale-in activity for the scaling policy.

```
{
    "TargetValue": 70.0,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    },
    "DisableScaleIn": true
}
```

Scale-out

To manually scale-out, adjust the minimum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the `--min-capacity` argument, or use the Application Auto Scaling API's `MinCapacity` parameter.

Disable scale-out activity

To prevent scale-out, adjust the maximum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the `--max-capacity` argument, or use the Application Auto Scaling API's `MaxCapacity` parameter.

Edit a scaling policy (Console)

To edit a scaling policy with the AWS Management Console, use the same procedure that you used to Configure model autoscaling with the console (p. 2691).

Edit a scaling policy (AWS CLI or Application Auto Scaling API)

You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- With the AWS CLI, specify the name of the policy that you want to edit in the `--policy-name` parameter. Specify new values for the parameters that you want to change.
- With the Application Auto Scaling API, specify the name of the policy that you want to edit in the `PolicyName` parameter. Specify new values for the parameters that you want to change.
For more information, see Apply a scaling policy (p. 2695).

Delete a scaling policy

You can delete a scaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API. You must delete a scaling policy if you wish to update a model's endpoint.

Delete a scaling policy (Console)

To delete an automatic scaling policy (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Endpoints.
3. Choose the endpoint for which you want to delete automatic scaling.
4. For Endpoint runtime settings, choose the variant that you want to configure.
5. Choose Configure auto scaling.
6. Choose Deregister auto scaling.

Delete a scaling policy (AWS CLI or Application Auto Scaling API)

You can use the AWS CLI or the Application Auto Scaling API to delete a scaling policy from a variant.

Delete a scaling policy (AWS CLI)

To delete a scaling policy from a variant, use the delete-scaling-policy AWS CLI command with the following parameters:

- --policy-name—The name of the scaling policy.
- --resource-id—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- --service-namespace—Set this value to sagemaker.
- --scalable-dimension—Set this value to sagemaker:variant:DesiredInstanceCount.

Example

The following example deletes a target-tracking scaling policy named myscalablepolicy from a variant named myscalablevariant.

```
aws application-autoscaling delete-scaling-policy \\
  --policy-name myscalablepolicy \\
  --resource-id endpoint/MyEndpoint/variant/MyVariant \\
  --service-namespace sagemaker \\
  --scalable-dimension sagemaker:variant:DesiredInstanceCount
```

Delete a scaling policy (Application Auto Scaling API)

To delete a scaling policy from your variant, use the DeleteScalingPolicy Application Auto Scaling API action with the following parameters:

- PolicyName—The name of the scaling policy.
Automatically scale models

- **ServiceNamespace**—Set this value to sagemaker.
- **ResourceId**—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- **ScalableDimension**—Set this value to sagemaker:variant:DesiredInstanceCount.

**Example**

The following example uses the Application Auto Scaling API to delete a target-tracking scaling policy named myscalablepolicy from a variant named myscalablevariant.

```json
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount"
}
```

**Query Endpoint Autoscaling History**

You can view the status of scaling activities from your endpoint using `DescribeScalingActivities`. `DescribeScalingActivities` provides descriptive information about the scaling activities in the specified namespace from the previous six weeks.

**How To Query Endpoint Autoscaling Actions**

Query your autoscaling endpoints with `DescribeScalingActivities`. To do so, specify `ServiceNameSpace` parameter. `ServiceNameSpace` is the name of the AWS service that provides the resource.

Valid service name values include the following:

- ecs | elasticmapreduce | ec2 | appstream | dynamodb | rds | sagemaker | custom-resource | comprehend | lambda | cassandra

In this situation you need to set `ServiceNameSpace` to sagemaker.

Use the following AWS CLI command to view details about all of your sagemaker endpoints that have a scaling policy:

```
aws application-autoscaling describe-scaling-activities --service-namespace sagemaker
```

You can search for a specific endpoint using `ResourceId`:

```
aws application-autoscaling describe-scaling-activities --resource-ids
```
When you run this command, it returns the following output:

```
{
"ActivityId": "activity-id",
"ServiceNamespace": "sagemaker",
"ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
"ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
"Description": "string",
"Cause": "string",
"StartTime": timestamp,
"EndTime": timestamp,
"StatusCode": "string",
"StatusMessage": "string"
}
```

### How to Identify Blocked AutoScaling Due to Instance Quotas

When you scale out or add more instances, you might reach your account-level instance quota. You can use `DescribeScalingActivities` to check whether you have reached your instance quota. When you exceed your quota, automatic scaling is blocked.

To check if you have reached your instance quota, use the AWS CLI command as shown in the proceeding example where you specified the `ResourceId`:

```
aws application-autoscaling describe-scaling-activities \
   --service-namespace sagemaker \
   --resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

Within the return syntax, check the `StatusCode` and `StatusMessage` keys and their associated values. `StatusCode` returns `Failed`. Within `StatusMessage` there is a message indicating that the account-level service quota was reached. The following is an example of what that message might look like:

```
{
"ActivityId": "activity-id",
"ServiceNamespace": "sagemaker",
"ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
"ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
"Description": "string",
"Cause": "minimum capacity was set to 110",
"StartTime": timestamp,
"EndTime": timestamp,
"StatusCode": "Failed",
"StatusMessage": "Failed to set desired instance count to 110. Reason: The account-level service limit 'ml.xx.xxxxxx for endpoint usage' is 1000 Instances, with current utilization of 997 Instances and a request delta of 20 Instances. Please contact AWS support to request an increase for this limit. (Service: AmazonSageMaker; Status Code: 400; Error Code: ResourceLimitExceeded; Request ID: request-id)."
}
```

### Update or delete endpoints that use automatic scaling

**Topics**

- Update endpoints that use automatic scaling (p. 2701)
Update endpoints that use automatic scaling

When you update an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If the update would change the instance type for any model that is a target for automatic scaling, the update fails.

In the AWS Management Console, you see a warning that you must deregister the model from automatic scaling before you can update it. If you are trying to update the endpoint by calling the `UpdateEndpoint` API, the call fails. Before you update the endpoint, delete any scaling policies configured for it by calling the `DeleteScalingPolicy` Application Auto Scaling API action, then call `DeregisterScalableTarget` to deregister the variant as a scalable target. After you update the endpoint, you can register the variant as a scalable target and attach an automatic scaling policy to the updated variant.

There is one exception. If you change the model for a variant that is configured for automatic scaling, Amazon SageMaker automatic scaling allows the update. This is because changing the model doesn’t typically affect performance enough to change automatic scaling behavior. If you do update a model for a variant configured for automatic scaling, ensure that the change to the model doesn’t significantly affect performance and automatic scaling behavior.

When you update SageMaker endpoints that have automatic scaling applied, complete the following steps:

**To update an endpoint that has automatic scaling applied**

1. Deregister the endpoint as a scalable target by calling `DeregisterScalableTarget`.
2. Because automatic scaling is blocked while the update operation is in progress (or if you turned off automatic scaling in the previous step), you might want to take the additional precaution of increasing the number of instances for your endpoint during the update. To do this, update the instance counts for the production variants hosted at the endpoint by calling `UpdateEndpointWeightsAndCapacities`.
3. Call `DescribeEndpoint` repeatedly until the value of the `EndpointStatus` field of the response is `InService`.
4. Call `DescribeEndpointConfig` to get the values of the current endpoint config.
5. Create a new endpoint config by calling `CreateEndpointConfig`. For the production variants where you want to keep the existing instance count or weight, use the same variant name from the response from the call to `DescribeEndpointConfig` in the previous step. For all other values, use the values that you got as the response when you called `DescribeEndpointConfig` in the previous step.
6. Update the endpoint by calling `UpdateEndpoint`. Specify the endpoint config you created in the previous step as the `EndpointConfig` field. If you want to retain the variant properties like instance count or weight, set the value of the `RetainAllVariantProperties` parameter to `True`. This specifies that production variants with the same name will are updated with the most recent `DesiredInstanceCount` from the response from the call to `DescribeEndpoint`, regardless of the values of the `InitialInstanceCount` field in the new `EndpointConfig`.
7. (Optional) Re-enable automatic scaling by calling `RegisterScalableTarget`.

**Note**
Steps 1 and 7 are required only if you are updating an endpoint with the following changes:

- Changing the instance type for a production variant that has automatic scaling configured
- Removing a production variant that has automatic scaling configured.
Delete endpoints configured for automatic scaling

If you delete an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If any are and you have permission to deregister the model, Application Auto Scaling deregisters those models as scalable targets without notifying you. If you use a custom permission policy that doesn’t provide permission for the DeleteScalingPolicy and DeregisterScalableTarget actions, you must delete automatic scaling policies and deregister scalable targets and before deleting the endpoint.

**Note**
You, as an IAM user, might not have sufficient permission to delete an endpoint if another IAM user configured automatic scaling for a variant on that endpoint.

Load testing your autoscaling configuration

Perform load tests to choose an automatic scaling configuration that works the way you want.

For an example of load testing to optimize automatic scaling for an Amazon SageMaker endpoint, see Load test and optimize an Amazon SageMaker endpoint using automatic scaling.

The following guidelines for load testing assume you are using an automatic scaling policy that uses the predefined target metric SageMakerVariantInvocationsPerInstance.

**Topics**
- Determine the performance characteristics (p. 2702)
- Calculate the target load (p. 2702)

Determine the performance characteristics

Perform load testing to find the peak InvocationsPerInstance that your model’s production variant can handle, and the latency of requests, as concurrency increases.

This value depends on the instance type chosen, payloads that clients of your model typically send, and the performance of any external dependencies your model has.

To find the peak requests-per-second (RPS) your model's production variant can handle and latency of requests

1. Set up an endpoint with your model using a single instance. For information about how to set up an endpoint, see **Deploy the Model to SageMaker Hosting Services** (p. 84).
2. Use a load testing tool to generate an increasing number of parallel requests, and monitor the RPS and model latency in the output of the load testing tool.

   **Note**
   You can also monitor requests-per-minute instead of RPS. In that case don’t multiply by 60 in the equation to calculate SageMakerVariantInvocationsPerInstance shown below.

   When the model latency increases or the proportion of successful transactions decreases, this is the peak RPS that your model can handle.

Calculate the target load

After you find the performance characteristics of the variant, you can determine the maximum RPS we should allow to be sent to an instance. The threshold used for scaling must be less than this maximum
value. Use the following equation in combination with load testing to determine the correct value for the `SageMakerVariantInvocationsPerInstance` target metric in your automatic scaling configuration.

\[
\text{SageMakerVariantInvocationsPerInstance} = (\text{MAX\_RPS} \times \text{SAFETY\_FACTOR}) \times 60
\]

Where `MAX\_RPS` is the maximum RPS that you determined previously, and `SAFETY\_FACTOR` is the safety factor that you chose to ensure that your clients don't exceed the maximum RPS. Multiply by 60 to convert from RPS to invocations-per-minute to match the per-minute CloudWatch metric that SageMaker uses to implement automatic scaling (you don't need to do this if you measured requests-per-minute instead of requests-per-second).

**Note**

SageMaker recommends that you start testing with a `SAFETY\_FACTOR` of 0.5. Test your automatic scaling configuration to ensure it operates in the way you expect with your model for both increasing and decreasing customer traffic on your endpoint.

**Use AWS CloudFormation to update autoscaling policies**

The following is an example for how to enable autoscaling on an endpoint using AWS CloudFormation.

```
Endpoint:
  Type: "AWS::SageMaker::Endpoint"
Properties:
  EndpointName: yourEndpointName
  EndpointConfigName: yourEndpointConfigName

ScalingTarget:
  Type: "AWS::ApplicationAutoScaling::ScalableTarget"
Properties:
  MaxCapacity: 10
  MinCapacity: 2
  ResourceId: endpoint/MyEndPoint/variant/MyVariant
  RoleARN: arn
  ScalableDimension: sagemaker:variant:DesiredInstanceCount
  ServiceNamespace: sagemaker

ScalingPolicy:
  Type: "AWS::ApplicationAutoScaling::ScalingPolicy"
Properties:
  PolicyName: myscalablepolicy
  PolicyType: TargetTrackingScaling
  ScalingTargetId:
    Ref: ScalingTarget
  TargetTrackingScalingPolicyConfiguration:
    TargetValue: 75.0
    ScaleInCooldown: 600
    ScaleOutCooldown: 30
    PredefinedMetricSpecification:
      PredefinedMetricType: SageMakerVariantInvocationsPerInstance
```

For more details, refer to AWS CloudFormation's AutoScalingPlans API reference.

**Host instance storage volumes**

When you create an endpoint, Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances that hosts the endpoint. The size of the storage volume is scalable, and storage options are divided into two categories: SSD-backed storage and HDD-backed storage.
For more information about Amazon EBS storages and features, see the following pages.

- Amazon EBS Features
- Amazon EBS User Guide

For a full list of the host instance storage volumes, see Host Instance Storage Volumes Table

**Note**
Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances only when you create Asynchronous inference (p. 2791) or Real-time inference (p. 2641) endpoint types.

**Safely update models in production**

In production ML workflows, data scientists and engineers frequently try to improve their models in various ways, such as by performing Perform Automatic Model Tuning with SageMaker (p. 2360), training on additional or more-recent data, and improving feature selection. Performing A/B testing between a new model and an old model with production traffic can be an effective final step in the validation process for a new model. In A/B testing, you test different variants of your models and compare how each variant performs. If the newer version of the model delivers better performance than the previously-existing version, replace the old version of the model with the new version in production.

Amazon SageMaker enables you to test multiple models or model versions behind the same endpoint using production variants. Each production variant identifies a machine learning (ML) model and the resources deployed for hosting the model. By using production variants, you can test ML models that have been trained using different datasets, trained using different algorithms and ML frameworks, or are deployed to different instance type, or any combination of all of these. You can distribute endpoint invocation requests across multiple production variants by providing the traffic distribution for each variant, or you can invoke a specific variant directly for each request. In this topic, we look at both methods for testing ML models.

**Topics**

- Test models by specifying traffic distribution (p. 2704)
- Test models by invoking specific variants (p. 2705)
- Model A/B test example (p. 2706)

**Test models by specifying traffic distribution**

To test multiple models by distributing traffic between them, specify the percentage of the traffic that gets routed to each model by specifying the weight for each production variant in the endpoint configuration. For information, see `CreateEndpointConfig`. The following diagram shows how this works in more detail.
Test models by invoking specific variants

To test multiple models by invoking specific models for each request, specify the specific version of the model you want to invoke by providing a value for the `TargetVariant` parameter when you call `InvokeEndpoint`. SageMaker ensures that the request is processed by the production variant you specify. If you have already provided traffic distribution and specify a value for the `TargetVariant` parameter, the targeted routing overrides the random traffic distribution. The following diagram shows how this works in more detail.
Model A/B test example

The following example shows how to perform A/B model testing. For a sample notebook that implements this example, see "A/B Testing ML models in production.

Step 1: Create and deploy models

First, we define where our models are located in Amazon S3. These locations are used when we deploy our models in subsequent steps:

```python
model_url = f"s3://(path_to_model_1)"
model_url2 = f"s3://(path_to_model_2)"
```

Next, we create the model objects with the image and model data. These model objects are used to deploy production variants on an endpoint. The models are developed by training ML models on different data sets, different algorithms or ML frameworks, and different hyperparameters:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
model_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}" model_name2 = f"DEMO-xgb-churn-pred2-{datetime.now():%Y-%m-%d-%H-%M-%S}" image_uri = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-1')
```
We now create two production variants, each with its own different model and resource requirements (instance type and counts). This enables you to also test models on different instance types.

We set an initial_weight of 1 for both variants. This means that 50% of requests go to Variant1, and the remaining 50% of requests to Variant2. The sum of weights across both variants is 2 and each variant has weight assignment of 1. This means that each variant receives 1/2, or 50%, of the total traffic.

Finally we're ready to deploy these production variants on a SageMaker endpoint.

Step 2: Invoke the deployed models

Now we send requests to this endpoint to get inferences in real time. We use both traffic distribution and direct targeting.

First, we use traffic distribution that we configured in the previous step. Each inference response contains the name of the production variant that processes the request, so we can see that traffic to the two production variants is roughly equal.
for row in f:
    print('.', end='', flush=True)
payload = row.rstrip('
')
sm_runtime.invoke_endpoint(EndpointName=endpoint_name,
    ContentType="text/csv",
    Body=payload)
time.sleep(0.5)
print("Done!")

SageMaker emits metrics such as Latency and Invocations for each variant in Amazon CloudWatch. For a complete list of metrics that SageMaker emits, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498). Let’s query CloudWatch to get the number of invocations per variant, to show how invocations are split across variants by default:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Variant1</th>
<th>Variant2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-06-05 15:34:00</td>
<td>44.0</td>
<td>60.0</td>
</tr>
<tr>
<td>2020-06-05 15:35:00</td>
<td>7.0</td>
<td>9.0</td>
</tr>
</tbody>
</table>

Now let’s invoke a specific version of the model by specifying Variant1 as the TargetVariant in the call to invoke_endpoint.

```python
print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")
with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print('.', end='', flush=True)
payload = row.rstrip('n')
sm_runtime.invoke_endpoint(EndpointName=endpoint_name,
    ContentType="text/csv",
    Body=payload,
    *TargetVariant="Variant1") # Notice the new parameter
time.sleep(0.5)
```

To confirm that all new invocations were processed by Variant1, we can query CloudWatch to get the number of invocations per variant. We see that for the most recent invocations (latest timestamp), all requests were processed by Variant1, as we had specified. There were no invocations made for Variant2.
Step 3: Evaluate model performance

To see which model version performs better, let's evaluate the accuracy, precision, recall, F1 score, and Receiver operating characteristic/Area under the curve for each variant. First, let's look at these metrics for Variant1:

- Accuracy: 0.9583333333333334
- Precision: 0.9411764705882351
- Recall: 0.8
- F1 Score: 0.8648648648648648
- AUC is 0.895

Now let's look at the metrics for Variant2:
For most of our defined metrics, Variant2 is performing better, so this is the one that we want to use in production.

**Step 4: Increase traffic to the best model**

Now that we have determined that Variant2 performs better than Variant1, we shift more traffic to it. We can continue to use TargetVariant to invoke a specific model variant, but a simpler approach is to update the weights assigned to each variant by calling `UpdateEndpointWeightsAndCapacities`. This changes the traffic distribution to your production variants without requiring updates to your endpoint. Recall from the setup section that we set variant weights to split traffic 50/50. The CloudWatch metrics for the total invocations for each variant below show us the invocation patterns for each variant:

Now we shift 75% of the traffic to Variant2 by assigning new weights to each variant using `UpdateEndpointWeightsAndCapacities`. SageMaker now sends 75% of the inference requests to Variant2 and remaining 25% of requests to Variant1.

```python
sm.update_endpoint_weights_and_capacities(  
    EndpointName=endpoint_name,  
    DesiredWeightsAndCapacities=[  
        {  
            "DesiredWeight": 25,  
            "VariantName": variant1["VariantName"]  
        },  
        {  
            "DesiredWeight": 75,  
            "VariantName": variant2["VariantName"]  
        }  
    ]  
)
```
The CloudWatch metrics for total invocations for each variant shows us higher invocations for Variant2 than for Variant1:

![Graph showing CloudWatch metrics for Variant1 and Variant2](image)

We can continue to monitor our metrics, and when we're satisfied with a variant's performance, we can route 100% of the traffic to that variant. We use `UpdateEndpointWeightsAndCapacities` to update the traffic assignments for the variants. The weight for Variant1 is set to 0 and the weight for Variant2 is set to 1. SageMaker now sends 100% of all inference requests to Variant2.

```python
sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 0,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 1,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```

The CloudWatch metrics for the total invocations for each variant show that all inference requests are being processed by Variant2 and there are no inference requests processed by Variant1.

![Graph showing CloudWatch metrics for Variant1 and Variant2 after update](image)

You can now safely update your endpoint and delete Variant1 from your endpoint. You can also continue testing new models in production by adding new variants to your endpoint and following steps 2 - 4.

**Best practices**

This topic provides guidance on best practices for deploying machine learning models in Amazon SageMaker.
Topics

- Best practices for deploying models on SageMaker Hosting Services (p. 2712)
- Low latency real-time inference with AWS PrivateLink (p. 2713)
- Troubleshoot Amazon SageMaker model deployments (p. 2714)

Best practices for deploying models on SageMaker Hosting Services

When hosting models using SageMaker hosting services, consider the following:

- Typically, a client application sends requests to the SageMaker HTTPS endpoint to obtain inferences from a deployed model. You can also send requests to this endpoint from your Jupyter notebook during testing.

- You can deploy a model trained with SageMaker to your own deployment target. To do that, you need to know the algorithm-specific format of the model artifacts that were generated by model training. For more information about output formats, see the section corresponding to the algorithm you are using in Common Data Formats for Training (p. 1912).

- You can deploy multiple variants of a model to the same SageMaker HTTPS endpoint. This is useful for testing variations of a model in production. For example, suppose that you've deployed a model into production. You want to test a variation of the model by directing a small amount of traffic, say 5%, to the new model. To do this, create an endpoint configuration that describes both variants of the model. You specify the ProductionVariant in your request to the CreateEndPointConfig. For more information, see ProductionVariant.

- You can configure a ProductionVariant to use Application Auto Scaling. For information about configuring automatic scaling, see Automatically Scale Amazon SageMaker Models (p. 2688).

- You can modify an endpoint without taking models that are already deployed into production out of service. For example, you can add new model variants, update the ML Compute instance configurations of existing model variants, or change the distribution of traffic among model variants. To modify an endpoint, you provide a new endpoint configuration. SageMaker implements the changes without any downtime. For more information see, UpdateEndpoint and UpdateEndpointWeightsAndCapacities.

- Changing or deleting model artifacts or changing inference code after deploying a model produces unpredictable results. If you need to change or delete model artifacts or change inference code, modify the endpoint by providing a new endpoint configuration. Once you provide the new endpoint configuration, you can change or delete the model artifacts corresponding to the old endpoint configuration.

- If you want to get inferences on entire datasets, consider using batch transform as an alternative to hosting services. For information, see Use Batch Transform (p. 2807)

Deploy Multiple Instances Across Availability Zones

Create robust endpoints when hosting your model. SageMaker endpoints can help protect your application from Availability Zone outages and instance failures. If an outage occurs or an instance fails, SageMaker automatically attempts to distribute your instances across Availability Zones. For this reason, we strongly recommended that you deploy multiple instances for each production endpoint.

If you are using an Amazon Virtual Private Cloud (VPC), configure the VPC with at least two Subnets, each in a different Availability Zone. If an outage occurs or an instance fails, Amazon SageMaker automatically attempts to distribute your instances across Availability Zones.

In general, to achieve more reliable performance, use more small Instance Types in different Availability Zones to host your endpoints.
Low latency real-time inference with AWS PrivateLink

Amazon SageMaker provides low latency for real-time inferences while maintaining high availability and resiliency using multi-AZ deployment. The end-to-end application latency is made up of two primary components: infrastructure or overhead latency and model inference latency. Reduction of overhead latency opens up new possibilities such as deploying more complex, deep, and accurate models or splitting monolithic applications into scalable and maintainable microservice modules. You can reduce the latency for real-time inferences with SageMaker using an AWS PrivateLink deployment. With AWS PrivateLink, you can privately access all SageMaker API operations from your Virtual Private Cloud (VPC) in a scalable manner by using interface VPC endpoints. An interface VPC endpoint is an elastic network interface in your subnet with private IP addresses that serves as an entry point for all SageMaker API calls.

By default, a SageMaker endpoint with 2 or more instances is deployed in at least 2 AWS Availability Zones (AZs) and instances in any AZ can process invocations. This results in one or more AZ “hops” that contribute to the overhead latency. An AWS PrivateLink deployment with the privateDNSEnabled option set as true alleviates this by achieving two objectives:

- It keeps all inference traffic within your VPC.
- It keeps invocation traffic in the same AZ as the client that originated it when using SageMaker. This avoids the “hops” between AZs reducing the overhead latency.

The following sections of this guide demonstrate how you can reduce the latency for real-time inferences with AWS PrivateLink deployment.

Topics
- Deploy AWS PrivateLink (p. 2713)
- Deploy SageMaker endpoint in a VPC (p. 2713)
- Invoke the SageMaker endpoint (p. 2714)

Deploy AWS PrivateLink

To deploy AWS PrivateLink first create an interface endpoint for the VPC from which you connect to the SageMaker endpoints. Please follow the steps in Access an AWS service using an interface VPC endpoint to create the interface endpoint. While creating the endpoint select the following settings in the console interface:

- Select Enable DNS name checkbox under Additional Settings
- Select the appropriate security groups and the subnets to be used with the SageMaker endpoints.

Also make sure that the VPC has DNS hostnames turned on. For more information on how to change DNS attributes for your VPC, see View and update DNS attributes for your VPC.

Deploy SageMaker endpoint in a VPC

To achieve low overhead latency, create a SageMaker endpoint using the same subnets that you specified when deploying AWS PrivateLink. These subnets should match the AZs of your client application, as shown in the following example.

```python
vpc = 'vpc-011637c01ab03da77'
subnet_a = 'subnet-057a11df635ecb698'
subnet_b = 'subnet-0db1981c3f99a1ed1'
security_group = 'sg-08c49f29f6b429373'
```
create_model_response = sm_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = role,
    PrimaryContainer = primary_container
)
VpcConfig={
    'SecurityGroupIds': [security_group],
    'Subnets': [subnet_a, subnet_b],
}
....

Invoke the SageMaker endpoint

Finally, specify the SageMaker client and invoke the SageMaker endpoint as shown in the following example.

....
runtime_client = boto3.client('sagemaker-runtime')
response = runtime_client.invoke_endpoint(EndpointName=endpoint_name,
    ContentType='text/csv',
    Body=payload)
....

Troubleshoot Amazon SageMaker model deployments

If you encounter an issue when deploying machine learning models in Amazon SageMaker, see the following guidance.

Topics
- Detection Errors in the Active CPU Count (p. 2714)

Detection Errors in the Active CPU Count

If you deploy a SageMaker model with a Linux Java Virtual Machine (JVM), you might encounter detection errors that prevent using available CPU resources. This issue affects some JVMs that support Java 8 and Java 9, and most that support Java 10 and Java 11. These JVMs implement a mechanism that detects and handles the CPU count and the maximum memory available when running a model in a Docker container, and, more generally, within Linux taskset commands or control groups (cgroups). SageMaker deployments take advantage of some of the settings that the JVM uses for managing these resources. Currently, this causes the container to incorrectly detect the number of available CPUs.

SageMaker doesn’t limit access to CPUs on an instance. However, the JVM might detect the CPU count as 1 when more CPUs are available for the container. As a result, the JVM adjusts all of its internal settings to run as if only 1 CPU core is available. These settings affect garbage collection, locks, compiler threads, and other JVM internals that negatively affect the concurrency, throughput, and latency of the container.

For an example of the misdetection, in a container configured for SageMaker that is deployed with a JVM that is based on Java8_191 and that has four available CPUs on the instance, run the following command to start your JVM:

```
java -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:
Monitor models for data and model quality, bias, and explainability

Amazon SageMaker Model Monitor continuously monitors the quality of Amazon SageMaker machine learning models in production. With Model Monitor, you can set alerts that notify you when there are deviations in the model quality. Early and proactive detection of these deviations enables you to take corrective actions, such as retraining models, auditing upstream systems, or fixing quality issues without having to monitor models manually or build additional tooling. You can use Model Monitor predefined monitoring capabilities that do not require coding. You also have the flexibility to monitor models by coding to provide custom analysis.

Model Monitor provides the following types of monitoring:

- Monitor data quality (p. 2717) - Monitor drift in data quality.
- Monitor model quality (p. 2722) - Monitor drift in model quality metrics, such as accuracy.
- Monitor Bias Drift for Models in Production (p. 2729) - Monitor bias in your model's predictions.
- Monitor Feature Attribution Drift for Models in Production (p. 2736) - Monitor drift in feature attribution.
How Model Monitor Works

Amazon SageMaker Model Monitor automatically monitors machine learning (ML) models in production and notifies you when quality issues arise. Model Monitor uses rules to detect drift in your models and alerts you when it happens. The following figure shows how this process works.

To enable model monitoring, you take the following steps, which follow the path of the data through the various data collection, monitoring, and analysis processes:

- Enable the endpoint to capture data from incoming requests to a trained ML model and the resulting model predictions.
- Create a baseline from the dataset that was used to train the model. The baseline computes metrics and suggests constraints for the metrics. Real-time predictions from your model are compared to the constraints, and are reported as violations if they are outside the constrained values.
- Create a monitoring schedule specifying what data to collect, how often to collect it, how to analyze it, and which reports to produce.
- Inspect the reports, which compare the latest data with the baseline, and watch for any violations reported and for metrics and notifications from Amazon CloudWatch.
Amazon SageMaker Developer Guide
Monitor models for data and model quality, bias, and explainability

Notes

- Model Monitor currently supports only tabular data.
- Model Monitor currently supports only endpoints that host a single model and does not support monitoring multi-model endpoints. For information on using multi-model endpoints, see Host multiple models in one container behind one endpoint (p. 2652).
- Model Monitor supports monitoring inference pipelines, but capturing and analyzing data is done for the entire pipeline, not for individual containers in the pipeline.
- To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.
- If you launch SageMaker Studio in a custom Amazon VPC, you need to create VPC endpoints to enable Model Monitor to communicate with Amazon S3 and CloudWatch. For information about VPC endpoints, see VPC endpoints in the Amazon Virtual Private Cloud User Guide. For information about launching SageMaker Studio in a custom VPC, see Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3466).

Model Monitor Sample Notebooks

For a sample notebook that takes you through the full end-to-end workflow for Model Monitor, see the Introduction to Amazon SageMaker Model Monitor.

For a sample notebook that visualizes the statistics.json file for a selected execution in a monitoring schedule, see the Model Monitor Visualization.

For instructions that show you how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose the notebook’s Use tab and choose Create copy.

Monitor data quality

Data quality monitoring automatically monitors machine learning (ML) models in production and notifies you when data quality issues arise. ML models in production have to make predictions on real-life data that is not carefully curated like most training datasets. If the statistical nature of the data that your model receives while in production drifts away from the nature of the baseline data it was trained on, the model begins to lose accuracy in its predictions. Amazon SageMaker Model Monitor uses rules to detect data drift and alerts you when it happens. To monitor data quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint and stores the data in Amazon S3. For more information, see Capture data (p. 2745).
- Create a baseline. In this step, you run a baseline job that analyzes an input dataset that you provide. The baseline computes baseline schema constraints and statistics for each feature using Deequ, an open source library built on Apache Spark, which is used to measure data quality in large datasets. For more information, see Create a Baseline (p. 2718).
- Define and schedule data quality monitoring jobs. For more information, see Schedule monitoring jobs (p. 2750).
- View data quality metrics. For more information, see Schema for Statistics (statistics.json file) (p. 2719).
- Integrate data quality monitoring with Amazon CloudWatch. For more information, see CloudWatch Metrics (p. 2720).
- Interpret the results of a monitoring job. For more information, see Interpret results (p. 2753).
- Use SageMaker Studio to enable data quality monitoring and visualize results. For more information, see Visualize results in Amazon SageMaker Studio (p. 2755).
Amazon SageMaker Model Monitor currently supports only tabular data.

Topics
- Create a Baseline (p. 2718)
- Schema for Statistics (statistics.json file) (p. 2719)
- CloudWatch Metrics (p. 2720)
- Schema for Violations (constraint_violations.json file) (p. 2721)

Create a Baseline

The baseline calculations of statistics and constraints are needed as a standard against which data drift and other data quality issues can be detected. Model Monitor provides a built-in container that provides the ability to suggest the constraints automatically for CSV and flat JSON input. This `sagemaker-model-monitor-analyzer` container also provides you with a range of model monitoring capabilities, including constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark and is built with Deequ. All column names in your baseline dataset must be compliant with Spark. For column names, use only lowercase characters, and _ as the only special character.

The training dataset that you used to trained the model is usually a good baseline dataset. The training dataset data schema and the inference dataset schema should exactly match (the number and order of the features). Note that the prediction/output columns are assumed to be the first columns in the training dataset. From the training dataset, you can ask SageMaker to suggest a set of baseline constraints and generate descriptive statistics to explore the data. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already stored the training dataset in Amazon S3, you can point to it directly.

To Create a baseline from a training dataset

When you have your training data ready and stored in Amazon S3, start a baseline processing job with `DefaultModelMonitor.suggest_baseline(.,)` using the Amazon SageMaker Python SDK. This uses an Amazon SageMaker Model Monitor prebuilt container (p. 2752) that generates baseline statistics and suggests baseline constraints for the dataset and writes them to the `output_s3_uri` location that you specify.

```python
from sagemaker.model_monitor import DefaultModelMonitor
from sagemaker.model_monitor.dataset_format import DatasetFormat

my_default_monitor = DefaultModelMonitor(  
    role=role,  
    instance_count=1,  
    instance_type='ml.m5.xlarge',  
    volume_size_in_gb=20,  
    max_runtime_in_seconds=3600,  
)

my_default_monitor.suggest_baseline(  
    baseline_dataset=baseline_data_uri+'training-dataset-with-header.csv',  
    dataset_format=DatasetFormat.csv(header=True),  
    output_s3_uri=baseline_results_uri,  
    wait=True  
)
```

Note
If you provide the feature/column names in the training dataset as the first row and set the `header=True` option as shown in the previous code sample, SageMaker uses the feature name in the constraints and statistics file.
The baseline statistics for the dataset are contained in the `statistics.json` file and the suggested baseline constraints are contained in the `constraints.json` file in the location you specify with `output_s3_uri`.

### Output Files for Tabular Dataset Statistics and Constraints

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>statistics.json</code></td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. For more information about the schema for this file, see [Schema for Statistics](statistics.json file) (p. 2766).</td>
</tr>
<tr>
<td><code>constraints.json</code></td>
<td>This file is expected to have the constraints on the features observed. For more information about the schema for this file, see [Schema for Constraints](constraints.json file) (p. 2768).</td>
</tr>
</tbody>
</table>

The Amazon SageMaker Python SDK provides convenience functions described to generate the baseline statistics and constraints. But if you want to call processing job directly for this purpose instead, you need to set the `Environment` map as shown in the following example:

```json
"Environment": {
    "dataset_format": "{\"csv\": { \"header\": true}}",
    "dataset_source": "/opt/ml/processing/sm_input",
    "output_path": "/opt/ml/processing/sm_output",
    "publish_cloudwatch_metrics": "Disabled",
}
```

### Schema for Statistics (statistics.json file)

Amazon SageMaker Model Monitor prebuilt container computes per column/feature statistics. The statistics are calculated for the baseline dataset and also for the current dataset that is being analyzed.

```json
{
    "version": 0,
    "dataset": {
        "item_count": number
    },
    "features": [
        {
            "name": "feature-name",
            "inferred_type": "Fractional" | "Integral",
            "numerical_statistics": {
                "common": {
                    "num_present": number,
                    "num_missing": number
                },
                "mean": number,
                "sum": number,
                "std_dev": number,
                "min": number,
                "max": number,
                "distribution": {
                    "kll": {
                        "buckets": [
                            {
                                "lower_bound": number,
                            }...
```
Note the following:

- The prebuilt containers compute **KLL sketch**, which is a compact quantiles sketch.
- By default, we materialize the distribution in 10 buckets. This is not currently configurable.

**CloudWatch Metrics**

You can use the built-in Amazon SageMaker Model Monitor container for CloudWatch metrics. When the `emit_metrics` option is Enabled in the baseline constraints file, SageMaker emits these metrics
for each feature/column observed in the dataset in the /aws/sagemaker/Endpoints/data-metric namespace with EndpointName and ScheduleName dimensions.

For numerical fields, the built-in container emits the following CloudWatch metrics:

- Metric: Max → query for MetricName: feature_data_{feature_name}, Stat: Max
- Metric: Min → query for MetricName: feature_data_{feature_name}, Stat: Min
- Metric: Sum → query for MetricName: feature_data_{feature_name}, Stat: Sum
- Metric: SampleCount → query for MetricName: feature_data_{feature_name}, Stat: SampleCount
- Metric: Average → query for MetricName: feature_data_{feature_name}, Stat: Average

For both numerical and string fields, the built-in container emits the following CloudWatch metrics:

- Metric: Completeness → query for MetricName: feature_non_null_{feature_name}, Stat: Sum
- Metric: Baseline Drift → query for MetricName: feature_baseline_drift_{feature_name}, Stat: Sum

Schema for Violations (constraint_violations.json file)

The violations file is generated as the output of a MonitoringExecution, which lists the results of evaluating the constraints (specified in the constraints.json file) against the current dataset that was analyzed. The Amazon SageMaker Model Monitor prebuilt container provides the following violation checks.

```json
{
  "violations": [{
    "feature_name": "string",
    "constraint_check_type":
      "data_type_check",
    | "completeness_check",
    | "baseline_drift_check",
    | "missing_column_check",
    | "extra_column_check",
    | "categorical_values_check"
    "description": "string"
  ]
}
```

Types of Violations Monitored

<table>
<thead>
<tr>
<th>Violation Check Type</th>
<th>Description</th>

<td>If there are more unknown values in the current dataset than in the baseline dataset, this violation is flagged. This value is dictated by the threshold in monitoring_config.domain_content_threshold.</td>
</tr>
</tbody>
</table>

Monitor model quality

Model quality monitoring jobs monitor the performance of a model by comparing the predictions that the model makes with the actual ground truth labels that the model attempts to predict. To do this, model quality monitoring merges data that is captured from real-time inference with actual labels that you store in an Amazon S3 bucket, and then compares the predictions with the actual labels.

To measure model quality, model monitor uses metrics that depend on the ML problem type. For example, if your model is for a regression problem, one of the metrics evaluated is mean square error (mse). For information about all of the metrics used for the different ML problem types, see Model Quality Metrics (p. 2725).

Model quality monitoring follows the same steps as data quality monitoring, but adds the additional step of merging the actual labels from Amazon S3 with the predictions captured from the real-time inference endpoint. To monitor model quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint and stores the data in Amazon S3. For more information, see Capture data (p. 2745).
- Create a baseline. In this step, you run a baseline job that compares predictions from the model with ground truth labels in a baseline dataset. The baseline job automatically creates baseline statistical rules and constraints that define thresholds against which the model performance is evaluated. For more information, see Create a Model Quality Baseline (p. 2723).
- Define and schedule model quality monitoring jobs. For more information, see Schedule Model Quality Monitoring Jobs (p. 2724).
- Ingest ground truth labels that model monitor merges with captured prediction data from real-time inference endpoint. For more information, see Ingest Ground Truth Labels and Merge Them With Predictions (p. 2725).
- Integrate model quality monitoring with Amazon CloudWatch. For more information, see Model Quality CloudWatch Metrics (p. 2728).
• Interpret the results of a monitoring job. For more information, see Interpret results (p. 2753).
• Use SageMaker Studio to enable model quality monitoring and visualize results. For more information, see Visualize results in Amazon SageMaker Studio (p. 2755).

Topics
• Create a Model Quality Baseline (p. 2723)
• Schedule Model Quality Monitoring Jobs (p. 2724)
• Ingest Ground Truth Labels and Merge Them With Predictions (p. 2725)
• Model Quality Metrics (p. 2725)
• Model Quality CloudWatch Metrics (p. 2728)

Create a Model Quality Baseline

Create a baseline job that compares your model predictions with ground truth labels in a baseline dataset that you have stored in Amazon S3. Typically, you use a training dataset as the baseline dataset. The baseline job calculates metrics for the model and suggests constraints to use to monitor model quality drift.

To create a baseline job, you need to have a dataset that contains predictions from your model along with labels that represent the ground truth for your data.

To create a baseline job use the ModelQualityMonitor class provided by the SageMaker Python SDK, and complete the following steps.

To create a model quality baseline job

1. First, create an instance of the ModelQualityMonitor class. The following code snippet shows how to do this.
   
   ```python
   from sagemaker import get_execution_role, session, Session
   from sagemaker.model_monitor import ModelQualityMonitor

   role = get_execution_role()
   session = Session()

   model_quality_monitor = ModelQualityMonitor(
       role=role,
       instance_count=1,
       instance_type='ml.m5.xlarge',
       volume_size_in_gb=20,
       max_runtime_in_seconds=1800,
       sagemaker_session=session
   )
   ```

2. Now call the suggest_baseline method of the ModelQualityMonitor object to run a baseline job. The following code snippet assumes that you have a baseline dataset that contains both predictions and labels stored in Amazon S3.

   ```python
   baseline_job_name = "MyBaseLineJob"
   job = model_quality_monitor.suggest_baseline(
       job_name=baseline_job_name,
       baseline_dataset=baseline_dataset_uri, # The S3 location of the validation dataset.
       dataset_format=DatasetFormat.csv(header=True),
       output_s3_uri = baseline_results_uri, # The S3 location to store the results.
       problem_type='BinaryClassification',
       inference_attribute="prediction", # The column in the dataset that contains predictions.
   )
   ```
probability_attribute= "probability", # The column in the dataset that contains probabilities.
   ground_truth_attribute= "label" # The column in the dataset that contains ground truth labels.
)  
job.wait(logs=False)

3. After the baseline job finishes, you can see the constraints that the job generated. First, get the results of the baseline job by calling the latest_baselining_job method of the ModelQualityMonitor object.

```python
baseline_job = model_quality_monitor.latest_baselining_job
```

4. The baseline job suggests constraints, which are thresholds for metrics that model monitor measures. If a metric goes beyond the suggested threshold, Model Monitor reports a violation. To view the constraints that the baseline job generated, call the suggested_constraints method of the baseline job. The following code snippet loads the constraints for a binary classification model into a Pandas dataframe.

```python
import pandas as pd
pd.DataFrame(baseline_job.suggested_constraints().body_dict["binary_classification_constraints"]).T
```

We recommend that you view the generated constraints and modify them as necessary before using them for monitoring. For example, if a constraint is too aggressive, you might get more alerts for violations than you want.

5. When you are satisfied with the constraints, pass them as the constraints parameter when you create a monitoring schedule. For more information, see Schedule Model Quality Monitoring Jobs (p. 2724).

The suggested baseline constraints are contained in the constraints.json file in the location you specify with output_s3_uri. For information about the schema for this file in the Schema for Constraints (constraints.json file) (p. 2768).

Schedule Model Quality Monitoring Jobs

For general information about scheduling monitoring jobs, see the section called “Schedule monitoring jobs” (p. 2750). For model quality monitoring, you also have to consider the fact that the availability of ground truth labels might be delayed.

To address this, use offsets. Model quality jobs include StartOffset and EndOffset, which are fields of the ModelQualityJobInput parameter of the create_model_quality_job_definition method that work as follows:

- **StartOffset** - If specified, jobs subtract this time from the start time.
- **EndOffset** - If specified, jobs subtract this time from the end time.

The format of the offsets are, for example, -P7H, where 7H is 7 hours. You can use -P#H or -P#D, where H=hours, D=days, and M=minutes, and # is the number.

For example, if your ground truth starts coming in after 1 day, but is not complete for a week, set StartOffset to -P8D and EndOffset to -P1D. Then, if you schedule a job to run at 2020-01-09T13:00, it analyzes data from between 2020-01-01T13:00 and 2020-01-08T13:00.

**Important**
The schedule cadence should be such that one execution finishes before the next execution starts, which allows the ground truth merge job and monitoring job from the execution to complete. The maximum runtime of an execution is divided between the two jobs, so for an
hourly model quality monitoring job, the value of MaxRuntimeInSeconds specified as part of StoppingCondition should be no more than 1800.

**Ingest Ground Truth Labels and Merge Them With Predictions**

Model quality monitoring compares the predictions your model makes with ground truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint and upload it to Amazon S3.

To match ground truth labels with captured prediction data, there must be a unique identifier for each record in the dataset. The structure of each record for ground truth data is as follows:

```json
{
    "groundTruthData": {
        "data": "1",
        "encoding": "CSV" # only CSV supported at launch, we assume "data" only consists of label
    },
    "eventMetadata": {
        "eventId": "aaaa-bbbb-cccc"
    },
    "eventVersion": "0"
}
```

In the `groundTruthData` structure, `eventId` can be one of the following:

- `eventId` – This ID is automatically generated when a user invokes the endpoint.
- `inferenceId` – The caller supplies this ID when they invoke the endpoint.

If `inferenceId` is present in captured data records, Model Monitor uses it to merge captured data with ground truth records. You are responsible for making sure that the `inferenceId` in the ground truth records match the `inferenceId` in the captured records. If `inferenceId` is not present in captured data, model monitor uses `eventId` from the captured data records to match them with a ground truth record.

You must upload ground truth data to an Amazon S3 bucket that has the same path format as captured data, which is of the following form:

`s3://bucket/prefixyyyy/mm/dd/hh`

The date in this path is the date when the ground truth label is collected, and does not have to match the date when the inference was generated.

After you create and upload the ground truth labels, include the location of the labels as a parameter when you create the monitoring job. If you are using AWS SDK for Python (Boto3), do this by specifying the location of ground truth labels as the `S3Uri` field of the `GroundTruthS3Input` parameter in a call to the `create_model_quality_job_definition` method. If you are using the SageMaker Python SDK, specify the location of the ground truth labels as the `ground_truth_input` parameter in the call to the `create_monitoring_schedule` of the `ModelQualityMonitor` object.

**Model Quality Metrics**

Model quality monitoring jobs compute different metrics depending on the ML problem type. The following sections list the metrics analyzed for each ML problem type.

**Note**

Standard deviation for metrics are provided only when at least 200 samples are available. Model Monitor computes standard deviation by randomly sampling 80% of the data 5 times, computing the metric, and taking the standard deviation for those results.
Regression Metrics

The following shows an example of the metrics that model quality monitor computes for a regression problem.

```
"regression_metrics" : {
    "mae" : {
        "value" : 0.3711832061068702,
        "standard_deviation" : 0.0037566388129940394
    },
    "mse" : {
        "value" : 0.3711832061068702,
        "standard_deviation" : 0.0037566388129940524
    },
    "rmse" : {
        "value" : 0.609248066149471,
        "standard_deviation" : 0.003079253267651125
    },
    "r2" : {
        "value" : -1.3766111872212665,
        "standard_deviation" : 0.022653980022771227
    }
}
```

Binary Classification Metrics

The following shows an example of the metrics that model quality monitor computes for a binary classification problem.

```
"binary_classification_metrics" : {
    "confusion_matrix" : {
        "0" : {
            "0" : 1,
            "1" : 2
        },
        "1" : {
            "0" : 0,
            "1" : 1
        }
    },
    "recall" : {
        "value" : 1.0,
        "standard_deviation" : "NaN"
    },
    "precision" : {
        "value" : 0.3333333333333333,
        "standard_deviation" : "NaN"
    },
    "accuracy" : {
        "value" : 0.5,
        "standard_deviation" : "NaN"
    },
    "recall_best_constant_classifier" : {
        "value" : 1.0,
        "standard_deviation" : "NaN"
    },
    "precision_best_constant_classifier" : {
        "value" : 0.25,
        "standard_deviation" : "NaN"
    },
    "accuracy_best_constant_classifier" : {
        "value" : 0.25,
        "standard_deviation" : "NaN"
    }
}
```
Monitor models for data and model quality, bias, and explainability

Multiclass Metrics

The following shows an example of the metrics that model quality monitor computes for a multiclass classification problem.

```
"multiclass_classification_metrics" : {
    "confusion_matrix" : {
        "0" : {
            "0" : 1180,
            ...
        }
    }
}
```
Monitor models for data and model quality, bias, and explainability

Model Quality CloudWatch Metrics

If you set the value of the `enable_cloudwatch_metrics` to True when you create the monitoring schedule, model quality monitoring jobs send all metrics to Amazon CloudWatch.

Model quality metrics appear in the `aws/sagemaker/Endpoints/model-metrics` namespace. For a list of the metrics that are emitted, see Model Quality Metrics (p. 2725).
You can use CloudWatch metrics to create an alarm when a specific metric doesn't meet the threshold you specify. For instructions about how to create CloudWatch alarms, see Create a CloudWatch Alarm Based on a Static Threshold in the Amazon CloudWatch User Guide.

Monitor Bias Drift for Models in Production

Amazon SageMaker Clarify bias monitoring helps data scientists and ML engineers monitor predictions for bias on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing bias in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if bias beyond a certain threshold is detected. Bias can be introduced or exacerbated in deployed ML models when the training data differs from the data that the model sees during deployment (that is, the live data). These kinds of changes in the live data distribution might be temporary (for example, due to some short-lived, real-world events) or permanent. In either case, it might be important to detect these changes. For example, the outputs of a model for predicting home prices can become biased if the mortgage rates used to train the model differ from current, real-world mortgage rates.

With bias detection capabilities in Model Monitor, when SageMaker detects bias beyond a certain threshold, it automatically generates metrics that you can view in SageMaker Studio and through Amazon CloudWatch alerts.

In general, measuring bias only during the train-and-deploy phase might not be sufficient. It is possible that after the model has been deployed, the distribution of the data that the deployed model sees (that is, the live data) is different from data distribution in the training dataset. This change might introduce bias in a model over time. The change in the live data distribution might be temporary (for example, due to some short-lived behavior like the holiday season) or permanent. In either case, it might be important to detect these changes and take steps to reduce the bias when appropriate.

To detect these changes, SageMaker Clarify provides functionality to monitor the bias metrics of a deployed model continuously and raise automated alerts if the metrics exceed a threshold. For example, consider the DPPL bias metric. Specify an allowed range of values $A=(a_{\text{min}}, a_{\text{max}})$, for instance an interval of $(-0.1, 0.1)$, that DPPL should belong to during deployment. Any deviation from this range should raise a bias detected alert. With SageMaker Clarify, you can perform these checks at regular intervals.

For example, you can set the frequency of the checks to 2 days. This means that SageMaker Clarify computes the DPPL metric on data collected during a 2-day window. In this example, $D_{\text{win}}$ is the data that the model processed during last 2-day window. An alert is issued if the DPPL value $b_{\text{win}}$ computed on $D_{\text{win}}$ falls outside of an allowed range $A$. This approach to checking if $b_{\text{win}}$ is outside of $A$ can be somewhat noisy. $D_{\text{win}}$ might consist of very few samples and might not be representative of the live data distribution. The small sample size means that the value of bias $b_{\text{win}}$ computed over $D_{\text{win}}$ might not be a very robust estimate. In fact, very high (or low) values of $b_{\text{win}}$ may be observed purely due to chance. To ensure that the conclusions drawn from the observed data are statistically significant, SageMaker Clarify makes use of confidence intervals. Specifically, it uses the Normal Bootstrap Interval method to construct an interval $C=(c_{\text{min}}, c_{\text{max}})$ such that SageMaker Clarify is confident that the true bias value computed over the full live data is contained in $C$ with high probability. Now, if the confidence interval $C$ overlaps with the allowed range $A$, SageMaker Clarify interprets it as “it is likely that the bias metric value of the live data distribution falls within the allowed range”. If $C$ and $A$ are disjoint, SageMaker Clarify is confident that the bias metric does not lie in $A$ and raises an alert.

Model Monitor Sample Notebook

Amazon SageMaker Clarify provides the following sample notebook that shows how to capture real-time inference data, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 132). If you're prompted to choose a kernel, choose Python 3 (Data Science). The following
topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

Topics
- Create a Bias Drift Baseline (p. 2730)
- Bias Drift Violations (p. 2731)
- Configure Parameters to Monitor Bias Drift (p. 2732)
- Schedule Bias Drift Monitoring Jobs (p. 2735)
- Inspect Reports for Data Bias Drift (p. 2735)
- CloudWatch Metrics for Bias Drift Analysis (p. 2736)

Create a Bias Drift Baseline

After you have configured your application to capture real-time inference data, the first task to monitor for bias drift is to create a baseline. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job.

Model bias monitor can detect bias drift of ML models on a regular basis. Similar to the other monitoring types, the standard procedure of creating a model bias monitor is first baselining and then establishing a monitoring schedule.

```python
model_bias_monitor = ModelBiasMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)
```

DataConfig stores information about the dataset to be analyzed (for example, the dataset file), its format (that is, CSV or JSON Lines), headers (if any) and label.

```python
model_bias_baselining_job_result_uri = f"{baseline_results_uri}/model_bias"
model_bias_data_config = DataConfig(
    s3_data_input_path=validation_dataset,
    s3_output_path=model_bias_baselining_job_result_uri,
    label=label_header,
    headers=all_headers,
    dataset_type=dataset_type,
)
```

BiasConfig is the configuration of the sensitive groups in the dataset. Typically, bias is measured by computing a metric and comparing it across groups. The group of interest is called the facet. For posttraining bias, you should also take the positive label into account.

```python
model_bias_config = BiasConfig(
    label_values_or_threshold=[1],
    facet_name="Account Length",
    facet_values_or_threshold=[100],
)
```

ModelPredictedLabelConfig specifies how to extract a predicted label from the model output. In this example, the 0.8 cutoff has been chosen in anticipation that customers will turn over frequently. For more complicated outputs, there are a few more options, like "label" is the index, name, or JSONPath to locate predicted label in endpoint response payload.
```
model.predicted.label.config = ModelPredictedLabelConfig(
    probability_threshold=0.8,
)
```

**ModelConfig** is the configuration related to the model to be used for inferencing. In order to compute posttraining bias metrics, the computation needs to get inferences for the model name provided. To accomplish this, the processing job uses the model to create an ephemeral endpoint (also known as **shadow endpoint**). The processing job deletes the shadow endpoint after the computations are completed. This configuration is also used by the explainability monitor.

```
model_config = ModelConfig(
    model_name=model_name,
    instance_count=endpoint_instance_count,
    instance_type=endpoint_instance_type,
    content_type=dataset_type,
    accept_type=dataset_type,
)
```

Now you can start the baselining job.

```
model.bias_monitor.suggest_baseline(
    model_config=model_config,
    data_config=model.bias_data_config,
    bias_config=model.bias_config,
    model.predicted.label.config=model.predicted.label.config,
)
print(f"ModelBiasMonitor baselining job: {model.bias_monitor.latest.baselining.job.name}")
```

The scheduled monitor automatically picks up baselining job name and waits for it before monitoring begins.

**Bias Drift Violations**

Bias drift jobs evaluate the baseline constraints provided by the baseline configuration against the analysis results of current MonitoringExecution. If violations are detected, the job lists them to the **constraint_violations.json** file in the execution output location, and marks the execution status as **Interpret results**.

Here is the schema of the bias drift violations file.

- **facet** – The name of the facet, provided by the monitoring job analysis configuration facet name_or_index.
- **facet.value** – The value of the facet, provided by the monitoring job analysis configuration facet value_or_threshold.
- **metric.name** – The short name of the bias metric. For example, "CI" for class imbalance. See Measure Pretraining Bias (p. 778) for the short names of each of the pretraining bias metrics and Measure Posttraining Data and Model Bias (p. 2548) for the short names of each of the posttraining bias metrics.
- **constraint.check.type** – The type of violation monitored. Currently only **bias_drift_check** is supported.
- **description** – A descriptive message to explain the violation.

```
{
    "version": "1.0",
    "violations": [{
        "facet": "string",
```
If the value of a bias metric in the baseline constraints file is different from its peer in the job analysis results file (analysis.json), the monitoring jobs log a violation. The following output provides an example of several logged violations.

```
{
    "version": "1.0",
    "violations": [{
        "facet": "Age",
        "facet_value": "40",
        "metric_name": "CI",
        "constraint_check_type": "bias_drift_check",
        "description": "Value 0.0751544567666083 does not meet the constraint requirement"
    }, {
        "facet": "Age",
        "facet_value": "40",
        "metric_name": "DPPL",
        "constraint_check_type": "bias_drift_check",
        "description": "Value -0.0791244970125596 does not meet the constraint requirement"
    }]
}
```

### Configure Parameters to Monitor Bias Drift

Amazon SageMaker Clarify bias monitoring reuses a subset of the parameters used in the analysis configuration of Configure the Analysis (p. 2537). After describing the configuration parameters, this topic provides examples of JSON files. These files are used to configure CSV and JSON Lines datasets to monitor them for bias drift when machine learning models are in production.

The following parameters must be provided in a JSON file. The path to this JSON file must be provided in the `ConfigUri` parameter of the `ModelBiasAppSpecification` API.

- **"version"** – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.
- **"headers"** – (Optional) A list of column names in the dataset. If the `dataset_type` is "application/jsonlines" and "label" is specified, then the last header becomes the header of the label column.
- **"label"** – (Optional) Target attribute for the model to be used for bias metrics. Specified either as a column name, or an index (if dataset format is CSV), or as a JSONPath (if dataset format is JSON Lines).
- **"label_values_or_threshold"** – (Optional) List of label values or threshold. Indicates positive outcome used for bias metrics.
- **"facet"** – (Optional) A list of features that are sensitive attributes, referred to as facets. Facets are used for bias metrics in the form of pairs, and include the following:
  - "name_or_index" – Facet column name or index.
  - "value_or_threshold" – (Optional) List of values or threshold that the facet column can take. Indicates the sensitive group, such as the group that is used to measure bias against. If not provided, bias metrics are computed as one group for every unique value (rather than all values). If the facet column is numeric, this threshold value is applied as the lower bound to select the sensitive group.
- **"group_variable"** – (Optional) A column name or index to indicate the group variable to be used for the bias metric Conditional Demographic Disparity.
Monitor models for data and model quality, bias, and explainability

The other parameters should be provided in EndpointInput of the `ModelBiasJobInput` API.

- **FeaturesAttribute** – This parameter is required if endpoint input data format is "application/jsonlines". It is the JSONPath used to locate the feature columns if the dataset format is JSON Lines.
- **InferenceAttribute** – Index or JSONPath location in the model output for the target attribute to be used for monitored for bias using bias metrics. If it is not provided in the CSV `accept_type` case, then it is assumed that the model output is a single numeric value corresponding to a score or probability.
- **ProbabilityAttribute** – Index or JSONPath location in the model output for probabilities. If the model output is JSON Lines with a list of labels and probabilities, for example, then the label that corresponds to the maximum probability is selected for bias computations.
- **ProbabilityThresholdAttribute** – (Optional) A float value to indicate the threshold to select the binary label, in the case of binary classification. The default value is 0.5.

### Example JSON Configuration Files for CSV and JSON Lines Datasets

Here are examples of the JSON files used to configure CSV and JSON Lines datasets to monitor them for bias drift.

**Topics**

- CSV Datasets (p. 2733)
- JSON Lines Datasets (p. 2734)

**CSV Datasets**

Consider a dataset that has four feature columns and one label column, where the first feature and the label are binary, as in the following example.

| 0, 0.5814568701544718, 0.6651538910132964, 0.3138080342665499, 0 | 1, 0.6711642728531724, 0.7466687034026017, 0.1215477472819713, 1 |
| 0, 0.0453256543003371, 0.6377430803264152, 0.3558625219713576, 1 | 1, 0.4785191813363956, 0.0265841045263860, 0.0376935084990697, 1 |

Assume that the model output has two columns, where the first one is the predicted label and the second one is the probability, as in the following example.

| 1, 0.5385257417814224 |

Then the following JSON configuration file shows an example of how this CSV dataset can be configured.

```json
{
    "headers": [
        "feature_0",
        "feature_1",
        "feature_2",
        "feature_3",
        "target"
    ],
    "label": "target",
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "feature_1",
            "value_or_threshold": [1]
        }
    ]
}
```
Amazon SageMaker Developer Guide
Monitor models for data and model
quality, bias, and explainability

The predicted label is selected by the "InferenceAttribute" parameter. Zero-based numbering is
used, so 0 indicates the ﬁrst column of the model output,
"EndpointInput": {
...
"InferenceAttribute": 0
...
}

Alternatively, you can use diﬀerent parameters to convert probability values to binary predicted labels.
Zero-based numbering is used: 1 indicates the second column; the ProbabilityThresholdAttribute
value of 0.6 indicates that a probability greater than 0.6 predicts the binary label as 1.
"EndpointInput": {
...
"ProbabilityAttribute": 1,
"ProbabilityThresholdAttribute": 0.6
...
}

JSON Lines Datasets
Consider a dataset that has four feature columns and one label column, where the ﬁrst feature and the
label are binary, as in the following example.
{"features":[0,
{"features":[1,
{"features":[0,
{"features":[1,

0.5814568701544718,
0.6711642728531724,
0.0453256543003371,
0.4785191813363956,

0.6651538910132964,
0.7466687034026017,
0.6377430803264152,
0.0265841045263860,

0.3138080342665499],
0.1215477472819713],
0.3558625219713576],
0.0376935084990697],

"label":0}
"label":1}
"label":1}
"label":1}

Assume that the model output has two columns, where the ﬁrst is a predicted label and the second is a
probability.
{"predicted_label":1, "probability":0.5385257417814224}

The following JSON conﬁguration ﬁle shows an example of how this JSON Lines dataset can be
conﬁgured.
{

}

"headers": [
"feature_0",
"feature_1",
"feature_2",
"feature_3",
"target"
],
"label": "label",
"label_values_or_threshold": [1],
"facet": [{
"name_or_index": "feature_1",
"value_or_threshold": [1]
}]

Then, the "features" parameter value in EndpointInput is used to locate the features in the dataset,
and the "predicted_label" parameter value selects the predicted label from the model output.
"EndpointInput": {

2734


Monitor models for data and model quality, bias, and explainability

Alternatively, you can convert probability values to predicted binary labels using the ProbabilityThresholdAttribute parameter value. A value of 0.6, for example, indicates that a probability greater than 0.6 predicts the binary label as 1.

```
"EndpointInput": {
  ...
  "FeaturesAttribute": "features",
  "ProbabilityAttribute": "probability",
  "ProbabilityThresholdAttribute": 0.6
  ...
}
```

Schedule Bias Drift Monitoring Jobs

Now that you have a baseline, you can call the create_monitoring_schedule() method to schedule an hourly monitor to analyze the data with a monitoring schedule. If you have submitted a baselining job, the monitor automatically picks up analysis configuration from the baselining job. If you skip the baselining step or the capture dataset has a different nature from the training dataset, you must provide the analysis configuration.

```
model_bias_analysis_config = None
if not model_bias_monitor.latest_baselining_job:
    model_bias_analysis_config = BiasAnalysisConfig(
        model_bias_config,
        headers=all_headers,
        label=label_header,
    )
model_bias_monitor.create_monitoring_schedule(
    analysis_config=model_bias_analysis_config,
    output_s3_uri=s3_report_path,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
        start_time_offset="-PT1H",
        end_time_offset="-PT0H",
        probability_threshold_attribute=0.8,
    ),
    ground_truth_input=ground_truth_upload_path,
    schedule_cron_expression=schedule_expression,
)
print(f"Model bias monitoring schedule: {model_bias_monitor.monitoring_schedule_name}"
)
```

Inspect Reports for Data Bias Drift

If you are not able to inspect the results of the monitoring in the generated reports in SageMaker Studio, you can print them out as follows:

```
schedule_desc = model_bias_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_bias_monitor_execution = model_bias_monitor.list_executions()[0]
    last_model_bias_monitor_execution_report_uri =
    last_model_bias_monitor_execution.output.destination
```
print(f'Report URI: {last_model_bias_monitor_execution_report_uri}

last_model_bias_monitor_execution_report_files = sorted(S3Downloader.list(last_model_bias_monitor_execution_report_uri))
print("Found Report Files:")
print("\n ".join(last_model_bias_monitor_execution_report_files))
else:
    last_model_bias_monitor_execution = None
    print("====STOP==== 
    No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")

If there are violations compared to the baseline, they are listed here:

```python
if last_model_bias_monitor_execution:
    model_bias_violations = last_model_bias_monitor_execution.constraint_violations()
    if model_bias_violations:
        print(model_bias_violations.body_dict)
```

In SageMaker Studio, you can see visualizations of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

### CloudWatch Metrics for Bias Drift Analysis

This guide shows CloudWatch metrics and their properties that you can use for bias drift analysis in SageMaker Clarify. Bias drift monitoring jobs compute both pretraining bias metrics and posttraining bias metrics, and publish them to the CloudWatch namespace `aws/sagemaker/Endpoints/bias-metrics`. The CloudWatch metric name appends the metric's short name to `bias_metric`.

For example, **bias_metric_CI** is the bias metric for class imbalance (CI).

**Note**

+/- infinity is published as the floating point number +/- 2.348543e108, and errors including null values are not published.

Each metric has the following properties:

- **Endpoint**: The name of the monitored endpoint.
- **MonitoringSchedule**: The name of the schedule for the monitoring job.
- **BiasStage**: The name of the stage of the bias drift monitoring job. Choose either Pre-training or Post-Training.
- **Label**: The name of the target feature, provided by the monitoring job analysis configuration `label`.
- **LabelValue**: The value of the target feature, provided by the monitoring job analysis configuration `label_values_or_threshold`.
- **Facet**: The name of the facet, provided by the monitoring job analysis configuration `facet_name_or_index`.
- **FacetValue**: The value of the facet, provided by the monitoring job analysis configuration `facet_value_or_threshold`.

To stop the monitoring jobs from publishing metrics, set `publish_cloudwatch_metrics` to `Disabled` in the Environment map of the **model bias job** definition.

### Monitor Feature Attribution Drift for Models in Production

A drift in the distribution of live data for models in production can result in a corresponding drift in the feature attribution values, just as it could cause a drift in bias when monitoring bias metrics. Amazon SageMaker Clarify feature attribution monitoring helps data scientists and ML engineers monitor predictions for feature attribution drift on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing feature attributions in SageMaker Studio and configure alerts.
in Amazon CloudWatch to receive notifications if it is detected that the attribution values drift beyond a certain threshold.

To illustrate this with a specific situation, consider a hypothetical scenario for college admissions. Assume that we observe the following (aggregated) feature attribution values in the training data and in the live data:

**College Admission Hypothetical Scenario**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Attribution in training data</th>
<th>Attribution in live data</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAT score</td>
<td>0.70</td>
<td>0.10</td>
</tr>
<tr>
<td>GPA</td>
<td>0.50</td>
<td>0.20</td>
</tr>
<tr>
<td>Class rank</td>
<td>0.05</td>
<td>0.70</td>
</tr>
</tbody>
</table>

The change from training data to live data appears significant. The feature ranking has completely reversed. Similar to the bias drift, the feature attribution drifts might be caused by a change in the live data distribution and warrant a closer look into the model behavior on the live data. Again, the first step in these scenarios is to raise an alarm that a drift has happened.

We can detect the drift by comparing how the ranking of the individual features changed from training data to live data. In addition to being sensitive to changes in ranking order, we also want to be sensitive to the raw attribution score of the features. For instance, given two features that fall in the ranking by the same number of positions going from training to live data, we want to be more sensitive to the feature that had a higher attribution score in the training data. With these properties in mind, we use the Normalized Discounted Cumulative Gain (NDCG) score for comparing the feature attributions rankings of training and live data.

Specifically, assume we have the following:

- \( F = [f_1, \ldots, f_m] \) is the list of features sorted with respect to their attribution scores in the training data where \( m \) is the total number of features. For instance, in our case, \( F = \{ \text{SAT Score, GPA, Class Rank} \} \).
- \( a(f) \) is a function that returns the feature attribution score on the training data given a feature \( f \). For example, \( a(\text{SAT Score}) = 0.70 \).
- \( F' = [f'_1, \ldots, f'_m] \) is the list of features sorted with respect to their attribution scores in the live data. For example, \( F' = \{ \text{Class Rank, GPA, SAT Score} \} \).

Then, we can compute the NDCG as:

\[
\text{NDCG} = \frac{\text{DCG}}{\text{iDCG}}
\]

with

- \( \text{DCG} = \sum_{i=1}^{m} \frac{a(f'_i)}{\log_2(i+1)} \)
- \( \text{iDCG} = \sum_{i=1}^{m} a(f'_i)/\log_2(i+1) \)

The quantity DCG measures whether features with high attribution in the training data are also ranked higher in the feature attribution computed on the live data. The quantity iDCG measures the *ideal score* and it's just a normalizing factor to ensure that the final quantity resides in the range \([0, 1]\), with 1 being the best possible value. A NDCG value of 1 means that the feature attribution ranking in the live data is the same as the one in the training data. In this particular example, because the ranking changed by quite a bit, the NDCG value is 0.69.

In SageMaker Clarify, if the NDCG value is below 0.90, we automatically raise an alert.
Model Monitor Example Notebook

SageMaker Clarify provides the following example notebook that shows how to capture real-time inference data, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in SageMaker Studio only. If you need instructions on how to open a notebook in SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 132). If you're prompted to choose a kernel, choose Python 3 (Data Science). The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

Topics
- Create a SHAP Baseline for Models in Production (p. 2738)
- Model Feature Attribution Drift Violations (p. 2739)
- Configure Parameters to Monitor Attribution Drift (p. 2740)
- Schedule Feature Attribute Drift Monitoring Jobs (p. 2743)
- Inspect Reports for Feature Attribute Drift in Production Models (p. 2744)
- CloudWatch Metrics for Feature Drift Analysis (p. 2744)

Create a SHAP Baseline for Models in Production

Explanations are typically contrastive, that is, they account for deviations from a baseline. For information on explainability baselines, see SHAP Baselines for Explainability (p. 2571).

In addition to providing explanations for per-instance inferences, SageMaker Clarify also supports global explanation for ML models that helps you understand the behavior of a model as a whole in terms of its features. SageMaker Clarify generates a global explanation of an ML model by aggregating the Shapley values over multiple instances. SageMaker Clarify supports the following different ways of aggregation, which you can use to define baselines:

- mean_abs – Mean of absolute SHAP values for all instances.
- median – Median of SHAP values for all instances.
- mean_sq – Mean of squared SHAP values for all instances.

After you have configured your application to capture real-time inference data, the first task to monitor for drift in feature attribution is to create a baseline to compare against. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job. Model explainability monitor can explain the predictions of a deployed model that's producing inferences and detect feature attribution drift on a regular basis.

```python
model_explainability_monitor = ModelExplainabilityMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)
```

In this example, the explainability baselining job shares the test dataset with the bias baselining job, so it uses the same DataConfig, and the only difference is the job output URI.
model_explainability_baselining_job_result_uri = f"{baseline_results_uri}/model_explainability"
model_explainability_data_config = DataConfig(
    s3_data_input_path=validation_dataset,
    s3_output_path=model_explainability_baselining_job_result_uri,
    label=label_header,
    headers=all_headers,
    dataset_type=dataset_type,
)

Currently the SageMaker Clarify explainer offers a scalable and efficient implementation of SHAP, so the explainability config is SHAPConfig, including the following:

- **baseline** – A list of rows (at least one) or S3 object URI to be used as the baseline dataset in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns/values and omit the label column/values.
- **num_samples** – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
- **agg_method** – Aggregation method for global SHAP values. Following are valid values:
  - **mean_abs** – Mean of absolute SHAP values for all instances.
  - **median** – Median of SHAP values for all instances.
  - **mean_sq** – Mean of squared SHAP values for all instances.
  - **use_logit** – Indicator of whether the logit function is to be applied to the model predictions. Default is False. If use_logit is True, the SHAP values will have log-odds units.
  - **save_local_shap_values** (bool) – Indicator of whether to save the local SHAP values in the output location. Default is False.

# Here use the mean value of test dataset as SHAP baseline
test_dataframe = pd.read_csv(test_dataset, header=None)
shap_baseline = [list(test_dataframe.mean())]
shap_config = SHAPConfig(
    baseline=shap_baseline,
    num_samples=100,
    agg_method="mean_abs",
    save_local_shap_values=False,
)

Start a baselining job. The same model_config is required because the explainability baselining job needs to create a shadow endpoint to get predictions for the generated synthetic dataset.

model_explainability_monitor.suggest_baseline(
    data_config=model_explainability_data_config,
    model_config=model_config,
    explainability_config=shap_config,
)
print(f"ModelExplainabilityMonitor baselining job: {model_explainability_monitor.latest_baselining_job_name}"

Model Feature Attribution Drift Violations

Feature attribution drift jobs evaluate the baseline constraints provided by the baseline configuration against the analysis results of current MonitoringExecution. If violations are detected, the job lists them to the constraint_violations.json file in the execution output location, and marks the execution status as Interpret results (p. 2753).
Here is the schema of the feature attribution drift violations file.

- **label** – The name of the label, job analysis configuration `label_headers` or a placeholder such as "label0".
- **metric_name** – The name of the explainability analysis method. Currently only `shap` is supported.
- **constraint_check_type** – The type of violation monitored. Currently only `feature_attribution_drift_check` is supported.
- **description** – A descriptive message to explain the violation.

```
{
  "version": "1.0",
  "violations": [{
    "label": "string",
    "metric_name": "string",
    "constraint_check_type": "string",
    "description": "string"
  }]
}
```

For each label in the explanations section, the monitoring jobs calculate the nDCG score of its global SHAP values in the baseline constraints file and in the job analysis results file (`analysis.json`). If the score is less than 0.9, then a violation is logged. The combined global SHAP value is evaluated, so there are no “feature” fields in the violation entry. The following output provides an example of several logged violations.

```
{
  "version": "1.0",
  "violations": [{
    "label": "label0",
    "metric_name": "shap",
    "constraint_check_type": "feature_attribution_drift_check",
    "description": "Feature attribution drift 0.7639720923277322 exceeds threshold 0.9"
  }, {
    "label": "label1",
    "metric_name": "shap",
    "constraint_check_type": "feature_attribution_drift_check",
    "description": "Feature attribution drift 0.7323763972092327 exceeds threshold 0.9"
  }]
}
```

### Configure Parameters to Monitor Attribution Drift

Amazon SageMaker Clarify explainability monitor reuses a subset of the parameters used in the analysis configuration of Configure the Analysis (p. 2537). The following parameters must be provided in a JSON file and the path must be provided in the `ConfigUri` parameter of `ModelExplainabilityAppSpecification`.

- **version** – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.
- **headers** – (Optional) A list of feature names in the dataset. Explainability analysis does not require labels.
- **methods** – A list of methods and their parameters for the analyses and reports. If any section is omitted, then it is not computed.
- **shap** – (Optional) Section on SHAP value computation.
  - **baseline** – (Optional) A list of rows (at least one), or an Amazon Simple Storage Service Amazon S3 object URI. To be used as the baseline dataset (also known as a background dataset)
in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns (or values). Before you send each row to the model, omit any column that must be excluded.

- "num_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values. If not provided, then a SageMaker Clarify job chooses the value based on a count of features.

- "agg_method" – Aggregation method for global SHAP values. Valid values are as follows:
  - "mean_abs" – Mean of absolute SHAP values for all instances.
  - "median" – Median of SHAP values for all instances.
  - "mean_sq" – Mean of squared SHAP values for all instances.
  - "use_logit" – (Optional) Boolean value to indicate if the logit function is to be applied to the model predictions. If "use_logit" is true, then the SHAP values have log-odds units. The default value is false.
  - "save_local_shap_values" – (Optional) Boolean value to indicate if local SHAP values are to be saved in the output location. Use true to save them. Use false to not save them. The default is false.

- "predictor" – (Optional) Section on model parameters, required if "shap" and "post_training_bias" sections are present.
  - "model_name" – Model name created by CreateModel API, with container mode as SingleModel.
  - "instance_type" – Instance type for the shadow endpoint.
  - "initial_instance_count" – Instance count for the shadow endpoint.
  - "content_type" – (Optional) The model input format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable Computer Vision explainability. The default value is the same as the dataset_type format.
  - "accept_type" – (Optional) The model output format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines. If omitted, SageMaker Clarify uses the response data type of the captured data.
  - "content_template" – (Optional) A template string used to construct the model input from dataset instances. It is only used when "content_type" is "application/jsonlines". The template should have only one placeholder, $features, which is replaced by the features list at runtime. For example, given "content_template":"{"myfeatures":$features}"; if an instance (no label) is 1, 2, 3, then model input becomes JSON Lines ‘{"myfeatures":[1,2,3]}’.
  - "label_headers" – (Optional) A list of values that the "label" takes in the dataset. Associates the scores returned by the model endpoint with their corresponding label values. If it is provided, then the analysis report uses the headers instead of placeholders like "label0".

The other parameters should be provided in EndpointInput of the ModelExplainabilityJobInput API.

- FeaturesAttribute – This parameter is required if endpoint input data format is "application/jsonlines". It is the JSONPath used to locate the feature columns if the dataset format is JSON Lines.

- ProbabilityAttribute – Index or JSONPath location in the model output for probabilities. If the model output is JSON Lines with a list of labels and probabilities, for example, then the label that corresponds to the maximum probability is selected for bias computations.

Example JSON Configuration Files for CSV and JSON Lines Datasets

Here are examples of the JSON files used to configure CSV and JSON Lines datasets to monitor them for feature attribution drift.
Topics

- CSV Datasets (p. 2742)
- JSON Lines Datasets (p. 2742)

CSV Datasets

Consider a dataset that has three numerical feature columns, as in the following example.

| 0.5814568701544718, 0.6651538910132964, 0.3138080342665499 |
| 0.6711642728531724, 0.7466687034026017, 0.1215477472819713 |
| 0.0453256543003371, 0.6377430803264152, 0.3558625219713576 |
| 0.4785191813363956, 0.0265841045263860, 0.0376935084990697 |

Assume that the model output has two columns, where the first one is the predicted label and the second one is the probability, as in the following example.

1, 0.5385257417814224

The following example JSON configuration file shows how this CSV dataset can be configured.

```json
{
    "headers": [
        "feature_1",
        "feature_2",
        "feature_3"
    ],
    "methods": {
        "shap": {
            "baseline": [0.441164946610942, 0.5190374448171748, 0.20722795300473712],
            "num_samples": 100,
            "agg_method": "mean_abs"
        }
    },
    "predictor": {
        "model_name": "my_model",
        "instance_type": "ml.m5.xlarge",
        "initial_instance_count": 1
    }
}
```

The predicted label is selected by the "ProbabilityAttribute" parameter. Zero-based numbering is used, so 1 indicates the second column of the model output.

```json
"EndpointInput": {
    ...
    "ProbabilityAttribute": 1
    ...
}
```

JSON Lines Datasets

Consider a dataset that has four feature columns and one label column, where the first feature and the label are binary, as in the following example.

```json
{"features": [0, 0.5814568701544718, 0.6651538910132964, 0.3138080342665499], "label": 0}
```
The model input is the same as the dataset format, and the model output are JSON Lines, as in the following example.

{"predicted_label":1, "probability":0.5385257417814224}

In the following example, the JSON configuration file shows how this JSON Lines dataset can be configured.

```json
{
  "headers": [
    "feature_1",
    "feature_2",
    "feature_3"
  ],
  "methods": {
    "shap": {
      "baseline": [
        {"features":[0.4441164946610942, 0.5190374448171748, 0.20722795300473712]}
      ],
      "num_samples": 100,
      "agg_method": "mean_abs"
    }
  },
  "predictor": {
    "model_name": "my_model",
    "instance_type": "ml.m5.xlarge",
    "initial_instance_count": 1,
    "content_template": "{"features":$features}"
  }
}
```

Then the "features" parameter value in EndpointInput is used to locate the features in the dataset, and the "probability" parameter value selects the probability value from model output.

```
"EndpointInput": {
  ...
  "FeaturesAttribute": "features",
  "ProbabilityAttribute": "probability",
  ...
}
```

**Schedule Feature Attribute Drift Monitoring Jobs**

Model explainability monitoring helps you understand and interpret the predictions made by your ML models. When Model Monitor is configured to monitor model explainability, SageMaker automatically detects any drift in relative importance of features and creates reports explaining feature attributions.

Call the `create_monitoring_schedule()` method to schedule an hourly monitor to analyze the data with a monitoring schedule. If a baselining job has been submitted, the monitor automatically picks up analysis configuration from the baselining job. However, if you skip the baselining step or the capture dataset has a different nature from the training dataset, you have to provide the analysis configuration. `ModelConfig` is required by `ExplainabilityAnalysisConfig` for the same reason that it's required for the baselining job. Note that only features are required for computing feature attribution, so you should exclude ground truth labeling.
Inspect Reports for Feature Attribute Drift in Production Models

After the schedule that you set up is started by default, you need to wait for its first execution to start, and then stop the schedule to avoid incurring charges.

To inspect the reports, use the following code:

```python
schedule_desc = model_explainability_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_explainability_monitor_execution =
    model_explainability_monitor.list_executions()[-1]
    last_model_explainability_monitor_execution_report_uri =
    last_model_explainability_monitor_execution.output.destination
    print(f"Report URI: {last_model_explainability_monitor_execution_report_uri}")
    last_model_explainability_monitor_execution_report_files =
    sorted(S3Downloader.list(last_model_explainability_monitor_execution_report_uri))
    print("Found Report Files:")
    print(" \
    ".join(last_model_explainability_monitor_execution_report_files))
else:
    last_model_explainability_monitor_execution = None
    print("====STOP==== \
    No completed executions to inspect further. Please wait till an
evaluation completes or investigate previously reported failures.")
```

If there are any violations compared to the baseline, they are listed here:

```python
if last_model_explainability_monitor_execution:
    model_explainability_violations =
    last_model_explainability_monitor_execution.constraint_violations()
    if model_explainability_violations:
        print(model_explainability_violations.body_dict)
```

In SageMaker Studio, you can see visualizations of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

**CloudWatch Metrics for Feature Drift Analysis**

This guide shows CloudWatch metrics and their properties that you can use for feature attribute drift analysis in SageMaker Clarify. Feature attribute drift monitoring jobs compute and publish two types of metrics:

- The global SHAP value of each feature.

  **Note**
  The name of this metric appends the feature name provided by the job analysis configuration to `feature_`. For example, `feature_X` is the global SHAP value for feature X.

- The **ExpectedValue** of the metric.

These metrics are published to the CloudWatch namespace `aws/sagemaker/Endpoints/explainability-metrics`.

Each metric has the following properties:

- **Endpoint**: The name of the monitored endpoint.
- **MonitoringSchedule**: The name of the schedule for the monitoring job.
- **ExplainabilityMethod**: The method used to compute Shapley values. Choose **KernelShap**.
Monitor models for data and model quality, bias, and explainability

- **Label**: The name provided by job analysis configuration `label_headers`, or a placeholder like `label0`.
- **ValueType**: The type of the value returned by the metric. Choose either `GlobalShapValues` or `ExpectedValue`.

To stop the monitoring jobs from publishing metrics, set `publish_cloudwatch_metrics` to `Disabled` in the `Environment` map of `model explainability job` definition.

**Capture data**

To log the inputs to your endpoint and the inference outputs from SageMaker Real-time endpoints to Amazon S3, you can enable a feature called *Data Capture*. It is commonly used to record information that can be used for training, debugging, and monitoring. Amazon SageMaker Model Monitor automatically parses this captured data and compares metrics from this data with a baseline that you create for the model. For more information about Model Monitor see *Monitor models for data and model quality, bias, and explainability* (p. 2715).

**Note**

To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.

To capture data, you must deploy a model using SageMaker hosting services. This requires that you create a SageMaker model, define an endpoint configuration, and create an HTTPS endpoint.

The steps required to enable data capture are similar regardless if you use the AWS SDK for Python (Boto) or the SageMaker Python SDK. If you use the AWS SDK, define the `DataCaptureConfig` dictionary, along with required fields, within the `CreateEndpointConfig` method to enable data capture. If you use the SageMaker Python SDK, import the `DataCaptureConfig` Class and initialize an instance from this class. Then, pass this object to the `DataCaptureConfig` parameter in the `sagemaker.model.Model.deploy()` method.

To use the proceeding code snippets, replace the *italicized placeholder text* in the example code with your own information.

**How to enable data capture**

Specify a data capture configuration. You can capture the request payload, the response payload, or both with this configuration. The proceeding code snippet demonstrates how to enable data capture using the AWS SDK for Python (Boto) and the SageMaker Python SDK.

**Note**

You do not need to use Model Monitor to capture request or response payloads.

**AWS SDK for Python (Boto)**

Configure the data you want to capture with the `DataCaptureConfig` dictionary when you create an endpoint using the `CreateEndpointConfig` method. Set `EnableCapture` to the boolean value `True`. In addition, provide the following mandatory parameters:

- **EndpointConfigName**: the name of your endpoint configuration. You will use this name when you make a `CreateEndpoint` request.
- **ProductionVariants**: a list of models you want to host at this endpoint. Define a dictionary data type for each model.
- **DataCaptureConfig**: dictionary data type where you specify an integer value that corresponds to the initial percentage of data to sample (`InitialSamplingPercentage`), the Amazon S3 URI where you want captured data to be stored, and a capture options (`CaptureOptions`) list. Specify either `Input` or `Output` for `CaptureMode` within the `CaptureOptions` list.
You can optionally specify how SageMaker should encode captured data by passing key-value pair arguments to the `CaptureContentTypeHeader` dictionary.

```python
# Create an endpoint config name.
endpoint_config_name = '<endpoint-config-name>'

# The name of the production variant.
variant_name = '<name-of-production-variant>'

# This is the name that you want to host.
# This is the name that you specified when creating the model.
model_name = '<The_name_of_your_model>'

instance_type = '<instance-type>'
    # Example

# Number of instances to launch initially.
initial_instance_count = <integer>

# Sampling percentage. Choose an integer value between 0 and 100
initial_sampling_percentage = <integer>

# The S3 URI of where to store captured data in S3
s3_capture_upload_path = 's3://<bucket-name>/<data_capture_s3_key>'

# Specify either Input, Output, or both
capture_modes = ["Input", "Output"]
# Example - If you want to capture input only

capture_mode = ["Input"]

endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    # List of ProductionVariant objects, one for each model that you want to host at
    # this endpoint.
    ProductionVariants=[
        {
            "VariantName": variant_name,
            "ModelName": model_name,
            "InstanceType": instance_type, # Specify the compute instance type.
            "InitialInstanceCount": initial_instance_count # Number of instances to
            launch initially.
        }
    ],
    DataCaptureConfig={
        "EnableCapture": True, # Whether data should be captured or not.
        "InitialSamplingPercentage": initial_sampling_percentage,
        "DestinationS3Uri": s3_capture_upload_path,
        "CaptureOptions": [{"CaptureMode": capture_mode} for capture_mode in
        capture_modes] # Example - Use list comprehension to capture both Input and Output
    }
)
```

For more information about other endpoint configuration options, see the `CreateEndpointConfig` API in the Amazon SageMaker Service API Reference Guide.

**SageMaker Python SDK**

Import the `DataCaptureConfig` Class from the `sagemaker.model_monitor` module. Enable data capture by setting `EnableCapture` to the boolean value `True`.

Optionally provide arguments for the following parameters:
• SamplingPercentage: an integer value that corresponds to percentage of data to sample. If you
do not provide a sampling percentage, SageMaker will sample a default of 20 (20%) of your data.

• DestinationS3Uri: the Amazon S3 URI SageMaker will use to store captured data. If you do
not provide one, SageMaker will store captured data in "s3://<default-session-bucket>/
model-monitor/data-capture".

from sagemaker.model_monitor import DataCaptureConfig

# Set to True to enable data capture
enable_capture = True

# Optional - Sampling percentage. Choose an integer value between 0 and 100
sampling_percentage = <int>
# sampling_percentage = 30 # Example 30%

# Optional - The S3 URI of where to store captured data in S3
s3_capture_upload_path = 's3://<bucket-name>/<data_capture_s3_key>'

# Specify either Input, Output or both.
capture_modes = ['REQUEST', 'RESPONSE'] # In this example, we specify both
# capture_mode = ['REQUEST'] # Example - If you want to only capture input.

# Configuration object passed in when deploying Models to SM endpoints
data_capture_config = DataCaptureConfig(
    enable_capture = enable_capture,
    sampling_percentage = sampling_percentage, # Optional
    destination_s3_uri = s3_capture_upload_path, # Optional
    capture_options = [{"CaptureMode": capture_mode} for capture_mode in capture_modes]
)

Deploy your model

Deploy your model and create an HTTPS endpoint with DataCapture enabled.

AWS SDK for Python (Boto3)

Provide the endpoint configuration to SageMaker. The service launches the ML compute instances
and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the CreateEndpoint API to create your
endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon
SageMaker uses the endpoint to provision resources and deploy models.

# The name of the endpoint. The name must be unique within an AWS Region in your AWS
account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)

For more information, see the CreateEndpoint API.
SageMaker Python SDK

Define a name for your endpoint. This step is optional. If you do not provide one, SageMaker will create a unique name for you:

```python
from datetime import datetime

endpoint_name = f"DEMO-{datetime.utcnow():%Y-%m-%d-%H%M}"
print("EndpointName =", endpoint_name)
```

Deploy your model to a real-time, HTTPS endpoint with the Model object’s built-in `deploy()` method. Provide the name of the Amazon EC2 instance type to deploy this model to in the `instance_type` field along with the initial number of instances to run the endpoint on for the `initial_instance_count` field:

```python
initial_instance_count=<integer>
# initial_instance_count=1 # Example

instance_type='<instance-type>'
# instance_type='ml.m4.xlarge' # Example

# Uncomment if you did not define this variable in the previous step
#data_capture_config = '<name-of-data-capture-configuration>

model.deploy(
    initial_instance_count=initial_instance_count,
    instance_type=instance_type,
    endpoint_name=endpoint_name,
    data_capture_config=data_capture_config
)
```

View Captured Data

Create a predictor object from the SageMaker Python SDK `Predictor` Class. You will use the object returned by the `Predictor` Class to invoke your endpoint in a future step. Provide the name of your endpoint (defined earlier as `endpoint_name`), along with serializer and deserializer objects for the serializer and deserializer, respectively. For information about serializer types, see the `Serializers` Class in the SageMaker Python SDK.

```python
from sagemaker.predictor import Predictor
from sagemaker.serializers import <Serializer>
from sagemaker.deserializers import <Deserializer>

predictor = Predictor(endpoint_name=endpoint_name,
                       serializer = <Serializer_Class>,
                       deserializer = <Deserializer_Class>)

# Example
# from sagemaker.predictor import Predictor
# from sagemaker.serializers import CSVSerializer
# from sagemaker.deserializers import JSONDeserializer
# predictor = Predictor(endpoint_name=endpoint_name,
#                        serializer=CSVSerializer(),
#                        deserializer=JSONDeserializer())
```

In the proceeding code example scenario we invoke the endpoint with sample validation data that we have stored locally in a CSV file named `validation_with_predictions`. Our sample validation set contains labels for each input.
The first few lines of the with statement first opens the validation set CSV file, then splits each row within the file by the comma character ",", and then stores the two returned objects into a label and input_cols variables. For each row, the input (input_cols) is passed to the predictor variable's (predictor) objects built-in method Predictor.predict().

Suppose the model returns a probability. Probabilities range between integer values of 0 and 1.0. If the probability returned by the model is greater than 80% (0.8) we assign the prediction an integer value label of 1. Otherwise, we assign the prediction an integer value label of 0.

```
from time import sleep

validate_dataset = "validation_with_predictions.csv"

# Cut off threshold of 80%
cutoff = 0.8

limit = 200  # Need at least 200 samples to compute standard deviations

i = 0

with open(f"test_data/{validate_dataset}", "w") as validation_file:
    validation_file.write("probability,prediction,label\n")  # CSV header

with open("test_data/validation.csv", "r") as f:
    for row in f:
        label, input_cols = row.split("", 1)
        probability = float(predictor.predict(input_cols))
        prediction = "1" if probability > cutoff else "0"
        baseline_file.write(f"{probability},{prediction},{label}\n")
        i += 1
        if i > limit:
            break
    print(".", end="", flush=True)
    sleep(0.5)
    print("Done!")
```

Because you enabled the data capture in the previous steps, the request and response payload, along with some additional meta data, is saved in the Amazon S3 location that you specified in DataCaptureConfig. The delivery of capture data to Amazon S3 can require a couple of minutes.

View captured data by listing the data capture files stored in Amazon S3. The format of the Amazon S3 path is: s3://{endpoint-name}/{variant-name}/yyyy/mm/dd/hh/filename.jsonl.

Expect to see different files from different time periods, organized based on the hour when the invocation occurred. Run the following to print out the contents of a single capture file:

```
print("\n".join(capture_file[-3:-1]))
```

This will return a SageMaker specific JSON-line formatted file. The following is a response sample taken from a real-time endpoint that we invoked using csv/text data:

```
{"captureData":{"endpointInput":{"observedContentType":"text/csv","mode":"INPUT","data":"69,0,153.7,109,194.0,105,256.1,114,14.1,6,1,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,1,0,0,0,1,0,1,0,1
","encoding":"CSV"},"endpointOutput":{"observedContentType":"text/csv; charset=utf-8","mode":"OUTPUT","data":"0.0254181120544672"","encoding":"CSV"}},"eventMetadata":{"eventId":"aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeee","inferenceTime":"2022-02-14T17:25:49Z"},"eventVersion":"0"},
{"captureData":{"endpointInput":{"observedContentType":"text/csv","mode":"INPUT","data":"94,23,197.1,125,214.5,136,282.2,103,9.5,5,4,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,1,0,0,0,1,0,1,0,1
","encoding":"CSV"},"endpointOutput":{"observedContentType":"text/csv; charset=utf-8","mode":"OUTPUT","data":"0.07675473392009735"","encoding":"CSV"}},"eventMetadata":{"eventId":"aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeee","inferenceTime":"2022-02-14T17:25:49Z"},"eventVersion":"0"}
```
In the proceeding example, the `capture_file` object is a list type. Index the first element of the list to view a single inference request.

```python
# The capture_file object is a list. Index the first element to view a single inference request
print(json.dumps(json.loads(capture_file[0]), indent=2))
```

This will return a response similar to the following. The values returned will differ based on your endpoint configuration, SageMaker model, and captured data:

```
{
  "captureData": {
    "endpointInput": {
      "observedContentType": "text/csv", # data MIME type
      "mode": "INPUT",
      "data": "50,0,188.9,94,203.9,104,151.8,124,11.6,8,3,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,1,0,0,0,0,0,0,0,0,0,1,1,0,1,0",
      "encoding": "CSV"
    },
    "endpointOutput": {
      "observedContentType": "text/csv; charset=character-encoding",
      "mode": "OUTPUT",
      "data": "0.023190177977085114",
      "encoding": "CSV"
    }
  },
  "eventMetadata": {
    "eventId": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
    "inferenceTime": "2022-02-14T17:25:06Z"
  }
}
```

**Schedule monitoring jobs**

Amazon SageMaker Model Monitor provides you the ability to continuously monitor the data collected from the endpoints on a schedule. You can create a monitoring schedule with the `CreateMonitoringSchedule` API with a predefined periodic interval. For example, every \( x \) hours (\( x \) can range from 1 to 23).

With a monitoring schedule, SageMaker can kick off processing jobs at a specified frequency to analyze the data collected during a given period. SageMaker provides a prebuilt container for performing analysis on tabular datasets. In the processing job, SageMaker compares the dataset for the current analysis with the baseline statistics, constraints provided and generate a violations report. In addition, CloudWatch metrics are emitted for each feature under analysis. Alternatively, you could choose to bring your own container as outlined in the Bring Your Own Containers (p. 2764) topic.

You can create a model monitoring schedule for the endpoint created earlier. Use the baseline resources (constraints and statistics) to compare against the real-time traffic. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already have it in Amazon S3, you can point to it directly.

```python
# copy over the training dataset to Amazon S3 (if you already have it in Amazon S3, you could reuse it)
baseline_prefix = prefix + '/baselining'
baseline_data_prefix = baseline_prefix + '/data'
baseline_results_prefix = baseline_prefix + '/results'
baseline_data_uri = 's3://{}/{}'.format(bucket,baseline_data_prefix)
```
baseline_results_uri = 's3://{}/{}'.format(bucket, baseline_results_prefix)
print('Baseline results uri: {}' .format(baseline_results_uri))

print('Baseline data uri: {}'.format(baseline_data_uri))

training_data_file = open("test_data/training-dataset-with-header.csv", 'rb')
s3_key = os.path.join(baseline_prefix, 'data', 'training-dataset-with-header.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(s3_key).upload_fileobj(training_data_file)

Create a model monitoring schedule for the endpoint using the baseline constraints and statistics to compare against real-time traffic.

from sagemaker.model_monitor import CronExpressionGenerator
from time import gmtime, strftime

mon_schedule_name = 'DEMO-xgb-churn-pred-model-monitor-schedule-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
my_default_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    endpoint_input=predictor.endpoint,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)

Describe and inspect the schedule: After you describe it, observe that the MonitoringScheduleStatus in MonitoringScheduleSummary returned by the ListMonitoringSchedules API changes to Scheduled.

desc_schedule_result = my_default_monitor.describe_schedule()
print('Schedule status: {}' .format(desc_schedule_result['MonitoringScheduleStatus']))

The cron expression for monitoring schedule

To provide details for the monitoring schedule, use ScheduleConfig, which is a cron expression that describes details about the monitoring schedule.

Amazon SageMaker Model Monitor supports the following cron expressions:

- To set the job to start every hour, use the following:
  
  Hourly: cron(0 * * * *)

- To run the job daily, use the following:
  
  cron(0 [00-23] ? * * *)

For example, the following are valid cron expressions:

- Daily at 12 PM UTC: cron(0 12 ? * * *)
- Daily at 12 AM UTC: cron(0 0 ? * * *)

To support running every 6, 12 hours, Model Monitor supports the following expression:

cron(0 [00-23]/[01-24] ? * * *)
For example, the following are valid cron expressions:

- Every 12 hours, starting at 5 PM UTC: `cron(0 17/12 ? * *)`
- Every two hours, starting at 12 AM UTC: `cron(0 0/2 ? * *)`

Notes

- Although the cron expression is set to start at 5 PM UTC, note that there could be a delay of 0-20 minutes from the actual requested time to run the execution.
- If you want to run on a daily schedule, don’t provide this parameter. SageMaker picks a time to run every day.
- Currently, SageMaker only supports hourly integer rates between 1 hour and 24 hours.

Amazon SageMaker Model Monitor prebuilt container

SageMaker provides a built-in image called `sagemaker-model-monitor-analyzer` that provides you with a range of model monitoring capabilities, including constraint suggestion, statistics generation, constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This image is based on Spark and is built with Deequ.

Note

You can not pull the built-in `sagemaker-model-monitor-analyzer` image directly. You can use the `sagemaker-model-monitor-analyzer` image when you submit a baseline processing or monitoring job using one of the AWS SDKs.

Use the SageMaker Python SDK (see `image_uris.retrieve` in the SageMaker Python SDK reference guide) to generate the ECR image URI for you, or specify the ECR image URI directly. The prebuilt image for SageMaker Model Monitor can be accessed as follows:

`<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-model-monitor-analyzer`

For example: `159807026194.dkr.ecr.us-west-2.amazonaws.com/sagemaker-model-monitor-analyzer`

If you are in an AWS region in China, the prebuilt images for SageMaker Model Monitor can be accessed as follows:

`<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com.cn/sagemaker-model-monitor-analyzer`

The following table lists the supported values for account IDs and corresponding AWS Region names.

<table>
<thead>
<tr>
<th>ACCOUNT_ID</th>
<th>REGION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>156813124566</td>
<td>us-east-1</td>
</tr>
<tr>
<td>777275614652</td>
<td>us-east-2</td>
</tr>
<tr>
<td>890145073186</td>
<td>us-west-1</td>
</tr>
<tr>
<td>159807026194</td>
<td>us-west-2</td>
</tr>
<tr>
<td>875698925577</td>
<td>af-south-1</td>
</tr>
<tr>
<td>001633400207</td>
<td>ap-east-1</td>
</tr>
</tbody>
</table>
To write your own analysis container, see the container contract described in Customize monitoring (p. 2761).

Interpret results

After you run a baseline processing job and obtained statistics and constraint for your dataset, you can execute monitoring jobs that calculate statistics and list any violations encountered relative to the baseline constraints. Amazon CloudWatch metrics are also reported in your account by default. For information on viewing the results of monitoring in Amazon SageMaker Studio, see Visualize results in Amazon SageMaker Studio (p. 2755).

List Executions

The schedule starts monitoring jobs at the specified intervals. The following code lists the latest five executions. If you are running this code after creating the hourly schedule, the executions might be empty, and you might have to wait until you cross the hour boundary (in UTC) to see the executions start. The following code includes the logic for waiting.

```python
mon_executions = my_default_monitor.list_executions()
print("We created a hourly schedule above and it will kick off executions ON the hour (plus 0 - 20 min buffer.\nWe will have to wait till we hit the hour...")
```
Monitor models for data and model quality, bias, and explainability

```python
while len(mon_executions) == 0:
    print("Waiting for the 1st execution to happen...")
    time.sleep(60)
    mon_executions = my_default_monitor.list_executions()

Inspect a Specific Execution

In the previous step, you picked up the latest completed or failed scheduled execution. You can explore what went right or wrong. The terminal states are:

- **Completed** – The monitoring execution completed and no issues were found in the violations report.
- **CompletedWithViolations** – The execution completed, but constraint violations were detected.
- **Failed** – The monitoring execution failed, possibly due to client error (for example, a role issues) or infrastructure issues. To identify the cause, see the `FailureReason` and `ExitMessage`.

```python
latest_execution = mon_executions[-1] # latest execution's index is -1, previous is -2 and so on...
    time.sleep(60)
    latest_execution.wait(logs=False)
    print("Latest execution status: {}".format(latest_execution.describe()['ProcessingJobStatus']))
    print("Latest execution result: {}".format(latest_execution.describe()['ExitMessage']))

latest_job = latest_execution.describe()
if (latest_job['ProcessingJobStatus'] != 'Completed'):
    print("====STOP====
No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")
```

```python
report_uri=latest_execution.output.destination
print('Report Uri: {}'.format(report_uri))
```

List Generated Reports

List the generated reports

```python
from urllib.parse import urlparse
s3uri = urlparse(report_uri)
report_bucket = s3uri.netloc
report_key = s3uri.path.lstrip('/')
print('Report bucket: {}' .format(report_bucket))
print('Report key: {}.' .format(report_key))

s3_client = boto3.Session().client('s3')
result = s3_client.list_objects(Bucket=report_bucket, Prefix=report_key)
report_files = [report_file.get("Key") for report_file in result.get('Contents')]
print("Found Report Files:")
print("\n" .join(report_files))
```

Violations Report

If there are violations compared to the baseline, they are generated in the violations report. Use the following code to list the violations.

```python
violations = my_default_monitor.latest_monitoring_constraint_violations()
```
This applies only to datasets that contain tabular data. The following schema files specify the statistics calculated and the violations monitored for.

### Output Files for Tabular Datasets

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>Contains columnar statistics for each feature in the dataset that is analyzed. See the schema of this file in the next topic.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>This file is created only for data quality monitoring.</td>
</tr>
<tr>
<td>constraints_violations.json</td>
<td>Contains a list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the baseline_constraints and baseline_statistics paths.</td>
</tr>
</tbody>
</table>

The Amazon SageMaker Model Monitor prebuilt container (p. 2752) saves a set of Amazon CloudWatch metrics for each feature by default.

The container code can emit CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`.

**Visualize results in Amazon SageMaker Studio**

You can also visualize the results of monitoring in Amazon SageMaker Studio. You can view the details of any monitoring job run, and you can create charts that show the baseline and captured values for any metric that the monitoring job calculates.

**To view the detailed results of a monitoring job**

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).
2. In the left navigation pane, choose the **Components and registries** icon.
3. Choose **Endpoints** in the drop-down menu.
4. On the endpoint tab, choose the monitoring type for which you want to see job details.

5. Choose the name of the monitoring job run for which you want to view details from the list of monitoring jobs.
6. The **MONITORING JOB DETAILS** tab opens with a detailed report of the monitoring job.

You can create a chart that displays the baseline and captured metrics for a time period.
To create a chart in SageMaker Studio to visualize monitoring results

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).
2. In the left navigation pane, choose the Components and registries icon (획).
3. Choose Endpoints in the drop-down menu.
4. On the Endpoint tab, choose the monitoring type you want to create a chart for. This example shows a chart for the Model quality monitoring type.
5. Choose Add chart.

6. On the CHART PROPERTIES tab, choose the time period, statistic, and metric that you want to chart. This example shows a chart for a Timeline of 1 week, the Average Statistic of, and the F1 Metric.
7. The chart that shows the baseline and current metric statistic you chose in the previous step shows up in the **Endpoint** tab.
Advanced topics

The following sections contain more advanced tasks that explain how to customize monitoring using preprocessing and postprocessing scripts, how to build your own container, and how to use AWS CloudFormation to create a monitoring schedule.

Topics
- Customize monitoring (p. 2761)
- Create a Monitoring Schedule with an AWS CloudFormation Custom Resource (p. 2771)

Customize monitoring

In addition to using the built-in monitoring mechanisms, you can create your own custom monitoring schedules and procedures using preprocessing and postprocessing scripts or by using or building your own container.

Topics
- Preprocessing and Postprocessing (p. 2761)
- Bring Your Own Containers (p. 2764)

Preprocessing and Postprocessing

In addition to using the built-in mechanisms, you can extend the code with the preprocessing and postprocessing scripts.

Topics
- Postprocessing Script (p. 2761)
- Preprocessing Script (p. 2762)

Postprocessing Script

You can extend the code with the postprocessing script by following this contract:

```python
def postprocess_handler():
```
print("Hello from post-proc script!")

Specify it as a path in Amazon Simple Storage Service (Amazon S3) in the CreateMonitoringSchedule request, as shown following:

```
```

**Preprocessing Script**

The Amazon SageMaker Model Monitor container works only with tabular or flattened JSON structures. We provide a per-record preprocessor for some small changes required to transform the dataset. For example, if your output is an array [1.0, 2.1], you need to convert this into a flattened JSON, like {"prediction0": 1.0, "prediction1": 2.1}. A sample implementation might look like the following:

```python
def preprocess_handler(inference_record):
    input_data = inference_record.endpoint_input.data
    output_data = inference_record.endpoint_output.data.rstrip("\n")
    data = output_data + "\n" + input_data
    return { str(i).zfill(20) : d for i, d in enumerate(data.split("\n")) }
```

Specify it as a path in Amazon S3 in the CreateMonitoringSchedule request:

```
```

**The structure of the inference_record is defined as follows:**

```python
KEY_EVENT_METADATA = "eventMetadata"
KEY_EVENT_METADATA_EVENT_ID = "eventId"
KEY_EVENT_METADATA_EVENT_TIME = "inferenceTime"
KEY_EVENT_METADATA_CUSTOM_ATTR = "customAttributes"

KEY_EVENTDATA = "captureData"
KEY_EVENTDATA_INPUT = "endpointInput"
KEY_EVENTDATA_OUTPUT = "endpointOutput"
KEY_EVENTDATA_ENCODING = "encoding"
KEY_EVENTDATA_DATA = "data"
KEY_EVENTDATA_OBSERVED_CONTENT_TYPE = "observedContentType"
KEY_EVENTDATA_MODE = "mode"

KEY_EVENT_VERSION = "eventVersion"

"""
{
"captureData": {
    "endpointInput": {
        "observedContentType": "text/csv",
        "mode": "INPUT",
        "data": "132,25,113.2,96,269.9,107,,0,0,0,0,0,0,1,0,1,0,0,1",
        "encoding": "CSV"
    },
    "endpointOutput": {
        "observedContentType": "text/csv; charset=utf-8",
        "mode": "OUTPUT",
        "data": "0.01076381653547287",
        "encoding": "CSV"
    }
},
"eventMetadata": {
    "eventId": "feca1ab1-8025-47e3-8f6a-99e3fdd7b8d9",
    "inferenceTime": "2019-11-20T23:33:12Z"
}
"""
```
"eventVersion": "0"
}
"

```python
class EventConfig:
    def __init__(self, endpoint, variant, start_time, end_time):
        self.endpoint = endpoint
        self.variant = variant
        self.start_time = start_time
        self.end_time = end_time

Bring Your Own Containers

Amazon SageMaker Model Monitor provides a prebuilt container with ability to analyze the data captured from endpoints for tabular datasets. If you would like to bring your own container, Model Monitor provides extension points which you can leverage.

Under the hood, when you create a MonitoringSchedule, Model Monitor ultimately kicks off processing jobs. Hence the container needs to be aware of the processing job contract documented in the Build Your Own Processing Container (Advanced Scenario) (p. 985) topic. Note that Model Monitor kicks off the processing job on your behalf per the schedule. While invoking, Model Monitor sets up additional environment variables for you so that your container has enough context to process the data for that particular execution of the scheduled monitoring. For additional information on container inputs, see the Container Contract Inputs (p. 2764).

In the container, using the above environment variables/context, you can now analyze the dataset for the current period in your custom code. After this analysis is complete, you can chose to emit your reports to be uploaded to an S3 bucket. The reports that the prebuilt container generates are documented in Container Contract Outputs (p. 2766). If you would like the visualization of the reports to work in SageMaker Studio, you should follow the same format. You can also choose to emit completely custom reports.

You also emit CloudWatch metrics from the container by following the instructions in CloudWatch Metrics for Bring Your Own Containers (p. 2770).

Topics
- Container Contract Inputs (p. 2764)
- Container Contract Outputs (p. 2766)
- CloudWatch Metrics for Bring Your Own Containers (p. 2770)

Container Contract Inputs

The Amazon SageMaker Model Monitor platform invokes your container code according to a specified schedule. If you chose to write your own container code, the following environment variables are available for your container code. In this context, you can analyze the current dataset or evaluate the constraints if you chose to and emit metrics, if applicable.

```
"Environment": {
  "dataset_format": "{"sagemakerCaptureJson": {""captureIndexNames": ["endpointInput", "endpointOutput"]}}",
  "dataset_source": "/opt/ml/processing/endpointdata",
  "end_time": "2019-12-01T16: 20: 00Z",
  "output_path": "/opt/ml/processing/resultdata",
  "publish_cloudwatch_metrics": "Disabled",
  "sagemaker_endpoint_name": "endpoint-name",
  "sagemaker_monitoring_schedule_name": "schedule-name",
  "start_time": "2019-12-01T15: 20: 00Z"
}
```

Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataset_format</td>
<td>For a job started from a MonitoringSchedule backed by an Endpoint, this is</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sageMakerCaptureJson</td>
<td>with the capture indices endpointInput, or endpointOutput, or both.</td>
</tr>
<tr>
<td>dataset_source</td>
<td>The local path in which the data corresponding to the monitoring period, as specified by start_time and end_time, are available. At this path, the data is available in /{endpoint-name}/{variant-name}/yyyy/mm/dd/hh. We sometimes download more than what is specified by the start and end times. It is up to the container code to parse the data as required.</td>
</tr>
<tr>
<td>output_path</td>
<td>The local path to write output reports and other files. You specify this parameter in the CreateMonitoringSchedule request as MonitoringOutputConfig.MonitoringOutput[0].LocalPath. It is uploaded to the S3Uri path specified in MonitoringOutputConfig.MonitoringOutput[0].S3Uri.</td>
</tr>
<tr>
<td>publish_cloudwatch_metrics</td>
<td>For a job launched by CreateMonitoringSchedule, this parameter is set to Enabled. The container can choose to write the Amazon CloudWatch output file at [filepath].</td>
</tr>
<tr>
<td>sagemaker_endpoint_name</td>
<td>The name of the Endpoint that this scheduled job was launched for.</td>
</tr>
<tr>
<td>sagemaker_monitoring_schedule_name</td>
<td>The name of the MonitoringSchedule that launched this job.</td>
</tr>
<tr>
<td><em>sagemaker_endpoint_datacapture_prefix</em></td>
<td>The prefix specified in the DataCaptureConfig parameter of the Endpoint. The container can use this if it needs to directly access more data than already downloaded by SageMaker at the dataset_source path.</td>
</tr>
<tr>
<td>start_time, end_time</td>
<td>The time window for this analysis run. For example, for a job scheduled to run at 05:00 UTC and a job that runs on 20/02/2020, start_time: is 2020-02-19T06:00:00Z and end_time: is 2020-02-20T05:00:00Z</td>
</tr>
<tr>
<td>baseline_constraints</td>
<td>The local path of the baseline constraint file specified in BaselineConfig.ConstraintResource.S3Uri. This is available only if this parameter was specified in the CreateMonitoringSchedule request.</td>
</tr>
</tbody>
</table>
Parameter Name | Description
--- | ---
baseline_statistics | The local path to the baseline statistics file specified in `BaselineConfig.StatisticsResource.S3Uri`. This is available only if this parameter was specified in the `CreateMonitoringSchedule` request.

**Container Contract Outputs**

The container can analyze the data available in the `*dataset_source` path and write reports to the path in `*output_path` path. The container code can write any reports that suit your needs.

If you use the following structure and contract, certain output files are treated specially by SageMaker in the visualization and API. This applies only to tabular datasets.

**Output Files for Tabular Datasets**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints_violations.json</td>
<td>This file is expected to have the list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the <code>baseline_constraints</code> and <code>baseline_statistics</code> path.</td>
</tr>
</tbody>
</table>

In addition, if the `publish_cloudwatch_metrics` value is "Enabled" container code can emit Amazon CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`. The schema for these files is described in the following sections.

**Topics**

- Schema for Statistics (statistics.json file) (p. 2766)
- Schema for Constraints (constraints.json file) (p. 2768)

**Schema for Statistics (statistics.json file)**

The schema defined in the `statistics.json` file specifies the statistical parameters to be calculated for the baseline and data that is captured. It also configures the bucket to be used by KLL, a very compact quantiles sketch with lazy compaction scheme.

```json
{
    "version": 0,
    "dataset": {
        "dataset": {
            "item_count": number
        }
    }
}
```

                "value": "string",
                "count": number
              }
            ]
          }#n
        }#distribution
      }#string
    }#string
  }#features
Notes

- The specified metrics are recognized by SageMaker in later visualization changes. The container can emit more metrics if required.
- **KLL sketch** is the recognized sketch. Custom containers can write their own representation, but it won't be recognized by SageMaker in visualizations.
- By default, the distribution is materialized in 10 buckets. You can't change this.

Schema for Constraints (constraints.json file)

A constraints.json file is used to express the constraints that a dataset must satisfy. Amazon SageMaker Model Monitor containers can use the constraints.json file to evaluate datasets against. Prebuilt containers provide the ability to generate the constraints.json file automatically for a baseline dataset. If you bring your own container, you can provide it with similar abilities or you can create the constraints.json file in some other way. Here is the schema for the constraint file that the prebuilt container uses. Bring your own containers can adopt the same format or enhance it as required.

```json
{
  "version": 0,
  "features": [
    {
      "name": "string",
      "inferred_type": "Integral" | "Fractional" | "String" | "Unknown",
      "completeness": number, # denotes observed non-null value percentage
      "num_constraints": {
        "is_non_negative": boolean,
      },
      "string_constraints": {
        "domains": [
          "list of",
          "observed values",
          "for small cardinality"
        ],
      },
      "monitoringConfigOverrides": {
      }
    }
  ]

  # options to control monitoring for this feature with monitoring jobs
  # See the following table for notes on what each constraint is doing.
  "monitoring_config": {
    "evaluate_constraints": "Enabled",
    "emit_metrics": "Enabled",
    "datatype_check_threshold": 0.1,
    "domain_content_threshold": 0.1,
    "distribution_constraints": {
      "perform_comparison": "Enabled",
      "comparison_threshold": 0.1,
      "comparison_method": "Simple"||"Robust"
    }
  }
}
```
### Monitoring Constraints

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evaluate_constraints</td>
<td>When Enabled, evaluates whether the current dataset being analyzed satisfies the constraints specified in the constraints.json file taken as a baseline. Valid values: Enabled or Disabled. Default: Enabled.</td>
</tr>
<tr>
<td>emit_metrics</td>
<td>When Enabled, emits CloudWatch metrics for the data contained in the file. Valid values: Enabled or Disabled. Default: Enabled.</td>
</tr>
<tr>
<td>datatype_check_threshold</td>
<td>If the threshold is above the value of the specified datatype_check_threshold, this causes a failure that is treated as a violation in the violation report. If the data types in the current execution are not the same as in the baseline dataset, this threshold is used to evaluate if it needs to be flagged as a violation. Valid values: float. Default: 0.1.</td>
</tr>
<tr>
<td>domain_content_threshold</td>
<td>If there are more unknown values for a String field in the current dataset than in the baseline dataset, this threshold can be used to dictate if it needs to be flagged as a violation. Valid values: float. Default: 0.1.</td>
</tr>
<tr>
<td>distribution_constraints</td>
<td>perform_comparison When Enabled, this flag instructs the code to perform a distribution comparison between the baseline distribution and the distribution observed for the current dataset. Valid values: Enabled or Disabled. Default: Enabled.</td>
</tr>
<tr>
<td>Constraint</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>comparison_threshold</td>
<td>If the threshold is above the value set for the comparison_threshold, this causes a failure that is treated as a violation in the violation report. The distance is calculated by getting the maximum absolute difference between the cumulative distribution functions of two distributions.</td>
</tr>
<tr>
<td></td>
<td>Valid values: float</td>
</tr>
<tr>
<td>comparison_method</td>
<td>Whether to calculate linf_simple or linf_robust. The linf_simple is based on the maximum absolute difference between the cumulative distribution functions of two distributions. Calculating linf_robust is based on linf_simple, but is used when there are not enough samples. The linf_robust formula is based on the Two-sample Kolmogorov–Smirnov test.</td>
</tr>
<tr>
<td></td>
<td>Valid values: linf_simple or linf_robust.</td>
</tr>
</tbody>
</table>

**CloudWatch Metrics for Bring Your Own Containers**

If the publish_cloudwatch_metrics value is Enabled in the Environment map in the `/opt/ml/processing/processingjobconfig.json` file, the container code emits Amazon CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`.

The schema for this file is closely based on the CloudWatch PutMetrics API. The namespace is not specified here. It defaults to `/aws/sagemaker/Endpoint/data-metrics`. However, you can specify dimensions. We recommend that you add the Endpoint and MonitoringSchedule dimensions at a minimum.

```json
{
  "MetricName": "", # Required
  "Timestamp": "2019-11-26T03:00:00Z", # Required
  "Dimensions" : [{"Name":"Endpoint","Value":"endpoint_0"},
                   {"Name":"MonitoringSchedule","Value":"schedule_0"}]
  "Value": Float,
  # Either the Value or the StatisticValues field can be populated and not both.
  "StatisticValues": { # Optional
    "SampleCount": Float,
    "Sum": Float,
    "Minimum": Float,
    "Maximum": Float
  },
  "Unit": "Count"
}
```
Create a Monitoring Schedule with an AWS CloudFormation Custom Resource

To use AWS CloudFormation to create a monitoring schedule, use an AWS CloudFormation custom resource. The custom resource is in Python. To deploy it, see Python Lambda deployment.

Custom Resource

Start by adding a custom resource to your AWS CloudFormation template. This points to a AWS Lambda function that you create in the next step.

This resource enables you to customize the parameters for the monitoring schedule You can add or remove more parameters by modifying the AWS CloudFormation resource and the Lambda function in the following example resource.

```json
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "MonitoringSchedule": {
            "Type": "Custom::MonitoringSchedule",
            "Version": "1.0",
            "Properties": {
                "ScheduleName": "YourScheduleName",
                "EndpointName": "YourEndpointName",
                "BaselineConstraintsUri": "s3://your-baseline-constraints/constraints.json",
                "BaselineStatisticsUri": "s3://your-baseline-stats/statistics.json",
                "PostAnalyticsProcessorSourceUri": "s3://your-post-processor/postprocessor.py",
                "RecordPreprocessorSourceUri": "s3://your-preprocessor/preprocessor.py",
                "InputLocalPath": "/opt/ml/processing/endpointdata",
                "OutputLocalPath": "/opt/ml/processing/localpath",
                "OutputS3URI": "s3://your-output-uri",
                "ImageURI": "11111111111.dkr.ecr.us-west-2.amazonaws.com/your-image",
                "ScheduleExpression": "cron(0 * * * *)",
                "PassRoleArn": "arn:aws:iam::111111111111:role/AmazonSageMaker-ExecutionRole"
            }
        }
    }
}
```

Lambda Custom Resource Code

This AWS CloudFormation custom resource uses the Custom Resource Helper AWS library, which you can install with pip using `pip install crhelper`.

This Lambda function is invoked by AWS CloudFormation during the creation and deletion of the stack. This Lambda function is responsible for creating and deleting the monitoring schedule and using the parameters defined in the custom resource described in the preceding section.

```python
import boto3
import botocore
import logging
from crhelper import CfnResource
from botocore.exceptions import ClientError

logger = logging.getLogger(__name__)
sm = boto3.client('sagemaker')
```
# cfnhelper makes it easier to implement a CloudFormation custom resource
helper = CfnResource()

# CFN Handlers

def delete_monitoring_schedule(schedule_name):
Invoke real-time endpoints

After you deploy your model using SageMaker hosting services, you can test your model on that endpoint by sending it test data. You can test your endpoints using Amazon SageMaker Studio, the AWS CLI, or AWS SDKs.

Test Your Endpoint Using Amazon SageMaker Studio

After you deploy your model to an endpoint (see Create your endpoint and deploy your model (p. 2642)) you can check that endpoint with Amazon SageMaker Studio.

Note
Note: SageMaker only supports endpoint testing with Amazon SageMaker Studio for real-time endpoints.

1. Launch Amazon SageMaker Studio.
2. Select the SageMaker Components and registries icon on the left sidebar.
3. From the dropdown, choose Endpoints.
4. Search for your endpoint by name and double-click on the name of your endpoint. The endpoint names listed within the SageMaker resources panel are defined when you deploy a model. You can deploy your model in several ways:
   - The SageMaker Python SDK Model Class sagemaker.model.Model.deploy.
   - The AWS SDK for Python (Boto3) SageMaker Service Client API CreateEndpoint.
   - The SageMaker console. Select Inference in the left panel and then select Endpoint configuration.
     Provide an endpoint name within the Endpoint name field.
5. (Optional) You can optionally provide a custom URL to send your request to. In the Configure endpoint URL and headers field provide the URL of where your model is hosted. Leave this field blank if you are using a SageMaker endpoint. You can also optionally add multiple key-value headers to pass additional information to the inference request.
6. A new tab will populate in the Studio workspace. Select the Test inference tab.
7. Send a request to your endpoint by providing sample data in JSON format. Use the JSON editor to submit a request to your endpoint.
8. Select Send Request.
9. When you send the request an Inference output card will appear on the right-hand side of the console.

The top of the card will display the type of request that was sent to the endpoint (currently only JSON is accepted). Within the card there are four main fields: Status, Execution Length, Request Time, and Result Time.

- **Status**: displays the request status. There are three types of statuses:
  - **Complete** - If the request is successful, the status will display Complete and the execution length will be calculated by tracking the request time.
  - **Failed** - If the request fails for any reason. A failure response will appear within the Failure Reason accordion.
- **Pending**: A spinning, circular icon will appear while the inference request is pending.

- **Execution Length**: How long the invocation takes (end time minus the start time) in milliseconds.

- **Request Time**: How many minutes have passed since the request was sent.

- **Result Time**: How many minutes have passed since the result was returned.

## Test Your Endpoint Using AWS SDKs

After you deploy your model to an endpoint (see Create your endpoint and deploy your model (p. )), you can check your endpoint with the `InvokeEndpoint` API using one of the AWS SDKs. If the invocation is successful, SageMaker will return an HTTP 200 response. You can index the returned response dictionary object to find out more about the response headers. For more information, see `InvokeEndpoint`.

The following demonstrates how to use `InvokeEndpoint` to check the status of your endpoint using the AWS SDK for Python (Boto3). Provide the name of your endpoint. This is the name you specified for `EndpointName` when you created your endpoint with `CreateEndpoint`.

Provide input data in the Body field for SageMaker to pass to the model. The data must be in the same format that was used for training.

```python
import boto3

# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>'

# After you deploy a model into production using SageMaker hosting services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    Body=bytes('{{"features": ["This is great!"]}}', 'utf-8')
)

# Optional - Print the response body and decode it so it is human read-able.
print(response['Body'].read().decode('utf-8'))
```

Once you have the response object (in the aforementioned example it is stored in a variable called `response`) you can index it to check the HTTP status, the name of the deployed model (InvokedProductionVariant), and other fields.

The proceeding code snippet prints the `HTTPStatusCode` stored in the `response` variable:

```python
print(response['HTTPStatusCode'])
```

For more information, see `InvokeEndpoint` in the SageMaker API Reference Guide.

## Test Your Endpoint Using the AWS CLI

The following demonstrates how to use `InvokeEndpoint` to check the status of your endpoint using the AWS CLI. Provide the name of your endpoint. This is the name you specified for `EndpointName` when you created your endpoint with `CreateEndpoint`.

```bash
import boto3

# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>'

# After you deploy a model into production using SageMaker hosting services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    Body=bytes('{{"features": ["This is great!"]}}', 'utf-8')
)

# Optional - Print the response body and decode it so it is human read-able.
print(response['Body'].read().decode('utf-8'))
```

For more information, see `InvokeEndpoint` in the SageMaker API Reference Guide.
Provide input data in the Body field for SageMaker to pass to the model. The data must be in the same format that was used for training. The example code template shows how to send binary data to your endpoint.

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name endpoint_name \
  --body fileb://$file_name \
  output_file.txt
```

For more information on when to use `file://` over `fileb://` when passing contents of a file to a parameter of the AWS CLI, see Best Practices for Local File Parameters.

See `invoke-endpoint` in the AWS CLI Command Reference guide for more information on additional parameters you can pass.

If the above invocation shows a snippet such as following, it means the command executed successfully. Otherwise, check whether input payload is in correct format.

```json
{
   "ContentType": "<content_type>; charset=utf-8",
   "InvokedProductionVariant": "<Variant>"
}
```

View the output of the invocation by checking the file `output_file.txt` (in this example).

```
mores output_file.txt
```

---

## Serverless Inference

Amazon SageMaker Serverless Inference is a purpose-built inference option that makes it easy for you to deploy and scale ML models. Serverless Inference is ideal for workloads which have idle periods between traffic spurts and can tolerate cold starts. Serverless endpoints automatically launch compute resources and scale them in and out depending on traffic, eliminating the need to choose instance types or manage scaling policies. This takes away the undifferentiated heavy lifting of selecting and managing servers. Serverless Inference integrates with AWS Lambda to offer you high availability, built-in fault tolerance and automatic scaling.

With a pay-per-use model, Serverless Inference is a cost-effective option if you have an infrequent or unpredictable traffic pattern. During times when there are no requests, Serverless Inference scales your endpoint down to 0, helping you to minimize your costs. For more information about pricing for Serverless Inference, see [Amazon SageMaker Pricing](https://aws.amazon.com/sagemaker/pricing).

You can integrate Serverless Inference with your MLOps Pipelines to streamline your ML workflow, and you can use a serverless endpoint to host a model registered with [Model Registry](https://docs.aws.amazon.com/sagemaker/latest/dg/model-registry.html).

Serverless Inference is generally available in all AWS commercial Regions where SageMaker is available (except the AWS China Regions). For more information about Amazon SageMaker regional availability, see the [AWS Regional Services List](https://aws.amazon.com/regions/global/).

## How it works

The following diagram shows the workflow of Serverless Inference and the benefits of using a serverless endpoint.
When you create a serverless endpoint, SageMaker provisions and manages the compute resources for you. Then, you can make inference requests to the endpoint and receive model predictions in response. SageMaker scales the compute resources up and down as needed to handle your request traffic, and you only pay for what you use.

The following sections provide additional details about Serverless Inference and how it works.

**Topics**
- Container support (p. 2777)
- Memory size (p. 2777)
- Concurrent invocations (p. 2778)
- Cold starts (p. 2778)
- Feature exclusions (p. 2778)

**Container support**

For your endpoint container, you can choose either a SageMaker-provided container or bring your own. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a list of available SageMaker images, see Available Deep Learning Containers Images. If you are bringing your own container, you must modify it to work with SageMaker. For more information about bringing your own container, see Adapting Your Own Inference Container (p. 3027).

For serverless endpoints, we recommend creating only one worker in the container and only loading one copy of the model. Note that this is unlike real-time endpoints, where some SageMaker containers may create a worker for each vCPU to process inference requests and load the model in each worker.

If you already have a container for a real-time endpoint, you can use the same container for your serverless endpoint, though some capabilities are excluded. To learn more about the container capabilities that are not supported in Serverless Inference, see Feature exclusions (p. 2778). If you choose to use the same container, SageMaker escrows (retains) a copy of your container image until you delete all endpoints that use the image. SageMaker encrypts the copied image at rest with a SageMaker-owned AWS KMS key.

**Memory size**

Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs. Choose your endpoint's memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection.
for your model based on your latency SLAs. The memory size increments have different pricing; see the Amazon SageMaker pricing page for more information.

Regardless of the memory size you choose, your serverless endpoint has 5 GB of ephemeral disk storage available. For help with container permissions issues when working with storage, see Troubleshooting (p. 2790).

**Concurrent invocations**

Serverless Inference manages predefined scaling policies and quotas for the capacity of your endpoint. Serverless endpoints have a quota for how many concurrent invocations can be processed at the same time. If the endpoint is invoked before it finishes processing the first request, then it handles the second request concurrently. For the US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Europe (Frankfurt), and Europe (Ireland) Regions, the total concurrency you can share between all serverless endpoints per Region in your account is 1000. For the US West (N. California), Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Mumbai), Asia Pacific (Osaka), Asia Pacific (Seoul), Canada (Central), Europe (London), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo) Regions, the total concurrency per Region is 500. You can set the maximum concurrency for a single endpoint up to 200, and the total number of serverless endpoints you can host in a Region is 50. The maximum concurrency for an individual endpoint prevents that endpoint from taking up all of the invocations allowed for your account, and any endpoint invocations beyond the maximum are throttled.

To learn how to set the maximum concurrency for your endpoint, see Create an endpoint configuration (p. 2783). For more information about quotas and limits, see Amazon SageMaker endpoints and quotas in the AWS General Reference. To request a service limit increase, contact AWS Support. For instructions on how to request a service limit increase, see Supported Regions and Quotas (p. 32).

**Cold starts**

If your endpoint does not receive traffic for a while and then your endpoint suddenly receives new requests, it can take some time for your endpoint to spin up the compute resources to process the requests. This is called a cold start. Since serverless endpoints provision compute resources on demand, your endpoint may experience cold starts. A cold start can also occur if your concurrent requests exceed the current concurrent request usage. The cold start time depends on your model size, how long it takes to download your model, and the start-up time of your container.

To monitor how long your cold start time is, you can use the Amazon CloudWatch metric ModelSetupTime to monitor your serverless endpoint. This metric tracks the time it takes to launch new compute resources for your endpoint. To learn more about using CloudWatch metrics with serverless endpoints, see Monitor a Serverless Endpoint (p. 2790).

**Feature exclusions**

Some of the features currently available for SageMaker Real-time Inference are not supported for Serverless Inference, including GPUs, AWS marketplace model packages, private Docker registries, Multi-Model Endpoints, VPC configuration, network isolation, data capture, multiple production variants, Model Monitor, and inference pipelines.

You cannot convert your instance-based, real-time endpoint to a serverless endpoint. If you try to update your real-time endpoint to serverless, you receive a ValidationError message. You can convert a serverless endpoint to real-time, but once you make the update, you cannot roll it back to serverless.

**Getting started**

You can create, update, describe, and delete a serverless endpoint using the SageMaker console, the AWS SDKs, the Amazon SageMaker Python SDK, and the AWS CLI. You can invoke your endpoint using...
the AWS SDKs, the Amazon SageMaker Python SDK, and the AWS CLI. For more information about how to set up and use a serverless endpoint, read the guide Create, Invoke, Update, and Delete an Endpoint (p. 2779).

Example notebooks and blogs

For Jupyter notebook examples that show end-to-end serverless endpoint workflows, see the Serverless Inference example notebooks.

Create, Invoke, Update, and Delete an Endpoint

Unlike other SageMaker real-time endpoints, Serverless Inference manages compute resources and scaling policies for you, reducing complexity so you can focus on your ML model instead of on managing infrastructure. The following guide highlights the key capabilities of serverless endpoints: how to create, invoke, update, describe, or delete an endpoint. You can use the SageMaker console, the AWS SDKs, the Amazon SageMaker Python SDK, or the AWS CLI to manage your serverless endpoints.

Topics
- Prerequisites (p. 2779)
- Create a serverless endpoint (p. 2781)
- Invoke a serverless endpoint (p. 2788)
- Update a serverless endpoint (p. 2788)
- Describe a serverless endpoint (p. 2789)
- Delete a serverless endpoint (p. 2790)

Prerequisites

Before you can create a serverless endpoint, complete the following prerequisites.

1. **Set up an AWS account.** You first need an AWS account and an AWS Identity and Access Management administrator user. For instructions on how to set up an AWS account, see How do I create and activate a new AWS account?. For instructions on how to secure your account with an IAM administrator user, see Creating your first IAM admin user and user group in the IAM User Guide.

2. **Create an Amazon S3 bucket.** You use an Amazon S3 bucket to store your model artifacts. To learn how to create a bucket, see Create your first S3 bucket in the Amazon S3 User Guide.

3. **Upload your model artifacts to your S3 bucket.** For instructions on how to upload your model to your bucket, see Upload an object to your bucket in the Amazon S3 User Guide.

4. **Create an IAM role for Amazon SageMaker.** Amazon SageMaker needs access to the S3 bucket that stores your model. Create an IAM role with a policy that gives SageMaker read access to your bucket. The following procedure shows how to create a role in the console, but you can also use the CreateRole API from the IAM User Guide. For information on giving your role more granular permissions based on your use case, see SageMaker Roles (p. 3391).
   
   a. Sign in to the IAM console.
   b. In the navigation tab, choose Roles.
   c. Choose Create Role.
   d. For Select type of trusted entity, choose AWS service and then choose SageMaker.
   e. Choose Next: Permissions and then choose Next: Tags.
   f. (Optional) Add tags as key-value pairs if you want to have metadata for the role.
   g. Choose Next: Review.
h. For **Role name**, enter a name for the new role that is unique within your AWS account. You cannot edit the role name after creating the role.

i. (Optional) For **Role description**, enter a description for the new role.

j. Choose **Create role**.

5. **Attach S3 bucket permissions to your SageMaker role.** After creating an IAM role, attach a policy that gives SageMaker permission to access the S3 bucket containing your model artifacts.

   a. In the IAM console navigation tab, choose **Roles**.
   
   b. From the list of roles, search for the role you created in the previous step by name.
   
   c. Choose your role, and then choose **Attach policies**.
   
   d. For **Attach permissions**, choose **Create policy**.
   
   e. In the **Create policy** view, select the **JSON** tab.
   
   f. Add the following policy statement into the JSON editor. Make sure to replace `<your-bucket-name>` with the name of the S3 bucket that stores your model artifacts. If you want to restrict the access to a specific folder or file in your bucket, you can also specify the Amazon S3 folder path, for example, `<your-bucket-name>/<model-folder>`.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "VisualEditor0",
   "Effect": "Allow",
   "Action": "s3:GetObject",
   "Resource": "arn:aws:s3:::<your-bucket-name>/*"
   }
   ]
   }
   ```

   g. Choose **Next: Tags**.

   h. (Optional) Add tags in key-value pairs to the policy.

   i. Choose **Next: Review**.

   j. For **Name**, enter a name for the new policy.

   k. (Optional) Add a **Description** for the policy.

   l. Choose **Create policy**.

   m. After creating the policy, return to **Roles** in the IAM console and select your SageMaker role.

   n. Choose **Attach policies**.

   o. For **Attach permissions**, search for the policy you created by name. Select it and choose **Attach policy**.

6. **Select a prebuilt Docker container image or bring your own.** The container you choose serves inference on your endpoint. SageMaker provides containers for built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see Available Deep Learning Containers Images.

   If none of the existing SageMaker containers meet your needs, you may need to create your own Docker container. For information about how to create your Docker image and make it compatible with SageMaker, see Use Your Own Inference Code (p. 3037). To use your container with a serverless endpoint, the container image must reside in an Amazon ECR repository within the same AWS account that creates the endpoint.

7. **(Optional) Register your model with Model Registry.** SageMaker Model Registry (p. 2834) helps you catalog and manage versions of your models for use in ML pipelines. For more information about registering a version of your model, see Create a Model Group (p. 2835) and Register a Model.
For an example of a Model Registry and Serverless Inference workflow, see the following example notebook.

8. **(Optional) Bring an AWS KMS key.** When setting up a serverless endpoint, you have the option to specify a KMS key that SageMaker uses to encrypt your Amazon ECR image. Note that the key policy for the KMS key must grant access to the IAM role you specify when setting up your endpoint. To learn more about KMS keys, see the AWS Key Management Service Developer Guide.

Create a serverless endpoint

To create a serverless endpoint, you can use the Amazon SageMaker console, the APIs, or the AWS CLI. You can create a serverless endpoint using a similar process as a real-time endpoint (p. 2641).

**Topics**
- Create a model (p. 2781)
- Create an endpoint configuration (p. 2783)
- Create an endpoint (p. 2785)

Create a model

To create your model, you must provide the location of your model artifacts and container image. You can also use a model version from SageMaker Model Registry (p. 2834). The examples in the following sections show you how to create a model using the CreateModel API, Model Registry, and the Amazon SageMaker console.

To create a model (using Model Registry)

Model Registry (p. 2834) is a feature of SageMaker that helps you catalog and manage versions of your model for use in ML pipelines. To use Model Registry with Serverless Inference, you must first register a model version in a Model Registry model group. To learn how to register a model in Model Registry, follow the procedures in Create a Model Group (p. 2835) and Register a Model Version (p. 2840).

The following example requires you to have the ARN of a registered model version and uses the AWS SDK for Python (Boto3) to call the CreateModel API. For Serverless Inference, Model Registry is currently only supported by the AWS SDK for Python (Boto3). For the example, specify the following values:

- For `model_name`, enter a name for the model.
- For `sagemaker_role`, you can use the default SageMaker-created role or a customized SageMaker IAM role from Step 4 of the Prerequisites (p. 2779) section.
- For `ModelPackageName`, specify the ARN for your model version, which must be registered to a model group in Model Registry.

```python
#Setup
import boto3
import sagemaker
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker permission to access AWS services.
sagemaker_role = sagemaker.get_execution_role()

#Specify a name for the model
model_name = "<name-for-model>"

#Specify a Model Registry model version
container_list = [
    
]"
To create a model (using API)

The following example uses the AWS SDK for Python (Boto3) to call the CreateModel API. Specify the following values:

- For `sagemaker_role`, you can use the default SageMaker-created role or a customized SageMaker IAM role from Step 4 of the Prerequisites (p. 2779) section.
- For `model_url`, specify the Amazon S3 URI to your model.
- For `container`, retrieve the container you want to use by its Amazon ECR path. This example uses a SageMaker-provided XGBoost container. If you have not selected a SageMaker container or brought your own, see Step 6 of the Prerequisites (p. 2779) section for more information.
- For `model_name`, enter a name for the model.

```python
#Setup
import boto3
import sagemaker
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker permission to access AWS services.
sagemaker_role = sagemaker.get_execution_role()

#Get model from S3
model_url = "s3://DOC-EXAMPLE-BUCKET/models/model.tar.gz"

#Get container image (prebuilt example)
from sagemaker import image_uris
container = image_uris.retrieve("xgboost", region, "0.90-1")

#Create model
model_name = "<name-for-model>"
response = client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    Containers = [{
        "Image": container,
        "Mode": "SingleModel",
        "ModelDataUrl": model_url,
    }]
)
```

To create a model (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Models.
4. Choose Create model.
5. For **Model name**, enter a name for the model that is unique to your account and AWS Region.
6. For **IAM role**, either select an IAM role you have already created (see Prerequisites (p. 2779)) or allow SageMaker to create one for you.
7. In **Container definition 1**, for **Container input options**, select **Provide model artifacts and input location**.
8. For **Provide model artifacts and inference image options**, select **Use a single model**.
9. For **Location of inference code image**, enter an Amazon ECR path to a container. The image must either be a SageMaker-provided first party image (e.g. TensorFlow, XGBoost) or an image that resides in an Amazon ECR repository within the same account in which you are creating the endpoint. If you do not have a container, go back to Step 6 of the Prerequisites (p. 2779) section for more information.
10. For **Location of model artifacts**, enter the Amazon S3 URI to your ML model. For example, `s3://DOC-EXAMPLE-BUCKET/models/model.tar.gz`.
11. (Optional) For **Tags**, add key-value pairs to create metadata for your model.
12. Choose **Create model**.

**Create an endpoint configuration**

After you create a model, create an endpoint configuration. You can then deploy your model using the specifications in your endpoint configuration. In the configuration, you specify whether you want a real-time or serverless endpoint. To create a serverless endpoint configuration, you can use the Amazon SageMaker console, the CreateEndpointConfig API, or the AWS CLI. The API and console approaches are outlined in the following sections.

**To create an endpoint configuration (using API)**

The following example uses the AWS SDK for Python (Boto3) to call the CreateEndpointConfig API. Specify the following values:

- For **EndpointConfigName**, choose a name for the endpoint configuration. The name should be unique within your account in a Region.
- (Optional) For **KmsKeyId**, use the key ID, key ARN, alias name, or alias ARN for an AWS KMS key that you want to use. SageMaker uses this key to encrypt your Amazon ECR image.
- For **ModelName**, use the name of the model you want to deploy. It should be the same model that you used in the Create a model (p. 2781) step.
- For **ServerlessConfig**:
  - Set **MemorySizeInMB** to 2048. For this example, we set the memory size to 2048 MB, but you can choose any of the following values for your memory size: 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB.
  - Set **MaxConcurrency** to 20. For this example, we set the maximum concurrency to 20. The maximum number of concurrent invocations you can set for a serverless endpoint is 200, and the minimum value you can choose is 1.

```python
response = client.create_endpoint_config(
    EndpointConfigName="<your-endpoint-configuration>",
    KmsKeyId="arn:aws:kms:us-east-1:123456789012:key/134ef68f-76fd-45e3-abba-ed28fc8d3d5e",
    ProductionVariants=[
        {
            "ModelName": "<your-model-name>",
            "VariantName": "AllTraffic",
            "ServerlessConfig": {
                "MemorySizeInMB": 2048,
                "MaxConcurrency": 20
            }
        }
    ]
)
```
To create an endpoint configuration (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoint configurations.
4. Choose Create endpoint configuration.
5. For Endpoint configuration name, enter a name that is unique within your account in a Region.
6. For Type of endpoint, select Serverless.

7. For Production variants, choose Add model.
8. Under Add model, select the model you want to use from the list of models and then choose Save.
9. After adding your model, under Actions, choose Edit.
10. For Memory size, choose the memory size you want in GB.
11. For **Max Concurrency**, enter your desired maximum concurrent invocations for the endpoint. The maximum value you can enter is 200 and the minimum is 1.

12. Choose **Save**.

13. (Optional) For **Tags**, enter key-value pairs if you want to create metadata for your endpoint configuration.

14. Choose **Create endpoint configuration**.

**Create an endpoint**

To create a serverless endpoint, you can use the Amazon SageMaker console, the CreateEndpoint API, or the AWS CLI. The API and console approaches are outlined in the following sections. Once you create your endpoint, it can take a few minutes for the endpoint to become available.

**To create an endpoint (using API)**

The following example uses the AWS SDK for Python (Boto3) to call the CreateEndpoint API. Specify the following values:

- For **EndpointName**, enter a name for the endpoint that is unique within a Region in your account.
- For **EndpointConfigName**, use the name of the endpoint configuration that you created in the previous section.

```python
response = client.create_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-endpoint-config>"
)  
```
To create an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. Choose Create endpoint.
5. For Endpoint name, enter a name than is unique within a Region in your account.
6. For Attach endpoint configuration, select Use an existing endpoint configuration.
7. For Endpoint configuration, select the name of the endpoint configuration you created in the previous section and then choose Select endpoint configuration.
8. (Optional) For Tags, enter key-value pairs if you want to create metadata for your endpoint.
9. Choose Create endpoint.
Create and configure endpoint

To deploy models to Amazon SageMaker, first create an endpoint. Provide an endpoint configuration to specify which models to deploy and the hardware requirements for each. See Deploying a Model on Amazon SageMaker Hosting Services [Learn more about the API](#).

**Endpoint**

**Endpoint name**
Your application uses this name to access this endpoint.

*example-endpoint*

Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an AWS Region.

**Attach endpoint configuration**

- Use an existing endpoint configuration
  Use an existing endpoint configuration or clone an endpoint configuration.

- Create a new endpoint configuration
  Add models and configure the instance and initial weight for each model.

**New endpoint configuration**

**Endpoint configuration name**
*example-epc*

**Encryption key**
*

**Production variants**

<table>
<thead>
<tr>
<th>Model name</th>
<th>Training job</th>
<th>Variant name</th>
<th>Memory Size</th>
<th>Max Concurrency</th>
</tr>
</thead>
<tbody>
<tr>
<td>example-model</td>
<td>-</td>
<td>variant-name-1</td>
<td>1 GB</td>
<td>20</td>
</tr>
</tbody>
</table>

**Tags** - optional

[Create endpoint]
Invoke a serverless endpoint

In order to perform inference using a serverless endpoint, you must send an HTTP request to the endpoint. You can use the `InvokeEndpoint` API or the AWS CLI, which make a `POST` request to invoke your endpoint. The maximum request and response payload size for serverless invocations is 4 MB. Note that a cold start (or a delay in spinning up compute resources) on the endpoint may delay the response time to up to 4 minutes:

- The model must download and the server must respond successfully to `/ping` within 3 minutes.
- The timeout for the container to respond to inference requests to `/invocations` is 1 minute.

For more information on cold starts for serverless endpoints, see Cold starts (p. 2778).

To invoke an endpoint

The following example uses the AWS SDK for Python (Boto3) to call the `InvokeEndpoint` API. Note that unlike the other API calls in this guide, for `InvokeEndpoint`, you must use SageMaker Runtime as the client. Specify the following values:

- For `endpoint_name`, use the name of the in-service serverless endpoint you want to invoke.
- For `content_type`, specify the MIME type of your input data in the request body (for example, `application/json`).
- For `payload`, use your request payload for inference. Your payload should be in bytes or a file-like object.

```python
runtime = boto3.client("sagemaker-runtime")
endpoint_name = "<your-endpoint-name>"
content_type = "<request-mime-type>"
payload = <your-request-body>

response = client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType=content_type,
    Body=payload
)
```

Update a serverless endpoint

Before updating your endpoint, create a new endpoint configuration or use an existing endpoint configuration. The endpoint configuration is where you specify the changes for your update. Then, you can update your endpoint with the SageMaker console, the `UpdateEndpoint` API, or the AWS CLI. The process for updating a serverless endpoint is the same as the process for updating a real-time endpoint (p. 2641). Note that when updating your endpoint, you can experience cold starts when making requests to the endpoint because SageMaker must re-initialize your container and model.

Create a new endpoint configuration

To create a new serverless endpoint configuration, see the previous procedure in Create an endpoint configuration (p. 2783). You can also create a real-time endpoint configuration to switch from serverless to instance-based capacity.

Update the endpoint

Examples of how to update your endpoint using the `UpdateEndpoint` API and the SageMaker console are outlined in the following sections.
To update the endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the UpdateEndpoint API. Specify the following values:

- For EndpointName, use the name of the endpoint you’re updating.
- For EndpointConfigName, use the name of the endpoint configuration that you want to use for the update.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<new-endpoint-config>",
)
```

To update the endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, select the endpoint you want to update.
5. Choose Update endpoint.
6. For Change the Endpoint configuration, choose Use an existing endpoint configuration.
7. From the list of endpoint configurations, select the one you want to use for your update.
8. Choose Select endpoint configuration.
9. Choose Update endpoint.

Describe a serverless endpoint

You might want to retrieve information about your endpoint, including details such as the endpoint's ARN, current status, deployment configuration, and failure reasons. You can find information about your endpoint using the SageMaker console, the DescribeEndpoint API, or the AWS CLI.

To describe an endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the DescribeEndpoint API. For EndpointName, use the name of the endpoint you want to check.

```python
response = client.describe_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To describe an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, choose the endpoint you want to check.

The endpoint page contains the information about your endpoint.
Delete a serverless endpoint

You can delete your serverless endpoint using the SageMaker console, the DeleteEndpoint API, or the AWS CLI. The following examples show you how to delete your endpoint through the API and the SageMaker console.

To delete an endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the DeleteEndpoint API. For EndpointName, use the name of the serverless endpoint you want to delete.

```python
response = client.delete_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To delete an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, select the endpoint you want to delete.
5. Choose the Actions drop-down list, and then choose Delete.
6. When prompted again, choose Delete.

Your endpoint should now begin the deletion process.

Monitor a Serverless Endpoint

To monitor your serverless endpoint, you can use Amazon CloudWatch alarms. CloudWatch is a service that collects metrics in real time from your AWS applications and resources. An alarm watches metrics as they are collected and gives you the ability to pre-specify a threshold and the actions to take if that threshold is breached. For example, your CloudWatch alarm can send you a notification if your endpoint breaches an error threshold. By setting up CloudWatch alarms, you gain visibility into the performance and functionality of your endpoint.

To learn more about CloudWatch metrics you can use to monitor your endpoints in SageMaker, see SageMaker Endpoint Invocation Metrics (p. 3499). The ModelSetupTime metric tracks the cold start time for your endpoint, or the time it takes to launch new compute resources for your serverless endpoint. This metric depends on your model size and the container’s start-up time. Serverless endpoints can also use the Invocations4XXErrors, Invocations5XXErrors, and Invocations metrics in the AWS/SageMaker namespace. In the aws/sagemaker/Endpoints namespace, they can use the MemoryUtilization metric. For more information about CloudWatch alarms, see Using Amazon CloudWatch User Guide.

If you want to monitor the logs from your endpoint for debugging or progress analysis, you can use Amazon CloudWatch Logs. The SageMaker-provided log group that you can use for serverless endpoints is /aws/sagemaker/Endpoints/[EndpointName]. For more information about using CloudWatch Logs in SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3510). To learn more about CloudWatch Logs, see What is Amazon CloudWatch Logs? in the Amazon CloudWatch Logs User Guide.

Troubleshooting

If you are having trouble with Serverless Inference, refer to the following troubleshooting tips.
Container issues

If the container you use for a serverless endpoint is the same one you used on an instance-based endpoint, your container may not have permissions to write files. This can happen for the following reasons:

- Your serverless endpoint fails to create or update due to a ping health check failure.
- The Amazon CloudWatch logs for the endpoint show that the container is failing to write to some file or directory due to a permissions error.

To fix this issue, you can try to add read, write, and execute permissions for other on the file or directory and then rebuild the container. You can perform the following steps to complete this process:

1. In the Dockerfile you used to build your container, add the following command: `RUN chmod o+rwx <file or directory name>`
2. Rebuild the container.
3. Upload the new container image to Amazon ECR.
4. Try to create or update the serverless endpoint again.

Asynchronous inference

Amazon SageMaker Asynchronous Inference is a new capability in SageMaker that queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes (up to 1GB), long processing times (up to 15 minutes), and near real-time latency requirements. Asynchronous Inference enables you to save on costs by autoscaling the instance count to zero when there are no requests to process, so you only pay when your endpoint is processing requests.

How It Works

Creating an asynchronous inference endpoint is similar to creating real-time inference endpoints. You can use your existing SageMaker models and only need to specify the AsyncInferenceConfig object while creating your endpoint configuration with the EndpointConfig field in the CreateEndpointConfig API. The following diagram shows the architecture and workflow of Asynchronous Inference.
To invoke the endpoint, you need to place the request payload in Amazon S3 and provide a pointer to this payload as a part of the InvokeEndpointAsync request. Upon invocation, SageMaker queues the request for processing and returns an identifier and output location as a response. Upon processing, SageMaker places the result in the Amazon S3 location. You can optionally choose to receive success or error notifications with Amazon SNS. For more information about how to set up asynchronous notifications, see Check prediction results (p. 2803).

Note
The presence of an asynchronous inference configuration (AsyncInferenceConfig) object in the endpoint configuration implies that the endpoint can only receive asynchronous invocations.

How Do I Get Started?

If you are a first-time user of Amazon SageMaker Asynchronous Inference, we recommend that you do the following:

- Read Create, invoke, and update an Asynchronous Endpoint (p. 2792) for information on how to create, invoke, update, and delete an asynchronous endpoint.
- Explore the Asynchronous Inference example notebook in the aws/amazon-sagemaker-examples GitHub repository.

Note that if your endpoint uses any of the features listed in this Exclusions (p. 2832) page, you cannot use Asynchronous Inference.

Create, invoke, and update an Asynchronous Endpoint

This guide demonstrates the prerequisites you must satisfy to create an asynchronous endpoint, along with how to create, invoke, and delete your asynchronous endpoints. You can create, update, delete, and invoke asynchronous endpoints with the AWS SDKs and the Amazon SageMaker Python SDK.

Topics
- Prerequisites (p. 2793)
Create, invoke, and update an Asynchronous Endpoint

- Create an Asynchronous Inference Endpoint (p. 2795)
- Invoke an Asynchronous Endpoint (p. 2799)
- Update an Asynchronous Endpoint (p. 2800)
- Delete an Asynchronous Endpoint (p. 2800)

Prerequisites

To use asynchronous endpoints, first make sure you have met these prerequisites.

1. **Create an IAM role for Amazon SageMaker.**

   Asynchronous Inference needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3 and Amazon SNS. Using this role, SageMaker can run under your account and access your Amazon S3 bucket and Amazon SNS topics.

   You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.
   
   a. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
   b. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
   c. For **Select type of trusted entity**, choose **AWS service**.
   d. Choose the service that you want to allow to assume this role. In this case, choose **SageMaker**. Then choose **Next: Permissions**.
      - This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.
   e. Choose **Next: Tags**.
   f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see **Tagging IAM resources**.
   g. Choose **Next: Review**.
   h. Type in a **Role name**.
   i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
   j. (Optional) For **Role description**, type a description for the new role.
   k. Review the role and then choose **Create role**.

   Note the SageMaker role ARN. To find the role ARN using the console, do the following:
   
   i. Go to the IAM console: [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/)
   ii. Select **Roles**.
   iii. Search for the role you just created by typing in the name of the role in the search field.
   iv. Select the role.
   v. The role ARN is at the top of the **Summary** page.

2. **Add Amazon SageMaker, Amazon S3 and Amazon SNS Permissions to your IAM Role.**

   Once the role is created, grant SageMaker, Amazon S3, and optionally Amazon SNS permissions to your IAM role.

   2793
Choose **Roles** in the IAM console. Search for the role you created by typing in your role name in the **Search** field.

a. Choose your role.

b. Next, choose **Attach Policies**.

c. Amazon SageMaker Asynchronous Inference needs permissions to perform the following actions: "sagemaker:CreateModel", "sagemaker:CreateEndpointConfig", "sagemaker:CreateEndpoint", and "sagemaker:InvokeEndpointAsync".

   These actions are included in the **AmazonSageMakerFullAccess** policy. Add this policy to your IAM role. Search for **AmazonSageMakerFullAccess** in the **Search** field. Select AmazonSageMakerFullAccess.

d. Choose **Attach policy**.

e. Next, choose **Attach Policies** to add Amazon S3 permissions.

f. Select **Create policy**.

g. Select the **JSON** tab.

h. Add the following policy statement:

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Action": [
   "s3:GetObject",
   "s3:PutObject",
   "s3:AbortMultipartUpload",
   "s3:ListBucket"
   ],
   "Effect": "Allow",
   "Resource": "arn:aws:s3:::<bucket_name>/*"
   }
   ]
   }
   ```

i. Choose **Next: Tags**.

j. Type in a **Policy name**.

k. Choose **Create policy**.

l. Repeat the same steps you completed to add Amazon S3 permissions in order to add Amazon SNS permissions. For the policy statement, attach the following:

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Action": [
   "sns:Publish"
   ],
   "Effect": "Allow",
   }
   ]
   }
   ```

3. **Upload your inference data (e.g., machine learning model, sample data) to Amazon S3.**

4. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**
SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see Available Deep Learning Containers Images. If you choose to use a SageMaker provided container, you can increase the endpoint timeout and payload sizes from the default by setting the environment variables in the container. To learn how to set the different environment variables for each framework, see the Create a Model step of creating an asynchronous endpoint.

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. See Use Your Own Inference Code (p. 3037) for information on how to create your Docker image.

5. **Create an Amazon SNS topic (optional)**

Create an Amazon Simple Notification Service (Amazon SNS) topic that sends notifications about requests that have completed processing. Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. You can specify Amazon SNS topics when you create an EndpointConfig object when you specify AsyncInferenceConfig using the EndpointConfig API.

Follow the steps to create and subscribe to an Amazon SNS topic.

a. Using Amazon SNS console, create a topic. For instructions, see Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

b. Subscribe to the topic. For instructions, see Subscribing to an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

c. When you receive email requesting that you confirm your subscription to the topic, confirm the subscription.

d. Note the topic Amazon Resource Name (ARN). The Amazon SNS topic you created is another resource in your AWS account, and it has a unique ARN. The ARN is in the following format:

   arn:aws:sns:aws-region:account-id:topic-name

For more information about Amazon SNS, see the Amazon SNS Developer Guide.

### Create an Asynchronous Inference Endpoint

Create an asynchronous endpoint the same way you would create an endpoint using SageMaker hosting services:

- Create a model in SageMaker with CreateModel.
- Create an endpoint configuration with CreateEndpointConfig.
- Create an HTTPS endpoint with CreateEndpoint.

To create an endpoint, you first create a model with CreateModel, where you point to the model artifact and a Docker registry path (Image). You then create a configuration using CreateEndpointConfig where you specify one or more models that were created using the CreateModel API to deploy and the resources that you want SageMaker to provision. Create your endpoint with CreateEndpoint using the endpoint configuration specified in the request. You can update an asynchronous endpoint with the UpdateEndpoint API. Send and receive inference requests from the model hosted at the endpoint with InvokeEndpointAsync. You can delete your endpoints with the DeleteEndpoint API.
For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. See Use Your Own Inference Code (p. 3037) for information on how to create your Docker image.

Create a Model

The following example shows how to create a model using the AWS SDK for Python (Boto3). The first few lines define:

- `sagemaker_client`: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.

```python
import boto3
# Specify your AWS Region
aws_region='<aws_region>'
# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)
# Role to give SageMaker permission to access AWS services.
sagemaker_role = "arn:aws:iam::<account>::role/*"
```

Next, specify the location of the pre-trained model stored in Amazon S3. In this example, we use a pre-trained XGBoost model named `demo-xgboost-model.tar.gz`. The full Amazon S3 URI is stored in a string variable `model_url`:

```python
#Create a variable w/ the model S3 URI
s3_bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
bucket_prefix = 'saved_models'
model_s3_key = f'{bucket_prefix}/demo-xgboost-model.tar.gz'
#Specify S3 bucket w/ model
model_url = f's3://{s3_bucket}/{model_s3_key}'
```

Specify a primary container. For the primary container, you specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

In this example, we specify an XGBoost built-in algorithm container image:

```python
from sagemaker import image_uris
# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region, framework='xgboost', version='0.90-1')
```

Create a model in Amazon SageMaker with `CreateModel`. Specify the following:

- `ModelName`: A name for your model (in this example it is stored as a string variable called `model_name`).
- `ExecutionRoleArn`: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- `PrimaryContainer`: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.
model_name = 'The_name_of_the_model'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    }
)

If you're using a SageMaker provided container, you can increase the model server timeout and payload sizes from the default values to the framework-supported maximums by setting environment variables in this step. You might not be able to leverage the maximum timeout and payload sizes that Asynchronous Inference supports if you don't explicitly set these variables. The following example shows how you can set the environment variables for a PyTorch Inference container based on TorchServe.

model_name = 'The_name_of_the_model'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
        'Environment': {
            'TS_MAX_REQUEST_SIZE': '100000000',
            'TS_MAX_RESPONSE_SIZE': '100000000',
            'TS_DEFAULT_RESPONSE_TIMEOUT': '1000'
        }
    }
)

After you finish creating your endpoint, you should test that you've set the environment variables correctly by printing them out from your inference.py script. The following table lists the environment variables for several frameworks that you can set to change the default values.

<table>
<thead>
<tr>
<th>Framework</th>
<th>Environment variables</th>
</tr>
</thead>
</table>
| PyTorch 1.8 (based on TorchServe)        | 'TS_MAX_REQUEST_SIZE': '100000000'
|                                          | 'TS_MAX_RESPONSE_SIZE': '100000000'
|                                          | 'TS_DEFAULT_RESPONSE_TIMEOUT': '1000'
| PyTorch 1.4 (based on MMS)               | 'MMS_MAX_REQUEST_SIZE': '1000000000'
|                                          | 'MMS_MAX_RESPONSE_SIZE': '1000000000'
|                                          | 'MMS_DEFAULT_RESPONSE_TIMEOUT': '900'
| HuggingFace Inference Container (based on MMS) | 'MMS_MAX_REQUEST_SIZE': '2000000000'
|                                          | 'MMS_MAX_RESPONSE_SIZE': '2000000000'
|                                          | 'MMS_DEFAULT_RESPONSE_TIMEOUT': '900'
Create an Endpoint Configuration

Once you have a model, create an endpoint configuration with `CreateEndpointConfig`. Amazon SageMaker hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using with `CreateModel`, to deploy the resources that you want Amazon SageMaker to provision. Specify the `AsyncInferenceConfig` object and provide an output Amazon S3 location for `OutputConfig`. You can optionally specify Amazon SNS topics on which to send notifications about prediction results. For more information about Amazon SNS topics, see Configuring Amazon SNS.

The following example shows how to create an endpoint configuration using AWS SDK for Python (Boto3):

```python
import datetime
from time import gmtime, strftime

# Create an endpoint config name. Here we create one based on the date
# so it we can search endpoints based on creation time.
endpoint_config_name = f"XGBoostEndpointConfig-{strftime('%Y-%m-%d-%H-%M-%S', gmtime())}"

# The name of the model that you want to host. This is the name that you specified when
# creating the model.
model_name='<The_name_of_your_model>'

create_endpoint_config_response = sagemaker_client.create_endpoint_config(  
    EndpointConfigName=endpoint_config_name, # You will specify this name in a
    # CreateEndpoint request.
    ProductionVariants=[  
        {  
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {  
            "S3OutputPath": f"s3://(s3_bucket)/(bucket_prefix)/output"  
            # (Optional) specify Amazon SNS topics
            "NotificationConfig": {  
            }
        },
        "ClientConfig": {  
            "MaxConcurrentInvocationsPerInstance": 4
        }
    }
)

print(f"Created EndpointConfig: {create_endpoint_config_response['EndpointConfigArn']}")
```

In the aforementioned example, you specify the following keys for `OutputConfig` for the `AsyncInferenceConfig` field:

- `S3OutputPath`: Location to upload response outputs when no location is provided in the request.
Create, invoke, and update an Asynchronous Endpoint

- **NotificationConfig**: (Optional) SNS topics that post notifications to you when an inference request is successful (*SuccessTopic*) or if it fails (*ErrorTopic*).

You can also specify the following optional argument for **ClientConfig** in the **AsyncInferenceConfig** field:

- **MaxConcurrentInvocationsPerInstance**: (Optional) The maximum number of concurrent requests sent by the SageMaker client to the model container.

### Create Endpoint

Once you have your model and endpoint configuration, use the **CreateEndpoint** API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name = '<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
```

When you call the **CreateEndpoint** API, Amazon SageMaker Asynchronous Inference sends a test notification to check that you have configured an Amazon SNS topic. This lets SageMaker check that you have the required permissions. The notification can simply be ignored. The test notification has the following form:

```json
{
    "eventVersion": "1.0",
    "eventSource": "aws:sagemaker",
    "eventName": "TestNotification"
}
```

### Invoke an Asynchronous Endpoint

Get inferences from the model hosted at your asynchronous endpoint with **InvokeEndpointAsync**.

**Note**

If you have not done so already, upload your inference data (e.g., machine learning model, sample data) to Amazon S3.

Specify the location of your inference data in the **InputLocation** field and the name of your endpoint for **EndpointName**:

```python
# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the location of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'
```
Create, invoke, and update an Asynchronous Endpoint

# After you deploy a model into production using SageMaker hosting services, your client applications use this API to get inferences from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint_async(    EndpointName=endpoint_name,    InputLocation=input_location)

You receive a response as a JSON string with your request ID and the name of the Amazon S3 bucket that will have the response to the API call after it is processed.

Update an Asynchronous Endpoint

Update an asynchronous endpoint with the UpdateEndpoint API. When you update an endpoint, SageMaker first provisions and switches to the new endpoint configuration you specify before it deletes the resources that were provisioned in the previous endpoint configuration. Do not delete an EndpointConfig with an endpoint that is live or while the UpdateEndpoint or CreateEndpoint operations are being performed on the endpoint.

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

sagemaker_client.update_endpoint(    EndpointConfigName=endpoint_config_name,    EndpointName=endpoint_name)

When Amazon SageMaker receives the request, it sets the endpoint status to Updating. After updating the asynchronous endpoint, it sets the status to InService. To check the status of an endpoint, use the DescribeEndpoint API. For a full list of parameters you can specify when updating an endpoint, see the UpdateEndpoint API.

Delete an Asynchronous Endpoint

Delete an asynchronous endpoint in a similar manner to how you would delete a SageMaker hosted endpoint with the DeleteEndpoint API. Specify the name of the asynchronous endpoint you want to delete. When you delete an endpoint, SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

Delete your SageMaker model with the DeleteModel API or with the SageMaker console.

Boto3

import boto3

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.delete_endpoint(EndpointName='<endpoint-name>')

SageMaker console

2. Expand the Inference dropdown list.
3. Select Endpoints.
4. Search for endpoint in the **Search endpoints** search bar.
5. Select your endpoint.
6. Choose **Delete**.

In addition to deleting the asynchronous endpoint, you might want to clear up other resources that were used to create the endpoint, such as the Amazon ECR repository (if you created a custom inference image), the SageMaker model, and the asynchronous endpoint configuration itself.

## Monitor asynchronous endpoint

You can monitor SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. With Amazon CloudWatch, you can access historical information and gain a better perspective on how your web application or service is performing. For more information about Amazon CloudWatch, see **What is Amazon CloudWatch?**

### Monitoring with CloudWatch

The metrics below are an exhaustive list of metrics for asynchronous endpoints. Any metric not listed below is not published if the endpoint is enabled for asynchronous inference. Such metrics include (but are not limited to):

- **OverheadLatency**
- **Invocations**
- **InvocationsPerInstance**

### Common Endpoint Metrics

These metrics are the same as the metrics published for real-time endpoints today. For more information about other metrics in Amazon CloudWatch, see **Monitor SageMaker with Amazon CloudWatch**.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
</table>
| **Invocation4XXErrors** | The number of requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent.                                                                                   | Units: None  
Valid statistics: Average, Sum                                         |
| **Invocation5XXErrors** | The number of InvokeEndpoint requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent.                                                                    | Units: None  
Valid statistics: Average, Sum                                         |
| **ModelLatency**   | The interval of time taken by a model to respond as viewed from SageMaker. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container. | Units: Microseconds  
Valid statistics: Average, Sum, Min, Max, Sample Count            |
Asynchronous Inference Endpoint Metrics

These metrics are published for endpoints enabled for asynchronous inference. The following metrics are published with the `EndpointName` dimension:

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApproximateBacklogSize</td>
<td>The number of items in the queue for an endpoint that are currently being processed or yet to be processed.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ApproximateBacklogSizePerInstance</td>
<td>Number of items in the queue divided by the number of instances behind an endpoint. This metric is primarily used for setting up application autoscaling for an async-enabled endpoint.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ApproximateAgeOfOldestRequest</td>
<td>Age of the oldest request in the queue.</td>
<td>Units: Seconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
</tbody>
</table>

The following metrics are published with the `EndpointName` and `VariantName` dimensions:

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequestDownloadFailures</td>
<td>When an inference failure occurs due to an issue downloading the request from Amazon S3.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>ResponseUploadFailures</td>
<td>When an inference failure occurs due to an issue uploading the response to Amazon S3.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>NotificationFailures</td>
<td>When an issue occurs publishing notifications.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>RequestDownloadLatency</td>
<td>Total time to download the request payload.</td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ResponseUploadLatency</td>
<td>Total time to upload the response payload.</td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ExpiredRequests</td>
<td>Number of requests in the queue that fail due to reaching their specified request TTL.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>InvocationFailures</td>
<td>If an invocation fails for any reason.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>Metric Name</td>
<td>Description</td>
<td>Unit/Stats</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td>InvocationsProcessed</td>
<td>Number of async invocations processed by the endpoint.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
<td></td>
</tr>
<tr>
<td>TimeInBacklog</td>
<td>Total time the request was queued before being processed. This does not include the actual processing time (i.e. downloading time, uploading time, model latency).</td>
<td>Units: Milliseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
<td></td>
</tr>
<tr>
<td>TotalProcessingTime</td>
<td>Time the inference request was received by SageMaker to the time the request finished processing. This includes time in backlog and time to upload and send response notifications, if any.</td>
<td>Units: Milliseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
<td></td>
</tr>
</tbody>
</table>

Amazon SageMaker Asynchronous Inference also includes host-level metrics. For information on host-level metrics, see SageMaker Jobs and Endpoint Metrics.

**Logs**

In addition to the Model container logs that are published to Amazon CloudWatch in your account, you also get a new platform log for tracing and debugging inference requests.

The new logs are published under the Endpoint Log Group:

/aws/sagemaker/Endpoints/[EndpointName]

The log stream name consists of:

[production-variant-name]/[instance-id]/data-log.

Log lines contain the request’s inference ID so that errors can be easily mapped to a particular request.

**Check prediction results**

There are several ways you can check predictions results from your asynchronous endpoint. Some options are:

1. Amazon SNS topics.
2. Check for outputs in your Amazon S3 bucket.

**Amazon SNS Topics**

Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. Amazon SageMaker Asynchronous Inference posts
notifications when you create an endpoint with `CreateEndpointConfig` and specify an Amazon SNS topic.

**Note**
In order to receive Amazon SNS notifications, your IAM role must have `sns:Publish` permissions. See the Prerequisites (p. 2793) for information on requirements you must satisfy to use Asynchronous Inference.

To use Amazon SNS to check prediction results from your asynchronous endpoint, you first need to create a topic, subscribe to the topic, confirm your subscription to the topic, and note the Amazon Resource Name (ARN) of that topic. For detailed information on how to create, subscribe, and find the Amazon ARN of an Amazon SNS topic, see Configuring Amazon SNS.

Provide the Amazon SNS topic ARN(s) in the `AsyncInferenceConfig` field when you create an endpoint configuration with `CreateEndpointConfig`. You can specify both an Amazon SNS ErrorTopic and a SuccessTopic.

```python
import boto3
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.create_endpoint_config(
    EndpointConfigName=<endpoint_config_name>, # You specify this name in a CreateEndpoint request.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": "model_name",
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {
            # Location to upload response outputs when no location is provided in the request.
            "S3OutputPath": "s3://<bucket>/<output_directory>"
        }
    }
)
```

After creating your endpoint and invoking it, you receive a notification from your Amazon SNS topic. For example, if you subscribed to receive email notifications from your topic, you receive an email notification every time you invoke your endpoint. The following example shows the JSON content of a successful invocation email notification.

```json
{
    "awsRegion": "us-east-1",
    "eventTime": "2022-01-25T22:46:00.608Z",
    "receivedTime": "2022-01-25T22:46:00.455Z",
    "invocationStatus": "Completed",
    "requestParameters": {
        "contentType": "text/csv",
        "endpointName": "<example-endpoint>",
        "inputLocation": "s3://<bucket>/<input-directory>/input-data.csv"
    }
}
```
Check Your S3 Bucket

When you invoke an endpoint with `InvokeEndpointAsync`, it returns a response object. You can use the response object to get the Amazon S3 URI where your output is stored. With the output location, you can use a SageMaker Python SDK SageMaker session class to programmatically check for on an output.

The following stores the output dictionary of `InvokeEndpointAsync` as a variable named `response`. With the response variable, you then get the Amazon S3 output URI and store it as a string variable called `output_location`.

```python
import uuid
import boto3

sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the S3 URI of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

response = sagemaker_runtime.invoke_endpoint_async(
    EndpointName='<endpoint-name>',
    InputLocation=input_location,
    InferenceId=str(uuid.uuid4()),
    ContentType="text/libsvm"  # Specify the content type of your data
)

output_location = response['OutputLocation']
print(f"OutputLocation: {output_location}")
```

For information about supported content types, see Common Data Formats for Inference (p. 1915).

With the Amazon S3 output location, you can then use a SageMaker Python SDK SageMaker Session Class to read in Amazon S3 files. The following code example shows how to create a function `get_output` that repeatedly attempts to read a file from the Amazon S3 output location:

```python
import sagemaker
import urllib, time
from botocore.exceptions import ClientError

sagemaker_session = sagemaker.session.Session()

def get_output(output_location):
    output_url = urllib.parse.urlparse(output_location)
    bucket = output_url.netloc
    key = output_url.path[1:]
    while True:
        try:
            return sagemaker_session.read_s3_file(
                bucket=bucket,
                key_prefix=key
            )
        except ClientError as e:
            if e.response['Error']['Code'] == 'NoSuchKey':
                return None
                time.sleep(1)
```
print("waiting for output..."))
time.sleep(2)
continue
raise
output = get_output(output_location)
print(f"Output: {output}")

Autoscale an asynchronous endpoint

Amazon SageMaker supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models Amazon SageMaker supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up.

To autoscale your asynchronous endpoint you must at a minimum:

- Register a deployed model (production variant).
- Define a scaling policy.
- Apply the autoscaling policy.

Before you can use autoscaling, you must have already created a SageMaker model deployment. Deployed models are referred to as a production variant. See Deploy the Model to SageMaker Hosting Services for more information about deploying a model endpoint. To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. For information on how to define a scaling policy, see Define a scaling policy. After registering your model and defining a scaling policy, apply the scaling policy to the registered model. For information on how to apply the scaling policy, see Apply a scaling policy.

For details on other prerequisites and components used with autoscaling, see the Prerequisites section in the SageMaker autoscaling documentation.

Define a Scaling Policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. Define the scaling policy as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

For asynchronous endpoints SageMaker strongly recommends that you create a policy configuration for target-tracking scaling for a variant. In this configuration example, we use a custom metric, CustomizedMetricSpecification, called ApproximateBacklogSizePerInstance.

```json
TargetTrackingScalingPolicyConfiguration={
    'TargetValue': 5.0, # The target value for the metric. Here the metric is:
    'SageMakerVariantInvocationsPerInstance': {
        'MetricName': 'ApproximateBacklogSizePerInstance',
        'Namespace': 'AWS/SageMaker',
        'Dimensions': [
            {'Name': 'EndpointName', 'Value': <endpoint_name> }
        ],
        'Statistic': 'Average',
    }
}
```
Define a Scaling Policy that Scales to 0

The following shows you how to both define and register your endpoint variant with application autoscaling using the AWS SDK for Python (Boto3). After defining a low-level client object representing application autoscaling with Boto3, we use the `RegisterScalableTarget` method to register the production variant. We set `MinCapacity` to 0 because Asynchronous Inference enables you to autoscale to 0 when there are no requests to process.

```python
# Common class representing application autoscaling for SageMaker
client = boto3.client('application-autoscaling')

# This is the format in which application autoscaling references the endpoint
resource_id='endpoint/' + <endpoint_name> + '/variant/' + <'variant1'>

# Define and register your endpoint variant
response = client.register_scalable_target(
    ServiceNamespace='sagemaker',
    ResourceId=resource_id,
    ScalableDimension='sagemaker:variant:DesiredInstanceCount', # The number of EC2 instances for your Amazon SageMaker model endpoint variant.
    MinCapacity=0,
    MaxCapacity=5
)
```

For detailed description about the Application Autoscaling API, see the Application Scaling Boto3 documentation.

Use Batch Transform

Use batch transform when you need to do the following:

- Preprocess datasets to remove noise or bias that interferes with training or inference from your dataset.
- Get inferences from large datasets.
- Run inference when you don’t need a persistent endpoint.
- Associate input records with inferences to assist the interpretation of results.

To filter input data before performing inferences or to associate input records with inferences about those records, see Associate Prediction Results with Input Records (p. 2810). For example, you can filter input data to provide context for creating and interpreting reports about the output data.

Topics

- Use Batch Transform to Get Inferences from Large Datasets (p. 2808)
- Speed up a Batch Transform Job (p. 2809)
- Use Batch Transform to Test Production Variants (p. 2809)
- Batch Transform Errors (p. 2809)
- Batch Transform Sample Notebooks (p. 2810)
- Associate Prediction Results with Input Records (p. 2810)
- Storage in Batch Transform (p. 2815)
Use Batch Transform to Get Inferences from Large Datasets

Batch transform automatically manages the processing of large datasets within the limits of specified parameters. For example, suppose that you have a dataset file, input1.csv, stored in an S3 bucket. The content of the input file might look like the following example.

```
Record1-Attribute1, Record1-Attribute2, ..., Record1-AttributeM
Record2-Attribute1, Record2-Attribute2, ..., Record2-AttributeM
Record3-Attribute1, Record3-Attribute2, ..., Record3-AttributeM
...
RecordN-Attribute1, RecordN-Attribute2, ..., RecordN-AttributeM
```

When a batch transform job starts, SageMaker initializes compute instances and distributes the inference or preprocessing workload between them. Batch Transform partitions the Amazon S3 objects in the input by key and maps Amazon S3 objects to instances. When you have multiple files, one instance might process `input1.csv`, and another instance might process the file named `input2.csv`. If you have one input file but initialize multiple compute instances, only one instance processes the input file and the rest of the instances are idle.

You can also split input files into mini-batches. For example, you might create a mini-batch from `input1.csv` by including only two of the records.

```
Record3-Attribute1, Record3-Attribute2, ..., Record3-AttributeM
Record4-Attribute1, Record4-Attribute2, ..., Record4-AttributeM
```

**Note**
SageMaker processes each input file separately. It doesn't combine mini-batches from different input files to comply with the MaxPayloadInMB limit.

To split input files into mini-batches when you create a batch transform job, set the SplitType parameter value to Line. If SplitType is set to None or if an input file can't be split into mini-batches, SageMaker uses the entire input file in a single request. Note that Batch Transform doesn't support CSV-formatted input that contains embedded newline characters. You can control the size of the mini-batches by using the BatchStrategy and MaxPayloadInMB parameters. MaxPayloadInMB must not be greater than 100 MB. If you specify the optional MaxConcurrentTransforms parameter, then the value of (MaxConcurrentTransforms * MaxPayloadInMB) must also not exceed 100 MB.

If the batch transform job successfully processes all of the records in an input file, it creates an output file with the same name and the .out file extension. For multiple input files, such as `input1.csv` and `input2.csv`, the output files are named `input1.csv.out` and `input2.csv.out`. The batch transform job stores the output files in the specified location in Amazon S3, such as `s3://awsexamplebucket/output/`.

The predictions in an output file are listed in the same order as the corresponding records in the input file. The output file `input1.csv.out`, based on the input file shown earlier, would look like the following.

```
Inference1-Attribute1, Inference1-Attribute2, ..., Inference1-AttributeM
Inference2-Attribute1, Inference2-Attribute2, ..., Inference2-AttributeM
Inference3-Attribute1, Inference3-Attribute2, ..., Inference3-AttributeM
```
To combine the results of multiple output files into a single output file, set the `AssembleWith` parameter to `Line`.

When the input data is very large and is transmitted using HTTP chunked encoding, to stream the data to the algorithm, set `MaxPayloadInMB` to 0. Amazon SageMaker built-in algorithms don't support this feature.

For information about using the API to create a batch transform job, see the `CreateTransformJob` API. For more information about the correlation between batch transform input and output objects, see `OutputDataConfig`. For an example of how to use batch transform, see (Optional) Make Prediction with Batch Transform (p. 85).

### Speed up a Batch Transform Job

If you are using the `CreateTransformJob` API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as `MaxPayloadInMB`, `MaxConcurrentTransforms`, or `BatchStrategy`. The ideal value for `MaxConcurrentTransforms` is equal to the number of compute workers in the batch transform job. If you are using the SageMaker console, you can specify these optimal parameter values in the `Additional configuration` section of the Batch transform job configuration page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

### Use Batch Transform to Test Production Variants

To test different models or various hyperparameter settings, create a separate transform job for each new model variant and use a validation dataset. For each transform job, specify a unique model name and location in Amazon S3 for the output file. To analyze the results, use Inference Pipeline Logs and Metrics (p. 2681).

### Batch Transform Errors

SageMaker uses the Amazon S3 Multipart Upload API to upload results from a batch transform job to Amazon S3. If an error occurs, the uploaded results are removed from Amazon S3. In some cases, such as when a network outage occurs, an incomplete multipart upload might remain in Amazon S3. To avoid incurring storage charges, we recommend that you add the S3 bucket policy to the S3 bucket lifecycle rules. This policy deletes incomplete multipart uploads that might be stored in the S3 bucket. For more information, see Object Lifecycle Management.

If a batch transform job fails to process an input file because of a problem with the dataset, SageMaker marks the job as failed. If an input file contains a bad record, the transform job doesn't create an output file for that input file because doing so prevents it from maintaining the same order in the transformed data as in the input file. When your dataset has multiple input files, a transform job continues to process input files even if it fails to process one. The processed files still generate useable results.

Exceeding the `MaxPayloadInMB` limit causes an error. This might happen with a large dataset if it can't be split, the `SplitType` parameter is set to `none`, or individual records within the dataset exceed the limit.

If you are using your own algorithms, you can use placeholder text, such as `ERROR`, when the algorithm finds a bad record in an input file. For example, if the last record in a dataset is bad, the algorithm places the placeholder text for that record in the output file.
Batch Transform Sample Notebooks

For a sample notebook that uses batch transform with a principal component analysis (PCA) model to reduce data in a user-item review matrix, followed by the application of a density-based spatial clustering of applications with noise (DBSCAN) algorithm to cluster movies, see Batch Transform with PCA and DBSCAN Movie Clusters. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 283). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the NTM algorithms are located in the Advanced functionality section. To open a notebook, choose its Use tab, then choose Create copy.

Associate Prediction Results with Input Records

When making predictions on a large dataset, you can exclude attributes that aren't needed for prediction. After the predictions have been made, you can associate some of the excluded attributes with those predictions or with other input data in your report. By using batch transform to perform these data processing steps, you can often eliminate additional preprocessing or postprocessing. You can use input files in JSON and CSV format only.

Topics

- Workflow for Associating Inferences with Input Records (p. 2810)
- Use Data Processing in Batch Transform Jobs (p. 2811)
- Supported JSONPath Operators (p. 2811)
- Batch Transform Examples (p. 2812)

Workflow for Associating Inferences with Input Records

The following diagram shows the workflow for associating inferences with input records.
To associate inferences with input data, there are three main steps:

1. Filter the input data that is not needed for inference before passing the input data to the batch transform job. Use the `InputFilter` parameter to determine which attributes to use as input for the model.

2. Associate the input data with the inference results. Use the `JoinSource` parameter to combine the input data with the inference.

3. Filter the joined data to retain the inputs that are needed to provide context for interpreting the predictions in the reports. Use `OutputFilter` to store the specified portion of the joined dataset in the output file.

**Use Data Processing in Batch Transform Jobs**

When creating a batch transform job with `CreateTransformJob` to process data:

1. Specify the portion of the input to pass to the model with the `InputFilter` parameter in the `DataProcessing` data structure.

2. Join the raw input data with the transformed data with the `JoinSource` parameter.

3. Specify which portion of the joined input and transformed data from the batch transform job to include in the output file with the `OutputFilter` parameter.

4. Choose either JSON- or CSV-formatted files for input:
   - For JSON- or JSON Lines-formatted input files, SageMaker either adds the `SageMakerOutput` attribute to the input file or creates a new JSON output file with the `SageMakerInput` and `SageMakerOutput` attributes. For more information, see `DataProcessing`.
   - For CSV-formatted input files, the joined input data is followed by the transformed data and the output is a CSV file.

If you use an algorithm with the `DataProcessing` structure, it must support your chosen format for both input and output files. For example, with the `TransformOutput` field of the `CreateTransformJob` API, you must set both the `ContentType` and `Accept` parameters to one of the following values: `text/csv`, `application/json`, or `application/jsonlines`. The syntax for specifying columns in a CSV file and specifying attributes in a JSON file are different. Using the wrong syntax causes an error. For more information, see Batch Transform Examples (p. 2812). For more information about input and output file formats for built-in algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1051).

The record delimiters for the input and output must also be consistent with your chosen file input. The `SplitType` parameter indicates how to split the records in the input dataset. The `AssembleWith` parameter indicates how to reassemble the records for the output. If you set input and output formats to `text/csv`, you must also set the `SplitType` and `AssembleWith` parameters to `line`. If you set the input and output formats to `application/jsonlines`, you can set both `SplitType` and `AssembleWith` to `line`.

For CSV files, you cannot use embedded newline characters. For JSON files, the attribute name `SageMakerOutput` is reserved for output. The JSON input file can't have an attribute with this name. If it does, the data in the input file might be overwritten.

**Supported JSONPath Operators**

To filter and join the input data and inference, use a JSONPath subexpression. SageMaker supports only a subset of the defined JSONPath operators. The following table lists the supported JSONPath operators. For CSV data, each row is taken as a JSON array, so only index based JSONPaths can be applied, e.g. `@[0]`, `@[1:]`. CSV data should also follow RFC format.
### JSONPath Operator

<table>
<thead>
<tr>
<th>JSONPath Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>The root element to a query. This operator is required at the beginning of all path expressions.</td>
<td>$</td>
</tr>
<tr>
<td>.&lt;name&gt;</td>
<td>A dot-notated child element.</td>
<td>$.id</td>
</tr>
<tr>
<td>*</td>
<td>A wildcard. Use in place of an attribute name or numeric value.</td>
<td>$.id.*</td>
</tr>
<tr>
<td>['&lt;name&gt;' (, '&lt;name&gt;')]</td>
<td>A bracket-notated element or multiple child elements.</td>
<td>$['id', 'SageMakerOutput']</td>
</tr>
<tr>
<td>[&lt;number&gt; (, &lt;number&gt;)]</td>
<td>An index or array of indexes. Negative index values are also supported. A -1 index refers to the last element in an array.</td>
<td>$[1], $[1,3,5]</td>
</tr>
<tr>
<td>[&lt;start&gt;:&lt;end&gt;]</td>
<td>An array slice operator. The array slice() method extracts a section of an array and returns a new array. If you omit &lt;start&gt;, SageMaker uses the first element of the array. If you omit &lt;end&gt;, SageMaker uses the last element of the array.</td>
<td>$[2:5], $[:5], $[2:]</td>
</tr>
</tbody>
</table>

When using the bracket-notation to specify multiple child elements of a given field, additional nesting of children within brackets is not supported. For example, $.field1['child1', 'child2'] is supported while $.field1['child1', 'child2.grandchild'] is not.

For more information about JSONPath operators, see JsonPath on GitHub.

### Batch Transform Examples

The following examples show some common ways to join input data with prediction results.

#### Topics

- **Example: Output Only Inferences** (p. 2812)
- **Example: Output Inferences Joined with Input Data** (p. 2813)
- **Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input (CSV)** (p. 2814)
- **Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input (CSV)** (p. 2814)

#### Example: Output Only Inferences

By default, the **DataProcessing** parameter doesn't join inference results with input. It outputs only the inference results.

If you want to explicitly specify to not join results with input, use the Amazon SageMaker Python SDK and specify the following settings in a transformer call.

```python
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$", join_source= "None", output_filter="$")
```
To output inferences using the AWS SDK for Python, add the following code to your CreateTransformJob request. The following code mimics the default behavior.

```json
{
  "DataProcessing": {
    "InputFilter": 
    "JoinSource": "None",
    "OutputFilter": ""}
}
```

**Example: Output Inferences Joined with Input Data**

If you're using the [Amazon SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/transforming-outputs-with-python-sdk.html) to combine the input data with the inferences in the output file, specify the `assemble_with` and `accept` parameters when initializing the transformer object. When you use the transform call, specify `Input` for the `join_source` parameter, and specify the `split_type` and `content_type` parameters as well. The `split_type` parameter must have the same value as `assemble_with`, and the `content_type` parameter must have the same value as `accept`. For more information about the parameters and their accepted values, see the Transformer page in the [Amazon SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/transforming-outputs-with-python-sdk.html).

```python
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/csv")
sm_transformer.transform(…, join_source="Input", split_type="Line", content_type="text/csv")
```

If you're using the AWS SDK for Python (Boto 3), join all input data with the inference by adding the following code to your `CreateTransformJob` request. The values for `Accept` and `ContentType` must match, and the values for `AssembleWith` and `SplitType` must also match.

```json
{
  "DataProcessing": {
    "JoinSource": "Input"
  },
  "TransformOutput": {
    "Accept": "text/csv",
    "AssembleWith": "Line"
  },
  "TransformInput": {
    "ContentType": "text/csv",
    "SplitType": "Line"
  }
}
```

For JSON or JSON Lines input files, the results are in the `SageMakerOutput` key in the input JSON file. For example, if the input is a JSON file that contains the key-value pair `{"key":1}`, the data transform result might be `{"label":1}`.

SageMaker stores both in the input file in the `SageMakerInput` key.

```json
{
  "key":1,
  "SageMakerOutput":{"label":1}
}
```

**Note**

The joined result for JSON must be a key-value pair object. If the input isn't a key-value pair object, SageMaker creates a new JSON file. In the new JSON file, the input data is stored in the `SageMakerInput` key and the results are stored as the `SageMakerOutput` value.
For a CSV file, for example, if the record is \([1, 2, 3]\), and the label result is \([1]\), then the output file would contain \([1, 2, 3, 1]\).

**Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input (CSV)**

If you are using the Amazon SageMaker Python SDK to join your input data with the inference output while excluding an ID column from the transformer input, specify the same parameters from the preceding example as well as a JSONPath subexpression for the `input_filter` in your transformer call. For example, if your input data includes five columns and the first one is the ID column, use the following transform request to select all columns except the ID column as features. The transformer still outputs all of the input columns joined with the inferences. For more information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```python
sm_transformer = sagemaker.transformer.Transformer(..., assemble_with="Line", accept="text/csv")
sm_transformer.transform(..., split_type="Line", content_type="text/csv",
    input_filter="$[1:]", join_source="Input")
```

If you are using the AWS SDK for Python (Boto 3), add the following code to your `CreateTransformJob` request.

```json
{
    "DataProcessing": {
        "InputFilter": "$[1:]",
        "JoinSource": "Input"
    },
    "TransformOutput": {
        "Accept": "text/csv",
        "AssembleWith": "Line"
    },
    "TransformInput": {
        "ContentType": "text/csv",
        "SplitType": "Line"
    }
}
```

To specify columns in SageMaker, use the index of the array elements. The first column is index 0, the second column is index 1, and the sixth column is index 5.

To exclude the first column from the input, set `InputFilter` to "$[1:]". The colon (:) tells SageMaker to include all of the elements between two values, inclusive. For example, "$[1:4]" specifies the second through fifth columns.

If you omit the number after the colon, for example, "$[:5]", the subset includes all columns from the 6th column through the last column. If you omit the number before the colon, for example, "[5:]", the subset includes all columns from the first column (index 0) through the sixth column.

**Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input (CSV)**

If you are using the Amazon SageMaker Python SDK, you can specify the output to join only specific input columns (such as the ID column) with the inferences by specifying the `output_filter` in the transformer call. The `output_filter` uses a JSONPath subexpression to specify which columns to return as output after joining the input data with the inference results. The following request shows how you can make predictions while excluding an ID column and then join the ID column with the inferences. Note that in the following example, the last column (-1) of the output contains the inferences. If you are using JSON files, SageMaker stores the inference results in the attribute `SageMakerOutput`. For more
information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```python
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/csv")
sm_transformer.transform(…, split_type="Line", content_type="text/csv",
input_filter="$[1:]", join_source="Input", output_filter="$[0,-1]"
```

If you are using the AWS SDK for Python (Boto 3), join only the ID column with the inferences by adding the following code to your CreateTransformJob request.

```json
{
  "DataProcessing": {
    "InputFilter": "$[1:]",
    "JoinSource": "Input",
    "OutputFilter": "$[0,-1]"
  },
  "TransformOutput": {
    "Accept": "text/csv",
    "AssembleWith": "Line"
  },
  "TransformInput": {
    "ContentType": "text/csv",
    "SplitType": "Line"
  }
}
```

**Warning**
If you are using a JSON-formatted input file, the file can't contain the attribute name `SageMakerOutput`. This attribute name is reserved for the inferences in the output file. If your JSON-formatted input file contains an attribute with this name, values in the input file might be overwritten with the inference.

### Storage in Batch Transform

When you run a batch transform job, Amazon SageMaker attaches an Amazon Elastic Block Store storage volume to Amazon EC2 instances that process your job. The volume stores your model, and the size of the storage volume is fixed at 30 GB. You have the option to encrypt your model at rest in the storage volume.

**Note**
If you have a large model, you may encounter an InternalServerError.

For more information about Amazon EBS storage and features, see the following pages:

- Amazon EBS in the Amazon EC2 User Guide for Linux Instances
- Amazon EBS volumes in the Amazon EC2 User Guide for Linux Instances

**Note**
G4dn instances come with their own local SSD storage. To learn more about G4dn instances, see the Amazon EC2 G4 Instances page.

### Deployment guardrails

Deployment guardrails are a set of model deployment options in Amazon SageMaker Inference to update your machine learning models in production. Using the fully managed deployment options, you can control the switch from the current model in production to a new one. Traffic shifting modes, such
as canary and linear, give you granular control over the traffic shifting process from your current model to the new one during the course of the update. There are also built-in safeguards such as auto-rollbacks that help you catch issues early and automatically take corrective action before they significantly impact production.

Deployment guardrails provide the following benefits:

- **Deployment safety while updating production environments.** A regressive update to a production environment can cause unplanned downtime and business impact, such as increased model latency and high error rates. Deployment guardrails help you mitigate those risks by providing best practices and built-in operational safety guardrails.

- **Fully managed deployment.** SageMaker takes care of setting up and orchestrating these deployments and integrates them with endpoint update mechanisms. You do not need to build and maintain orchestration, monitoring, or rollback mechanisms. You can leverage SageMaker to set up and orchestrate these deployments and focus on leveraging ML for your applications.

- **Visibility.** You can track the progress of your deployment through the DescribeEndpoint API or through Amazon CloudWatch Events (for supported endpoints). To learn more about events in SageMaker, see the Endpoint deployment state change section in Automating Amazon SageMaker with Amazon EventBridge. Note that if your endpoint uses any of the features in the Exclusions page, you cannot use CloudWatch Events.

**Note**

Deployment guardrails only apply to Asynchronous inference (p. 2791) and Real-time inference (p. 2641) endpoint types.

## How to Get Started

We support blue/green deployments with multiple traffic shifting modes (p. 2819). A traffic shifting mode is a configuration that specifies how SageMaker routes endpoint traffic to a new fleet containing your updates. The following traffic shifting modes provide you with different levels of control over the endpoint update process:

- **Blue/Green: All At Once (p. 2820)** shifts all of your endpoint traffic from the blue fleet to the green fleet. Once the traffic shifts to the green fleet, your pre-specified Amazon CloudWatch alarms begin monitoring the green fleet for a set amount of time (the baking period). If no alarms trip during the baking period, then SageMaker terminates the blue fleet.

- **Blue/Green: Canary (p. 2823)** lets you shift one small portion of your traffic (a canary) to the green fleet and monitor it for a baking period. If the canary succeeds on the green fleet, then SageMaker shifts the rest of the traffic from the blue fleet to the green fleet before terminating the blue fleet.

- **Blue/Green: Linear (p. 2828)** provides even more customization over the number of traffic-shifting steps and the percentage of traffic to shift for each step. While canary shifting lets you shift traffic in two steps, linear shifting extends this to \( n \) linearly spaced steps.

You can create and manage your deployment through the UpdateEndpoint and CreateEndpoint SageMaker API and AWS Command Line Interface commands. See the individual deployment pages for more details on how to set up your deployment. Note that if your endpoint uses any of the features listed in the Exclusions page, you cannot use deployment guardrails.

To follow guided examples that shows how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

## Auto-Rollback Configuration and Monitoring

Amazon CloudWatch alarms are a prerequisite for using baking periods in deployment guardrails. You can only use the auto-rollback functionality in deployment guardrails if you set up CloudWatch
alarms that can monitor an endpoint. If any of your alarms trip during the specified monitoring period, SageMaker initiates a complete rollback to the old endpoint to protect your application. If you do not have any CloudWatch alarms set up to monitor your endpoint, then the auto-rollback functionality does not work during your deployment.

To learn more about Amazon CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide.

Alarm Examples

To help you get started, we provide the following examples to demonstrate the capabilities of CloudWatch alarms. In addition to using or modifying the following examples, you can create your own alarms and configure the alarms to monitor various metrics on the specified fleets for a certain period of time. To see more SageMaker metrics and dimensions you can add to your alarms, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3498).

Topics

- Monitor invocation errors on both old and new fleets (p. 2817)
- Monitor model latency on the new fleet (p. 2818)

Monitor invocation errors on both old and new fleets

The following CloudWatch alarm monitors an endpoint’s average error rate. You can use this alarm with any deployment guardrails traffic shifting type to provide overall monitoring on both the old and new fleets. If the alarm trips, then SageMaker initiates a rollback to the old fleet.

Invocation errors coming from both the old fleet and new fleet contribute to the average error rate. If the average error rate exceeds the specified threshold, then the alarm trips. This particular example monitors the 4xx errors (client errors) on both the old and new fleets for the duration of a deployment. You can also monitor the 5xx errors (server errors) by using the metric Invocation5XXErrors.

Note

For this alarm type, if your old fleet trips the alarm during the deployment, SageMaker terminates your deployment. Therefore, if your current production fleet already causes errors, consider using or modifying one of the following examples that only monitors the new fleet for errors.

```json
#Applied deployment type: all types
{
    "AlarmName": "EndToEndDeploymentHighErrorRateAlarm",
    "AlarmDescription": "Monitors the error rate of 4xx errors",
    "MetricName": "Invocation4XXErrors",
    "Namespace": "AWS/SageMaker",
    "Statistic": "Average",
    "Dimensions": [
        {
            "Name": "EndpointName",
            "Value": "<your-endpoint-name>
        },
        {
            "Name": "VariantName",
            "Value": "AllTraffic"
        }
    ],
    "Period": 600,
    "EvaluationPeriods": 2,
    "Threshold": 1,
    "ComparisonOperator": "GreaterThanThreshold",
    "TreatMissingData": "notBreaching"
}
```

2817
In the previous example, note the values for the following fields:

- For **AlarmName** and **AlarmDescription**, enter a name and description you choose for the alarm.
- For **MetricName**, use the value *Invocation4XXErrors* to monitor for 4xx errors on the endpoint.
- For **Namespace**, use the value *AWS/SageMaker*. You can also specify your own custom metric, if applicable.
- For **Statistic**, use *Average*. This means that the alarm takes the average error rate over the evaluation periods when calculating whether the error rate has exceeded the threshold.
- For the dimension **EndpointName**, use the name of the endpoint you are updating as the value.
- For the dimension **VariantName**, use the value *AllTraffic* to specify all endpoint traffic.
- For **Period**, use 600. This sets the alarm's evaluation periods to 10 minutes long.
- For **EvaluationPeriods**, use 2. This value tells the alarm to consider the two most recent evaluation periods when determining the alarm status.

### Monitor model latency on the new fleet

The following CloudWatch alarm example monitors the new fleet's model latency during your deployment. You can use this alarm to monitor only the new fleet and exclude the old fleet. The alarm lasts for the entire deployment. This example gives you comprehensive, end-to-end monitoring of the new fleet and initiates a rollback to the old fleet if the new fleet has any response time issues.

CloudWatch publishes the metrics with the dimension **EndpointConfigName**: *(New-Ep-Config)* after the new fleet starts receiving traffic, and these metrics last even after the deployment is complete.

You can use the following alarm example with any deployment type.

```json
#Applied deployment type: all types
{
    "AlarmName": "NewEndpointConfigVersionHighModelLatencyAlarm",
    "AlarmDescription": "Monitors the model latency on new fleet",
    "MetricName": "ModelLatency",
    "Namespace": "AWS/SageMaker",
    "Statistic": "Average",
    "Dimensions": [
        {
            "Name": "EndpointName",
            "Value": <your-endpoint-name>
        },
        {
            "Name": "VariantName",
            "Value": "AllTraffic"
        },
        {
            "Name": "EndpointConfigName",
            "Value": <your-config-name>
        }
    ],
    "Period": 300,
    "EvaluationPeriods": 2,
    "Threshold": 100000, # 100ms
    "ComparisonOperator": "GreaterThanThreshold",
    "TreatMissingData": "notBreaching"
}
```

In the previous example, note the values for the following fields:
For MetricName, use the value ModelLatency to monitor the model's response time.

For Namespace, use the value AWS/SageMaker. You can also specify your own custom metric, if applicable.

For the dimension EndpointName, use the name of the endpoint you are updating as the value.

For the dimension VariantName, use the value AllTraffic to specify all endpoint traffic.

For the dimension EndpointConfigName, the value should refer to the endpoint configuration name for your new or updated endpoint.

**Note**
If you want to monitor your old fleet instead of the new fleet, you can change the dimension EndpointConfigName to specify the name of your old fleet's configuration.

### Blue/Green Deployments

When you update your endpoint, Amazon SageMaker automatically uses a blue/green deployment to maximize the availability of your endpoints. In a blue/green deployment, SageMaker provisions a new fleet with the updates (the green fleet). Then, SageMaker shifts traffic from the old fleet (the blue fleet) to the green fleet. Once the green fleet operates smoothly for a set evaluation period (called the baking period), SageMaker terminates the blue fleet. With the additional capabilities in blue/green deployments, you can utilize traffic shifting modes and auto-rollback monitoring to protect your endpoint from significant production impact.

The following list describes the key features of blue/green deployments in SageMaker:

- **Traffic shifting modes.** The traffic shifting modes for deployment guardrails let you control the volume of traffic and number of traffic-shifting steps between the blue fleet and the green fleet. This capability gives you the ability to progressively evaluate the performance of the green fleet without fully committing to a 100% traffic shift.

- **Baking period.** The baking period is a set amount of time to monitor the green fleet before proceeding to the next deployment stage. If any of the pre-specified alarms trip during any baking period, then all endpoint traffic rolls back to the blue fleet. The baking period helps you to build confidence in your update before making the traffic shift permanent.

- **Auto-rollback.** You can specify Amazon CloudWatch alarms that SageMaker uses to monitor the green fleet. If an issue with the updated code trips any of the alarms, SageMaker initiates an auto-rollback to the blue fleet in order to maintain availability thereby minimizing risk.

### Traffic Shifting Modes

The various traffic shifting modes in blue/green deployments give you more granular control over traffic shifting between the blue fleet and the green fleet. The available traffic shifting modes for blue/green deployments are all at once, canary, and linear. The following table shows a comparison of the options.

<table>
<thead>
<tr>
<th>Name</th>
<th>What is it?</th>
<th>Pros</th>
<th>Cons</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>All at once</td>
<td>Shifts all of the traffic to the new fleet</td>
<td>Minimizes the overall update duration.</td>
<td>Regressive updates affect</td>
<td>Use this option to minimize update time and cost.</td>
</tr>
<tr>
<td>Name</td>
<td>What is it?</td>
<td>Pros</td>
<td>Cons</td>
<td>Recommendation</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fleet in a single step.</td>
<td>100% of the traffic.</td>
<td>Confines the blast radius of regressive updates to only the canary fleet.</td>
<td>Both fleets are operational in parallel for entire deployment.</td>
<td>Use this option to balance between minimizing the blast radius of regressive updates and minimizing the time that two fleets are operational.</td>
</tr>
<tr>
<td>Canary</td>
<td>Traffic shifts in two steps. The first (canary) step shifts a small portion of the traffic followed by the second step, which shifts the remainder of the traffic.</td>
<td>Minimizes the risk of regressive updates by shifting traffic over several steps.</td>
<td>The update duration and cost are proportional to the number of steps.</td>
<td>Use this option to minimize risk by spreading out deployment across multiple steps.</td>
</tr>
<tr>
<td>Linear</td>
<td>A fixed portion of the traffic shifts in a pre-specified number of equally spaced steps.</td>
<td>Minimizes the risk of regressive updates by shifting traffic over several steps.</td>
<td>The update duration and cost are proportional to the number of steps.</td>
<td>Use this option to minimize risk by spreading out deployment across multiple steps.</td>
</tr>
</tbody>
</table>

**Get Started**

Once you specify your desired deployment configuration, SageMaker handles provisioning new instances, terminating old instances, and shifting traffic for you. You can create and manage your deployment through the existing UpdateEndpoint and CreateEndpoint SageMaker API and AWS Command Line Interface commands. Note that if your endpoint uses any of the features listed in the Exclusions (p. 2832) page, you cannot use deployment guardrails. See the individual deployment pages for more details on how to set up your deployment:

- Blue/Green Update with All At Once Traffic Shifting (p. 2820)
- Blue/Green Update with Canary Traffic Shifting (p. 2823)
- Blue/Green Update with Linear Traffic Shifting (p. 2823)

To follow guided examples that show how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

**All At Once Traffic Shifting**

With all at once traffic shifting, you can quickly roll out an endpoint update using the safety guardrails of a blue/green deployment. You can use this traffic shifting option to minimize the update duration while still taking advantage of the availability guarantees of blue/green deployments. The baking period feature helps you to monitor the performance and functionality of your new instances before terminating your old instances, ensuring that your new fleet is fully operational.

The following diagram shows how all at once traffic shifting manages the old and new fleets.
When you use all at once traffic shifting, SageMaker routes 100% of the traffic to the new fleet (green fleet). Once the green fleet starts receiving traffic, the baking period begins. The baking period is a set amount of time in which pre-specified Amazon CloudWatch alarms monitor the performance of the green fleet. If no alarms trip during the baking period, SageMaker terminates the old fleet (blue fleet). If any alarms trip during the baking period, then an auto-rollback initiates and 100% of the traffic shifts back to the blue fleet.

**Prerequisites**

Before setting up a deployment with all at once traffic shifting, you must create Amazon CloudWatch alarms to watch metrics from your endpoint. If any of the alarms trip during the baking period, then the traffic rolls back to your blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see...
the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2816). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

Configure All At Once Traffic Shifting

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the SageMaker UpdateEndpoint API or the update-endpoint command in the AWS Command Line Interface to initiate the deployment.

Topics

• How to update an endpoint (API) (p. 2822)
• How to update an endpoint with an existing blue/green update policy (API) (p. 2823)
• How to update an endpoint (CLI) (p. 2823)

How to update an endpoint (API)

The following example shows how you can update your endpoint with all at once traffic shifting using UpdateEndpoint in the Amazon SageMaker API.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "ALL_AT_ONCE"
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>"
                }
            ]
        }
    }
)
```

To configure the all at once traffic shifting option, do the following:

• For EndpointName, use the name of the existing endpoint you want to update.
• For EndpointConfigName, use the name of the endpoint configuration you want to use.
• Under DeploymentConfig and BlueGreenUpdatePolicy, in TrafficRoutingConfiguration, set the Type parameter to ALL_AT_ONCE. This specifies that the deployment uses the all at once traffic shifting mode.
• For TerminationWaitInSeconds, use 600. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 10 minutes after the final baking period before terminating the blue fleet.
• For MaximumExecutionTimeoutInSeconds, use 1800. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
• In `AutoRollbackConfiguration`, within the `Alarms` field, you can add your CloudWatch alarms by name. Create one `AlarmName: <your-cw-alarm>` entry for each alarm you want to use.

**How to update an endpoint with an existing blue/green update policy (API)**

When you use the `CreateEndpoint` API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same `DeploymentConfig` options as the previous `UpdateEndpoint` API example. There are no changes to the `CreateEndpoint` API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the `UpdateEndpoint` API to update your endpoint. When updating your endpoint, you can use the `RetainDeploymentConfig` option to keep the deployment configuration you specified when you created the endpoint.

When calling the `UpdateEndpoint` API, set `RetainDeploymentConfig` to `True` to keep the `DeploymentConfig` options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

**How to update an endpoint (CLI)**

If you are using the AWS CLI, the following example shows how to start a blue/green all at once deployment using the `update-endpoint` command.

```bash
update-endpoint
    --endpoint-name <your-endpoint-name>
    --endpoint-config-name <your-config-name>
    --deployment-config "BlueGreenUpdatePolicy": {"TrafficRoutingConfiguration": {"Type": "ALL_AT_ONCE"},
    "TerminationWaitInSeconds": 600, "MaximumExecutionTimeoutInSeconds": 1800},
    "AutoRollbackConfiguration": {"Alarms": [{"AlarmName": "<your-alarm>"}]}
```

To configure the all at once traffic shifting option, do the following:

• For `endpoint-name`, use the name of the endpoint you want to update.
• For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
• For `deployment-config`, use a `BlueGreenUpdatePolicy` JSON object.

**Note**

If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the *AWS CLI User Guide*.

**Canary Traffic Shifting**

With canary traffic shifting, you can test a portion of your endpoint traffic on the new fleet while the old fleet serves the remainder of the traffic. This testing step is a safety guardrail that validates the new fleet’s functionality before shifting all of your traffic to the new fleet. You still have the benefits of a blue/green deployment, and the added canary feature lets you ensure that your new (green) fleet can serve inference before letting it handle 100% of the traffic.
The portion of your green fleet that turns on to receive traffic is called the canary, and you can choose the size of this canary. Note that the canary size should be less than or equal to 50% of the new fleet's capacity. Once the baking period finishes and no pre-specified Amazon CloudWatch alarms trip, the rest of the traffic shifts from the old (blue) fleet to the green fleet. Canary traffic shifting provides you with more safety during your deployment since any issues with the updated model only impact the canary.

The following diagram shows how canary traffic shifting manages the distribution of traffic between the blue and green fleets.
Blue/Green Deployments

Deployment Stages

- Canary - Create
- Canary - CanaryFlipTraffic
- Canary - CanaryBake
- Canary - FirstFlipTraffic
- Canary - FirstBake
- Canary - Cleanup
Once SageMaker provisions the green fleet, SageMaker routes a portion of the incoming traffic (for example, 25%) to the canary. Then the baking period begins, during which your CloudWatch alarms monitor the performance of the green fleet. During this time, both the blue fleet and green fleet are partially active and receiving traffic. If any of the alarms trip during the baking period, then SageMaker initiates a rollback and all traffic returns to the blue fleet. If none of the alarms trip, then all of the traffic shifts to the green fleet and there is a final baking period. If the final baking period finishes without tripping any alarms, then the green fleet serves all traffic and SageMaker terminates the blue fleet.

**Prerequisites**

Before setting up a deployment with canary traffic shifting, you must create Amazon CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2816). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

**Configure Canary Traffic Shifting**

Once you are ready for your deployment and have set up Amazon CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker UpdateEndpoint API or the `update-endpoint` command in the AWS CLI to initiate the deployment.

**Topics**

- How to update an endpoint (API) (p. 2826)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2827)
- How to update an endpoint (CLI) (p. 2827)

**How to update an endpoint (API)**

The following example of the `UpdateEndpoint` API shows how you can update an endpoint with canary traffic shifting.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "CANARY",
                "CanarySize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 30
                },
                "WaitIntervalInSeconds": 600
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {"AlarmName": "<your-cw-alarm>"}
            ]
        }
    }
)
```

2826
To configure the canary traffic shifting option, do the following:

- For **EndpointName**, use the name of the existing endpoint you want to update.
- For **EndpointConfigName**, use the name of the endpoint configuration you want to use.
- Under **DeploymentConfig** and **BlueGreenUpdatePolicy**, in **TrafficRoutingConfiguration**, set the **Type** parameter to **CANARY**. This specifies that the deployment uses canary traffic shifting.
- In the **CanarySize** field, you can change the size of the canary by modifying the **Type** and **Value** parameters. For **Type**, use **CAPACITY_PERCENT**, meaning the percentage of your green fleet you want to use as the canary, and then set **Value** to 30. In this example, you use 30% of the green fleet's capacity as the canary. Note that the canary size should be equal to or less than 50% of the green fleet's capacity.
- For **WaitIntervalInSeconds**, use 600. The parameter tells SageMaker to wait for the specified amount of time (in seconds) between each interval shift. This interval is the duration of the canary baking period. In the preceding example, SageMaker waits for 10 minutes after the canary shift and then completes the second and final traffic shift.
- For **TerminationWaitInSeconds**, use 600. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 10 minutes after the final baking period before terminating the blue fleet.
- For **MaximumExecutionTimeoutInSeconds**, use 1800. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
- In **AutoRollbackConfiguration**, within the **Alarms** field, you can add your CloudWatch alarms by name. Create one **AlarmName**: `<your-cw-alarm>` entry for each alarm you want to use.

**How to update an endpoint with an existing blue/green update policy (API)**

When you use the `CreateEndpoint` API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same `DeploymentConfig` options as the previous `UpdateEndpoint` API example. There are no changes to the `CreateEndpoint` API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the `UpdateEndpoint` API to update your endpoint. When updating your endpoint, you can use the `RetainDeploymentConfig` option to keep the deployment configuration you specified when you created the endpoint.

When calling the `UpdateEndpoint` API, set `RetainDeploymentConfig` to `True` to keep the `DeploymentConfig` options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

**How to update an endpoint (CLI)**

If you are using the AWS CLI, the following example shows how to start a blue/green canary deployment using the `update-endpoint` command.
To configure the canary traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a `BlueGreenUpdatePolicy` JSON object.

**Note**

If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.

### Linear Traffic Shifting

Linear traffic shifting enables you to gradually shift traffic from your old fleet (blue fleet) to your new fleet (green fleet). With linear traffic shifting, you can shift traffic in multiple steps, minimizing the chance of a disruption to your endpoint. This blue/green deployment option gives you the most granular control over traffic shifting.

You can choose either the number of instances or the percentage of the green fleet's capacity to activate during each step. Each linear step should only be between 10-50% of the green fleet's capacity. For each step, there is a baking period during which your pre-specified Amazon CloudWatch alarms monitor metrics on the green fleet. Once the baking period finishes and no alarms trip, the active portion of your green fleet continues receiving traffic and a new step begins. If alarms trip during any of the baking periods, 100% of the endpoint traffic rolls back to the blue fleet.

The following diagram shows how linear traffic shifting routes traffic to the blue and green fleets.
Blue/Green Deployments
Once SageMaker provisions the new fleet, the first portion of the green fleet turns on and receives traffic. SageMaker deactivates the same size portion of the blue fleet, and the baking period begins. If any alarms trip, all of the endpoint traffic rolls back to the blue fleet. If the baking period finishes, then the next step begins. Another portion of the green fleet activates and receives traffic, part of the blue fleet deactivates, and another baking period begins. The same process repeats until the blue fleet is fully deactivated and the green fleet is fully active and receiving all traffic. If an alarm goes off at any point, SageMaker terminates the shifting process and 100% of the traffic rolls back to the blue fleet.

**Prerequisites**

Before setting up a deployment with linear traffic shifting, you must create CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2816). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

**Configure Linear Traffic Shifting**

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker UpdateEndpoint API or the update-endpoint command in the AWS CLI to initiate the deployment.

**Topics**

- How to update an endpoint (API) (p. 2830)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2831)
- How to update an endpoint (CLI) (p. 2827)

**How to update an endpoint (API)**

The following example of the UpdateEndpoint API shows how you can update an endpoint with linear traffic shifting.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "LINEAR",
                "LinearStepSize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 20
                },
                "WaitIntervalInSeconds": 300
            },
            "TerminationWaitInSeconds": 300,
            "MaximumExecutionTimeoutInSeconds": 3600
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>
                }
            ]
        }
    }
)
```
To configure the linear traffic shifting option, do the following:

- For **EndpointName**, use the name of the existing endpoint you want to update.
- For **EndpointConfigName**, use the name of the endpoint configuration you want to use.
- Under **DeploymentConfig** and **BlueGreenUpdatePolicy**, in **TrafficRoutingConfiguration**, set the **Type** parameter to **LINEAR**. This specifies that the deployment uses linear traffic shifting.
  - In the **LinearStepSize** field, you can change the size of the steps by modifying the **Type** and **Value** parameters. For **Type**, use **CAPACITY_PERCENT**, meaning the percentage of your green fleet you want to use as the step size, and then set **Value** to 20. In this example, you turn on 20% of the green fleet’s capacity for each traffic shifting step. Note that when customizing your linear step size, you should only use steps that are 10-50% of the green fleet’s capacity.
  - For **WaitIntervalInSeconds**, use **300**. The parameter tells SageMaker to wait for the specified amount of time (in seconds) between each traffic shift. This interval is the duration of the baking period between each linear step. In the preceding example, SageMaker waits for 5 minutes between each traffic shift.
  - For **TerminationWaitInSeconds**, use **300**. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 5 minutes after the final baking period before terminating the blue fleet.
  - For **MaximumExecutionTimeoutInSeconds**, use **3600**. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 1 hour to finish.
  - In **AutoRollbackConfiguration**, within the **Alarms** field, you can add your CloudWatch alarms by name. Create one **AlarmName**: `<your-cw-alarm>` entry for each alarm you want to use.

**How to update an endpoint with an existing blue/green update policy (API)**

When you use the **CreateEndpoint** API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same **DeploymentConfig** options as the previous **UpdateEndpoint** API example. There are no changes to the **CreateEndpoint** API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the **UpdateEndpoint** API to update your endpoint. When updating your endpoint, you can use the **RetainDeploymentConfig** option to keep the deployment configuration you specified when you created the endpoint.

When calling the **UpdateEndpoint** API, set **RetainDeploymentConfig** to **True** to keep the **DeploymentConfig** options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

**How to update an endpoint (CLI)**

If you are using the AWS CLI, the following example shows how to start a blue/green linear deployment using the **update-endpoint** command.

```bash
update-endpoint
```
To configure the linear traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a `BlueGreenUpdatePolicy` JSON object.

**Note**
If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.

---

**Exclusions**

You can only use deployment guardrails with newly created endpoints. There are also feature-based exclusions that make your endpoint incompatible with deployment guardrails at this time. If your endpoint uses any of the following features, you cannot use deployment guardrails on your endpoint, and your endpoint will fall back to using a blue/green deployment with all at once traffic shifting and no final baking period.

- Marketplace containers
- Multi-container endpoints
- Multi-model endpoints
- Multi-variant endpoints
- Endpoints that use Inf1 (Inferentia-based) instances
- Endpoints that use Amazon SageMaker Model Monitor (with data capture enabled)
- Amazon Elastic Inference endpoints

---

**Inference cost optimization best practices**

The following content provides techniques and considerations for optimizing the cost of endpoints. You can use these recommendations to optimize the cost for both new and existing endpoints.

---

**Best practices**

To optimize your SageMaker Inference costs, follow these best practices.

**Pick the best inference option for the job.**

SageMaker offers 4 different inference options to provide the best inference option for the job. You may be able to save on costs by picking the inference option that best matches your workload.

- Use real-time inference for low latency workloads with predictable traffic patterns that need to have consistent latency characteristics and are always available. You pay for using the instance.
• Use **serverless inference** for synchronous workloads that have a spiky traffic pattern and can accept variations in the p99 latency. Serverless inference automatically scales to meet your workload traffic so you don’t pay for any idle resources. You only pay for the duration of the inference request. The same model and containers can be used with both real-time and serverless inference so you can switch between these two modes if your needs change.

• Use **asynchronous inference** for asynchronous workloads that process up to 1 GB of data (such as text corpus, image, video, and audio) that are latency insensitive and cost sensitive. With asynchronous inference, you can control costs by specifying a fixed number of instances for the optimal processing rate instead of provisioning for the peak. You can also scale down to zero to save additional costs.

• Use **batch inference** for workloads for which you need inference for a large set of data for processes that happen offline (that is, you don’t need a persistent endpoint). You pay for the instance for the duration of the batch inference job.

### Opt in to a SageMaker Savings Plan.

• If you have a consistent usage level across all SageMaker services, you can opt in to a SageMaker Savings Plan to help reduce your costs by up to 64%.

• **Amazon SageMaker Savings Plans** provide a flexible pricing model for Amazon SageMaker, in exchange for a commitment to a consistent amount of usage (measured in $/hour) for a one-year or three-year term. These plans automatically apply to eligible SageMaker ML instance usages including SageMaker Studio Notebook, SageMaker On-Demand Notebook, SageMaker Processing, SageMaker Data Wrangler, SageMaker Training, SageMaker Real-Time Inference, and SageMaker Batch Transform regardless of instance family, size, or Region. For example, you can change usage from a CPU ml.c5.xlarge instance running in US East (Ohio) to a ml.Inf1 instance in US West (Oregon) for inference workloads at any time and automatically continue to pay the Savings Plans price.

### Optimize your model to run better.

• Unoptimized models can lead to longer run times and use more resources. You may choose to use more or bigger instances to improve performance; however, this leads to higher costs.

• By optimizing your models to be more performant, you may be able to lower costs by using fewer or smaller instances while keeping the same or better performance characteristics. You can use SageMaker Neo with SageMaker Inference to automatically optimize models. For more details and samples, see Optimize model performance using Neo (p. 2913).

### Use the most optimal instance type and size for real-time inference.

• SageMaker Inference has over 70 instance types and sizes that can be used to deploy ML models including AWS Inferentia and Graviton chipsets that are optimized for ML. Choosing the right instance for your model helps ensure you have the most performant instance at the lowest cost for your models.

• By using **Inference Recommender**, you can quickly compare different instances to understand the performance of the model and the costs. With these results, you can choose the instance to deploy with the best return on investment.

### Improve efficiency and costs by combining multiple endpoints into a single endpoint for real-time inference.

• Costs can quickly add up when you deploy multiple endpoints, especially if the endpoints don’t fully utilize the underlying instances. To understand if the instance is under-utilized, check the utilization metrics (CPU, GPU, etc) in Amazon CloudWatch for your instances. If you have more than one of
these endpoints, you can combine the models or containers on these multiple endpoints into a single endpoint.

• Using Multi-model endpoints (MME) or Multi-container endpoints (MCE), you can deploy multiple ML models or containers in a single endpoint to share the instance across multiple models or containers and improve your return on investment. To learn more, see this Save on inference costs by using Amazon SageMaker multi-model endpoints or Deploy multiple serving containers on a single instance using Amazon SageMaker multi-container endpoints on the AWS Machine Learning blog.

Set up autoscaling to match your workload requirements for real-time and asynchronous inference.

• Without autoscaling, you need to provision for peak traffic or risk model unavailability. Unless the traffic to your model is steady throughout the day, there will be excess unused capacity. This leads to low utilization and wasted resources.

• Autoscaling is an out-of-the-box feature that monitors your workloads and dynamically adjusts the capacity to maintain steady and predictable performance at the possible lowest cost. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances, helping you reduce your compute cost. To learn more, see Configuring autoscaling inference endpoints in Amazon SageMaker on the AWS Machine Learning blog.

Register and Deploy Models with Model Registry

With the SageMaker model registry you can do the following:

• Catalog models for production.
• Manage model versions.
• Associate metadata, such as training metrics, with a model.
• Manage the approval status of a model.
• Deploy models to production.
• Automate model deployment with CI/CD.

Catalog models by creating model package groups that contain different versions of a model. You can create a model group that tracks all of the models that you train to solve a particular problem. You can then register each model you train and the model registry adds it to the model group as a new model version. A typical workflow might look like the following:

• Create a model group.
• Create an ML pipeline that trains a model. For information about SageMaker pipelines, see Create and Manage SageMaker Pipelines (p. 3092).
• For each run of the ML pipeline, create a model version that you register in the model group you created in the first step.

Model Registry Structure

The SageMaker Model Registry is structured as several model groups with model packages in each group. Each model package in a model group corresponds to a trained model. The version of each model package is a numerical value that starts at 1 and is incremented with each new model package added to a model group. For example, if 5 model packages are added to a model group, the model package versions will be 1, 2, 3, 4, and 5. The example Model Registry shown in the following image contains 3 model groups, where each group contains the model packages related to a particular ML problem.
There are two types of model packages in SageMaker. One type is used in the AWS Marketplace, and the other is used in the Model Registry. Model packages used in the AWS Marketplace are not versionable entities and are not associated with model groups in the Model Registry. For more information about model packages used in the AWS Marketplace, see Buy and Sell Amazon SageMaker Algorithms and Models in AWS Marketplace (p. 3315).

The model packages used in the Model Registry are versioned, and must be associated with a model group. The ARN of this model package type has the structure: 

'arn:aws:sagemaker:region:account:model-group/version'

The following topics show you how to use the Model Registry.

Topics
- Create a Model Group (p. 2835)
- Delete a Model Group (p. 2839)
- Register a Model Version (p. 2840)
- View Model Groups and Versions (p. 2847)
- View the Details of a Model Version (p. 2849)
- Delete a Model Version (p. 2851)
- Update the Approval Status of a Model (p. 2853)
- Deploy a Model from the Registry (p. 2857)
- View the Deployment History of a Model (p. 2860)
- Amazon SageMaker Model Registry FAQ (p. 2863)

Create a Model Group

A model group contains a group of versioned models. Create a model group by using either the AWS SDK for Python (Boto3) or Amazon SageMaker Studio.

Create a Model Package Group (Boto3)

To create a model group by using Boto3, call the create_model_package_group method and specify a name and description as parameters. The following example shows how to create a model group. The
response from the `create_model_package_group` call is the Amazon Resource Name (ARN) of the new model package group.

First, import the required packages and set up the SageMaker Boto3 client.

```python
import time
import os
from sagemaker import get_execution_role, session
import boto3
region = boto3.Session().region_name
role = get_execution_role()
sm_client = boto3.client('sagemaker', region_name=region)
```

Now create the model group.

```python
model_package_group_name = "scikit-iris-detector-" + str(round(time.time()))
model_package_group_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageGroupDescription" : "Sample model package group"
}
create_model_package_group_response = sm_client.create_model_package_group(**model_package_group_input_dict)
print('ModelPackageGroup Arn : 
{}
'.format(create_model_package_group_response['ModelPackageGroupArn']))
```

Create a Model Package Group (Amazon SageMaker Studio)

To create a model group in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).
2. In the left navigation pane, choose the SageMaker Resources icon (§).
3. Choose Model registry.
Create a Model Group

4. Choose Create model group.
5. In the **Create new model group** dialog box, enter the following information:
   
   - Enter the name of the new model group in the **Name** field.
   - (Optional) Enter a description for the model group in the **Description** field.
   - (Optional) Enter any key-value pairs you want to associate with the model group in the **Tags** field. For information about using tags, see Tagging AWS resources in the **AWS General Reference**.
   - (Optional) Choose a project with which to associate the model group in the **Project** field. For information about projects, see Automate MLOps with SageMaker Projects (p. 3123).

6. Choose **Create model group**.
Delete a Model Group

This procedure demonstrates how to delete a model group in Amazon SageMaker Studio.

Delete a Model Package Group (Amazon SageMaker Studio)

To delete a model group in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).
2. In the left navigation pane, choose the SageMaker Resources icon ( ).
3. Choose Model registry in the dropdown menu at the top of the SageMaker resources panel.

A list of your model groups appears.
4. From the model groups list, double-click the model group you want to delete.

The model details tab opens to the right.
5. In the Actions dropdown menu in the top right corner of the model details tab, choose Delete.
6. In the confirmation dialog box, choose **Delete**.

### Register a Model Version

You can register an Amazon SageMaker model by creating a model version that specifies the model group to which it belongs. A model version must include both the model artifacts (the trained weights of a model) and the inference code for the model.

An *inference pipeline* is a SageMaker model composed of a linear sequence of two to fifteen containers that process inference requests. You register an inference pipeline by specifying the containers and the associated environment variables. For more information on inference pipelines, see [Host models along with pre-processing logic as serial inference pipeline behind one endpoint](p. 2674).

You can register a model with an inference pipeline, by specifying the containers and the associated environment variables. To create a model version with an inference pipeline by using either the AWS SDK for Python (Boto3) or by creating a step in a SageMaker model building pipeline, use the following steps.

**Topics**
- [Register a Model Version (SageMaker Pipelines)](p. 2841)
Register a Model Version (Boto3) (p. 2841)
Register a Model Version from a Different Account (p. 2841)

Register a Model Version (SageMaker Pipelines)

To register a model version by using a SageMaker model building pipeline, create a RegisterModel step in your pipeline. For information about creating a RegisterModel step as part of a pipeline, see Step 8: Define a RegisterModel Step to Create a Model Package (p. 3103).

Register a Model Version (Boto3)

To register a model version by using Boto3, call the `create_model_package` method.

First, you set up the parameter dictionary to pass to the `create_model_package` method.

```python
# Specify the model source
model_url = "s3://your-bucket-name/model.tar.gz"

modelpackage_inference_specification = {
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": '257758044811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-xgboost:1.2-1',
                "ModelDataUrl": model_url
            }
        ],
        "SupportedContentTypes": [ "text/csv" ],
        "SupportedResponseMIMETypes": [ "text/csv" ],
    }
}

# Alternatively, you can specify the model source like this:
# modelpackage_inference_specification["InferenceSpecification"]["Containers"][0]["ModelDataUrl"] = model_url

create_model_package_input_dict = {
    "ModelPackageGroupName" : model_package_group_name,
    "ModelPackageDescription" : "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
    "ModelApprovalStatus" : "PendingManualApproval"
}

create_model_package_input_dict.update(modelpackage_inference_specification)

Then you call the `create_model_package` method, passing in the parameter dictionary that you just set up.

```python
create_model_package_response = sm_client.create_model_package(**create_model_package_input_dict)
model_package_arn = create_model_package_response["ModelPackageArn"]
print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

Register a Model Version from a Different Account

To register model versions with a model package group created by a different AWS account, you must add a cross-account AWS Identity and Access Management resource policy to enable that account. For example, one AWS account in your organization is responsible for training models, and a different
account is responsible for managing, deploying, and updating models. You create IAM resource policies and apply the policies to the specific account resource to which you want to grant access for this case. For more information about cross-account resource policies in AWS, see Cross-account policy evaluation logic in the AWS Identity and Access Management User Guide.

**Note**

You must also use a KMS key to encrypt the output data config action during training for cross-account model deployment.

To enable cross-account model registry in SageMaker, you have to provide a cross-account resource policy for the model group that contains the model versions. The following is an example that creates cross-account policies for the model package group and applies these policies to that specific resource.

The following configuration must be set in the source account which registers models cross-account in a model package group. In this example, the source account is the model training account which will train and then register the model cross-account into the Model Registry of the model registry account.

The example assumes that you previously defined the following variables:

- `model_package_group_name` - The model group to which you want to grant access.
- `model_package_group_arn` - The model group arn to which you want to grant cross-account access.
- `bucket` - The S3 bucket where the model training artifacts are stored.

To be able to deploy a model created in a different account, the user must have a role that has access to SageMaker actions, such as a role with the `AmazonSageMakerFullAccess` managed policy. For information about SageMaker managed policies, see AWS Managed Policies for Amazon SageMaker (p. 3410).

**Required IAM resource policies**

The following diagram captures the policies required to allow cross-account model registration. As shown, these policies need to be active during model training to properly register the model into the model registry account.
Amazon ECR, Amazon S3, and AWS KMS policies are demonstrated in the following code samples.

**Sample Amazon ECR policy**

```json
{
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
```
Sample Amazon S3 policy

```json
{
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
            'Principal': {
                'AWS': 'arn:aws:iam::{model_registry_account}:root'
            },
            'Action': ['s3:GetObject', 's3:GetBucketAcl', 's3:GetObjectAcl'],
            'Resource': 'arn:aws:s3:::{bucket}/*'
        }
    ]
}
```

Sample AWS KMS policy

```json
{
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
            'Principal': {
                'AWS': 'arn:aws:iam::{model_registry_account}:root'
            },
            'Action': ['kms:Decrypt', 'kms:GenerateDataKey*'],
            'Resource': '*'
        }
    ]
}
```

Apply resource policies to accounts

The following policy configuration applies the policies discussed in the previous section and must be put in the model training account.

```python
import json

# The model registry account id of the model package group
model_registry_account = '111111111111'
```
# The model training account id where training happens
model_training_account = '222222222222'

# 1. Create a policy for access to the ECR repository
# in the model training account for the model registry account model package group
ecr_repository_policy = {'Version': '2012-10-17',
                       'Statement': [{'Sid': 'AddPerm',
                                      'Effect': 'Allow',
                                      'Principal': {'AWS': f'arn:aws:iam::{model_registry_account}:root'},
                                      'Action': ['ecr:BatchGetImage',
                                                 'ecr:Describe*']},
                       ]}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(registryId = model_training_account,
                                     repositoryName = 'decision-trees-sample',
                                     policyText = ecr_repository_policy)

# 2. Create a policy in the model training account for access to the S3 bucket
# where the model is present in the model registry account model package group
bucket_policy = {'Version': '2012-10-17',
                 'Statement': [{'Sid': 'AddPerm',
                                'Effect': 'Allow',
                                'Principal': {'AWS': f'arn:aws:iam::{model_registry_account}:root'},
                                'Action': ['s3:GetObject',
                                           's3:GetBucketAcl',
                                           's3:GetObjectAcl'],
                                'Resource': 'arn:aws:s3:::{bucket}/*'}],
                 }

# Convert the S3 policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new bucket policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(Bucket = bucket,
                                Policy = bucket_policy)

# 3. Create the KMS grant for the key used during training for encryption
# in the model training account to the model registry account model package group
client = boto3.client('kms')
response = client.create_grant(GranteePrincipal=model_registry_account,
                              KeyId=kms_key_id,
                              Operations=['Decrypt',
                                          'GenerateDataKey'],
                              ],
The following configuration needs to be put in the model registry account where the model package group exists.

```python
# The model registry account id of the model package group
model_registry_account = '111111111111'

# Create policy to allow the model training account to access the ModelPackageGroup
model_package_group_policy = {'Version': '2012-10-17',
                              'Statement': [
                                  {'Sid': 'AddPermModelPackageVersion',
                                   'Effect': 'Allow',
                                   'Principal': {'AWS': f'arn:aws:iam::{model_training_account}:root',
                                                 'Action': ['sagemaker:CreateModelPackage'],
                                                 'Resource': f'arn:aws:sagemaker:{region}:{model_registry_account}:model-package/{model_package_group_name}/*'}
                              ]}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)

# Set the new policy
response = sm_client.put_model_package_group_policy(ModelPackageGroupName=model_package_group_name,
                                                      ResourcePolicy=model_package_group_policy)
```

Finally, use the `create_model_package` action from the model training account to register the model package in the cross-account.

```python
# Specify the model source
model_url = "s3://(bucket)/model.tar.gz"

# Set up the parameter dictionary to pass to the create_model_package method
modelpackage_inference_specification = {
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": f'{model_training_account}.dkr.ecr.us-east-2.amazonaws.com/decision-trees-sample:latest',
                "ModelDataUrl": model_url
            }
        ],
        "SupportedContentTypes": [ "text/csv" ],
        "SupportedResponseMIMETypes": [ "text/csv" ],
    }
}

# Alternatively, you can specify the model source like this:
# modelpackage_inference_specification["InferenceSpecification"]["Containers"][0]["ModelDataUrl"]=model_url

create_model_package_input_dict = {
    "ModelPackageName": model_package_group_arn,
    "ModelPackageDescription": "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
    "ModelApprovalStatus": "PendingManualApproval"
}
```
create_model_package_input_dict.update(modelpackage_inference_specification)

# Create the model package in the model registry account
create_model_package_response =
    sm_client.create_model_package(**create_model_package_input_dict)
model_package_arn = create_model_package_response['ModelPackageArn']
print('ModelPackage Version ARN : {}'.format(model_package_arn))

View Model Groups and Versions

Model groups and versions help you organize your models. You can view a list of the model versions in a model group.

View a List of Model Versions in a Group

You can view all of the model versions that are associated with a model group. If a model group represents all models that you train to address a specific ML problem, you can view all of those related models.

View a List of Model Versions in a Group (Boto3)

To view model versions associated with a model group by using Boto3, call the list_model_packages method, and pass the name of the model group as the value of the ModelPackageGroupName parameter. The following code lists the model versions associated with the model group you created in Create a Model Package Group (Boto3) (p. 2835).

```python
sm_client.list_model_packages(ModelPackageGroupName=model_package_group_name)
```

View a List of Model Versions in a Group (Amazon SageMaker Studio)

To view a list of the model versions in a model group, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).
2. In the left navigation pane, choose the SageMaker Resources icon (✈).
3. Choose Model registry.
4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group, as shown in the following image.
View the Details of a Model Version

You can view details of a specific model version by using either the AWS SDK for Python (Boto3) or by using Amazon SageMaker Studio.

View the Details of a Model Version (Boto3)

To view the details of a model version by using Boto3, complete the following steps.

1. Call the `list_model_packages` method to view the model versions in a model group.

```python
sm_client.list_model_packages(ModelPackageGroupName="ModelGroup1")
```

The response is a list of model package summaries. You can get the Amazon Resource Name (ARN) of the model versions from this list.

```json
{
    'ModelPackageSummaryList': [{
        'ModelPackageGroupName': 'AbaloneMPG-16039329888329886',
        'ModelPackageVersion': 1,
        'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1',
        'ModelPackageDescription': 'TestMe',
        'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000, tzinfo=tzlocal()),
        'ModelPackageStatus': 'Completed',
        'ModelApprovalStatus': 'Approved'}],
    'ResponseMetadata': {'RequestId': '12345678-abcd-1234-abcd-aabbccddeeff',
        'HTTPStatusCode': 200,
        'HTTPHeaders': {'x-amzn-requestid': '12345678-abcd-1234-abcd-aabbccddeeff',
            'content-type': 'application/x-amz-json-1.1',
            'content-length': '349',
            'date': 'Mon, 23 Nov 2020 04:56:50 GMT'},
        'RetryAttempts': 0}}
```

2. Call `describe_model_package` to see the details of the model version. You pass in the ARN of a model version that you got in the output of the call to `list_model_packages`.

```python
sm_client.describe_model_package(ModelPackageName="arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1")
```

The output of this call is a JSON object with the model version details.

```json
{
    'ModelPackageGroupName': 'ModelGroup1',
    'ModelPackageVersion': 1,
    'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1',
    'ModelPackageDescription': 'Test Model',
    'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000, tzinfo=tzlocal()),
    'InferenceSpecification': {'Containers': [{
        'Image': '257758044811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-xgboost:1.0-1-cpu-py3',
        'ImageDigest': 'sha256:9fa6a02ccff19ae33297a5926f826847ca7bd42ab391b7d600300024eef803bca66',
        'ModelDataUrl': 's3://sagemaker-us-east-2-123456789012/output/model.tar.gz'}],
        'SupportedTransformInstanceTypes': ['ml.m5.xlarge'],
        'SupportedRealtimeInferenceInstanceTypes': ['ml.t2.medium', 'ml.m5.xlarge'],
        'SupportedContentTypes': ['text/csv'],
        'SupportedResponseMIMETypes': ['text/csv'],
        'ModelPackageStatus': 'Completed',
        'ModelPackageStatusDetails': {'ValidationStatuses': [],
            'ImageScanStatuses': []}}
```
View the Details of a Model Version (Amazon SageMaker Studio)

To view the details of a model version in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).

2. In the left navigation pane, choose the SageMaker Resources icon (gráfica).

3. Choose Model registry.

4. From the model groups list, double-click the model group you want to view.
5. A new tab appears with a list of the model versions in the model group, as shown in the following image.

6. In the list of model versions, double-click the model version for which you want to view details.

7. On the model version tab that opens, choose one of the following to see details about the model version:

   - **Activity**: Shows events for the model version, such as approval status updates.
   - **Metrics**: Shows quality metrics for the model. For metrics to appear, you must enable data capture for your model by using SageMaker Model Monitor. For information about capturing data, see Capture data (p. 2745).
   - **Settings**: Shows information such as the project with which the model version is associated, the pipeline that generated the model, the model group, and the model's location in Amazon S3.

---

**Delete a Model Version**

This procedure demonstrates how to delete a model version in Amazon SageMaker Studio.
Delete a Model Version (Amazon SageMaker Studio)

To delete a model version in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).

2. In the left navigation pane, choose the SageMaker Resources icon (🔍).

3. Choose Model registry in the dropdown menu at the top of the SageMaker resources panel.

   A list of your model groups appears.

4. From the model groups list, double-click the model group of the model version you want to delete.

   The model details tab opens to the right.

5. From the list of model versions in the model details tab, double-click the model version you want to delete.

   ![Model versions list]

6. Choose the Settings tab.

7. Choose Delete Version in the Settings tab.
Update Model Approval Status

After you create a model version, you typically want to evaluate its performance before you deploy it to a production endpoint. If it performs to your requirements, you can update the approval status of the model version to Approved. Setting the status to Approved can initiate CI/CD deployment for the model. If the model version does not perform to your requirements, you can update the approval status to Rejected.

You can manually update the approval status of a model version after you register it, or you can create a condition step to evaluate the model when you create a SageMaker pipeline. For information about creating a condition step in a SageMaker pipeline, see Pipeline Steps (p. 3057).

When you use one of the SageMaker provided project templates and the approval status of a model version changes, the following action occurs. Only valid transitions are shown.

- PendingManualApproval to Approved – initiates CI/CD deployment for the approved model version
- PendingManualApproval to Rejected – No action

8. In the confirmation dialog box, choose Delete.
You can update the approval status of a model version by using the AWS SDK for Python (Boto3) or by using Amazon SageMaker Studio. You can also update the approval status of a model version as part of a condition step in a SageMaker pipeline. For information about using a model approval step in a SageMaker pipeline, see SageMaker Pipelines Overview (p. 3050).

**Update the Approval Status of a Model (Boto3)**

When you created the model version in Register a Model Version (p. 2840), you set the ModelApprovalStatus to PendingManualApproval. You update the approval status for the model by calling update_model_package. Note that you can automate this process by writing code that, for example, sets the approval status of a model depending on the result of an evaluation of some measure of the model's performance. You can also create a step in a pipeline that automatically deploys a new model version when it is approved. The following code snippet shows how to manually change the approval status to Approved.

```python
model_package_update_input_dict = {
    "ModelPackageArn" : model_package_arn,
    "ModelApprovalStatus" : "Approved"
}
model_package_update_response = sm_client.update_model_package(**model_package_update_input_dict)
```

**Update the Approval Status of a Model (Amazon SageMaker Studio)**

The following procedure shows how to manually change the approval status from Approved to Rejected.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).
2. In the left navigation pane, choose the SageMaker Resources icon (🔍).
3. Choose Model registry.
4. From the model groups list, choose the model group you want to view. A new tab opens with a list of the model versions in the group.

5. In the list of model versions, right-click the model version you want to update and choose **Update model version status**.
6. In the **Update model version status** dialog box, for **Status** choose **Rejected**, and then choose **Update status**.
Deploy a Model from the Registry

After you register a model version and approve it for deployment, deploy it to a SageMaker endpoint for real-time inference.

When you create an MLOps project and choose an MLOps project template that includes model deployment, approved model versions in the model registry are automatically deployed to production. For information about using SageMaker MLOps projects, see Automate MLOps with SageMaker Projects (p. 3123).

You can also enable an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models.

Topics

- Deploy a Model from the Registry (SageMaker SDK) (p. 2857)
- Deploy a Model from the Registry (Boto3) (p. 2857)
- Deploy a Model Version from a Different Account (p. 2858)

Deploy a Model from the Registry (SageMaker SDK)

To deploy a model version using the Amazon SageMaker Python SDK use the following code snippet:

```python
from sagemaker import ModelPackage
from time import gmtime, strftime

model_package_arn = 'arn:aws:sagemaker:us-east-2:12345678901:model-package/modeltest/1'
model = ModelPackage(role=role,
                     model_package_arn=model_package_arn,
                     sagemaker_session=sagemaker_session)
model.deploy(initial_instance_count=1, instance_type='ml.m5.xlarge')
```

Deploy a Model from the Registry (Boto3)

To deploy a model version using the AWS SDK for Python (Boto3), complete the following steps:

1. Create a model object from the model version by calling the `create_model` method. Pass the Amazon Resource Name (ARN) of the model version as part of the `Containers` for the model object.

   The following code snippet assumes you have already created the SageMaker Boto3 client `sm_client`, and that you have already created a model version with an ARN that you have stored in a variable named `model_version_arn`.

   ```python
   model_name = 'DEMO-modelregistry-model-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
   print("Model name : {}".format(model_name))
   container_list = [{‘ModelPackageName’: model_version_arn}]
   create_model_response = sm_client.create_model(
       ModelName = model_name,
       ExecutionRoleArn = role,
       Containers = container_list
   )
   print("Model arn : {}".format(create_model_response["ModelArn"]))
   ```

2. Create an endpoint configuration by calling `create_endpoint_config`. The endpoint configuration specifies the number and type of Amazon EC2 instances to use for the endpoint.
3. Create the endpoint by calling `create_endpoint`.

```python
endpoint_name = 'DEMO-modelregistry-endpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("EndpointName={}".format(endpoint_name))
create_endpoint_response = sm_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response['EndpointArn'])
```

### Deploy a Model Version from a Different Account

You can permit an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models. When you create these resource policies, you apply the policy to the specific resource to which you want to grant access. For more information about cross-account resource policies in AWS, see [Cross-account policy evaluation logic](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_resourcelocation.html) in the *AWS Identity and Access Management User Guide*.

**Note**

You must use a KMS key to encrypt the `output data config` action during training for cross-account model deployment.

To enable cross-account model deployment in SageMaker, you have to provide a cross-account resource policy for the model group that contains the model versions you want to deploy, the Amazon ECR repository where the inference image for the model group resides, and the Amazon S3 bucket where the model versions are stored.

To be able to deploy a model that was created in a different account, you must have a role that has access to SageMaker actions, such as a role with the `AmazonSageMakerFullAccess` managed policy. For information about SageMaker managed policies, see [AWS Managed Policies for Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-policies.html) (p. 3410).

The following example creates cross-account policies for all three of these resources, and applies the policies to the resources.

The example assumes that you previously defined the following variables:

- `bucket` - The Amazon S3 bucket where the model versions are stored.
- `kms_key_id` - The KMS key used to encrypt the training output.
- `model_package_group_name` - The model group to which you want to grant cross-account access.
- `model_package_group_arn` - The model group arn to which you want to grant cross-account access.
import json

# The cross-account id to grant access to
cross_account_id = "123456789012"

# Create the policy for access to the ECR repository
ecr_repository_policy = {
    'Version': '2012-10-17',
    'Statement': [
        {'Sid': 'AddPerm',
         'Effect': 'Allow',
         'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'},
        'Action': ['ecr:*']
    ]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = account,
    repositoryName = 'decision-trees-sample',
    policyText = ecr_repository_policy
)

# Create a policy for accessing the S3 bucket
bucket_policy = {
    'Version': '2012-10-17',
    'Statement': [
        {'Sid': 'AddPerm',
         'Effect': 'Allow',
         'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'},
        'Action': 's3:*',
        'Resource': f'arn:aws:s3:::{bucket}/*'
    ]
}

# Convert the policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucket_policy)

# Create the KMS grant for encryption in the source account to the
# model registry account model package group
client = boto3.client('kms')
response = client.create_grant(
    GranteePrincipal=cross_account_id,
    KeyId=kms_key_id
    Operations=[
        'Decrypt',
        'GenerateDataKey',
    ],
)
View the Deployment History of a Model

View the deployments for a model version Amazon SageMaker Studio by opening the tab for that model version.

View the deployment history for a model version

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 35).
2. In the left navigation pane, choose the SageMaker Resources icon (🔍).
3. Choose Model registry.
4. From the model groups list, choose the model group you want to view.

5. A new tab appears with a list of the model versions in the model group.

6. In the list of model versions, double-click the model version for which you want to view details.
7. On the model version tab that opens, choose Activity. Deployments for the model version appear as events in the activity list with an Event type of ModelDeployment.
Amazon SageMaker Model Registry FAQ

Use the following FAQ items to find answers to commonly asked questions about SageMaker Model Registry.

Q. How should I organize my models into model groups and model packages in the SageMaker Model Registry?

A model package is the actual model that is registered into the model registry as a versioned entity. Please note there are two ways you can use model packages in SageMaker. One is with SageMaker Marketplace — these model packages are not versioned. The other is with the SageMaker Model Registry, in which the model package must be versioned. The model registry receives every new model that you retrain, gives it a version, and assigns it to a model group inside the model registry. The following image shows an example of a model group with 25 consecutively-versioned models.

Q. How does a model registry differ from Amazon Elastic Container Registry (Amazon ECR)?

SageMaker’s Model Registry is a metadata store for your machine learning models. Amazon Elastic Container Registry is a repository that stores all of your containers. Within the model registry, models are versioned and registered as model packages within model groups. Each model package contains an Amazon S3 URI to the model files associated with the trained model and an Amazon ECR URI that points to the container used while serving the model.

Deploy models at the edge with SageMaker Edge Manager

Amazon SageMaker Edge Manager provides model management for edge devices so you can optimize, secure, monitor, and maintain machine learning models on fleets of edge devices such as smart cameras, robots, personal computers, and mobile devices.

Why Use Edge Manager?

Many machine learning (ML) use cases require running ML models on a fleet of edge devices, which allows you to get predictions in real-time, preserves the privacy of the end users, and lowers the cost of network connectivity. With the increasing availability of low-power edge hardware designed for ML, it is now possible to run multiple complex neural network models on edge devices.

However, operating ML models on edge devices is challenging, because devices, unlike cloud instances, have limited compute, memory, and connectivity. After the model is deployed, you need to continuously monitor the models, because model drift can cause the quality of model to decay overtime. Monitoring models across your device fleets is difficult because you need to write custom code to collect data samples from your device and recognize skew in predictions. In addition, models are often hard-coded into the application. To update the model, you must rebuild and update the entire application or device firmware, which can disrupt your operations.

With SageMaker Edge Manager, you can optimize, run, monitor, and update machine learning models across fleets of devices at the edge.

How Does it Work?

At a high level, there are five main components in the SageMaker Edge Manager workflow: compiling models with SageMaker Neo, packaging Neo-compiled models, deploying models to your devices, running models on the SageMaker inference engine (Edge Manager agent), and maintaining models on the devices.
SageMaker Edge Manager uses SageMaker Neo to optimize your models for the target hardware in one click, then to cryptographically sign your models before deployment. Using SageMaker Edge Manager, you can sample model input and output data from edge devices and send it to the cloud for monitoring and analysis, and view a dashboard that tracks and visually reports on the operation of the deployed models within the SageMaker console.

SageMaker Edge Manager extends capabilities that were previously only available in the cloud to the edge, so developers can continuously improve model quality by using Amazon SageMaker Model Monitor for drift detection, then relabel the data with SageMaker Ground Truth and retrain the models in SageMaker.

**How Do I Use SageMaker Edge Manager?**

If you are a first time user of SageMaker Edge Manager, we recommend that you do the following:

1. **Read the Getting Started section** - This section walks you through setting up your first edge packaging job and creating your first fleet.
2. **Explore Edge Manager Jupyter notebook examples** - Example notebooks are stored in the amazon-sagemaker-examples GitHub repository in the sagemaker_edge_manager folder.

**Getting Started**

This guide demonstrates how to complete the necessary steps to register, deploy, and manage a fleet of devices, and how to satisfy Amazon SageMaker Edge Manager prerequisites.

**Topics**

- Setting Up (p. 2867)
- Train, Compile, and Package Your Model (p. 2869)
- Create and Register Fleets and Authenticate Devices (p. 2872)
- Download and Set Up Edge Manager (p. 2875)
- Run Agent (p. 2878)
Setting Up

Before you begin using SageMaker Edge Manager to manage models on your device fleets, you must first create IAM Roles for both SageMaker and AWS IoT. You will also want to create at least one Amazon S3 bucket where you will store your pre-trained model, the output of your SageMaker Neo compilation job, as well as input data from your edge devices.

1. **Set up an AWS account.**

   Create an AWS account and an IAM administrator user. For instructions on how to set up your AWS account, see How do I create and activate a new AWS account? For instructions on how to create an administrator user in your AWS account, see Creating your first IAM admin user and group.

2. **Create an IAM role for Amazon SageMaker.**

   SageMaker Edge Manager needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3. Using this role, SageMaker can run under your account and access to your Amazon S3 bucket.

   You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

   a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
   b. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
   c. For **Select type of trusted entity**, choose **AWS service**.
   d. Choose the service that you want to allow to assume this role. In this case, choose **SageMaker**. Then choose **Next: Permissions**.
   - This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.
   e. Choose **Next: Tags**.
   f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.
   g. Choose **Next: Review**.
   h. Type in a **Role name**.
   i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
   j. (Optional) For **Role description**, type a description for the new role.
   k. Review the role and then choose **Create role**.

   Note the SageMaker Role ARN, which you use to create a compilation job with SageMaker Neo and a packaging job with Edge Manager. To find out the role ARN using the console, do the following:

   i. Go to the IAM console: https://console.aws.amazon.com/iam/
   ii. Select **Roles**.
   iii. Search for the role you just created by typing in the name of the role in the search field.
   iv. Select the role.
   v. The role ARN is at the top of the **Summary** page.

3. **Create an IAM role for AWS IoT.**
The AWS IoT IAM role you create is used to authorize your thing objects. You also use the IAM role ARN to create and register device fleets with a SageMaker client object.

Configure an IAM role in your AWS account for the credentials provider to assume on behalf of the devices in your device fleet. Then, attach a policy to authorize your devices to interact with AWS IoT services.

Create a role for AWS IoT either programmatically or with the IAM console, similar to what you did when you created a role for SageMaker.

a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
c. For Select type of trusted entity, choose AWS service.
d. Choose the service that you want to allow to assume this role. In this case, choose IoT. Select IoT as the Use Case.
e. Choose Next: Permissions.
f. Choose Next: Tags.
g. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.
h. Choose Next: Review.
i. Type in a Role name. The role name must start with SageMaker.
j. (Optional) For Role description, type a description for the new role.
k. Review the role and then choose Create role.
l. Once the role is created, choose Roles in the IAM console. Search for the role you created by typing in role name in the Search field.
m. Choose your role.
n. Next, choose Attach Policies.
o. Search for AmazonSageMakerEdgeDeviceFleetPolicy in the Search field. Select AmazonSageMakerEdgeDeviceFleetPolicy.
p. Choose Attach policy.
q. Add the following policy statement to the trust relationship:

```json
{
    "Version": "2012-10-17",
    "Statement": [ 
        {
            "Effect": "Allow",
            "Principal": {"Service": "credentials.iot.amazonaws.com"},
            "Action": "sts:AssumeRole"
        },
        {
            "Effect": "Allow",
            "Principal": {"Service": "sagemaker.amazonaws.com"},
            "Action": "sts:AssumeRole"
        }
    ]
}
```

A trust policy is a JSON policy document in which you define the principals that you trust to assume the role. For more information about trust policies, see Roles terms and concepts.

r. Note the AWS IoT role ARN. You use the AWS IoT Role ARN to create and register the device fleet. To find the IAM role ARN with the console:
i. Go to the IAM console: https://console.aws.amazon.com/iam/
ii. Choose Roles.
iii. Search for the role you created by typing in the name of the role in the Search field.
iv. Select the role.
v. The role ARN is on the Summary page.

4. Create an Amazon S3 bucket.

SageMaker Neo and Edge Manager access your pre-compiled model and compiled model from an Amazon S3 bucket. Edge Manager also stores sample data from your device fleet in Amazon S3.

a. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
b. Choose Create bucket.
c. In Bucket name, enter a name for your bucket.
d. In Region, choose the AWS Region where you want the bucket to reside.
e. In Bucket settings for Block Public Access, choose the settings that you want to apply to the bucket.
f. Choose Create bucket.

For more information about creating Amazon S3 buckets, see Getting started with Amazon S3.

Train, Compile, and Package Your Model

In this section you will create SageMaker and AWS IoT client objects, download a pre-trained machine learning model, upload your model to your Amazon S3 bucket, compile your model for your target device with SageMaker Neo, and package your model so that it can be deployed with the Edge Manager agent.

1. Import libraries and create client objects.

   This tutorial uses the AWS SDK for Python (Boto3) to create clients to interact with SageMaker, Amazon S3, and AWS IoT.

   Import Boto3, specify your Region, and initialize the client objects you need as shown in the following example:

   ```python
   import boto3
   import json
   import time

   AWS_REGION = 'us-west-2'  # Specify your Region
   bucket = 'bucket-name'

   sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)
   iot_client = boto3.client('iot', region_name=AWS_REGION)
   ```

   Define variables and assign them the role ARN you created for SageMaker and AWS IoT as strings:

   ```python
   # Replace with the role ARN you created for SageMaker
   sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

   # Replace with the role ARN you created for AWS IoT.
   # Note: The name must start with 'SageMaker'
   iot_role_arn = "arn:aws:iam::<account>:role/SageMaker*"
   ```

2869
2. **Train a machine learning model.**

   See [Train a Model with Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/train-model-human-loop-function.html) for more information on how to train a machine learning model using SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

   If you do not have a model yet, you can use a pre-trained model for the next steps in this tutorial. For example, you can save the MobileNet V2 models from the TensorFlow framework. MobileNet V2 is an image classification model optimized for mobile applications. For more information about MobileNet V2, see the [MobileNet GitHub README](https://github.com/tensorflow/models/blob/master/research/slim/nets/mobile_inception_v2.md).

   Type the following into your Jupyter Notebook to save the pre-trained MobileNet V2 model:

   ```python
   # Save the MobileNet V2 model to local storage
   import tensorflow as tf
   model = tf.keras.applications.MobileNetV2()
   model.save("mobilenet_v2.h5")
   
   **Note**
   
   • If you do not have TensorFlow installed, you can do so by running `pip install tensorflow=2.4`
   • Use TensorFlow version 2.4 or lower for this tutorial.
   
   The model will be saved into the `mobilenet_v2.h5` file. Before packaging the model, you will need to first compile your model using SageMaker Neo. See [Supported Frameworks, Devices, Systems, and Architectures](https://docs.aws.amazon.com/sagemaker/latest/dg/neo-supported-features.html) to check if your version of TensorFlow (or other framework of choice) is currently supported by SageMaker Neo.

   SageMaker Neo requires models to be stored as a compressed TAR file. Repackage it as a compressed TAR file (*.tar.gz):

   ```python
   # Package MobileNet V2 model into a TAR file
   import tarfile
   tarfile_name='mobilenet-v2.tar.gz'
   with tarfile.open(tarfile_name, mode='w:gz') as archive:
     archive.add('mobilenet-v2.h5')
   
   3. **Upload your model to Amazon S3.**

   Once you have a machine learning model, store it in an Amazon S3 bucket. The following example uses an AWS CLI command to upload the model the to the Amazon S3 bucket you created earlier in a directory called `models`. Type in the following into your Jupyter Notebook:

   ```bash
   !aws s3 cp mobilenet-v2.tar.gz s3://{bucket}/models/
   ```

   4. **Compile your model with SageMaker Neo.**

   Compile your machine learning model with SageMaker Neo for an edge device. You need to know your Amazon S3 bucket URL where you stored the trained model, the machine learning framework you used to train your model, the shape of your model's input, and your target device.

   For the MobileNet V2 model, use the following:

   ```python
   framework = 'tensorflow'
   target_device = 'jetson_nano'
   ```
SageMaker Neo requires a specific model input shape and model format based on the deep learning framework you use. For more information about how to save your model, see What input data shapes does SageMaker Neo expect? (p. 2915). For more information about devices and frameworks supported by Neo, see Supported Frameworks, Devices, Systems, and Architectures (p. 2955).

Use the CreateCompilationJob API to create a compilation job with SageMaker Neo. Provide a name to the compilation job, the SageMaker Role ARN, the Amazon S3 URI where your model is stored, the input shape of the model, the name of the framework, the Amazon S3 URI where you want SageMaker to store your compiled model, and your edge device target.

```python
# Specify the path where your model is stored
model_directory = 'models'
s3_model_uri = 's3://{}/{}/{}'.format(bucket, model_directory, tarfile_name)

# Store compiled model in S3 within the 'compiled-models' directory
compilation_output_dir = 'compiled-models'
s3_output_location = 's3://{}/{}/'.format(bucket, compilation_output_dir)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
sagemaker_client.create_compilation_job(CompilationJobName=compilation_job_name,
                                      RoleArn=sagemaker_role_arn,
                                      InputConfig={'S3Uri': s3_model_uri,
                                                   'DataInputConfig': data_shape,
                                                   'Framework': framework.upper()},
                                      OutputConfig={'S3OutputLocation': s3_output_location,
                                                    'TargetDevice': target_device},
                                      StoppingCondition={'MaxRuntimeInSeconds': 900})

5. **Package your compiled model.**

Packaging jobs take SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent. To package your model, create an edge packaging job with the create_edge_packaging API or the SageMaker console.

You need to provide the name that you used for your Neo compilation job, a name for the packaging job, a role ARN (see Setting Up (p. 2867) section), a name for the model, a model version, and the Amazon S3 bucket URI for the output of the packaging job. Note that Edge Manager packaging job names are case-sensitive. The following is an example of how to create a packaging job using the API.

```python
edge_packaging_name='edge-packaging-demo'
model_name="sample-model"
model_version="1.1"

# Output directory where you want to store the output of the packaging job
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)

Use CreateEdgePackagingJob to package your Neo-compiled model. Provide a name for your edge packaging job and the name you provided for your compilation job (in this example, it was
stored in the variable `compilation_job_name`). Also provide a name for your model, a version for your model (this is used to help you keep track of what model version you are using), and the S3 URI where you want SageMaker to store the packaged model.

```python
sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
        "S3OutputLocation": packaging_s3_output
    }
)
```

Create and Register Fleets andAuthenticate Devices

In this section you will create your AWS IoT thing object, create a device fleet, register your device fleet so it can interact with the cloud, create X.509 certificates to authenticate your devices to AWS IoT Core, associate the role alias with AWS IoT that was generated when you created your fleet, get your AWS account-specific endpoint for the credentials provider, get an official Amazon Root CA file, and upload the Amazon CA file to Amazon S3.

1. **Create AWS IoT things.**

   SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and endpoints in the AWS cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

   To connect your device to AWS IoT, you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure the IAM role for your devices.

   First, create AWS IoT thing objects with the AWS IoT client (`iot_client`) you created earlier with Boto3. The following example shows how to create two thing objects:

   ```python
   iot_thing_name = 'sample-device'
   iot_thing_type = 'getting-started-demo'

   iot_client.create_thing_type(
       thingTypeName=iot_thing_type
   )

   # Create an AWS IoT thing objects
   iot_client.create_thing(
       thingName=iot_thing_name,
       thingTypeName=iot_thing_type
   )
   ```

2. **Create your device fleet.**

   Create a device fleet with the SageMaker client object defined in a previous step. You can also use the SageMaker console to create a device fleet.

   ```python
   import time
device_fleet_name="demo-device-fleet" + str(time.time()).split('.')[0]
device_name="sagemaker-edge-demo-device" + str(time.time()).split('.')[0]
```

   Specify your IoT role ARN. This lets AWS IoT grant temporary credentials to devices.
device_model_directory='device_output'
s3_device_fleet_output = 's3:///{}/'.format(bucket, device_model_directory)

sagemaker_client.create_device_fleet(
    DeviceFleetName=device_fleet_name,
    RoleArn=iot_role_arn, # IoT Role ARN specified in previous step
    OutputConfig={
        'S3OutputLocation': s3_device_fleet_output
    }
)

An AWS IoT role alias is created when you create a device fleet. This role alias is associated with AWS IoT using the `iot_client` object in a later step.

3. **Register your device fleet.**

To interact with the cloud, you need to register your device with SageMaker Edge Manager. In this example, you register a single device with the fleet you created. To register the device, you need to provide a device name and the AWS IoT thing name as shown in the following example:

```python
# Device name should be 36 characters
device_name = "sagemaker-edge-demo-device" + str(time.time()).split('.')[0]

sagemaker_client.register_devices(
    DeviceFleetName=device_fleet_name,
    Devices=[
        {
            "DeviceName": device_name,
            "IotThingName": iot_thing_name
        }
    ]
)
```

4. **Create X.509 certificates.**

After creating the AWS IoT thing object, you must create a X.509 device certificate for your thing object. This certificate authenticates your device to AWS IoT Core.

Use the following to create a private key, public key, and a X.509 certificate file using the AWS IoT client defined (`iot_client`) earlier.

```python
# Creates a 2048-bit RSA key pair and issues an X.509 certificate using the issued public key.
create_cert = iot_client.create_keys_and_certificate(setAsActive=True)

# Get certificate from dictionary object and save in its own
with open('./device.pem.crt', 'w') as f:
    for line in create_cert['certificatePem'].split('\n'):
        f.write(line)
        f.write('
')

# Get private key from dictionary object and save in its own
with open('./private.pem.key', 'w') as f:
    for line in create_cert['keyPair']['PrivateKey'].split('\n'):
        f.write(line)
        f.write('
')

# Get a private key from dictionary object and save in its own
with open('./public.pem.key', 'w') as f:
    for line in create_cert['keyPair']['PublicKey'].split('\n'):
        f.write(line)
```
5. **Associate the role alias with AWS IoT.**

When you create a device fleet with SageMaker (sagemaker_client.create_device_fleet()), a role alias is generated for you. An AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates, and then obtain short-lived AWS credentials from an IAM role that is associated with an AWS IoT role alias. The role alias allows you to change the role of the device without having to update the device. Use DescribeDeviceFleet to get the role alias name and ARN.

```python
# Print Amazon Resource Name (ARN) and alias that has access
# to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)

# Store iot role alias string in a variable
# Grabs role ARN
full_role_alias_name = sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)
[IotRoleAlias']
start_index = full_role_alias_name.find('SageMaker') # Find beginning of role name
role_alias_name = full_role_alias_name[start_index:]
```

Use the `iot_client` to facilitate associating the role alias generated from creating the device fleet with AWS IoT:

```python
role_alias = iot_client.describe_role_alias(
    roleAlias=role_alias_name)
```

For more information about IAM role alias, see [Role alias allows access to unused services](#).

You created and registered a certificate with AWS IoT earlier for successful authentication of your device. Now, you need to create and attach a policy to the certificate to authorize the request for the security token.

```python
alias_policy = {
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "iot:AssumeRoleWithCertificate",
        "Resource": role_alias['roleAliasDescription']['roleAliasArn']
    }
}
```

```python
policy_name = 'aliaspolicy-'+ str(time.time()).split('.')[0]
aliaspolicy = iot_client.create_policy(policyName=policy_name,
    policyDocument=json.dumps(alias_policy))
```

```python
# Attach policy
iot_client.attach_policy(policyName=policy_name,
    target=create_cert['certificateArn'])
```

6. **Get your AWS account-specific endpoint for the credentials provider.**

Edge devices need an endpoint in order to assume credentials. Obtain your AWS account-specific endpoint for the credentials provider.

```python
# Get the unique endpoint specific to your AWS account that is making the call.
iot_endpoint = iot_client.describe_endpoint(
    endpointType='iot:CredentialProvider'
)
7. **Get the official Amazon root CA file and upload it to the Amazon S3 bucket.**

Use the following in your Jupyter Notebook or AWS CLI (if you use your terminal, remove the '!' magic function):

```bash
!wget https://www.amazontrust.com/repository/AmazonRootCA1.pem
```

Use the endpoint to make an HTTPS request to the credentials provider to return a security token. The following example command uses **curl**, but you can use any HTTP client.

```bash
!curl --cert device.pem.crt --key private.pem.key --cacert AmazonRootCA1.pem $endpoint
```

If the certificate is verified, upload the keys and certificate to your Amazon S3 bucket URI:

```bash
!aws s3 cp private.pem.key s3://{bucket}/authorization-files/
!aws s3 cp device.pem.crt s3://{bucket}/authorization-files/
!aws s3 cp AmazonRootCA1.pem s3://{bucket}/authorization-files/
```

Clean your working directory by moving your keys and certificate to a different directory:

```bash
# Optional - Clean up working directory
!mkdir authorization-files
!mv private.pem.key device.pem.crt AmazonRootCA1.pem authorization-files/
```

### Download and Set Up Edge Manager

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals.

In this section you will set up your device with the agent. To do so, first copy a release artifact and signing root certificate from the release bucket locally to your machine. After you unzip the release artifact, upload it to Amazon S3. Next, define and save a configuration file for the agent. A template is provided for you to copy and paste. Finally, copy the release artifacts, configuration file, and credentials to your device.

1. **Download the SageMaker Edge Manager agent.**

   The agent is released in binary format for supported operating systems. This example runs inference on a Jetson Nano which uses a Linux operating system and has an ARM64 architecture. For more information about what operating system and architecture supported devices use, see [Supported Devices, Chip Architectures, and Systems](#).

   Fetch the latest version of binaries from the SageMaker Edge Manager release bucket from the us-west-2 Region.

   ```bash
   !aws s3 ls s3://sagemaker-edge-release-store-us-west-2-linux-armv8/Releases/ | sort -r
   ```

   This returns release artifacts sorted by their version.
The version has the following format: `<MAJOR_VERSION>.<YYYY-MM-DD>.<SHA-7>`. It consists of three components:

- `<MAJOR_VERSION>`: The release version. The release version is currently set to 1.
- `<YYYY-MM-DD>`: The timestamp of the artifact release.
- `<SHA-7>`: The repository commit ID from which the release is built.

Copy the zipped TAR file locally or to your device directly. The following example shows how to copy the latest release artifact at the time this document was released.

```
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/1.20201218.81f481f/1.20201218.81f481f.tgz ./
```

Once you have the artifact, unzip the zipped TAR file. The following unzips the TAR file and stores it in a directory called `agent_demo`:

```
!mkdir agent_demo
!tar -xvfz 1.20201218.81f481f.tgz -C ./agent_demo
```

Upload the agent release artifacts to your Amazon S3 bucket. The following code example copies the content within `agent_demo` and uploads it to a directory within your Amazon S3 bucket called `agent_demo`:

```
!aws s3 cp --recursive ./agent_demo s3://{bucket}/agent_demo
```

You also need the signing root certificates from the release bucket:

```
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Certificates/us-west-2/us-west-2.pem ./
```

Upload the signing root certificate to your Amazon S3 bucket:

```
!aws s3 cp us-west-2.pem s3://{bucket}/authorization-files/
```

2. **Define a SageMaker Edge Manager agent configuration file.**

First, define the agent configuration file as follows:

```python
sagemaker_edge_config = {
    "sagemaker_edge_core_device_name": "device_name",
    "sagemaker_edge_core_device_fleet_name": "device_fleet_name",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4,
    "sagemaker_edge_core_folder_prefix": "demo_capture",
    "sagemaker_edge_core_region": "us-west-2",
    "sagemaker_edge_core_root_certs_path": "/agent_demo/certificates",
    "sagemaker_edge_provider_aws_ca_cert_file": "/agent_demo/iot-credentials/AmazonRootCA1.pem",
}
```
Replace the following:

- "device_name" with the name of your device (this string was stored in an earlier step in a variable named device_name).
- "device_fleet_name" with the name of your device fleet (this string was stored in an earlier step in a variable named device_fleet_name).
- "endpoint" with your AWS account-specific endpoint for the credentials provider (this string was stored in an earlier step in a variable named endpoint).

Next, save it as a JSON file:

```python
edge_config_file = open("sagemaker_edge_config.json", "w")
json.dump(sagemaker_edge_config, edge_config_file, indent = 6)
edge_config_file.close()
```

Upload the configuration file to your Amazon S3 bucket:

```bash
!aws s3 cp sagemaker_edge_config.json s3://{bucket}/
```

3. **Copy the release artifacts, configuration file, and credentials to your device.**

The following instructions are performed on the edge device itself.

**Note**

You must first install Python, the AWS SDK for Python (Boto3), and the AWS CLI on your edge device.

Open a terminal on your device. Create a folder to store the release artifacts, your credentials, and the configuration file.

```bash
mkdir agent_demo
cd agent_demo
```

Copy the contents of the release artifacts that you stored in your Amazon S3 bucket to your device:

```bash
# Copy release artifacts
aws s3 cp s3://<bucket-name>/agent_demo/ ./ --recursive
```

(The contents of the release artifact was stored in a directory called agent_demo in a previous step. Replace <bucket-name> and agent_demo with the name of your Amazon S3 bucket and the file path to your release artifacts, respectively.)

Go the /bin directory and make the binary files executable:

```bash
cd bin
```
chmod +x sagemaker_edge_agent_binary
chmod +x sagemaker_edge_agent_client_example

cd agent_demo

Make a directory to store your AWS IoT credentials and copy your credentials from your Amazon S3 bucket to your edge device (use the same on you define in the variable `bucket`):

```
mkdir iot-credentials
cd iot-credentials
aws s3 cp s3://<bucket-name>/authorization-files/AmazonRootCA1.pem ./
aws s3 cp s3://<bucket-name>/authorization-files/device.pem.crt ./
aws s3 cp s3://<bucket-name>/authorization-files/private.pem.key ./

cd ../
```

Make a directory to store your model signing root certificates:

```
mkdir certificates
cd certificates
aws s3 cp s3://<bucket-name>/authorization-files/us-west-2.pem ./
```

Copy your configuration file to your device:

```
#Download config file from S3
aws s3 cp s3://<bucket-name>/sagemaker_edge_config.json ./
```

Your `agent_demo` directory on your edge device should look similar to the following:

```
###agent_demo
|    | bin
|    |   
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
|    |     
```

Run Agent

In this section you will run the agent as a binary using gRPC, and check that both your device and fleet are working and collecting sample data.
1. **Launch the agent.**

   The SageMaker Edge Manager agent can be run as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or can be linked against as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux.

   This example uses gRPC to run the agent. gRPC is an open source high-performance Remote Procedure Call (RPC) framework that can run in any environment. For more information about gRPC, see the gRPC documentation.

   To use gRPC, perform the following steps:
   
   
   b. Generate server and client code using the protocol buffer compiler.
   
   c. Use the Python (or other languages supported by gRPC) gRPC API to write the server for your service.
   
   d. Use the Python (or other languages supported by gRPC) gRPC API to write a client for your service.

   The release artifact you downloaded contains a gRPC application ready for you to run the agent. The example is located within the `/bin` directory of your release artifact. The `sagemaker_edge_agent_binary` binary executable is in this directory.

   To run the agent with this example, provide the path to your socket file (.sock) and JSON .config file:

   ```
   ./bin/sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c sagemaker_edge_config.json
   ```

2. **Check your device.**

   Check that your device is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

   Provide the name of the fleet to which the device belongs and the unique device identifier. From your local machine, run the following:

   ```
   sagemaker_client.describe_device(
       DeviceName=device_name,
       DeviceFleetName=device_fleet_name
   )
   ```

   For the given model, you can see the name, model version, latest sample time, and when the last inference was made.

   ```
   {
       "DeviceName": "sample-device",
       "DeviceFleetName": "demo-device-fleet",
       "IoTThingName": "sample-thing-name-1",
       "RegistrationTime": 1600977370,
       "LatestHeartbeat": 1600977370,
       "Models": [
           {
               "ModelName": "mobilenet_v2.tar.gz",
               "ModelVersion": "1.1",
               "LatestSampleTime": 1600977370,
               "LatestInference": 1600977370
           }
       ]
   }
   ```
3. **Check your fleet.**

Check that your fleet is working with `GetDeviceFleetReport`. Provide the name of the fleet the device belongs to.

```python
sagemaker_client.get_device_fleet_report(
    DeviceFleetName=device_fleet_name
)
```

For a given model, you can see the name, model version, latest sample time, and when the last inference was made, along with the Amazon S3 bucket URI where the data samples are stored.

```
# Sample output
{
    "DeviceFleetName": "sample-device-fleet",
    "OutputConfig": {
      "S3OutputLocation": "s3://fleet-bucket/package_output",
    },
    "AgentVersions": [{"Version": "1.1", "AgentCount": 2}]
    "DeviceStats": {
      "Connected": 2,
      "Registered": 2,
    }
    "Models": [{
      "ModelName": "sample-model",
      "ModelVersion": "1.1",
      "OfflineDeviceCount": 0,
      "ConnectedDeviceCount": 2,
      "ActiveDeviceCount": 2,
      "SamplingDeviceCount": 100
    ]
}
```

---

**Set Up Devices and Fleets**

Fleets are collections of logically grouped devices you can use to collect and analyze data. You can use SageMaker Edge Manager to operate machine learning models on a fleet of smart cameras, smart speakers, robots, and other edge devices.

Create a fleet and register your devices either programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console.

**Topics**

- Create a Fleet (p. 2880)
- Register a Device (p. 2884)
- Check Status (p. 2886)

**Create a Fleet**

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console [https://console.aws.amazon.com/sagemaker](https://console.aws.amazon.com/sagemaker).
Create a Fleet (Boto3)

Use the `CreateDeviceFleet` API to create a fleet. Specify a name for the fleet, your AWS IoT Role ARN for the `RoleArn` field, as well as an Amazon S3 URI where you want the device to store sampled data.

You can optionally include a description of the fleet, tags, and an AWS KMS Key ID.

```python
import boto3

# Create SageMaker client so you can interact and manage SageMaker resources
sagemaker_client = boto3.client("sagemaker", region_name="aws-region")

sagemaker_client.create_device_fleet(
    DeviceFleetName="sample-fleet-name",
    RoleArn="arn:aws:iam::999999999:role/rolename", # IoT Role ARN
    Description="fleet description",
    OutputConfig={
        S3OutputLocation="s3://bucket/",
        KMSKeyId: "1234abcd-12ab-34cd-56ef-1234567890ab",
    },
    Tags=[
        {
            "Key": "string",
            "Value" : "string"
        }
    ],
)
```

An AWS IoT Role Alias is created for you when you create a device fleet. The AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates and then obtain short-lived AWS credentials from an IAM role that is associated with the AWS IoT role alias.

Use `DescribeDeviceFleet` to get the role alias name and ARN.

```python
# Print Amazon Resource Name (ARN) and alias that has access
# to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)['IotRoleAlias']
```

Use `DescribeDeviceFleet` API to get a description of fleets you created.

```python
sagemaker_client.describe_device_fleet(
    DeviceFleetName="sample-fleet-name"
)
```

By default, it returns the name of the fleet, the device fleet ARN, the Amazon S3 bucket URI, the IAM role, the role alias created in AWS IoT, a timestamp of when the fleet was created, and a timestamp of when the fleet was last modified.

```json
{
    "DeviceFleetName": "sample-fleet-name",
    "IAMRole": "arn:aws:iam::9999999999:role/rolename",
    "Description": "this is a sample fleet",
    "OutputConfig": {
        "S3OutputLocation": "s3://bucket/folder",
        "KMSKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab"
    },
}
```
Create a Fleet (Console)

You can create a Edge Manager packaging job using the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker.

1. In the SageMaker console, choose **Edge Manager** and then choose **Edge device fleets**.
2. Choose **Create device fleet**.
3. Enter a name for the device fleet in the **Device fleet name** field. Choose **Next**.
4. On the **Output configuration** page, specify the Amazon S3 bucket URI where you want to store sample data from your device fleet. You can optionally add an encryption key as well by electing an existing AWS KMS key from the dropdown list or by entering a key's ARN. Choose **Submit**.
5. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the Device fleet tags section.

Register a Device

**Important**

Device registration is required to use any part of SageMaker Edge Manager.

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console at https://console.aws.amazon.com/sagemaker.

**Register a Device (Boto3)**

To register your device, first create and register an AWS IoT thing object and configure an IAM role. SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and the cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

To connect your device to AWS IoT you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure IAM role for your devices.

See the Getting Started Guide for an in-depth example or the Explore AWS IoT Core services in hands-on tutorial.

Use the `register_devices` API to register your device. Provide the name of the fleet of which you want the devices to be a part, as well as a name for the device. You can optionally add a description to the device, tags, and AWS IoT thing name associated with the device.

```python
sagemaker_client.register_devices(
    DeviceFleetName="sample-fleet-name",
)"
Register a Device (Console)

You can register your device using the SageMaker console at https://console.aws.amazon.com/sagemaker.

1. In the SageMaker console, choose Edge Inference and then choose Edge devices.
2. Choose Register devices.

3. In the Device properties section, enter the name of the fleet the device belongs to under the Device fleet name field. Choose Next.

4. In the Device source section, add your devices one by one. You must include a Device Name for each device in your fleet. You can optionally provide a description (in the Description field) and an
Internet of Things (IoT) object name (in the **IoT name** field). Choose **Submit** once you have added all your devices.

The **Devices** page displays the name of the device you have added, the fleet to which it belongs, when it was registered, the last heartbeat, and the description and AWS IoT name, if you provided one.

Choose a device to view the device's details, including the device name, fleet, ARN, description, IoT Thing name, when the device was registered, and the last heartbeat.

### Check Status

Check that your device or fleet is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Use the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/) to interactively choose a fleet for a status check. You can also use the AWS SDK for Python (Boto3). The following describes different APIs from Boto3 you can use to check the status of your device or fleet. Use the API that best fits your use case.

- **Check an individual device.**

  To check the status of an individual device, use `DescribeDevice` API. A list containing one or more models is provided if a models have been deployed to the device.

  ```python
  sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
  )
  
  Running `DescribeDevice` returns:
  ```
  ```json
  { "DeviceName": "sample-device", "Description": "this is a sample device", "DeviceFleetName": "sample-device-fleet", "IoTThingName": "SampleThing", ...
  ```
Check a fleet of devices.

To check the status of the fleet, use the GetDeviceFleetReport API. Provide the name of the device fleet to get a summary of the fleet.

```python
sagemaker_client.get_device_fleet_report(
    DeviceFleetName="sample-fleet-name"
)
```

Check for a heartbeat.

Each device within a fleet periodically generates a signal, or “heartbeat”. The heartbeat can be used to check that the device is communicating with Edge Manager. If the timestamp of the last heartbeat is not being updated, the device may be failing.

Check the last heartbeat with made by a device with the DescribeDevice API. Specify the name of the device and the fleet to which the edge device belongs.

```python
sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
)
```

Package Model

SageMaker Edge Manager packaging jobs take Amazon SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent.

Topics

- Prerequisites (p. 2887)
- Package a Model (Amazon SageMaker Console) (p. 2889)
- Package a Model (Boto3) (p. 2892)

Prerequisites

To package a model, you must do the following:

1. **Compile your machine learning model with SageMaker Neo.**

   If you have not already done so, compile your model with SageMaker Neo. For more information on how to compile your model, see Compile and Deploy Models with Neo. If you are first-time user of SageMaker Neo, go through Getting Started with Neo Edge Devices.

2. **Get the name of your compilation job.**
Provide the name of the compilation job name you used when you compiled your model with SageMaker Neo. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and choose Compilation jobs to find a list of compilations that have been submitted to your AWS account. The names of submitted compilation jobs are in the Name column.

3. Get your IAM ARN.

You need an Amazon Resource Name (ARN) of an IAM role that you can use to download and upload the model and contact SageMaker Neo.

Use one of the following methods to get your IAM ARN:

- **Programmatically with the SageMaker Python SDK**

```python
import sagemaker

# Initialize SageMaker Session object so you can interact with AWS resources
sess = sagemaker.Session()

# Get the role ARN
role = sagemaker.get_execution_role()

print(role)
>> arn:aws:iam::<your-aws-account-id>:role/<your-role-name>
```

For more information about using the SageMaker Python SDK, see the SageMaker Python SDK API.

- **Using the AWS Identity and Access Management (IAM) console**

Navigate to the IAM console at https://console.aws.amazon.com/iam/. In the IAM Resources section, choose Roles to view a list of roles in your AWS account. Select or create a role that has AmazonSageMakerFullAccess, AWSIoTFullAccess, and AmazonS3FullAccess.

For more information on IAM, see What is IAM?

4. Have an S3 bucket URI.

You need to have at least one Amazon Simple Storage Service (Amazon S3) bucket URI to store your Neo-compiled model, the output of the Edge Manager packaging job, and sample data from your device fleet.

Use one of the following methods to create an Amazon S3 bucket:

- **Programmatically with the SageMaker Python SDK**

You can use the default Amazon S3 bucket during a session. A default bucket is created based on the following format: sagemaker-{region}-{aws-account-id}. To create a default bucket with the SageMaker Python SDK, use the following:

```python
import sagemaker

session=sagemaker.create_session()

bucket=session.default_bucket()
```

- **Using the Amazon S3 console**

Package a Model (Amazon SageMaker Console)

You can create a SageMaker Edge Manager packaging job using the SageMaker console at https://console.aws.amazon.com/sagemaker/. Before continuing, make sure you have satisfied the Prerequisites (p. 2887).

1. In the SageMaker console, choose Edge Inference and then choose Edge packaging jobs, as shown in the following image.

2. On the Job properties page, enter a name for your packaging job under Edge packaging job name. Note that Edge Manager packaging job names are case-sensitive. Name your model and give it a version: enter this under Model name and Model version, respectively.

3. Next, select an IAM role. You can choose a role or let AWS create a role for you. You can optionally specify a resource key ARN and job tags.

4. Choose Next.
5. Specify the name of the compilation job you used when compiling your model with SageMaker Neo in the **Compilation job name** field. Choose **Next**.
6. On the **Output configuration** page, enter the Amazon S3 bucket URI in which you want to store the output of the packaging job.

   **Output configuration**
   
   Use the fields below to specify the S3 bucket URI where you want devices to store sample data. You can also (optionally) specify a KMS key.

   **S3 bucket URI**
   
   Enter your S3 bucket URI where you want devices to store sample data.

   ![s3://bucket-example/sagmaker-edge/device-output](image)

   To find a path, [go to Amazon S3](#)

   **Encryption key - optional**
   
   Encrypt your data. Choose an existing KMS key or enter a key's ARN.

   ![No Custom Encryption](image)

   The **Status** column on the **Edge packaging** jobs page should read **IN PROGRESS**. Once the packaging job is complete, the status updates to **COMPLETED**.

   Selecting a packaging job directs you to that job's settings. The **Job settings** section displays the job name, ARN, status, creation time, last modified time, duration of the packaging job, and role ARN.

   The **Input configuration** section displays the location of the model artifacts, the data input configuration, and the machine learning framework of the model.
The **Output configuration** section displays the output location of the packaging job, the target device for which the model was compiled, and any tags you created.

7. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the **Device fleet tags** section.

## Package a Model (Boto3)

You can create a SageMaker Edge Manager packaging job with the AWS SDK for Python (Boto3). Before continuing, make sure you have satisfied the [Prerequisites](p. 2887).

To request an edge packaging job, use `CreateEdgePackagingJob`. You need to provide a name to your edge packaging job, the name of your SageMaker Neo compilation job, your role Amazon resource name (ARN), a name for your model, a version for your model, and the Amazon S3 bucket URI where you want to store the output of your packaging job. Note that Edge Manager packaging job names and SageMaker Neo compilation job names are case-sensitive.

```python
# Import AWS SDK for Python (Boto3)
import boto3

# Create Edge client so you can submit a packaging job
sagemaker_client = boto3.client("sagemaker", region_name='aws-region')

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name",
    CompilationJobName="neo-compilation-name",
    RoleArn="arn:aws:iam::99999999999:role/rolename",
    ModelName="sample-model-name",
    ModelVersion="model-version",
    OutputConfig={
        "S3OutputLocation": "s3://your-bucket/",
    },
)

You can check the status of an edge packaging job using `DescribeEdgePackagingJob` and providing the case-sensitive edge packaging job name:

```python
response = sagemaker_client.describe_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name")
```

This returns a dictionary that can be used to poll the status of the packaging job:

```python
# Optional - Poll every 30 sec to check completion status
import time

while True:
    response = sagemaker_client.describe_edge_packaging_job(
        EdgePackagingJobName="edge-packaging-name")
    if response["EdgePackagingJobStatus"] == 'Completed':
        break
    elif response["EdgePackagingJobStatus"] == 'Failed':
        raise RuntimeError('Packaging job failed')
    print('Packaging model...')
    time.sleep(30)
print('Done!')
```
For a list of packaging jobs, use `ListEdgePackagingJobs`. You can use this API to search for a specific packaging job. Provide a partial name to filter packaging job names for `NameContains`, a partial name for `ModelNameContains` to filter for jobs in which the model name contains the name you provide. Also specify with which column to sort with `SortBy`, and by which direction to sort for `SortOrder` (either Ascending or Descending).

```python
generate_client().list_edge_packaging_jobs(
    "NameContains": "sample",
    "ModelNameContains": "sample",
    "SortBy": "column-name",
    "SortOrder": "Descending"
)
```

To stop a packaging job, use `StopEdgePackagingJob` and provide the name of your edge packaging job.

```python
generate_client().stop_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name"
)
```

For a full list of Edge Manager APIs, see the Boto3 documentation.

**Edge Manager Agent**

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals. Sample data is stored in your Amazon S3 bucket.

There are two methods of installing and deploying the Edge Manager agent onto your edge devices:

1. Download the agent as a binary from the Amazon S3 release bucket. For more information, see Download and Set Up Edge Manager Agent Manually (p. 2893).
2. Use the AWS IoT Greengrass V2 console or the AWS CLI to deploy `aws.greengrass.SageMakerEdgeManager`. See Create AWS IoT Greengrass V2 Components (p. 2899).

**Download and Set Up Edge Manager Agent Manually**

Download the Edge Manager agent based on your operating system, architecture, and your AWS Region. The agent is periodically updated, so you have the option to choose your agent based on release dates and versions. Once you have the agent, create a JSON configuration file. Specify the device IoT thing name, fleet name, device credentials, and other key-value pairs. See Running SageMaker Edge Manager Agent (p. 2895) for full a list of keys you must specify in the configuration file. You can run the agent as an executable binary or link against it as a Dynamic Shared Object.

**How the Agent Works**

The agent runs on the CPU of your devices. The agent runs inference on the framework and hardware of the target device you specified during the compilation job. For example, if you compiled your model for the Jetson Nano, the agent supports the GPU in the provided Deep Learning Runtime (DLR).

The agent is released in binary format for supported operating systems. Check that your operating system is supported and meets the minimum OS requirement in the following table:

**Linux**

Version: Ubuntu 18.04
**Supported Binary Formats:** x86-64 bit (ELF binary) and ARMv8 64 bit (ELF binary)

**Windows**

**Version:** Windows 10 version 1909

**Supported Binary Formats:** x86-32 bit (DLL) and x86-64 bit (DLL)

## Installing Edge Manager Agent

To use Edge Manager agent, you first must obtain the release artifacts and a Root Certificate. The release artifacts are stored in an Amazon S3 bucket in the US-west-2 Region. To download the artifacts, specify your operating system (<OS>) and the VERSION.

Based on your operating system, replace <OS> with one of the following:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Artifacts Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows 32-bit</td>
<td>windows-x86</td>
</tr>
<tr>
<td>Windows 64-bit</td>
<td>windows-x64</td>
</tr>
<tr>
<td>Linux x64</td>
<td>linux-x64</td>
</tr>
<tr>
<td>Linux ARMv8</td>
<td>linux-armv8</td>
</tr>
</tbody>
</table>

The VERSION is broken into three components: `<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>`, where:

- **MAJOR_VERSION**: The release version. The release version is currently set to 1.
- `<YYYY-MM-DD>`: The time stamp of the artifacts release.
- **SHA-7**: The repository commit ID from which the release is built.

You must provide the MAJOR_VERSION and the time stamp in `<YYYY-MM-DD>` format. We suggest you use the latest artifact release time stamp. Use the following to get the latest time stamp.

Run the following in your command line to get the latest time stamp. Replace <OS> with your operating system:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-<OS>/Releases/ | sort -r
```

For example, if you have a Windows 32-bit OS, run:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/ | sort -r
```

This returns:

```
2020-12-01 23:33:36 0
  PRE 1.20201218.81f481f/
  PRE 1.20201207.02d0e97/
```

The return output in this example shows two release artifacts. The first release artifact file notes that the release version has a major release version of 1, a time stamp of 20201218 (in `<YYYY-MM-DD>` format), and a 81f481f SHA-7 commit ID.

**Note**

The preceding command assumes you have configured the AWS Command Line Interface. For more information, about how to configure the settings that the AWS CLI uses to interact with AWS, see [Configuring the AWS CLI](#).

Based on your operating system, use the following commands to install the artifacts:
Windows 32-bit

```bash
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/<VERSION>/sha256_hex.shasum.
```

Windows 64-bit

```bash
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x64/Releases/<VERSION>/sha256_hex.shasum.
```

Linux x86-64

```bash
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/<VERSION>/sha256_hex.shasum.
```

Linux ARMv8

```bash
```

You also must download a Root Certificate. This certificate validates model artifacts signed by AWS before loading them onto your edge devices.

Replace `<OS>` corresponding to your platform from the list of supported operation systems and replace `<REGION>` with your AWS Region.

```bash
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-<OS>/Certificates/<REGION>/<REGION>.pem.
```

Running SageMaker Edge Manager Agent

You can run SageMaker Edge Manager agent as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or you can link against it as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux. Running as a shared object (.dll) is supported on Windows.

On Linux, we recommend that you run the binary via a service that’s a part of your initialization (init) system. If you want to run the binary directly, you can do so in a terminal as shown in the following example. If you have a modern OS, there are no other installations necessary prior to running the agent, since all the requirements are statically built into the executable. This gives you flexibility to run the agent on the terminal, as a service, or within a container.

To run the agent, first create a JSON configuration file. Specify the following key-value pairs:

- `sagemaker_edge_core_device_name`: The name of the device. This device name needs to be registered along with the device fleet in the SageMaker Edge Manager console.
- `sagemaker_edge_core_device_fleet_name`: The name of the fleet the device belongs to.
- `sagemaker_edge_core_region`: AWS region associated with the device, the fleet and Amazon S3 buckets. This corresponds to the region where the device is registered and where the Amazon S3
The models themselves can be compiled with SageMaker Neo in a different region, this configuration is not related to model compilation region.

- **sagemaker_edge_core_root_certs_path**: The absolute folder path to root certificates. This is used to validate the device with the relevant AWS account.
- **sagemaker_edge_provider_aws_ca_cert_file**: The absolute path to Amazon Root CA certificate (AmazonRootCA1.pem). This is used to validate the device with the relevant AWS account. AmazonCA is a certificate owned by AWS.
- **sagemaker_edge_provider_aws_cert_file**: The absolute path to AWS IoT signing root certificate (*.pem.crt).
- **sagemaker_edge_provider_aws_cert_pk_file**: The absolute path to AWS IoT private key. (*.pem.key).
- **sagemaker_edge_provider_aws_iot_cred_endpoint**: The AWS IoT credentials endpoint (identifier.iot.region.amazonaws.com). This endpoint is used for credential validation. See Connecting devices to AWS IoT for more information.
- **sagemaker_edge_provider_provider**: This indicates the implementation of provider interface being used. The provider interface communicates with the end network services for uploads, heartbeats and registration validation. By default this is set to "Aws". We allow custom implementations of the provider interface. Can be set to None for no provider or Custom for custom implementation with relevant shared object path provided.
- **sagemaker_edge_provider_provider_path**: Provides the absolute path to the provider implementation shared object (.so or .dll file). The "Aws" provider dll/so file is provided with the agent release. This field is mandatory.
- **sagemaker_edge_provider_s3_bucket_name**: The name of your Amazon S3 bucket (not the Amazon S3 bucket URI). The bucket must have a sagemaker string within its name.
- **sagemaker_edge_log_verbose** (Boolean.): Optional. Set debug log. Select either True or False.
- **sagemaker_edge_telemetry_libsystemd_path**: For Linux only, systemd implements the agent crash counter metric. Set the absolute path of libsystemd to enable the crash counter metric. The default libsystemd path can be found by running "whereis libsystemd" in the device terminal.
- **sagemaker_edge_core_capture_data_destination**: The destination for uploading capture data. Choose either Cloud or Disk. Default is set to "Disk". Setting to "Disk" will write the input/output tensor(s) and auxiliary data to the local file system at a location of preference. When writing to "Cloud" use the Amazon S3 bucket name provided in the sagemaker_edge_provider_s3_bucket_name configuration.
- **sagemaker_edge_core_capture_data_disk_path**: Set the absolute path in the local file system, where capture data files will be written into when "Disk" is the destination. This field is not used when "Cloud" is specified as the destination.
- **sagemaker_edge_core_folder_prefix**: The parent prefix in Amazon S3 where captured data is stored when you specify "Cloud" as the capture data destination (sagemaker_edge_core_capture_data_disk_path). Captured data is stored in a sub-folder under sagemaker_edge_core_capture_data_disk_path if "Disk" is set as the data destination.
- **sagemaker_edge_core_capture_data_buffer_size** (Integer value): The capture data circular buffer size. It indicates maximum number of requests stored in the buffer.
- **sagemaker_edge_core_capture_data_batch_size** (Integer value): The capture data batch size. It indicates size of a batch of requests that are handled from the buffer. This value must to be less than sagemaker_edge_core_capture_data_buffer_size. A maximum of half the size of the buffer is recommended for batch size.
- **sagemaker_edge_core_capture_data_push_period_seconds** (Integer value): The capture data push period in seconds. A batch of requests in the buffer is handled when there are batch size requests in the buffer, or when this time period hits (whichever comes first). This configuration sets that time period.
- **sagemaker_edge_core_capture_data_base64_embed_limit** (Integer value): The limit for uploading capture data in bytes. Integer value.
Your configuration file should look similar to the following (with your specific values specified). In this example the default AWS provider ("Aws") is used and no periodic upload is specified.

```json
{
    "sagemaker_edge_core_device_name": "device-name",
    "sagemaker_edge_core_device_fleet_name": "fleet-name",
    "sagemaker_edge_core_region": "region",
    "sagemaker_edge_core_root_certs_path": "<Absolute path to root certificates>",
    "sagemaker_edge_provider_provider": "Aws",
    "sagemaker_edge_provider_provider_path": "/path/to/libprovider-aws.so",
    "sagemaker_edge_provider_aws_ca_cert_file": "<Absolute path to Amazon Root CA certificate>/AmazonRootCA1.pem",
    "sagemaker_edge_provider_aws_cert_file": "<Absolute path to AWS IoT signing root certificate>/device.pem.crt",
    "sagemaker_edge_provider_aws_cert_pk_file": "<Absolute path to AWS IoT private key>.private.pem.key",
    "sagemaker_edge_provider_aws_iot_cred_endpoint": "https://<AWS IoT Endpoint Address>",
    "sagemaker_edge_core_capture_data_destination": "Cloud",
    "sagemaker_edge_core_folder_prefix": "Amazon S3 folder prefix",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_batch_size": 10,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4000,
    "sagemaker_edge_core_capture_data_base64_embed_limit": 2,
    "sagemaker_edge_log_verbose": false
}
```

Included in the release artifact is a binary executable called `sagemaker_edge_agent_binary` in the `/bin` directory. To run the binary, use the `-a` flag to create a socket file descriptor (.sock) in a directory of your choosing and specify the path of the agent JSON config file you created with the `-c` flag.

```
./sagemaker_edge_agent_binary -a <ADDRESS_TO_SOCKET> -c <PATH_TO_CONFIG_FILE>
```

For example:

```
./sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c sagemaker_edge_config.json
```

In this example, a socket file descriptor named `sagemaker_edge_agent_example.sock` is created in the `/tmp` directory and points to a configuration file that is in the same working directory as the agent called `sagemaker_edge_config.json`.

**Deploy Model Package and Edge Manager Agent with AWS IoT Greengrass**

SageMaker Edge Manager integrates AWS IoT Greengrass version 2 to simplify accessing, maintaining, and deploying the Edge Manager agent and model to your devices. Without AWS IoT Greengrass V2, setting up your devices and fleets to use SageMaker Edge Manager requires you to manually copy the Edge Manager agent from an Amazon S3 release bucket. You use the agent to make predictions with models loaded onto your edge devices. With AWS IoT Greengrass V2 and SageMaker Edge Manager integration, you can now use AWS IoT Greengrass V2 components. Components are pre-built software modules that can connect your edge devices to AWS services or third-party service via AWS IoT Greengrass.

You must install the AWS IoT Greengrass Core software onto your device(s) if you want to use AWS IoT Greengrass V2 to deploy the SageMaker Edge Manager agent and your model. For more information about device requirements and how to set up your devices, see Setting up AWS IoT Greengrass core devices in the AWS IoT Greengrass documentation.
You use a pre-built component, an autogenerated component, and a custom component for your Edge Manager application. The public SageMaker Edge Manager component is maintained by SageMaker. The private component is autogenerated when you package your machine learning model with the `CreateEdgePackagingJob` API and specify "GreengrassV2Component" for the Edge Manager API field `PresetDeploymentType`. The third component is the inference application that is responsible for preprocessing and making inferences on your device. You must create this component. See either Create a Hello World custom component (p. 2901) in the SageMaker Edge Manager documentation or Create custom AWS IoT Greengrass components in the AWS IoT Greengrass documentation for more information on how to create custom components.

**Prerequisites**

SageMaker Edge Manager uses AWS IoT Greengrass V2 to simplify the deployment of the Edge Manager agent, your machine learning models, and your inference application to your device(s) with the use of components. To make it easier to maintain your AWS IAM roles, Edge Manager allows you to reuse your existing AWS IoT role alias. If you do not have one yet, Edge Manager generates a role alias as part of the Edge Manager packaging job. You no longer need to associate a role alias generated from the SageMaker Edge Manager packaging job with your AWS IoT Role.

Before you start, you must:

1. Install the AWS IoT Greengrass Core software. For detailed information, see [Install the AWS IoT Greengrass Core software](#).
2. Set up AWS IoT Greengrass V2. For more information, see [Install AWS IoT Greengrass Core software with manual resource provisioning](#).

   **Note**

   - Make sure the AWS IoT thing name is all lowercase and does not contain characters except (optionally) dashes (#).
   - The IAM Role must start with `SageMaker*`

3. Attach the following permission and inline policy to the IAM role created during AWS IoT Greengrass V2 setup.

   - Navigate to the IAM console https://console.aws.amazon.com/iam/.
   - Search for the role you created by typing in the role name in the **Search** field.
   - Choose your role.
   - Next, choose **Attach policies**.
   - Search for **AmazonSageMakerEdgeDeviceFleetPolicy**.
   - Select **AmazonSageMakerFullAccess** (This is an optional step that makes it easier for you to reuse this IAM role in model compilation and packaging).
   - Select **Add inline policy**.

   ```json
   {
     "Version":"2012-10-17",
     "Statement": [
       {
         "Sid":"GreengrassComponentAccess",
         "Effect":"Allow",
         "Action": [
           "greengrass:CreateComponentVersion",
           "greengrass:DescribeComponent"
         ],
         "Resource":"*"
       }
     ]
   }
   ```

   - Click **Attach policy**.
- Select Trust relationship.
- Click Edit trust relationship.
- Replace the content with the following.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "credentials.iot.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

4. Create an Edge Manager device fleet. For information on how to create a fleet, see Set Up Devices and Fleets (p. 2880).

5. Register your device with the same name as your AWS IoT thing name created during the AWS IoT Greengrass V2 setup.

6. Create at least one custom private AWS IoT Greengrass component. This component is the application that runs inference on the device. See Create a Hello World custom component (p. 2901)

**Note**

- The SageMaker Edge Manager and AWS IoT Greengrass integration only works for AWS IoT Greengrass v2.
- Both your AWS IoT thing name and Edge Manager device name must be the same.
- SageMaker Edge Manager does not load local AWS IoT certificates and call the AWS IoT credential provider endpoint directly. Instead, SageMaker Edge Manager uses the AWS IoT Greengrass v2 TokenExchangeService and it fetches a temporary credential from a TES endpoint.

**Create AWS IoT Greengrass V2 Components**

AWS IoT Greengrass uses components, a software module that is deployed to and runs on a AWS IoT Greengrass core device. You will need (at a minimum) three components:

1. A public Edge Manager Agent AWS IoT Greengrass component.
2. A model component that is autogenerated when you package your machine learning model with either the AWS SDK for Python (Boto3) API or with the SageMaker console.
3. A private, custom component for the inference application.

The Edge Manager Agent AWS IoT Greengrass component (1) deploys the Edge Manager Agent binary. The model component (2) is autogenerated when you create an edge packaging job with either the AWS SDK for Python (Boto3) API or the SageMaker console. For information on how to generate the model component, see Autogenerated Component (p. 2900).
The private custom component (3) is the application that you use to implement the Edge Manager Agent client application, as well as do any preprocessing and post-processing of the inference results. For more information about how to create a custom component, see Autogenerated Component (p. 2900) or Create custom AWS IoT Greengrass components.

**Autogenerated Component**

Generate the model component with the `CreateEdgePackagingJob` API and specify GreengrassV2Component for the SageMaker Edge Manager packaging job API field `PresetDeploymentType`. When you call the `CreateEdgePackagingJob` API, Edge Manager takes your SageMaker Neo–compiled model in Amazon S3 and creates a model component. The model component is automatically stored in your account. You can view any of your components by navigating to the AWS IoT console https://console.aws.amazon.com/iot/. Select Greengrass and then select Core devices. The page has a list of AWS IoT Greengrass core devices associated with your account. If a model component name is not specified in `PresetDeploymentConfig`, the default name generated consists of "SagemakerEdgeManager" and the name of your SageMaker Edge Manager packaging job. The following example demonstrates how to specify Edge Manager to create a AWS IoT Greengrass V2 component with the CreateEdgePackagingJob API.

```python
import sagemaker
import boto3

# Create a SageMaker client object to make it easier to interact with other AWS services.
sagemaker_client = boto3.client('sagemaker', region='<YOUR_REGION>')

# Replace with your IAM Role ARN
sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

# Replace string with the name of your already created S3 bucket.
bucket = 'edge-manager-demo-bucket'

# Specify a name for your edge packaging job.
edge_packaging_name = "edge_packag_job_demo"

# Replace the following string with the name you used for the SageMaker Neo compilation job.
compilation_job_name = "getting-started-demo"

# The name of the model and the model version.
model_name = "sample-model"
model_version = "1.1"

# Output directory in S3 where you want to store the packaged model.
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)

# The name you want your Greengrass component to have.
component_name = "SagemakerEdgeManager" + edge_packaging_name

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
        "S3OutputLocation": packaging_s3_output,
        "PresetDeploymentType":"GreengrassV2Component",
        "PresetDeploymentConfig":{"ComponentName":"sample-component-name", "ComponentVersion":1.0.2}"
    }
)
```
You can also create the autogenerated component with the SageMaker console. Follow steps 1-6 in Package a Model (Amazon SageMaker Console) (p. 2889)

Enter the Amazon S3 bucket URI where you want to store the output of the packaging job and optional encryption key.

Complete the following to create the model component:

1. Choose **Preset deployment**.
2. Specify the name of the component for the **Component name** field.
3. Optionally, provide a description of the component, a component version, the platform OS, or the platform architecture for the **Component description**, **Component version**, **Platform OS**, and **Platform architecture**, respectively.
4. Choose **Submit**.

Create a Hello World custom component

The custom application component is used to perform inference on the edge device. The component is responsible for loading models to SageMaker Edge Manager, invoking the Edge Manager agent for inference, and unloading the model when the component is shut down. Before you create your component, ensure the agent and application can communicate with SageMaker Edge Manager. To do this, configure gRPC. The SageMaker Edge Manager agent uses methods defined in Protobuf Buffers and the gRPC server to establish communication with the client application on the edge device and the cloud.

To use gRPC, you must:

1. Create a gRPC stub using the .proto file provided when you download the Edge Manager agent from Amazon S3 release bucket.
2. Write client code with the language you prefer.

You do not need to define the service in a .proto file (1). The service .proto files are included in the compressed TAR file when you download the SageMaker Edge Manager agent release binary from the Amazon S3 release bucket.

Install gRPC and other necessary tools on your host machine and create gRPC stubs `agent_pb2_grpc.py` and `agent_pb2.py` in Python. Make sure you have `agent.proto` in your local directory.

```bash
pip install grpcio
pip install grpcio-tools
python3 -m grpc_tools.protoc --proto_path=. --python_out=. --grpc_python_out=. agent.proto
```

The preceding code generates the gRPC client and server interfaces from your .proto service definition (2). In other words, it creates the gRPC model in Python. The API folder contains the Protobuf specification for communicating with the agent.

Next, use the gRPC API to write a client and server for your service (2). The following example script, `edge_manager_python_example.py`, uses Python to load, list, and unload a yolov3 model to the edge device.

```python
import grpc
from PIL import Image
import agent_pb2
import agent_pb2_grpc
import os
```
model_path = '<PATH-TO-SagemakerEdgeManager-COMPONENT>'
agent_socket = 'unix:///tmp/aws.greengrass.SageMakerEdgeManager.sock'
agent_channel = grpc.insecure_channel(agent_socket, options=((‘grpc.enable_http_proxy’, 0),))
agent_client = agent_pb2_grpc.AgentStub(agent_channel)

def list_models():
    return agent_client.ListModels(agent_pb2.ListModelsRequest())

def list_model_tensors(models):
    return {
        model.name: {
            ‘inputs’: model.input_tensor_metadatas,
            ‘outputs’: model.output_tensor_metadatas
        }
        for model in list_models().models
    }

def load_model(model_name, model_path):
    load_request = agent_pb2.LoadModelRequest()
    load_request.url = model_path
    load_request.name = model_name
    return agent_client.LoadModel(load_request)

def unload_model(name):
    unload_request = agent_pb2.UnLoadModelRequest()
    unload_request.name = name
    return agent_client.UnLoadModel(unload_request)

def predict_image(model_name, image_path):
    image_tensor = agent_pb2.Tensor()
    image_tensor.byte_data = Image.open(image_path).tobytes()
    image_tensor_metadata = list_model_tensors(list_models())[model_name][‘inputs’][0]
    image_tensor.tensor_metadata.name = image_tensor_metadata.name
    image_tensor.tensor_metadata.data_type = image_tensor_metadata.data_type
    for shape in image_tensor_metadata.shape:
        image_tensor.tensor_metadata.shape.append(shape)
    predict_request = agent_pb2.PredictRequest()
    predict_request.name = model_name
    predict_request.tensors.append(image_tensor)
    predict_response = agent_client.Predict(predict_request)
    return predict_response

def main():
    try:
        unload_model(‘your-model’)
    except:
        pass

    print(‘LoadModel...’, end='')
    try:
        load_model(‘your-model’, model_path)
        print(‘done.’)
    except Exception as e:
        print()
        print(e)
Ensure `model_path` points to the name of the AWS IoT Greengrass component containing the model if you use the same client code example.

You can create your AWS IoT Greengrass V2 Hello World component once you have generated your gRPC stubs and you have your Hello World code ready. To do so:

- Upload your `edge_manager_python_example.py`, `agent_pb2_grpc.py`, and `agent_pb2.py` to your Amazon S3 bucket and note down their Amazon S3 path.
- Create a private component in the AWS IoT Greengrass V2 console and define the recipe for your component. Specify the Amazon S3 URI to your Hello World application and gRPC stub in the following recipe.

```json
---
RecipeFormatVersion: 2020-01-25
ComponentName: com.sagemaker.edgePythonExample
ComponentVersion: 1.0.0
ComponentDescription: Sagemaker Edge Manager Python example
ComponentPublisher: Amazon Web Services, Inc.
ComponentDependencies:
  - aws.greengrass.SageMakerEdgeManager:
    VersionRequirement: '>=1.0.0'
    DependencyType: HARD
Manifests:
  - Platform:
    os: linux
    architecture: '/amd64|x86/'
Lifecycle:
  install: |
    - apt-get install python3-pip
    pip3 install grpcio
    pip3 install grpcio-tools
    pip3 install protobuf
    pip3 install Pillow
  run:
    script: |
      python3 {{artifacts:path}}/edge_manager_python_example.py
Artifacts:
  - URI: <code-s3-path>
  - URI: <pb2-s3-path>
```
For detailed information about creating a Hello World recipe, see Create your first component in the AWS IoT Greengrass documentation.

**Deploy Components to Your Device**

Deploy your components with the AWS IoT console or with the AWS CLI.

**To deploy your components (console)**

Deploy your AWS IoT Greengrass components with the AWS IoT console.

1. In the AWS IoT Greengrass console at https://console.aws.amazon.com/iot/ navigation menu, choose **Deployments**.
2. On the **Components** page, on the **Public components** tab, choose `aws.greengrass.SageMakerEdgeManager`.
3. On the `aws.greengrass.SageMakerEdgeManager` page, choose **Deploy**.
4. From **Add to deployment**, choose one of the following:
   a. To merge this component to an existing deployment on your target device, choose **Add to existing deployment**, and then select the deployment that you want to revise.
   b. To create a new deployment on your target device, choose **Create new deployment**. If you have an existing deployment on your device, choosing this step replaces the existing deployment.
5. On the **Specify target** page, do the following:
   a. Under **Deployment information**, enter or modify the friendly name for your deployment.
   b. Under **Deployment targets**, select a target for your deployment, and choose **Next**. You cannot change the deployment target if you are revising an existing deployment.
6. On the **Select components** page, under **My components**, choose:
   - `com.<CUSTOM-COMPONENT-NAME>`
   - `aws.greengrass.SageMakerEdgeManager`
   - `SagemakerEdgeManager.<YOUR-PACKAGING-JOB>`
7. On the **Configure components** page, choose `com.greengrass.SageMakerEdgeManager`, and do the following.
   a. Choose **Configure component**.
   b. Under **Configuration update**, in **Configuration to merge**, enter the following configuration.

   ```json
   {
     "DeviceFleetName": "device-fleet-name",
     "BucketName": "DOC-EXAMPLE-BUCKET"
   }
   ```

   Replace `device-fleet-name` with the name of the edge device fleet that you created, and replace `DOC-EXAMPLE-BUCKET` with the name of the Amazon S3 bucket that is associated with your device fleet.
   c. Choose **Confirm**, and then choose **Next**.
8. On the **Configure advanced settings** page, keep the default configuration settings, and choose **Next**.
9. On the **Review** page, choose **Deploy**.

**To deploy your components (AWS CLI)**

1. Create a `deployment.json` file to define the deployment configuration for your SageMaker Edge Manager components. This file should look like the following example.
In the `targetArn` field, replace `targetArn` with the Amazon Resource Name (ARN) of the thing or thing group to target for the deployment, in the following format:
- Thing: `arn:aws:iot:region:account-id:thing/thingName`
- Thing group: `arn:aws:iot:region:account-id:thinggroup/thingGroupName`

In the `merge` field, replace `device-fleet-name` with the name of the edge device fleet that you created, and replace `DOC-EXAMPLE-BUCKET` with the name of the Amazon S3 bucket that is associated with your device fleet.

Replace the component versions for each component with the latest available version.

2. Run the following command to deploy the components on the device:

```bash/aws greengrassv2 create-deployment \
--cli-input-json file://path/to/deployment.json```

The deployment can take several minutes to complete. In the next step, check the component log to verify that the deployment completed successfully and to view the inference results.

For more information about deploying components to individual devices or groups of devices, see Deploy AWS IoT Greengrass components to devices.

## Manage Model

The Edge Manager agent can load multiple models at a time and make inference with loaded models on edge devices. The number of models the agent can load is determined by the available memory on the device. The agent validates the model signature and loads into memory all the artifacts produced by the edge packaging job. This step requires all the required certificates described in previous steps to be installed along with rest of the binary installation. If the model's signature cannot be validated, then loading of the model fails with appropriate return code and reason.

SageMaker Edge Manager agent provides a list of Model Management APIs that implement control plane and data plane APIs on edge devices. Along with this documentation, we recommend going through the sample client implementation which shows canonical usage of the below described APIs.
The proto file is available as a part of the release artifacts (inside the release tarball). In this doc, we list and describe the usage of APIs listed in this proto file.

**Note**
There is one-to-one mapping for these APIs on Windows release and a sample code for an application implement in C# is shared with the release artifacts for Windows. Below instructions are for running the Agent as a standalone process, applicable for to the release artifacts for Linux.

Extract the archive based on your OS. Where VERSION is broken into three components: `<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>`. See [Installing Edge Manager Agent (p. 2894)](#) for information on how to obtain the release version (`<MAJOR_VERSION>`), time stamp of the release artifact (`<YYYY-MM-DD>`), and the repository commit ID (`SHA-7`).

**Linux**

The zip archive can be extracted with the command:

```
    tar -xvzf <VERSION>.tgz
```

**Windows**

The zip archive can be extracted with the UI or command:

```
    unzip <VERSION>.tgz
```

The release artifact hierarchy (after extracting the tar/zip archive) is shown below. The agent proto file is available under api/.

```
0.20201205.7ee4b0b

**Topics**
- [Load Model (p. 2907)](#)
- [Unload Model (p. 2908)](#)
- [List Models (p. 2908)](#)
- [Describe Model (p. 2909)](#)
Load Model

The Edge Manager agent supports loading multiple models. This API validates the model signature and loads into memory all the artifacts produced by the EdgePackagingJob operation. This step requires all the required certificates to be installed along with rest of the agent binary installation. If the model's signature cannot be validated then this step fails with appropriate return code and error messages in the log.

```java
// perform load for a model
// Note:
// 1. currently only local filesystem paths are supported for loading models.
// 2. multiple models can be loaded at the same time, as limited by available device memory
// 3. users are required to unload any loaded model to load another model.
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist at the url
// 5. ALREADY_EXISTS - model with the same name is already loaded
// 6. RESOURCE_EXHAUSTED - memory is not available to load the model
// 7. FAILED_PRECONDITION - model is not compiled for the machine.
// rpc LoadModel(LoadModelRequest) returns (LoadModelResponse);
```

Input

```java
// request for LoadModel rpc call
// message LoadModelRequest {
  string url = 1;
  string name = 2;  // Model name needs to match regex "^[a-zA-Z0-9\(-*\[a-zA-Z0-9\])*\]$"
}
```

Output

```java
// response for LoadModel rpc call
// message LoadModelResponse {
  Model model = 1;
}
```

```java
// Model represents the metadata of a model
// url - url representing the path of the model
// name - name of model
// input_tensor_metadatas - TensorMetadata array for the input tensors
// output_tensor_metadatas - TensorMetadata array for the output tensors
// Note:
// 1. input and output tensor metadata could empty for dynamic models.
// message Model {
```
Unload Model

Unloads a previously loaded model. It is identified via the model alias which was provided during `loadModel`. If the alias is not found or model is not loaded then returns error.

```
// perform unload for a model
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist
// rpc UnLoadModel(UnLoadModelRequest) returns (UnLoadModelResponse);
```

Input

```
// request for UnLoadModel rpc call
// message UnLoadModelRequest {
  string name = 1; // Model name needs to match regex "^[a-zA-Z0-9]-*[a-zA-Z0-9]*$"
}
```

Output

```
// response for UnLoadModel rpc call
// message UnLoadModelResponse {}
```

List Models

Lists all the loaded models and their aliases.

```
// lists the loaded models
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// rpc ListModels(ListModelsRequest) returns (ListModelsResponse);
```

Input

```
// request for ListModels rpc call
// message ListModelsRequest {}
```
Output

```protobuf
// response for ListModels rpc call
message ListModelsResponse {
  repeated Model models = 1;
}
```

### Describe Model

Describes a model that is loaded on the agent.

```protobuf
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist at the url
// rpc DescribeModel(DescribeModelRequest) returns (DescribeModelResponse);
```

Input

```protobuf
// request for DescribeModel rpc call
message DescribeModelRequest {
  string name = 1;
}
```

Output

```protobuf
// response for DescribeModel rpc call
message DescribeModelResponse {
  Model model = 1;
}
```

### Capture Data

Allows the client application to capture input and output tensors in Amazon S3 bucket, and optionally the auxiliary. The client application is expected to pass a unique capture ID along with each call to this API. This can be later used to query status of the capture.

```protobuf
// allows users to capture input and output tensors along with auxiliary data.
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 5. ALREADY_EXISTS - capture initiated for the given capture_id
// 6. RESOURCE_EXHAUSTED - buffer is full cannot accept any more requests.
// 7. OUT_OF_RANGE - timestamp is in the future.
// 8. INVALID_ARGUMENT - capture_id is not of expected format.
```
// rpc CaptureData(CaptureDataRequest) returns (CaptureDataResponse);

Input

enum Encoding {
  CSV = 0;
  JSON = 1;
  NONE = 2;
  BASE64 = 3;
}

// AuxiliaryData represents a payload of extra data to be capture along with inputs and outputs of inference
// encoding - supports the encoding of the data
// data - represents the data of shared memory, this could be passed in two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment id and offset in bytes to location of multi-dimensional tensor array.
//
message AuxiliaryData {
  string name = 1;
  Encoding encoding = 2;
  oneof data {
    bytes byte_data = 3;
    SharedMemoryHandle shared_memory_handle = 4;
  }
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment id and offset in bytes to location of multi-dimensional tensor array.
//
message Tensor {
  TensorMetadata tensor_metadata = 1; //optional in the predict request
  oneof data {
    bytes byte_data = 4;
    // will only be used for input tensors
    SharedMemoryHandle shared_memory_handle = 5;
  }
}

// request for CaptureData rpc call
//
message CaptureDataRequest {
  string model_name = 1;
  string capture_id = 2; //uuid string
  Timestamp inference_timestamp = 3;
  repeated Tensor input_tensors = 4;
  repeated Tensor output_tensors = 5;
  repeated AuxiliaryData inputs = 6;
  repeated AuxiliaryData outputs = 7;
}

Output

//
Get Capture Status

Depending on the models loaded the input and output tensors can be large (for many edge devices). Capture to the cloud can be time consuming. So the `CaptureData()` is implemented as an asynchronous operation. A capture ID is a unique identifier that the client provides during capture data call, this ID can be used to query the status of the asynchronous call.

// allows users to query status of capture data operation
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - given capture id doesn't exist.
//
// rpc GetCaptureDataStatus(GetCaptureDataStatusRequest) returns
// (GetCaptureDataStatusResponse);

Input

// request for GetCaptureDataStatus rpc call
message GetCaptureDataStatusRequest {
  string capture_id = 1;
}

Output

enum CaptureDataStatus {
  FAILURE = 0;
  SUCCESS = 1;
  IN_PROGRESS = 2;
  NOT_FOUND = 3;
}

// response for GetCaptureDataStatus rpc call
message GetCaptureDataStatusResponse {
  CaptureDataStatus status = 1;
}

Predict

The `predict` API performs inference on a previously loaded model. It accepts a request in the form of a tensor that is directly fed into the neural network. The output is the output tensor (or scalar) from the model. This is a blocking call.

// perform inference on a model.
//
// Note:
// 1. users can chose to send the tensor data in the protobuf message or 
// through a shared memory segment on a per tensor basis, the Predict 
// method with handle the decode transparently. 
// 2. serializing large tensors into the protobuf message can be quite expensive, 
// based on our measurements it is recommended to use shared memory of 
// tenors larger than 256KB. 
// 3. SMEdge IPC server will not use shared memory for returning output tensors, 
// i.e., the output tensor data will always send in byte form encoded 
// in the tensors of PredictResponse. 
// 4. currently SMEdge IPC server cannot handle concurrent predict calls, all 
// these call will be serialized under the hood. this shall be addressed 
// in a later release. 
// Status Codes:
// 1. OK - prediction is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - when model not found
// 5. INVALID_ARGUMENT - when tenors types mismatch
//
// rpc Predict(PredictRequest) returns (PredictResponse);

// request for Predict rpc call
//
message PredictRequest {
  string name = 1;
  repeated Tensor tensors = 2;
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
//  tensor_metadata - represents metadata of the shared memory segment
//  data_or_handle - represents the data of shared memory, this could be passed in 
//  two ways:
//    a. send across the raw bytes of the multi-dimensional tensor 
//    array
//    b. send a SharedMemoryHandle which contains the posix shared 
//    memory segment 
// tensor array.
//
message Tensor {
  TensorMetadata tensor_metadata = 1; //optional in the predict request
  oneof data {
    bytes byte_data = 4; // will only be used for input tensors
    SharedMemoryHandle shared_memory_handle = 5;
  }
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
//  tensor_metadata - represents metadata of the shared memory segment
//  data_or_handle - represents the data of shared memory, this could be passed in 
//  two ways:
//    a. send across the raw bytes of the multi-dimensional tensor 
//    array
//    b. send a SharedMemoryHandle which contains the posix shared 
//    memory segment 
// tensor array.
//
message Tensor {

Optimize model performance using Neo

Neo is a capability of Amazon SageMaker that enables machine learning models to train once and run anywhere in the cloud and at the edge.

If you are a first time user of SageMaker Neo, we recommend you check out the Getting Started with Edge Devices section to get step-by-step instructions on how to compile and deploy to an edge device.

What is SageMaker Neo?

Generally, optimizing machine learning models for inference on multiple platforms is difficult because you need to hand-tune models for the specific hardware and software configuration of each platform. If you want to get optimal performance for a given workload, you need to know the hardware architecture, instruction set, memory access patterns, and input data shapes, among other factors. For traditional
software development, tools such as compilers and profilers simplify the process. For machine learning, most tools are specific to the framework or to the hardware. This forces you into a manual trial-and-error process that is unreliable and unproductive.

Neo automatically optimizes Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx. Neo is tested with computer vision models available in the model zoos across the frameworks. SageMaker Neo supports compilation and deployment for two main platforms: cloud instances (including Inferentia) and edge devices.

For more information about supported frameworks and cloud instance types you can deploy to, see Supported Instance Types and Frameworks (p. 2929) for cloud instances.

For more information about supported frameworks, edge devices, operating systems, chip architectures, and common machine learning models tested by SageMaker Neo for edge devices, see Supported Frameworks, Devices, Systems, and Architectures (p. 2955) for edge devices.

How it Works

Neo consists of a compiler and a runtime. First, the Neo compilation API reads models exported from various frameworks. It converts the framework-specific functions and operations into a framework-agnostic intermediate representation. Next, it performs a series of optimizations. Then it generates binary code for the optimized operations, writes them to a shared object library, and saves the model definition and parameters into separate files. Neo also provides a runtime for each target platform that loads and executes the compiled model.

You can create a Neo compilation job from either the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the SageMaker SDK. For information on how to compile a model, see Use Neo to Compile a Model (p. 2915). With a few CLI commands, an API invocation, or a
few clicks, you can convert a model for your chosen platform. You can deploy the model to a SageMaker endpoint or on an AWS IoT Greengrass device quickly.

Neo can optimize models with parameters either in FP32 or quantized to INT8 or FP16 bit-width.

### Neo Sample Notebooks

For sample notebooks that use SageMaker Neo to train, compile, optimize, and deploy machine learning models to make inferences, see:

- MNIST Training, Compilation and Deployment with MXNet Module
- MNIST Training, Compilation and Deployment with Tensorflow Module
- Deploying pre-trained PyTorch vision models with SageMaker Neo
- Model Optimization with an Image Classification Example
- Model Optimization with XGBoost Example

For instructions on how to run these example notebooks in SageMaker, see Example Notebooks (p. 298). If you need instructions on how to create a notebook instance to run these examples, see Use Amazon SageMaker Notebook Instances (p. 283). To navigate to the relevant example in your notebook instance, choose the Amazon SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab, then choose Create copy.

### Use Neo to Compile a Model

This section shows how to create, describe, stop, and list compilation jobs. The following options are available in Amazon SageMaker Neo for managing the compilation jobs for machine learning models: the Neo CLI, the Amazon SageMaker console, or the Amazon SageMaker SDK.

**Topics**

- Prepare Model for Compilation (p. 2915)
- Compile a Model (AWS Command Line Interface) (p. 2921)
- Compile a Model (Amazon SageMaker Console) (p. 2923)
- Compile a Model (Amazon SageMaker SDK) (p. 2928)

### Prepare Model for Compilation

SageMaker Neo requires machine learning models satisfy specific input data shape. The input shape required for compilation depends on the deep learning framework you use. Once your model input shape is correctly formatted, save your model according to the requirements below. Once you have a saved model, compress the model artifacts.

**Topics**

- What input data shapes does SageMaker Neo expect? (p. 2915)
- Saving Models for SageMaker Neo (p. 2917)

### What input data shapes does SageMaker Neo expect?

Before you compile your model, make sure your model is formatted correctly. Neo expects the name and shape of the expected data inputs for your trained model with JSON format or list format. The expected inputs are framework specific.

Below are the input shapes SageMaker Neo expects:
Keras

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Note that while Keras model artifacts should be uploaded in NHWC (channel-last) format, DataInputConfig should be specified in NCHW (channel-first) format. The dictionary formats required are as follows:

- For one input: `{'input_1':[1,3,224,224]}
- For two inputs: `{'input_1':[1,3,224,224], 'input_2':[1,3,224,224]}

MXNet/ONNX

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{data':[1,3,1024,1024]}
- For two inputs: `{var1': [1,1,28,28], 'var2':[1,1,28,28]}

PyTorch

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Alternatively, you can specify the shape only using a list format. The dictionary formats required are as follows:

- For one input in dictionary format: `{'input0':[1,3,224,224]}
- For one input in list format: `[1,3,224,224]`
- For two inputs in dictionary format: `{'input0':[1,3,224,224], 'input1':[1,3,224,224]}
- For two inputs in list format: `[1,3,224,224], [1,3,224,224]`

TensorFlow

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{input':[1,1024,1024,3]}
- For two inputs: `{data1': [1,28,28,1], 'data2':[1,28,28,1]}

TFLite

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{input':[1,224,224,3]}

Note

SageMaker Neo only supports TensorFlow Lite for edge device targets. For a list of supported SageMaker Neo edge device targets, see the SageMaker Neo Devices (p. 2957) page. For a list of supported SageMaker Neo cloud instance targets, see the SageMaker Neo Supported Instance Types and Frameworks (p. 2929) page.

XGBoost

An input data name and shape are not needed.
Saving Models for SageMaker Neo

The following code examples show how to save your model to make it compatible with Neo. Models must be packaged as compressed tar files (*.tar.gz).

**Keras**

Keras models require one model definition file (*.h5).

There are two options for saving your Keras model in order to make it compatible for SageMaker Neo:

1. Export to .h5 format with `model.save("<model-name>", save_format="h5")`.
2. Freeze the SavedModel after exporting.

Below is an example of how to export a tf.keras model as a frozen graph (option two):

```python
import os
import tensorflow as tf
from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras import backend

tf.keras.backend.set_learning_phase(0)
model = tf.keras.applications.ResNet50(weights='imagenet', include_top=False,
    input_shape=(224, 224, 3), pooling='avg')
model.summary()

# Save as a SavedModel
export_dir = 'saved_model/'
model.save(export_dir, save_format='tf')

# Freeze saved model
input_node_names = [inp.name.split(':')[0] for inp in model.inputs]
output_node_names = [output.name.split(':')[0] for output in model.outputs]
print("Input names: ", input_node_names)
with tf.Session() as sess:
    loaded = tf.saved_model.load(sess, export_dir=export_dir, tags=['serve'])
    frozen_graph = tf.graph_util.convert_variables_to_constants(sess,
        sess.graph.as_graph_def(),
        output_node_names)

    tf.io.write_graph(graph_or_graph_def=frozen_graph, logdir=".", name="frozen_graph.pb",
        as_text=False)

import tarfile
tar = tarfile.open("frozen_graph.tar.gz", "w:gz")
tar.add("frozen_graph.pb")
tar.close()
```

**Warning**

Do not export your model with the SavedModel class using `model.save(<path>, save_format='tf')`. This format is suitable for training, but it is not suitable for inference.

**MXNet**

MXNet models must be saved as a single symbol file *.symbol.json and a single parameter *.params files.

**Gluon Models**

Define the neural network using the HybridSequential Class. This will run the code in the style of symbolic programming (as opposed to imperative programming).

```python
from mxnet import nd, sym
```
Amazon SageMaker Developer Guide
Compile Models
from mxnet.gluon import nn
def get_net():
net = nn.HybridSequential() # Here we use the class HybridSequential.
net.add(nn.Dense(256, activation='relu'),
nn.Dense(128, activation='relu'),
nn.Dense(2))
net.initialize()
return net
# Define an input to compute a forward calculation.
x = nd.random.normal(shape=(1, 512))
net = get_net()
# During the forward calculation, the neural network will automatically infer
# the shape of the weight parameters of all the layers based on the shape of
# the input.
net(x)
# hybridize model
net.hybridize()
net(x)
# export model
net.export('<model_name>') # this will create model-symbol.json and model-0000.params
files
import tarfile
tar = tarfile.open("<model_name>.tar.gz", "w:gz")
for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
tar.add(name)
tar.close()

For more information about hybridizing models, see the MXNet hybridize documentation.
Gluon Model Zoo (GluonCV)
GluonCV model zoo models come pre-hybridized. So you can just export them.
import numpy as np
import mxnet as mx
import gluoncv as gcv
from gluoncv.utils import export_block
import tarfile
net = gcv.model_zoo.get_model('<model_name>', pretrained=True) # For example, choose
<model_name> as resnet18_v1
export_block('<model_name>', net, preprocess=True, layout='HWC')
tar = tarfile.open("<model_name>.tar.gz", "w:gz")
for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
tar.add(name)
tar.close()

Non Gluon Models
All non-Gluon models when saved to disk use *-symbol and *.params ﬁles. They are therefore
already in the correct format for Neo.
# Pass the following 3 parameters: sym, args, aux
mx.model.save_checkpoint('<model_name>',0,sym,args,aux) # this will create
<model_name>-symbol.json and <model_name>-0000.params files

2918


import tarfile
    tar = tarfile.open("<model_name>.tar.gz", "w:gz")
    for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
        tar.add(name)
    tar.close()

**PyTorch**

PyTorch models must be saved as a definition file (`.pt` or `.pth`) with input datatype of `float32`.

To save your model, use `torch.jit.trace` followed by `torch.save`. This will save an object to a disk file and by default uses Python pickle (`pickle_module=pickle`) to save the objects and some metadata. Next, convert the saved model to a compressed tar file.

```python
import torchvision
import torch

model = torchvision.models.resnet18(pretrained=True)
model.eval()
inp = torch.rand(1, 3, 224, 224)
model_trace = torch.jit.trace(model, inp)

# Save your model. The following code saves it with the .pth file extension
model_trace.save('model.pth')

# Save as a compressed tar file
import tarfile
with tarfile.open('model.tar.gz', 'w:gz') as f:
    f.add('model.pth')
    f.close()
```

**TensorFlow**

TensorFlow requires one `.pb` or one `.pbtxt` file and a variables directory that contains variables. For frozen models, only one `.pb` or `.pbtxt` file is required.

**Pre-Trained Model**

The following code example shows how to use the `tar` Linux command to compress your model. Run the following in your terminal or in a Jupyter notebook (if you use a Jupyter notebook, insert the `!` magic command at the beginning of the statement):

```bash
# Download SSD_MobileNet trained model
!wget http://download.tensorflow.org/models/object_detection/
ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# unzip the compressed tar file
!tar xvf ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# Compress the tar file and save it in a directory called 'model.tar.gz'
!tar czvf model.tar.gz ssd_mobilenet_v2_coco_2018_03_29/frozen_inference_graph.pb
```

The command flags used in this example accomplish the following:

- **c**: Create an archive
- **z**: Compress the archive with gzip
- **v**: Display archive progress
- **f**: Specify the filename of the archive
**Built-In Estimators**

Built-in estimators are either made by framework-specific containers or algorithm-specific containers. Estimator objects for both the built-in algorithm and framework-specific estimator saves the model in the correct format for you when you train the model using the built-in `.fit` method.

For example, you can use a `sagemaker.TensorFlow` to define a TensorFlow estimator:

```python
from sagemaker.tensorflow import TensorFlow
estimator = TensorFlow(entry_point='mnist.py',
    role=role,  # param role can be arn of a sagemaker execution role
    framework_version='1.15.3',
    py_version='py3',
    training_steps=1000,
    evaluation_steps=100,
    instance_count=2,
    instance_type='ml.c4.xlarge')
```

Then train the model with `.fit` built-in method:

```python
estimator.fit(inputs)
```

Before finally compiling model with the build in `compile_model` method:

```python
# Specify output path of the compiled model
output_path = '/'.join(estimator.output_path.split('/')[:-1])

# Compile model
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
    input_shape={'data':[1, 784]},  # Batch size 1, 3 channels, 224x224 Images.
    output_path=output_path,
    framework='tensorflow', framework_version='1.15.3')
```

You can also use the `sagemaker.estimator.Estimator` Class to initialize an estimator object for training and compiling a built-in algorithm with the `compile_model` method from the SageMaker Python SDK:

```python
import sagemaker
from sagemaker.image_uris import retrieve
sagemaker_session = sagemaker.Session()
aws_region = sagemaker_session.boto_region_name

# Specify built-in algorithm training image
training_image = retrieve(framework='image-classification',
    region=aws_region, image_scope='training')

training_image = retrieve(framework='image-classification', region=aws_region,
    image_scope='training')

# Create estimator object for training
estimator = sagemaker.estimator.Estimator(image_uri=training_image,
    role=role,  # param role can be arn of a sagemaker execution role
    instance_count=1,
    instance_type='ml.p3.8xlarge',
    volume_size = 50,
    max_run = 360000,
    input_mode = 'File',
    output_path=s3_training_output_location,
    base_job_name='image-classification-training')
```
# Setup the input data_channels to be used later for training.

```python
train_data = sagemaker.inputs.TrainingInput(s3_training_data_location,
                                           content_type='application/x-recordio',
                                           s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3_validation_data_location,
                                                content_type='application/x-recordio',
                                                s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}
```

# Train model

```python
estimator.fit(inputs=data_channels, logs=True)
```

# Compile model with Neo

```python
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
                                            input_shape={'data':[1, 3, 224, 224],
                                                         'softmax_label':[1]},
                                            output_path=s3_compilation_output_location,
                                            framework='mxnet',
                                            framework_version='1.7')
```

For more information about compiling models with the SageMaker Python SDK, see Compile a Model (Amazon SageMaker SDK) (p. 2928).

## Compile a Model (AWS Command Line Interface)

This section shows how to manage Amazon SageMaker Neo compilation jobs for machine learning models using AWS Command Line Interface (CLI). You can create, describe, stop, and list the compilation jobs.

1. **Create a Compilation Job**

   With the `CreateCompilationJob` API operation, you can specify the data input format, the S3 bucket in which to store your model, the S3 bucket to which to write the compiled model, and the target hardware device or platform.

   The following table demonstrates how to configure `CreateCompilationJob` API based on whether your target is a device or a platform.

   **Device Example**

   ```json
   {
     "CompilationJobName": "neo-compilation-job-demo",
     "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmdd2hmmss",
     "InputConfig": {
       "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
       "DataInputConfig": 
         {
           "data": [1,3,1024,1024]
         },
       "Framework": "MXNET"
     },
     "OutputConfig": {
       "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
       "TargetDevice": "ml_c5"
     },
     "StoppingCondition": 
       {
         "MaxRuntimeInSeconds": 300
       }
   }
   ```

2921
You can optionally specify the framework version you used with the `FrameworkVersion` field if you used the PyTorch framework to train your model and your target device is a `ml_*` target.

```json
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "PYTORCH",
        # The FrameworkVersion field is only supported when compiling for PyTorch framework and ml_* targets,
        # excluding ml_inf. Supported values are 1.4 or 1.5 or 1.6. Default is 1.6
        "FrameworkVersion": "1.6"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        # A target device specification example for a ml_c5 instance family
        "TargetDevice": "ml_c5",
        # When compiling for ml_* instances using PyTorch framework, use the
        "CompilerOptions" field in
        # OutputConfig to provide the correct data type ("dtype") of the model’s input. Default assumed is "float32"
        "CompilerOptions": "{'dtype': 'long'}"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

**Note**

This API field is only supported for PyTorch.

**Platform Example**

```json
{
    "CompilationJobName": "neo-test-compilation-job",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        # A target platform configuration example for a p3.2xlarge instance
        "TargetPlatform": {
            "Os": "LINUX",
            "Arch": "X86_64",
            "Accelerator": "NVIDIA"
        },
        "CompilerOptions": "{'cuda-ver': '10.0', 'trt-ver': '6.0.1', 'gpu-code': 'sm_70'}"
    }
}
```
Note

For the OutputConfig API operation, the TargetDevice and TargetPlatform API operations are mutually exclusive. You have to choose one of the two options.

To find the JSON string examples of DataInputConfig depending on frameworks, see What input data shapes Neo expects.

For more information about setting up the configurations, see the InputConfig, OutputConfig, and TargetPlatform API operations in the SageMaker API reference.

2. After you configure the JSON file, run the following command to create the compilation job:

```bash
aws sagemaker create-compilation-job \
--cli-input-json file://job.json \
--region us-west-2
# You should get CompilationJobArn
```

3. Describe the compilation job by running the following command:

```bash
aws sagemaker describe-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2
```

4. Stop the compilation job by running the following command:

```bash
aws sagemaker stop-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2
# There is no output for compilation-job operation
```

5. List the compilation job by running the following command:

```bash
aws sagemaker list-compilation-jobs \
--region us-west-2
```

**Compile a Model (Amazon SageMaker Console)**

You can create an Amazon SageMaker Neo compilation job in the Amazon SageMaker console.

1. In the Amazon SageMaker console, choose Compilation jobs, and then choose Create compilation job.
2. On the Create compilation job page, under Job name, enter a name. Then select an IAM role.

3. If you don’t have an IAM role, choose Create a new role.

4. On the Create an IAM role page, choose Any S3 bucket, and choose Create role.
5. Non PyTorch Frameworks

Within the Input configuration section, enter the full path of the Amazon S3 bucket URI that contains your model artifacts in the Location of model artifacts input field. Your model artifacts must be in a compressed tarball file format (.tar.gz).

For the Data input configuration field, enter the JSON string that specifies the shape of the input data. For Machine learning framework, choose the framework of your choice.

Input configuration
Amazon SageMaker needs to know where model artifacts are stored, what the shape of the data matrix is, and which machine learning framework to use. Learn more

Location of model artifacts
Amazon SageMaker needs the path to the model artifacts in Amazon S3. To find the path, look in your Amazon S3 directories.

s3://bucket-example/detect.tar.gz
To find a path, go to Amazon S3

Data input configuration
Amazon SageMaker needs to know what the shape of the data matrix is.

("data": [1, 224, 224, 3])

Machine learning framework
Choose the machine learning framework that your model was trained in.

TensorFlow

To find the JSON string examples of input data shapes depending on frameworks, see What input data shapes Neo expects.

PyTorch Framework

Similar instructions apply for compiling PyTorch models. However, if you trained with PyTorch and are trying to compile the model for ml_* (except ml_inf) target, you can optionally specify the version of PyTorch you used.
Compile Models

To find the JSON string examples of input data shapes depending on frameworks, see What input data shapes Neo expects.

Note
When compiling for ml_* instances using PyTorch framework, use Compiler options field in Output Configuration to provide the correct data type (dtype) of the model’s input. The default is set to "float32".

Warning
If you specify a Amazon S3 bucket URI path that leads to .pth file, you will receive the following error after starting compilation: ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file.
6. Go to the **Output configuration** section. Choose where you want to deploy your model. You can deploy your model to a **Target device** or a **Target platform**. Target devices include cloud and edge devices. Target platforms refer to specific OS, architecture, and accelerators you want your model to run on.

For **S3 Output location**, enter the path to the S3 bucket where you want to store the model. You can optionally add compiler options in JSON format under the **Compiler options** section.

7. Check the status of the compilation job when started. This status of the job can be found at the top of the **Compilation Job** page, as shown in the following screenshot. You can also check the status of it in the **Status** column.

8. Check the status of the compilation job when completed. You can check the status in the **Status** column as shown in the following screenshot.
Compile a Model (Amazon SageMaker SDK)

You can use the `compile_model` API in the Amazon SageMaker SDK for Python to compile a trained model and optimize it for specific target hardware. The API should be invoked on the estimator object used during model training.

**Note**
You must set `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable to 500 when compiling the model with MXNet or PyTorch. The environment variable is not needed for TensorFlow.

The following is an example of how you can compile a model using the `trained_model_estimator` object:

```python
# Replace the value of expected_trained_model_input below and
# specify the name & shape of the expected inputs for your trained model
# in json dictionary form
expected_trained_model_input = {'data':[1, 784]}

# Replace the example target_instance_family below to your preferred target_instance_family
compiled_model = trained_model_estimator.compile_model(target_instance_family='ml_c5',
input_shape=expected_trained_model_input,
output_path='insert s3 output path',
env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'})
```

The code compiles the model, saves the optimized model at `output_path`, and creates a SageMaker model that can be deployed to an endpoint. Sample notebooks of using the SDK for Python are provided in the Neo Model Compilation Sample Notebooks section.

Cloud Instances

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks such as TensorFlow, PyTorch, MXNet, and more. You can deploy your compiled model to cloud instances and AWS Inferentia instances. For a full list of supported frameworks and instances types, see Supported Instances Types and Frameworks.

You can compile your model in one of three ways: through the AWS CLI, the SageMaker Console, or the SageMaker SDK for Python. See, Use Neo to Compile a Model for more information. Once compiled, your model artifacts are stored in the Amazon S3 bucket URI you specified during the compilation job. You can deploy your compiled model to cloud instances and AWS Inferentia instances using the SageMaker SDK for Python, AWS SDK for Python (Boto3), AWS CLI, or the AWS console.

If you deploy your model using AWS CLI, the console, or Boto3, you must select a Docker image Amazon ECR URI for your primary container. See Neo Inference Container Images for a list of Amazon ECR URIs.

Topics
- Supported Instance Types and Frameworks (p. 2929)
### Supported Instance Types and Frameworks

Amazon SageMaker Neo supports popular deep learning frameworks for both compilation and deployment. You can deploy your model to cloud instances, AWS Inferentia instance types, or Amazon Elastic Inference accelerators.

The following describes frameworks SageMaker Neo supports and the target cloud instances you can compile and deploy to. For information on how to deploy your compiled model to a cloud or Inferentia instance, see [Deploy a Model with Cloud Instances](#). For information on how to deploy your compiled model with Elastic Inference accelerators, see [Use EI on Amazon SageMaker Hosted Endpoints](#).

### Cloud Instances

SageMaker Neo supports the following deep learning frameworks for CPU and GPU cloud instances:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.8.0</td>
<td>Supports 1.8.0 or earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>ONNX</td>
<td>1.7.0</td>
<td>Supports 1.7.0 or earlier</td>
<td>Image Classification, SVM</td>
<td>One model file (.onnx)</td>
<td></td>
</tr>
<tr>
<td>Keras</td>
<td>2.2.4</td>
<td>Supports 2.2.4 or earlier</td>
<td>Image Classification</td>
<td>One model definition file (.h5)</td>
<td></td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.4, 1.5, 1.6, 1.7 or 1.8</td>
<td>Supports 1.4, 1.5, 1.6, 1.7 and 1.8</td>
<td>Image Classification</td>
<td>One model definition file (.pt or .pth) with input dtype of float32</td>
<td></td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15.3 or 2.4</td>
<td>Supports 1.15.3 and 2.4</td>
<td>Image Classification</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory</td>
<td></td>
</tr>
</tbody>
</table>
### Frameworks and Models

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>XGBoost</td>
<td>1.3.3</td>
<td>Supports 1.3.3 or earlier</td>
<td>Decision Trees</td>
<td>One XGBoost model file (.model) where the number of nodes in a tree is less than $2^{31}$</td>
<td>that contains variables For frozen models, only one .pb or .pbtxt file</td>
</tr>
</tbody>
</table>

**Note**
“Model Version” is the version of the framework used to train and export the model.

### Instance Types

You can deploy your SageMaker compiled model to one of the cloud instances listed below:

<table>
<thead>
<tr>
<th>Instance</th>
<th>Compute Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1_c4</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_c5</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_m4</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_m5</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_p2</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>m1_p3</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>m1_g4dn</td>
<td>Accelerated computing</td>
</tr>
</tbody>
</table>

For information on the available vCPU, memory, and price per hour for each instance type, see Amazon SageMaker Pricing.

**Note**
When compiling for m1_* instances using PyTorch framework, use Compiler options field in Output Configuration to provide the correct data type (dtype) of the model's input. The default is set to "float32".

### AWS Inferentia

SageMaker Neo supports the following deep learning frameworks for Inferentia:
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.5 or 1.8</td>
<td>Supports 1.8, 1.5 and earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.7, 1.8 or 1.9</td>
<td>Supports 1.9 and earlier</td>
<td>Image Classification</td>
<td>One model definition file (.pt or .pth) with input dtype of float32</td>
<td></td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15 or 2.5</td>
<td>Supports 2.5, 1.15 and earlier</td>
<td>Image Classification</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory that contains variables For frozen models, only one .pb or .pbtxt file</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

"Model Version" is the version of the framework used to train and export the model.

You can deploy your SageMaker Neo-compiled model to AWS Inferentia-based Amazon EC2 Inf1 instances. AWS Inferentia is Amazon's first custom silicon chip designed to accelerate deep learning. Currently, you can use the ml_inf1 instance to deploy your compiled models.

**Amazon Elastic Inference**

SageMaker Neo supports the following deep learning frameworks for Elastic Inference:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>2.3.2</td>
<td>Supports 2.3</td>
<td>Image Classification, Object Detection, Semantic</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory that contains variables</td>
</tr>
</tbody>
</table>
You can deploy your SageMaker Neo-compiled model to an Elastic Inference Accelerator. For more information, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2987).

### Deploy a Model

To deploy an Amazon SageMaker Neo-compiled model to an HTTPS endpoint, you must configure and create the endpoint for the model using Amazon SageMaker hosting services. Currently, developers can use Amazon SageMaker APIs to deploy modules on to ml.c5, ml.c4, ml.m5, ml.m4, ml.p3, ml.p2, and ml.inf1 instances.

For Inf1 instances, models need to be compiled specifically for ml.inf1 instances. Models compiled for other instance types are not guaranteed to work with ml.inf1 instances.

For Elastic Inference accelerators, models need to be compiled specifically for ml_eia2 devices. For information on how to deploy your compiled model to an Elastic Inference accelerator, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2987).

When you deploy a compiled model, you need to use the same instance for the target that you used for compilation. This creates a SageMaker endpoint that you can use to perform inferences. You can deploy a Neo-compiled model using any of the following: Amazon SageMaker SDK for Python, SDK for Python (Boto3), AWS Command Line Interface, and the SageMaker console https://console.aws.amazon.com/SageMaker.

#### Note
For deploying a model using AWS CLI, the console, or Boto3, see Neo Inference Container Images to select the inference image URI for your primary container.

### Topics
- Prerequisites (p. 2932)
- Deploy a Compiled Model Using SageMaker SDK (p. 2938)
- Deploy a Compiled Model Using Boto3 (p. 2941)
- Deploy a Compiled Model Using the AWS CLI (p. 2942)
- Deploy a Compiled Model Using the Console (p. 2944)

### Prerequisites

#### Note
Follow the instructions in this section if you compiled your model using AWS SDK for Python (Boto3), AWS CLI, or the SageMaker console.

To create a SageMaker Neo-compiled model, you need the following:

1. A Docker image Amazon ECR URI. You can select one that meets your needs from [this list](https://docs.aws.amazon.com/sagemaker/latest/dg/neocompile-prereqs.html).
2. An entry point script file:
   a. For PyTorch and MXNet models:
If you trained your model using SageMaker, the training script must implement the functions described below. The training script serves as the entry point script during inference. In the example detailed in MNIST Training, Compilation and Deployment with MXNet Module and SageMaker Neo, the training script (mnist.py) implements the required functions.

If you did not train your model using SageMaker, you need to provide an entry point script (inference.py) file that can be used at the time of inference. Based on the framework—MXNet or PyTorch—the inference script location must conform to the SageMaker Python SDK Model Directory Structure for MxNet or Model Directory Structure for PyTorch.

When using Neo Inference Optimized Container images with PyTorch and MXNet on CPU and GPU instance types, the inference script must implement the following functions:

- **model_fn**: Loads the model. (Optional)
- **input_fn**: Converts the incoming request payload into a numpy array.
- **predict_fn**: Performs the prediction.
- **output_fn**: Converts the prediction output into the response payload.
- Alternatively, you can define **transform_fn** to combine **input_fn**, **predict_fn**, and **output_fn**.

The following are examples of inference.py script within a directory named code (code/inference.py) for PyTorch and MXNet (Gluon and Module). The examples first load the model and then serve it on image data on a GPU:

**MXNet Module**

```python
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401
from collections import namedtuple

Batch = namedtuple('Batch', ['data'])

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    sym, arg_params, aux_params = mx.model.load_checkpoint('compiled', 0)
    mod = mx.mod.Module(symbol=sym, context=ctx, label_names=None)
    exe = mod.bind(for_training=False,
                   data_shapes=[('data', (1,3,224,224))],
                   label_shapes=mod._label_shapes)
    mod.set_params(arg_params, aux_params, allow_missing=True)

    # Run warm-up inference on empty data during model load (required for GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    mod.forward(Batch([data]))
    return mod

def transform_fn(mod, image, input_content_type, output_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
                                           mean=mx.nd.array([0.485, 0.456, 0.406]),
                                           std=mx.nd.array([0.229, 0.224, 0.225]),
                                           min=0, max=1)
```
std=mx.nd.array([0.229, 0.224, 0.225]))

transposed = normalized.transpose((2, 0, 1))
batchified = transposed.expand_dims(axis=0)
casted = batchified.astype(dtype='float32')
processed_input = casted.as_in_context(ctx)

# prediction/inference
mod.forward(Batch([processed_input]))

# post-processing
prob = mod.get_outputs()[0].asnumpy().tolist()
prob_json = json.dumps(prob)
return prob_json, output_content_type

MXNet Gluon

```python
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    block = mx.gluon.nn.SymbolBlock.imports('compiled-symbol.json',
    ['data'], 'compiled-0000.params', ctx=ctx)

    # Hybridize the model & pass required options for Neo: static_alloc=True &
    # static_shape=True
    block.hybridize(static_alloc=True, static_shape=True)

    # Run warm-up inference on empty data during model load (required for GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    warm_up = block(data)
    return block

def input_fn(image, input_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
        mean=mx.nd.array([0.485, 0.456, 0.406]),
        std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batchified = transposed.expand_dims(axis=0)
    casted = batchified.astype(dtype='float32')
    processed_input = casted.as_in_context(ctx)
    return processed_input

def predict_fn(processed_input_data, block):
    # prediction/inference
    prediction = block(processed_input_data)
    return prediction

def output_fn(prediction, output_content_type):
    # post-processing
    prob = prediction.asnumpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type
```
PyTorch 1.4 and Older

import os
import torch
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision.transforms as transforms
from PIL import Image
import io
import json
import pickle

def model_fn(model_dir):
    """Load the model and return it.
    Providing this function is optional.
    There is a default model_fn available which will load the model
    compiled using SageMaker Neo. You can override it here.
    
    Keyword arguments:
    model_dir -- the directory path where the model artifacts are present
    """

    # The compiled model is saved as "compiled.pt"
    model_path = os.path.join(model_dir, 'compiled.pt')
    with torch.jit.load(model_path):
        device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
        model = model.to(device)

            if torch.is_tensor(model_input):
                model_input = model_input.to(device)
            elif isinstance(model_input, tuple):
                model_input = (inp.to(device) for inp in model_input if torch.is_tensor(inp))
            model(*model_input)
    return model

def transform_fn(model, request_body, request_content_type, response_content_type):
    """Run prediction and return the output.
    The function
    1. Pre-processes the input request
    2. Runs prediction
    3. Post-processes the prediction output.
    """

    # preprocess
    decoded = Image.open(io.BytesIO(request_body))
    preprocess = transforms.Compose([
        transforms.Resize(256),
        transforms.CenterCrop(224),
        transforms.ToTensor(),
        transforms.Normalize(
            mean=[
            ]
            ]
        )
    model(*model_input)
    return model
0.485, 0.456, 0.406], std=[
0.229, 0.224, 0.225]),
]
normalized = preprocess(decoded)
batchified = normalized.unsqueeze(0)
# predict
device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
batchified = batchified.to(device)
output = model.forward(batchified)
return json.dumps(output.cpu().numpy().tolist()), response_content_type

PyTorch 1.5 and Newer

        transforms.CenterCrop(224),
        transforms.ToTensor(),
        transforms.Normalize(
            mean=[
        ...]
b. **For inf1 instances or onnx, xgboost, keras container images**

For all other Neo Inference-optimized container images, or inferentia instance types, the entry point script must implement the following functions for Neo Deep Learning Runtime:

- **neo_preprocess**: Converts the incoming request payload into a numpy array.
- **neo_postprocess**: Converts the prediction output from Neo Deep Learning Runtime into the response body.

**Note**

The preceding two functions do not use any of the functionalities of MXNet, PyTorch, or TensorFlow.

For examples of how to use these functions, see Neo Model Compilation Sample Notebooks.

c. **For TensorFlow models**

If your model requires custom pre- and post-processing logic before data is sent to the model, then you must specify an entry point script `inference.py` file that can be used at the time of inference. The script should implement either a either a pair of `input_handler` and `output_handler` functions or a single handler function.

**Note**

Note that if handler function is implemented, `input_handler` and `output_handler` are ignored.

The following is a code example of `inference.py` script that you can put together with the `compile model` to perform custom pre- and post-processing on an image classification model. The SageMaker client sends the image file as an `application/x-image` content type to the `input_handler` function, where it is converted to JSON. The converted image file is then sent to the TensorFlow Model Server (TFX) using the REST API.

```python
import json
import numpy as np
import json
import io
from PIL import Image

def input_handler(data, context):
    """ Pre-process request input before it is sent to TensorFlow Serving REST API
    ""
    Args:
    data (obj): the request data, in format of dict or string
    context (Context): an object containing request and configuration details
    ""
    Returns:
    (dict): a JSON-serializable dict that contains request body and headers
    """
```
If there is no custom pre- or post-processing, the SageMaker client converts the file image to JSON in a similar way before sending it over to the SageMaker endpoint.

For more information, see the Deploying to TensorFlow Serving Endpoints in the SageMaker Python SDK.

3. The Amazon S3 bucket URI that contains the compiled model artifacts.

Deploy a Compiled Model Using SageMaker SDK

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow one of the following use cases to deploy a model compiled with SageMaker Neo based on how you compiled your model.

Topics
- If you compiled your model using the SageMaker SDK (p. 2938)
- If you compiled your model using MXNet or PyTorch (p. 2939)
- If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow (p. 2940)

If you compiled your model using the SageMaker SDK

The sagemaker.Model object handle for the compiled model supplies the deploy() function, which enables you to create an endpoint to serve inference requests. The function lets you set the number and type of instances that are used for the endpoint. You must choose an instance for which you have compiled your model. For example, in the job compiled in Compile a Model (Amazon SageMaker SDK) section, this is ml_c5.

```python
predictor = compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.c5.4xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```
If you compiled your model using MXNet or PyTorch

Create the SageMaker model and deploy it using the deploy() API under the framework-specific Model APIs. For MXNet, it is MXNetModel and for PyTorch, it is PyTorchModel. When you are creating and deploying an SageMaker model, you must set MMS_DEFAULT_RESPONSE_TIMEOUT environment variable to 500 and specify the entry_point parameter as the inference script (inference.py) and the source_dir parameter as the directory location (code) of the inference script. To prepare the inference script (inference.py) follow the Prerequisites step.

The following example shows how to use these functions to deploy a compiled model using the SageMaker SDK for Python:

**MXNet**

```python
from sagemaker.mxnet import MXNetModel

# Create SageMaker model and deploy an endpoint
sm_mxnet_compiled_model = MXNetModel(
    model_data='insert S3 path of compiled MXNet model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.8.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for MXNet',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_mxnet_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

**PyTorch 1.4 and Older**

```python
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.4.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

**PyTorch 1.5 and Newer**

```python
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.8.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```
# Create SageMaker model and deploy an endpoint

```python
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.5',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
)
```

Replace the example `instance_type` below to your preferred `instance_type`

```python
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')
```

# Print the name of newly created endpoint
```python
print(predictor.endpoint_name)
```

**Note**
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

### If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow

Construct a `TensorFlowModel` object, then call `deploy`:

```python
role='AmazonSageMaker-ExecutionRole'
model_path='S3 path for model file'
framework_image='inference container arn'
tf_model = TensorFlowModel(model_data=model_path,
    framework_version='1.15.3',
    role=role,
    image_uri=framework_image)
instance_type='ml.c5.xlarge'
predictor = tf_model.deploy(instance_type=instance_type,
    initial_instance_count=1)
```

See [Deploying directly from model artifacts](https://docs.aws.amazon.com/sagemaker/latest/dg/deploy-from-model-artifacts.html) for more information.

You can select a Docker image Amazon ECR URI that meets your needs from [this list](https://aws.amazon.com/ecr/).

For more information on how to construct a `TensorFlowModel` object, see the [SageMaker SDK](https://sagemaker.readthedocs.io/en/stable/api/guide/index.html).

**Note**
Your first inference request might have high latency if you deploy your model on a GPU. This is because an optimized compute kernel is made on the first inference request. We recommend that you make a warm-up file of inference requests and store that alongside your model file before sending it off to a TFX. This is known as “warming up” the model.

The following code snippet demonstrates how to produce the warm-up file for image classification example in the prerequisites section:

```python
import tensorflow as tf
from tensorflow_serving.apis import classification_pb2
from tensorflow_serving.apis import inference_pb2
from tensorflow_serving.apis import model_pb2
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_log_pb2
import numpy as np
```
with tf.python_io.TFRecordWriter("tf_serving_warmup_requests") as writer:
    img = np.random.uniform(0, 1, size=[224, 224, 3]).astype(np.float32)
    img = np.expand_dims(img, axis=0)
    test_data = np.repeat(img, 1, axis=0)
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'compiled_models'
    request.model_spec.signature_name = 'serving_default'
    request.inputs['Placeholder:0'].CopyFrom(tf.compat.v1.make_tensor_proto(test_data,
        shape=test_data.shape, dtype=tf.float32))
    log = prediction_log_pb2.PredictionLog(
        predict_log=prediction_log_pb2.PredictLog(request=request))
    writer.write(log.SerializeToString())

For more information on how to “warm up” your model, see the TensorFlow TFX page.

**Deploy a Compiled Model Using Boto3**

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using Amazon Web Services SDK for Python (Boto3).

**Topics**
- Deploy the Model (p. 2941)

**Deploy the Model**

After you have satisfied the prerequisites, use the create_model, create_endpoint_config, and create_endpoint APIs.

The following example shows how to use these APIs to deploy a model compiled with Neo:

```python
import boto3
client = boto3.client('sagemaker')

# create sagemaker model
create_model_api_response = client.create_model(
    ModelName='my-sagemaker-model',
    PrimaryContainer={
        'Image': '<insert the ECR Image URI>',
        'ModelDataUrl': 's3://path/to/model/artifact/model.tar.gz',
        'Environment': {}},
    ExecutionRoleArn='ARN for AmazonSageMaker-
endpoint-configuration',
)

print ("create_model API response", create_model_api_response)

# create sagemaker endpoint config
create_endpoint_config_api_response = client.create_endpoint_config(
    EndpointConfigName='sagemaker-neomxnet-endpoint-configuration',
    ProductionVariants=[
        { 'VariantName': '<provide your variant name>',
          'ModelName': 'my-sagemaker-model',
          'InitialInstanceCount': 1,
          'InstanceType': '<provide your instance type here>'}])
```

2941
### Deploy a Compiled Model Using the AWS CLI

You must satisfy the **prerequisites** section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the AWS CLI.

**Topics**
- Deploy the Model (p. 2942)

### Deploy the Model

After you have satisfied the **prerequisites**, use the `create-model`, `create-endpoint-config`, and `create-endpoint` AWS CLI commands. The following steps explain how to use these commands to deploy a model compiled with Neo:
Create a Model

From Neo Inference Container Images, select the inference image URI and then use create-model API to create a SageMaker model. You can do this with two steps:

1. Create a create_model.json file. Within the file, specify the name of the model, the image URI, the path to the model.tar.gz file in your Amazon S3 bucket, and your SageMaker execution role:

   ```json
   {
      "ModelName": "insert model name",
      "PrimaryContainer": {
         "Image": "insert the ECR Image URI",
         "ModelDataUrl": "insert S3 archive URL",
         "Environment": {"See details below"}
      },
      "ExecutionRoleArn": "ARN for AmazonSageMaker-ExecutionRole"
   }
   
   If you trained your model using SageMaker, specify the following environment variable:

   "Environment": {
      "SAGEMAKER_SUBMIT_DIRECTORY": "[Full S3 path for *.tar.gz file containing the training script]"
   }

   If you did not train your model using SageMaker, specify the following environment variables:

   **MXNet and PyTorch**

   "Environment": {
      "SAGEMAKER_PROGRAM": "inference.py",
      "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
      "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
      "SAGEMAKER_REGION": "insert your region",
      "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
   }

   **TensorFlow**

   "Environment": {
      "SAGEMAKER_PROGRAM": "inference.py",
      "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
      "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
      "SAGEMAKER_REGION": "insert your region"
   }

   **Note**

   The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

2. Run the following command:

   ```bash
   aws sagemaker create-model --cli-input-json file://create_model.json
   
   For the full syntax of the create-model API, see create-model.
   ```
Create an Endpoint Configuration

After creating a SageMaker model, create the endpoint configuration using the create-endpoint-config API. To do this, create a JSON file with your endpoint configuration specifications. For example, you can use the following code template and save it as create_config.json:

```json
{
    "EndpointConfigName": "<provide your endpoint config name>",
    "ProductionVariants": [
        {
            "VariantName": "<provide your variant name>",
            "ModelName": "my-sagemaker-model",
            "InitialInstanceCount": 1,
            "InstanceType": "<provide your instance type here>",
            "InitialVariantWeight": 1.0
        }
    ]
}
```

Now run the following AWS CLI command to create your endpoint configuration:

```
aws sagemaker create-endpoint-config --cli-input-json file://create_config.json
```

For the full syntax of the create-endpoint-config API, see create-endpoint-config.

Create an Endpoint

After you have created your endpoint configuration, create an endpoint using the create-endpoint API:

```
aws sagemaker create-endpoint --endpoint-name '<provide your endpoint name>' --endpoint-config-name '<insert your endpoint config name>'
```

For the full syntax of the create-endpoint API, see create-endpoint.

Deploy a Compiled Model Using the Console

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), the AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the SageMaker console https://console.aws.amazon.com/SageMaker.

Topics
- Deploy the Model (p. 2944)

Deploy the Model

After you have satisfied the prerequisites, use the following steps to deploy a model compiled with Neo:

1. Choose Models, and then choose Create models from the Inference group. On the Create model page, complete the Model name, IAM role, and VPC fields (optional), if needed.
2. To add information about the container used to deploy your model, choose Add container container, then choose Next. Complete the Container input options, Location of inference code image, and Location of model artifacts, and optionally, Container host name, and Environmental variables fields.
3. To deploy Neo-compiled models, choose the following:

- **Container input options**: Choose **Provide model artifacts and inference image**.
- **Location of inference code image**: Choose the inference image URI from Neo Inference Container Images, depending on the AWS Region and kind of application.
- **Location of model artifact**: Enter the Amazon S3 bucket URI of the compiled model artifact generated by the Neo compilation API.
- **Environment variables**:
  - Leave this field blank for **SageMaker XGBoost**.
  - If you trained your model using SageMaker, specify the environment variable `SAGEMAKER_SUBMIT_DIRECTORY` as the Amazon S3 bucket URI that contains the training script.
  - If you did not train your model using SageMaker, specify the following environment variables:

<table>
<thead>
<tr>
<th>Key</th>
<th>Values for MXNet and PyTorch</th>
<th>Values TensorFlow</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_PROGRAM</td>
<td>inference.py</td>
<td>inference.py</td>
</tr>
<tr>
<td>SAGEMAKER_SUBMIT_DIRECTORY</td>
<td>/opt/ml/model/code</td>
<td>/opt/ml/model/code</td>
</tr>
<tr>
<td>SAGEMAKER_CONTAINER_LOG_LEVEL</td>
<td>DEVLEVEL</td>
<td>20</td>
</tr>
</tbody>
</table>
### Key

<table>
<thead>
<tr>
<th>Key</th>
<th>Values for MXNet and PyTorch</th>
<th>Values TensorFlow</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_REGION</td>
<td>&lt;your region&gt;</td>
<td>&lt;your region&gt;</td>
</tr>
<tr>
<td>MMS_DEFAULT_RESPONSE_TIMEOUT</td>
<td>500</td>
<td>Leave this field blank for TF</td>
</tr>
</tbody>
</table>

4. Confirm that the information for the containers is accurate, and then choose **Create model**. On the Create model landing page, choose **Create endpoint**.

5. In **Create and configure endpoint** diagram, specify the **Endpoint name**. For **Attach endpoint configuration**, choose **Create a new endpoint configuration**.

6. In **New endpoint configuration** page, specify the **Endpoint configuration name**.
7. Choose **Edit** next to the name of the model and specify the correct **Instance type** on the **Edit Production Variant** page. It is imperative that the **Instance type** value match the one specified in your compilation job.
8. Choose Save.
9. On the New endpoint configuration page, choose Create endpoint configuration, and then choose Create endpoint.

Request Inferences from a Deployed Service

If you have followed instructions in Deploy a Model (p. 2932), you should have a SageMaker endpoint set up and running. Regardless of how you deployed your Neo-compiled model, there are three ways you can submit inference requests:

Topics

- Request Inferences from a Deployed Service (Amazon SageMaker SDK) (p. 2949)
- Request Inferences from a Deployed Service (Boto3) (p. 2951)
- Request Inferences from a Deployed Service (AWS CLI) (p. 2952)

Request Inferences from a Deployed Service (Amazon SageMaker SDK)

Use the following the code examples to request inferences from your deployed service based on the framework you used to train your model. The code examples for the different frameworks are similar. The main difference is that TensorFlow requires application/json as the content type.
PyTorch and MXNet

If you are using PyTorch v1.4 or later or MXNet 1.7.0 or later and you have an Amazon SageMaker endpoint InService, you can make inference requests using the predictor package of the SageMaker SDK for Python.

**Note**
The API varies based on the SageMaker SDK for Python version:

- For version 1.x, use the `RealTimePredictor` and `Predict` API.
- For version 2.x, use the `Predictor` and the `Predict` API.

The following code example shows how to use these APIs to send an image for inference:

**SageMaker Python SDK v1.x**

```python
from sagemaker.predictor import RealTimePredictor

endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = RealTimePredictor(endpoint=endpoint, content_type='application/x-image')
inference_response = predictor.predict(data=payload)
print (inference_response)
```

**SageMaker Python SDK v2.x**

```python
from sagemaker.predictor import Predictor

endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=payload)
print (inference_response)
```

**TensorFlow**
The following code example shows how to use the SageMaker Python SDK API to send an image for inference:

```python
from sagemaker.predictor import Predictor
from PIL import Image
import numpy as np
import json

endpoint = 'insert the name of your endpoint here'

# Read image into memory
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
```
```
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({'instances': image.tolist()})

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=body)
print(inference_response)
```

### Request Inferences from a Deployed Service (Boto3)

You can submit inference requests using SageMaker SDK for Python (Boto3) client and `invoke_endpoint()` API once you have an SageMaker endpoint InService. The following code example shows how to send an image for inference:

**PyTorch and MXNet**

```python
import boto3
import json

endpoint = 'insert name of your endpoint here'
runtime = boto3.Session().client('sagemaker-runtime')

# Read image into memory
with open(image, 'rb') as f:
    payload = f.read()
# Send image via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='application/x-image', Body=payload)
# Unpack response
result = json.loads(response['Body'].read().decode())
```

**TensorFlow**

For TensorFlow submit an input with `application/json` for the content type.

```python
from PIL import Image
import numpy as np
import json
import boto3

client = boto3.client('sagemaker-runtime')
image = Image.open(input_file)
batch_size = 1
image = np.array(image.resize((224, 224)))
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({'instances': image.tolist()})
ioc_predictor_endpoint_name = 'insert name of your endpoint here'
content_type = 'application/json'
ioc_response = client.invoke_endpoint(EndpointName=ioc_predictor_endpoint_name,
    Body=body,
    ContentType=content_type)
```

**XGBoost**

For an XGBoost application, you should submit a CSV text instead:
import boto3
import json

endpoint = 'insert your endpoint name here'
runtime = boto3.Session().client('sagemaker-runtime')

csv_text = '1,-1.0,1.0,1.5,2.6'
# Send CSV text via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='text/csv',
Body=csv_text)
# Unpack response
result = json.loads(response['Body'].read().decode())

Note that BYOM allows for a custom content type. For more information, see runtime_InvokeEndpoint.

**Request Inferences from a Deployed Service (AWS CLI)**

Inference requests can be made with the `sagemaker-runtime invoke-endpoint` once you have an Amazon SageMaker endpoint InService. You can make inference requests with the AWS Command Line Interface (AWS CLI). The following example shows how to send an image for inference:

```bash
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
--body fileb://image.jpg --content-type=application/x-image output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful.

For TensorFlow submit an input with `application/json` as the content type.

```bash
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
--body fileb://input.json --content-type=application/json output_file.txt
```

**Inference Container Images**

Based on your use case, replace the highlighted portion in the inference image URI template provided below with appropriate values.

**Amazon SageMaker XGBoost**

```bash
aws_account_id.dkr.ecr.aws_region.amazonaws.com/xgboost-neo:latest
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

**Keras**

```bash
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-keras:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 2.2.4.

Replace `instance_type` with either `cpu` or `gpu`.  

2952
MXNet

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-mxnet:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.8.0.

Replace `instance_type` with either `cpu` or `gpu`.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-mxnet:fx_version-instance_type-py3
```

Replace `aws_region` with either `us-east-1` or `us-west-2`.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.5.1.

Replace `instance_type` with `inf`.

ONNX

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-onnx:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.5.0.

Replace `instance_type` with either `cpu` or `gpu`.

PyTorch

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-pytorch:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.4, 1.5, 1.6, 1.7 or 1.8.

Replace `instance_type` with either `cpu` or `gpu`.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-pytorch:fx_version-instance_type-py3
```
Replace `aws_region` with either `us-east-1` or `us-west-2`.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with `1.5.1`.

Replace `instance_type` with `inf`.

**TensorFlow**

**CPU or GPU instance types**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with `1.15.3` or `2.4`.

Replace `instance_type` with either `cpu` or `gpu`.

**Inferentia instance types**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used. Note that for instance type `inf` only `us-east-1` and `us-west-2` are supported.

Replace `fx_version` with `1.15.0`.

Replace `instance_type` with `inf`.

The following table maps `aws_account_id` with `aws_region`. Use this table to find the correct inference image URI you need for your application.

<table>
<thead>
<tr>
<th><code>aws_account_id</code></th>
<th><code>aws_region</code></th>

</tbody>
</table>
Edge Devices

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks. You can deploy your Neo-compiled edge devices such as the Raspberry Pi 3, Texas Instruments’ Sitara, Jetson TX1, and more. For a full list of supported frameworks and edge devices, see Supported Frameworks, Devices, Systems, and Architectures.

You must configure your edge device so that it can use AWS services. One way to do this is to install DLR and Boto3 to your device. To do this, you must set up the authentication credentials. See Boto3 AWS Configuration for more information. Once your model is compiled and your edge device is configured, you can download the model from Amazon S3 to your edge device. From there, you can use the Deep Learning Runtime (DLR) to read the compiled model and make inferences.

For first-time users, we recommend you check out the Getting Started guide. This guide walks you through how to set up your credentials, compile a model, deploy your model to a Raspberry Pi 3, and make inferences on images.

Topics

- Supported Frameworks, Devices, Systems, and Architectures (p. 2955)

- Getting Started with Neo on Edge Devices (p. 2966)

Supported Frameworks, Devices, Systems, and Architectures

Amazon SageMaker Neo supports common machine learning frameworks, edge devices, operating systems, and chip architectures. Find out if Neo supports your framework, edge device, OS, and chip architecture by selecting one of the topics below.

You can find a list of models that have been tested by the Amazon SageMaker Neo Team in the Tested Models (p. 2959) section.

### Supported Frameworks, Devices, Systems, and Architectures

</table>
Note

- Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. For more information, see Troubleshoot Ambarella Errors (p. 2976).
- TIM-VX (libtim-vx.so) is required for i.MX 8M Plus. For information on how to build TIM-VX, see the TIM-VX GitHub repository.

Supported Frameworks

Amazon SageMaker Neo supports the following frameworks.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.8.0</td>
<td>Supports 1.8.0 or earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>ONNX</td>
<td>1.7.0</td>
<td>Supports 1.7.0 or earlier</td>
<td>Image Classification, SVM</td>
<td>One model file (.onnx)</td>
<td></td>
</tr>
<tr>
<td>Keras</td>
<td>2.2.4</td>
<td>Supports 2.2.4 or earlier</td>
<td>Image Classification</td>
<td>One model definition file (.h5)</td>
<td></td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.7.1, 1.8.1</td>
<td>Supports 1.7.1, 1.8.1 or earlier</td>
<td>Image Classification, Object Detection</td>
<td>One model definition file (.pth)</td>
<td></td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15.0, 2.4.2</td>
<td>Supports 1.15.0, 2.4.2 or earlier</td>
<td>Image Classification, Object Detection</td>
<td>*For saved models, one .pb or one .pbtxt file and a variables directory that contains variables *</td>
<td></td>
</tr>
</tbody>
</table>
Amazon SageMaker Developer Guide

Edge Devices

<table>
<thead>
<tr>
<th></th>

</tbody>
</table>

Supported Devices, Chip Architectures, and Systems

Amazon SageMaker Neo supports the following devices, chip architectures, and operating systems.

Devices

You can select a device using the dropdown list in the Amazon SageMaker console or by specifying the TargetDevice in the output configuration of the CreateCompilationJob API.

You can choose from one of the following edge devices:

<table>
<thead>
<tr>

</table>

### Tested Models

The following collapsible sections provide information about machine learning models that were tested by the Amazon SageMaker Neo team. Expand the collapsible section based on your framework to check if a model was tested.
Note
This is not a comprehensive list of models that can be compiled with Neo.

See Supported Frameworks (p. 2956) and SageMaker Neo Supported Operators to find out if you can compile your model with SageMaker Neo.

DarkNet

Deploy Models

You can deploy the compute module to resource-constrained edge devices by: downloading the compiled model from Amazon S3 to your device and using DLR, or you can use AWS IoT Greengrass.

Before moving on, make sure your edge device must be supported by SageMaker Neo. See, Supported Frameworks, Devices, Systems, and Architectures to find out what edge devices are supported. Make sure that you specified your target edge device when you submitted the compilation job, see Use Neo to Compile a Model.

Deploy a Compiled Model (DLR)

DLR is a compact, common runtime for deep learning models and decision tree models. DLR uses the TVM runtime, Treelite runtime, NVIDIA TensorRT™, and can include other hardware-specific runtimes. DLR provides unified Python/C++ APIs for loading and running compiled models on various devices.

You can install latest release of DLR package using the following pip command:

```
pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, please refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:
Deploy a Model (AWS IoT Greengrass)

AWS IoT Greengrass extends cloud capabilities to local devices. It enables devices to collect and analyze data closer to the source of information, react autonomously to local events, and communicate securely with each other on local networks. With AWS IoT Greengrass, you can perform machine learning inference at the edge on locally generated data using cloud-trained models. Currently, you can deploy models on to all AWS IoT Greengrass devices based on ARM Cortex-A, Intel Atom, and Nvidia Jetson series processors. For more information on deploying a Lambda inference application to perform machine learning inferences with AWS IoT Greengrass, see How to configure optimized machine learning inference using the AWS Management Console.

Getting Started with Neo on Edge Devices

This guide to getting started with Amazon SageMaker Neo shows you how to compile a model, set up your device, and make inferences on your device. Most of the code examples use Boto3. We provide commands using AWS CLI where applicable, as well as instructions on how to satisfy prerequisites for Neo.

Note
You can run the following code snippets on your local machine, within a SageMaker notebook, within SageMaker Studio, or (depending on your edge device) on your edge device. The setup is similar; however, there are two main exceptions if you run this guide within a SageMaker notebook instance or SageMaker Studio session:

- You do not need to install Boto3.
- You do not need to add the ‘AmazonSageMakerFullAccess’ IAM policy

This guide assumes you are running the following instructions on your edge device.

Prerequisites

1. **Install Boto3**
   
   If you are running these commands on your edge device, you must install the AWS SDK for Python (Boto3). Within a Python environment (preferably a virtual environment), run the following locally on your edge device's terminal or within a Jupyter notebook instance:

   Terminal
   ```bash
   pip install boto3
   ```

   Jupyter Notebook
   ```bash
   !pip install boto3
   ```

2. **Set Up AWS Credentials**
   
   You need to set up Amazon Web Services credentials on your device in order to run SDK for Python (Boto3). By default, the AWS credentials should be stored in the file `~/.aws/credentials` on your edge device. Within the credentials file, you should see two environment variables: `aws_access_key_id` and `aws_secret_access_key`.

   In your terminal, run:
The AWS General Reference Guide has instructions on how to get the necessary aws_access_key_id and aws_secret_access_key. For more information on how to set up credentials on your device, see the Boto3 documentation.

3. **Set up an IAM Role and attach policies.**

Neo needs access to your S3 bucket URI. Create an IAM role that can run SageMaker and has permission to access the S3 URI. You can create an IAM role either by using SDK for Python (Boto3), the console, or the AWS CLI. The following example illustrates how to create an IAM role using SDK for Python (Boto3):

```python
import boto3

AWS_REGION = 'aws-region'

# Create an IAM client to interact with IAM
iam_client = boto3.client('iam', region_name=AWS_REGION)

role_name = 'role-name'

# Create a dictionary describing the IAM policy you are attaching. This policy is used to create a new IAM role.

policy = {
    'Statement': [
        {
            'Action': 'sts:AssumeRole',
            'Effect': 'Allow',
            'Principal': {'Service': 'sagemaker.amazonaws.com'},
        },
    ],
    'Version': '2012-10-17'
}

# Create a new IAM role using the policy you defined above:

new_role = iam_client.create_role(
    AssumeRolePolicyDocument=json.dumps(policy),
    Path='/',
    RoleName=role_name
)

You need to know what your Amazon Resource Name (ARN) is when you create a compilation job in a later step, so store it in a variable as well.

```
Now that you have created a new role, attach the permissions it needs to interact with Amazon SageMaker and Amazon S3:

```python
iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonSageMakerFullAccess'
)

iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonS3FullAccess'
);
```

4. **Create an Amazon S3 bucket to store your model artifacts**

SageMaker Neo will access your model artifacts from Amazon S3

**Boto3**

```python
# Create an S3 client
s3_client = boto3.client('s3', region_name=AWS_REGION)

# Name buckets
bucket='name-of-your-bucket'

# Check if bucket exists
if boto3.resource('s3').Bucket(bucket) not in boto3.resource('s3').buckets.all():
    s3_client.create_bucket(
        Bucket=bucket,
        CreateBucketConfiguration={
            'LocationConstraint': AWS_REGION
        }
    )
else:
    print(f'Bucket {bucket} already exists. No action needed.')
```

**CLI**

```bash
aws s3 mb s3://'name-of-your-bucket' --region specify-your-region

# Check your bucket exists
aws s3 ls s3://'name-of-your-bucket'/
```

5. **Train a machine learning model**

See [Train a Model with Amazon SageMaker](#) for more information on how to train a machine learning model using Amazon SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

**Note**

Make sure the model is correctly formatted depending on the framework you used. See [What input data shapes does SageMaker Neo expect?](#)

If you do not have a model yet, use the `curl` command to get a local copy of the coco_ssd_mobilenet model from TensorFlow’s website. The model you just copied is an object detection model trained from the COCO dataset. Type the following into your Jupyter notebook:

```bash
model_zip_filename = './coco_ssd_mobilenet_v1_1.0.zip'
!curl http://storage.googleapis.com/download.tensorflow.org/models/tflite/coco_ssd_mobilenet_v1_1.0_quant_2018_06_29.zip \
```
Note that this particular example was packaged in a .zip file. Unzip this file and repackage it as a compressed tarfile (.tar.gz) before using it in later steps. Type the following into your Jupyter notebook:

```bash
# Extract model from zip file
!unzip -u {model_zip_filename}
model_filename = 'detect.tflite'
model_name = model_filename.split('.')[0]

# Compress model into .tar.gz so SageMaker Neo can use it
model_tar = model_name + '.tar.gz'
!tar -czf {model_tar} {model_filename}
```

6. **Upload trained model to an S3 bucket**

Once you have trained your machine learning mode, store it in an S3 bucket.

**Boto3**

```python
# Upload model
s3_client.upload_file(Filename=model_filename, Bucket=bucket, Key=model_filename)
```

**CLI**

Replace `your-model-filename` and `your-S3-bucket` with the name of your S3 bucket.

```bash
aws s3 cp your-model-filename s3://your-S3-bucket
```

### Step 1: Compile the Model

Once you have satisfied the Prerequisites, you can compile your model with Amazon SageMaker Neo. You can compile your model using the AWS CLI, the console or the Amazon Web Services SDK for Python (Boto3), see Use Neo to Compile a Model. In this example, you will compile your model with Boto3.

To compile a model, SageMaker Neo requires the following information:

1. **The Amazon S3 bucket URI where you stored the trained model.**

   If you followed the prerequisites, the name of your bucket is stored in a variable named `bucket`. The following code snippet shows how to list all of your buckets using the AWS CLI:

   ```bash
   aws s3 ls
   ```

   For example:

   ```bash
   # aws s3 ls
   2020-11-02 17:08:50 bucket
   ```

2. **The Amazon S3 bucket URI where you want to save the compiled model.**

   The code snippet below concatenates your Amazon S3 bucket URI with the name of an output directory called `output`:
3. **The machine learning framework you used to train your model.**

Define the framework you used to train your model.

```python
framework = 'framework-name'
```

For example, if you wanted to compile a model that was trained using TensorFlow, you could either use `tflite` or `tensorflow`. Use `tflite` if you want to use a lighter version of TensorFlow that uses less storage memory.

```python
framework = 'tflite'
```

For a complete list of Neo-supported frameworks, see Supported Frameworks, Devices, Systems, and Architectures.

4. **The shape of your model's input.**

Neo requires the name and shape of your input tensor. The name and shape are passed in as key-value pairs. `value` is a list of the integer dimensions of an input tensor and `key` is the exact name of an input tensor in the model.

```python
data_shape = '{"name": [tensor-shape]}'
```

For example:

```python
data_shape = '{"normalized_input_image_tensor": [1, 300, 300, 3]}'
```

**Note**

Make sure the model is correctly formatted depending on the framework you used. See What input data shapes does SageMaker Neo expect? The key in this dictionary must be changed to the new input tensor's name.

5. **Either the name of the target device to compile for or the general details of the hardware platform**

```python
target_device = 'target-device-name'
```

For example, if you want to deploy to a Raspberry Pi 3, use:

```python
target_device = 'rasp3b'
```

You can find the entire list of supported edge devices in Supported Frameworks, Devices, Systems, and Architectures.

Now that you have completed the previous steps, you can submit a compilation job to Neo.

```python
# Create a SageMaker client so you can submit a compilation job
sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
print(f'Compilation job for {compilation_job_name} started')
```
response = sagemaker_client.create_compilation_job(
    CompilationJobName=compilation_job_name,
    RoleArn=role_arn,
    InputConfig={
        'S3Uri': s3_input_location,
        'DataInputConfig': data_shape,
        'Framework': framework.upper()
    },
    OutputConfig={
        'S3OutputLocation': s3_output_location,
        'TargetDevice': target_device
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 900
    }
)

# Optional - Poll every 30 sec to check completion status
import time
while True:
    response =
    sagemaker_client.describe_compilation_job(CompilationJobName=compilation_job_name)
    if response['CompilationJobStatus'] == 'COMPLETED':
        break
    elif response['CompilationJobStatus'] == 'FAILED':
        raise RuntimeError('Compilation failed')
    print('Compiling ...')
    time.sleep(30)
print('Done!')

If you want additional information for debugging, include the following print statement:

print(response)

If the compilation job is successful, your compiled model is stored in the output Amazon S3 bucket you specified earlier (s3_output_location). Download your compiled model locally:

object_path = f'output/{model}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model}.tar.gz'
s3_client.download_file(bucket, object_path, neo_compiled_model)

Step 2: Set Up Your Device

You will need to install packages on your edge device so that your device can make inferences. You will also need to either install AWS IoT Greengrass core or Deep Learning Runtime (DLR). In this example, you will install packages required to make inferences for the coco_ssd.mobilenet object detection algorithm and you will use DLR.

1. Install additional packages

   In addition to Boto3, you must install certain libraries on your edge device. What libraries you install depends on your use case.

   For example, for the coco_ssd.mobilenet object detection algorithm you downloaded earlier, you need to install NumPy for data manipulation and statistics, PIL to load images, and Matplotlib to generate plots. You also need a copy of TensorFlow if you want to gauge the impact of compiling with Neo versus a baseline.
2. **Install inference engine on your device**

To run your Neo-compiled model, install the Deep Learning Runtime (DLR) on your device. DLR is a compact, common runtime for deep learning models and decision tree models. On x86_64 CPU targets running Linux, you can install the latest release of the DLR package using the following `pip` command:

```bash
!pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

```bash
```

### Step 3: Make Inferences on Your Device

In this example, you will use Boto3 to download the output of your compilation job onto your edge device. You will then import DLR, download an example images from the dataset, resize this image to match the model's original input, and then you will make a prediction.

1. **Download your compiled model from Amazon S3 to your device and extract it from the compressed tarfile.**

```bash
# Download compiled model locally to edge device
object_path = f'output/{model_name}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model_name}.tar.gz'
s3_client.download_file(bucket_name, object_path, neo_compiled_model)

# Extract model from .tar.gz so DLR can use it
!mkdir ./dlr_model # make a directory to store your model (optional)
!tar -xzvf ./compiled-detect.tar.gz --directory ./dlr_model
```

2. **Import DLR and an initialized DLRModel object.**

```python
import dlr

device = 'cpu'
model = dlr.DLRModel('./dlr_model', device)
```

3. **Download an image for inferencing and format it based on how your model was trained.**

For the coco_ssd_mobilenet example, you can download an image from the COCO dataset and then reform the image to 300x300:

```python
from PIL import Image

# Download an image for model to make a prediction
input_image_filename = './input_image.jpg'
!curl https://farm9.staticflickr.com/8325/8077197378_79efb4805e_z.jpg --output (input_image_filename)

# Format image so model can make predictions
resized_image = image.resize((300, 300))
```
4. **Use DLR to make inferences.**

Finally, you can use DLR to make a prediction on the image you just downloaded:

```python
x = np.array(resized_image).astype('uint8')
out = model.run(x)
```

For more examples using DLR to make inferences from a Neo-compiled model on an edge device, see the [neo-ai-dlr Github repository](https://github.com/aws-neo-ai/dlr).

## Troubleshoot Errors

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors. Before moving on, ask yourself the following questions:

**Did you encounter an error before you deployed your model?** If yes, see [Troubleshoot Neo Compilation Errors](#).

**Did you encounter an error after you compiled your model?** If yes, see [Troubleshoot Neo Inference Errors](#).

**Did you encounter an error trying to compile your model for Ambarella devices?** If yes, see [Troubleshoot Ambarella Errors](#).

### Error Classification Types

This list classifies the *user errors* you can receive from Neo. These include access and permission errors and load errors for each of the supported frameworks. All other errors are *system errors*.

#### Client permission error

Neo passes the errors for these straight through from the dependent service.

- *Access Denied* when calling `sts:AssumeRole`
- *Any 400* error when calling Amazon S3 to download or upload a client model
- *PassRole* error

#### Load error

Assuming that the Neo compiler successfully loaded `.tar.gz` from Amazon S3, check whether the tarball contains the necessary files for compilation. The checking criteria is framework-specific:

- **TensorFlow**: Expects only protobuf file (`*.pb` or `*.pbtxt`). For saved models, expects one variables folder.
- **Pytorch**: Expect only one pytorch file (`*.pth`).
- **MXNET**: Expect only one symbol file (`*.json`) and one parameter file (`*.params`).
- **XGBoost**: Expect only one XGBoost model file (`*.model`). The input model has size limitation.

#### Compilation error

Assuming that the Neo compiler successfully loaded `.tar.gz` from Amazon S3, and that the tarball contains necessary files for compilation. The checking criteria is:
Troubleshoot Errors

• **OperatorNotImplemented**: An operator has not been implemented.
• **OperatorAttributeNotImplemented**: The attribute in the specified operator has not been implemented.
• **OperatorAttributeRequired**: An attribute is required for an internal symbol graph, but it is not listed in the user input model graph.
• **OperatorAttributeValueNotValid**: The value of the attribute in the specific operator is not valid.

• Troubleshoot Ambarella Errors (p. 2976)

Troubleshoot Neo Compilation Errors

This section contains information about how to understand and prevent common compilation errors, the error messages they generate, and guidance on how to resolve these errors.

Topics

• How to Use This Page (p. 2974)
• Framework-Related Errors (p. 2974)
• Infrastructure-Related Errors (p. 2975)
• Check your compilation log (p. 2975)

How to Use This Page

Attempt to resolve your error by going through these sections in the following order:

1. Check that the input of your compilation job satisfies the input requirements. See What input data shapes does SageMaker Neo expect? (p. 2915)
2. Check common framework-specific errors.
3. Check if your error is an infrastructure error.
4. Check your compilation log.

Check your compilation log

2. Select the region you created the compilation job from the Region dropdown list in the top right.
3. In the navigation pane of the Amazon CloudWatch, choose Logs. Select Log groups.
4. Search for the log group called /aws/sagemaker/CompilationJobs. Select the log group.
5. Search for the logstream named after the compilation job name. Select the log stream.

**Troubleshoot Neo Inference Errors**

This section contains information about how to prevent and resolve some of the common errors you might encounter upon deploying and/or invoking the endpoint. This section applies to PyTorch 1.4.0 or later and MXNet v1.7.0 or later.

- Make sure the first inference (warm-up inference) on a valid input data is done in `model_fn()`, if you defined a `model_fn` in your inference script, otherwise the following error message may be seen on the terminal when `predict API` is called:

  ```
  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."
  ```

- Make sure that the environment variables in the following table are set. If they are not set, the following error message might show up:

  **On the terminal:**

  ```
  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (503) from <users-sagemaker-endpoint> with message '{ "code": 503, "type": "InternalServerException", "message": "Prediction failed" }'.
  ```

  **In CloudWatch:**

  ```
  W-9001-model-stdout com.amazonaws.ml.mms.wlm.WorkerLifeCycle - AttributeError: 'NoneType' object has no attribute 'transform'
  ```

<table>
<thead>
<tr>

<td>20</td>
</tr>
<tr>
<td>SAGEMAKER_REGION</td>
<td>&lt;your region&gt;</td>
</tr>
</tbody>
</table>

- Make sure that the `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable is set to 500 or a higher value while creating the Amazon SageMaker model; otherwise, the following error message may be seen on the terminal:

  ```
  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."
  ```

**Troubleshoot Ambarella Errors**

SageMaker Neo requires models to be packaged in a compressed TAR file (*.tar.gz). Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation.
Include the following files within your compressed TAR file if you want to compile a model for Ambarella targets with SageMaker Neo:

- A trained model using a framework supported by SageMaker Neo
- A JSON configuration file
- Calibration images

For example, the contents of your compressed TAR file should look similar to the following example:

```bash
###amba_config.json
###calib_data
|    ### data1
|    ### data2
|    ### .
|    ### .
|    ### .
|    ### data500
###mobilenet_v1_1.0_0224_frozen.pb
```

The directory is configured as follows:

- `amba_config.json`: Configuration file
- `calib_data`: Folder containing calibration images
- `mobilenet_v1_1.0_0224_frozen.pb`: TensorFlow model saved as a frozen graph

For information about frameworks supported by SageMaker Neo, see Supported Frameworks (p. 2956).

### Setting up the Configuration File

The configuration file provides information required by the Ambarella toolchain to compile the model. The configuration file must be saved as a JSON file and the name of the file must end with `*config.json`. The following chart shows the contents of the configuration file.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
</table>
| inputs          | Dictionary mapping input layers to attribute.                               | `{inputs:{"data":
|                 |                                                                                   | ...},"data1":{...}}`                         |
| "data"          | Input layer name. Note: "data" is an example of the name you can use to label the input layer. | "data"                                       |
| shape           | Describes the shape of the input to the model. This follows the same conventions that SageMaker Neo uses. | "shape": "1,3,224,224"                      |
| filepath        | Relative path to the directory containing calibration images. These can be binary or image files like JPG or PNG. | "filepath": "calib_data/"                   |
| colorformat     | Color format that model expects. This will be used while                     | "colorformat":"RGB"                          |
### Calibration Images

Quantize your trained model by providing calibration images. Quantizing your model improves the performance of the CVFlow engine on an Ambarella System on a Chip (SoC). The Ambarella toolchain uses the calibration images to determine how each layer in the model should be quantized to achieve optimal performance and accuracy. Each layer is quantized independently to INT8 or INT16 formats. The final model has a mix of INT8 and INT16 layers after quantization.

**How many images should you use?**

It is recommended that you include between 100–200 images that are representative of the types of scenes the model is expected to handle. The model compilation time increases linearly to the number of calibration images in the input file.

**What are the recommended image formats?**

Calibration images can be in a raw binary format or image formats such as JPG and PNG.

Your calibration folder can contain a mixture of images and binary files. If the calibration folder contains both images and binary files, the toolchain first converts the images to binary files. Once the conversion is complete, it uses the newly generated binary files along with the binary files that were originally in the folder.

---

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>converting images to binary. Supported values: [RGB, BGR]. Default is RGB.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mean</td>
<td>Mean value to be subtracted from the input. Can be a single value or a list of values. When the mean is given as a list the number of entries must match the channel dimension of the input.</td>
<td>&quot;mean&quot;:128.0</td>
</tr>
<tr>
<td>scale</td>
<td>Scale value to be used for normalizing the input. Can be a single value or a list of values. When the scale is given as a list, the number of entries must match the channel dimension of the input.</td>
<td>&quot;scale&quot;: 255.0</td>
</tr>
</tbody>
</table>

The following is a sample configuration file:

```json
{
  "inputs": {
    "data": {
      "shape": "1, 3, 224, 224",
      "filepath": "calib_data/",
      "colorformat": "RGB",
      "mean": [128, 128, 128],
      "scale": [128.0, 128.0, 128.0]
    }
  }
}
```
Can I convert the images into binary format first?

Yes. You can convert the images to the binary format with open-source packages such as OpenCV or PIL. Crop and resize the images so they satisfy the input layer of your trained model.

Mean and Scale

You can specify mean and scaling pre-processing options to the Amberalla toolchain. These operations are embedded into the network and are applied during inference on each input. Do not provide processed data if you specify the mean or scale. More specifically, do not provide data you have subtracted the mean from or have applied scaling to.

Use Amazon SageMaker Elastic Inference (EI)

By using Amazon Elastic Inference (EI), you can speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as Amazon SageMaker hosted models, but at a fraction of the cost of using a GPU instance for your endpoint. EI allows you to add inference acceleration to a hosted endpoint for a fraction of the cost of using a full GPU instance. Add an EI accelerator in one of the available sizes to a deployable model in addition to a CPU instance type, and then add that model as a production variant to an endpoint configuration that you use to deploy a hosted endpoint. You can also add an EI accelerator to a SageMaker notebook instance so that you can test and evaluate inference performance when you are building your models.

Elastic Inference is supported in EI-enabled versions of TensorFlow, Apache MXNet, and PyTorch. To use any other deep learning framework, export your model by using ONNX, and then import your model into MXNet. You can then use your model with EI as an MXNet model. For information about importing an ONNX model into MXNet, see Importing an ONNX model into MXNet.

Topics

- How EI Works (p. 2979)
- Choose an EI Accelerator Type (p. 2980)
- Use EI in a SageMaker Notebook Instance (p. 2980)
- Use EI on a Hosted Endpoint (p. 2981)
- Frameworks that Support EI (p. 2981)
- Use EI with SageMaker Built-in Algorithms (p. 2981)

- Set Up to Use EI (p. 2982)
- Attach EI to a Notebook Instance (p. 2985)
- Use EI on Amazon SageMaker Hosted Endpoints (p. 2987)

How EI Works

Amazon Elastic Inference accelerators are network attached devices that work along with SageMaker instances in your endpoint to accelerate your inference calls. Elastic Inference accelerates inference by allowing you to attach fractional GPUs to any SageMaker instance. You can select the client instance to run your application and attach an Elastic Inference accelerator to use the right amount of GPU acceleration for your inference needs. Elastic Inference helps you lower your cost when not fully utilizing your GPU instance for inference. We recommend trying Elastic Inference with your model using different CPU instances and accelerator sizes.
Choose an EI Accelerator Type

The following EI accelerator types are available. You can configure your endpoints or notebook instances with any EI accelerator type.

In the table, the throughput in teraflops (TFLOPS) is listed for both single-precision floating-point (F32) and half-precision floating-point (F16) operations. The memory in GB is also listed.

<table>
<thead>

</tbody>
</table>

Choose an EI Accelerator Type

Consider the following factors when choosing an accelerator type for a hosted model:

- Models, input tensors and batch sizes influence the amount of accelerator memory you need. Start with an accelerator type that provides at least as much memory as the file size of your trained model. Factor in that a model might use significantly more memory than the file size at runtime.
- Demands on CPU compute resources, main system memory, and GPU-based acceleration and accelerator memory vary significantly between different kinds of deep learning models. The latency and throughput requirements of the application also determine the amount of compute and acceleration you need. Thoroughly test different configurations of instance types and EI accelerator sizes to make sure you choose the configuration that best fits the performance needs of your application.

For more information on selecting an EI accelerator, see:

- Amazon Elastic Inference Overview
- Choosing an Instance and Accelerator Type for Your Model
- Optimizing costs in Amazon Elastic Inference with TensorFlow

Use EI in a SageMaker Notebook Instance

Typically, you build and test machine learning models in a SageMaker notebook before you deploy them for production. You can attach EI to your notebook instance when you create the notebook instance. You can set up an endpoint that is hosted locally on the notebook instance by using the local mode supported by TensorFlow, MXNet, and PyTorch estimators and models in the Amazon SageMaker Python SDK to test inference performance. Elastic Inference enabled PyTorch is not currently supported on notebook instances. For instructions on how to attach EI to a notebook instance and set up a local endpoint for inference, see Attach EI to a Notebook Instance. There are also Elastic Inference-enabled SageMaker Notebook Jupyter kernels for Elastic Inference-enabled versions of TensorFlow and Apache MXNet. For information about using SageMaker notebook instances, see Use Amazon SageMaker Notebook Instances.
Use EI on a Hosted Endpoint

When you are ready to deploy your model for production to provide inferences, you create a SageMaker hosted endpoint. You can attach EI to the instance where your endpoint is hosted to increase its performance at providing inferences. For instructions on how to attach EI to a hosted endpoint instance, see Use EI on Amazon SageMaker Hosted Endpoints.

Frameworks that Support EI

Amazon Elastic Inference is designed to be used with AWS enhanced versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks. These enhanced versions of the frameworks are automatically built into containers when you use the Amazon SageMaker Python SDK, or you can download them as binary files and import them in your own Docker containers.

You can download the EI-enabled TensorFlow binary files from the public amazonei-tensorflow Amazon S3 bucket to the TensorFlow serving containers. For more information about building a container that uses the EI-enabled version of TensorFlow, see Amazon Elastic Inference with TensorFlow in SageMaker.

You can download the EI-enabled MXNet binary files from the public amazonei-apachemxnet Amazon S3 bucket to the MXNet serving containers. For more information about building a container that uses the EI-enabled version of MXNet, see Amazon Elastic Inference with MXNet in SageMaker.

You can download the EI-enabled PyTorch binary files from the public amazonei-pytorch Amazon S3 bucket to the PyTorch serving containers. For more information about building a container that uses the EI-enabled version of PyTorch, see Amazon Elastic Inference with PyTorch in SageMaker.

To use Elastic Inference in a hosted endpoint, you can choose any of the following frameworks depending on your needs.

- SageMaker Python SDK - Deploy TensorFlow models
- SageMaker Python SDK - Deploy MXNet models
- SageMaker Python SDK - Deploy PyTorch models

If you need to create a custom container for deploying your model that is complex and requires extensions to a framework that the SageMaker pre-built containers do not support, use the low-level AWS SDK for Python (Boto 3).

Use EI with SageMaker Built-in Algorithms

Currently, the Image Classification - MXNet and Object Detection built-in algorithms support EI. For an example that uses the Image Classification algorithm with EI, see End-to-End Multiclass Image Classification Example.

EI Sample Notebooks

The following Sample notebooks provide examples of using EI in SageMaker:

- Using Amazon Elastic Inference with MXNet on Amazon SageMaker
- Using Amazon Elastic Inference with MXNet on an Amazon SageMaker Notebook Instance
- Using Amazon Elastic Inference with Neo-compiled TensorFlow model on SageMaker
- Using Amazon Elastic Inference with a pre-trained TensorFlow Serving model on SageMaker
Set Up to Use EI

Use the instructions in this topic only if one of the following applies to you:

- You want to use a customized role or permission policy.
- You want to use a VPC for your hosted model or notebook instance.

**Note**

If you already have an execution role that has the `AmazonSageMakerFullAccess` managed policy attached (this is true for any IAM role that you create when you create a notebook instance, training job, or model in the console) and you are not connecting to an EI model or notebook instance in a VPC, you do not need to make any of these changes to use EI in Amazon SageMaker.

**Topics**

- Set Up Required Permissions (p. 2982)
- Use a Custom VPC to Connect to EI (p. 2984)

Set Up Required Permissions

To use EI in SageMaker, the role that you use to open a notebook instance or create a deployable model must have a policy with the required permissions attached. You can attach the `AmazonSageMakerFullAccess` managed policy, which contains the required permissions, to the role, or you can add a custom policy that has the required permissions. For information about creating an IAM role, see Creating a Role for an AWS Service (Console) in the AWS Identity and Access Management User Guide. For information about attaching a policy to a role, see Adding and Removing IAM Policies.

Add these permissions specifically for connecting EI in an IAM policy.

```json
{"Effect": "Allow",
 "Action": [
   "elastic-inference:Connect",
   "ec2:DescribeVpcEndpoints"
  ],
 "Resource": "*"}
```

Use a Custom VPC to Connect to EI

To use EI with SageMaker in a VPC, you need to create and configure two security groups, and set up a PrivateLink VPC interface endpoint. EI uses VPC interface endpoint to communicate with SageMaker endpoints in your VPC. The security groups you create are used to connect to the VPC interface endpoint.

Set up Security Groups to Connect to EI

To use EI within a VPC, you need to create two security groups:

- A security group to control access to the VPC interface endpoint that you will set up for EI.
- A security group that allows SageMaker to call into the first security group.

To configure the two security groups

1. Create a security group with no outbound connections. You will attach this to the VPC endpoint interface you create in the next section.
2. Create a second security group with no inbound connections, but with an outbound connection to the first security group.
3. Edit the first security group to allow inbound connections only to the second security group and all outbound connections.
For more information about VPC security groups, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

Set up a VPC Interface Endpoint to Connect to EI

To use EI with SageMaker in a custom VPC, you need to set up a VPC interface endpoint (PrivateLink) for the EI service.

- Set up a VPC interface endpoint (PrivateLink) for the EI. Follow the instructions at Creating an Interface Endpoint. In the list of services, choose com.amazonaws.<region>.elastic-inference.runtime. For Security group, make sure you select the first security group you created in the previous section to the endpoint.
- When you set up the interface endpoint, choose all of the Availability Zones where EI is available. EI fails if you do not set up at least two Availability Zones. For information about VPC subnets, see VPCs and Subnets.

Attach EI to a Notebook Instance

To test and evaluate inference performance using EI, you can attach EI to a notebook instance when you create or update a notebook instance. You can then use EI in local mode to host a model at an endpoint hosted on the notebook instance. You should test various sizes of notebook instances and EI accelerators to evaluate the configuration that works best for your use case.

Set Up to Use EI

To use EI locally in a notebook instance, create a notebook instance with an EI instance.

To create a notebook instance with an EI instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Notebook instances.
3. Choose Create notebook instance.
4. For Notebook instance name, provide a unique name for your notebook instance.
5. For notebook instance type, choose a CPU instance such as ml.t2.medium.
6. For Elastic Inference (EI), choose an instance from the list, such as ml.eia2.medium.
7. For IAM role, choose an IAM role that has the required permissions to use SageMaker and EI.
8. (Optional) For VPC - Optional, if you want the notebook instance to use a VPC, choose one from the available list. Otherwise, leave it as No VPC. If you use a VPC follow the instructions at Use a Custom VPC to Connect to EI (p. 2984).
9. (Optional) For Lifecycle configuration - optional, either leave it as No configuration or choose a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 291).
10. (Optional) For Encryption key - optional, Optional) If you want SageMaker to use an AWS Key Management Service (AWS KMS) key to encrypt data in the ML storage volume attached to the notebook instance, specify the key.
11. (Optional) For Volume Size In GB - optional, leave the default value of 5.
12. (Optional) For Tags, add tags to the notebook instance. A tag is a label you assign to help manage your notebook instances. A tag consists of a key and a value, both of which you define.
13. Choose Create Notebook Instance.

After you create your notebook instance with EI attached, you can create a Jupyter notebook and set up an EI endpoint that is hosted locally on the notebook instance.
Use EI in Local Mode in SageMaker

To use EI locally in an endpoint hosted on a notebook instance, use local mode with the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch estimators or models. For more information about local mode support in the SageMaker Python SDK, see https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview.

Use EI in Local Mode with SageMaker TensorFlow Estimators and Models

To use EI with TensorFlow in local mode, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type` when you call the `deploy` method of an estimator or a model object. For more information about Amazon SageMaker Python SDK TensorFlow estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/tensorflow/index.html.

The following code shows how to use local mode with an estimator object. To call the `deploy` method, you must have previously either:

- Trained the model by calling the `fit` method of an estimator.
- Pass a model artifact when you initialize the model object.

```python
# Deploys the model to a local endpoint
tf_predictor = tf_model.deploy(initial_instance_count=1,
                                instance_type='local',
                                accelerator_type='local_sagemaker_notebook')
```

Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models

To use EI with MXNet in local mode, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type` when you call the `deploy` method of an estimator or a model object. For more information about Amazon SageMaker Python SDK MXNet estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html.

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
mxnet_predictor = mxnet_estimator.deploy(initial_instance_count=1,
                                          instance_type='local',
                                          accelerator_type='local_sagemaker_notebook')
```

For a complete example of using EI in local mode with MXNet, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference_local.html.
Use EI in Local Mode with SageMaker PyTorch Estimators and Models

To use EI with PyTorch in local mode, when you call the `deploy` method of an estimator or a model object, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type`. For more information about Amazon SageMaker Python SDK PyTorch estimators and models, see SageMaker PyTorch Estimators and Models.

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
pytorch_predictor = pytorch_estimator.deploy(initial_instance_count=1,
                                           instance_type='local',
                                           accelerator_type='local_sagemaker_notebook')
```

Use EI on Amazon SageMaker Hosted Endpoints

To use Elastic Inference (EI) in Amazon SageMaker with a hosted endpoint for real-time inference, specify an EI accelerator when you create the deployable model to be hosted at that endpoint. You can do this in one of the following ways:

- Use the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch and the SageMaker pre-built containers for TensorFlow, MXNet, and PyTorch
- Build your own container, and use the low-level SageMaker API (Boto 3). You will need to import the EI-enabled version of either TensorFlow, MXNet, or PyTorch from the provided Amazon S3 locations into your container, and use one of those versions to write your training script.
- Use either the Image Classification - MXNet (p. 2113) or Object Detection (p. 2137) build-in algorithms, and use the AWS SDK for Python (Boto3) to run your training job and create your deployable model and hosted endpoint.

Topics

- Use EI with a SageMaker TensorFlow Container (p. 2987)
- Use EI with a SageMaker MXNet Container (p. 2988)
- Use EI with a SageMaker PyTorch Container (p. 2988)
- Use EI with Your Own Container (p. 2989)

Use EI with a SageMaker TensorFlow Container

SageMaker provides default model training and inference code for your convenience. For custom file formats, you might need to implement custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
```
```python
predictor = estimator.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

### Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

### Use EI with a SageMaker MXNet Container

To use MXNet with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using MXNet in the Amazon SageMaker Python SDK, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

### Use an Estimator Object

To use an estimator object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

### Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

For a complete example of using EI with MXNet in SageMaker, see the sample notebook at https://github.com/awslabs/amazon-sagemaker-examples/blob/master/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference.ipynb

### Use EI with a SageMaker PyTorch Container

To use PyTorch with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument.
For information about using PyTorch in the Amazon SageMaker Python SDK, see SageMaker PyTorch Estimators and Models.

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

**Use an Estimator Object**

To use an estimator object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in this example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                            instance_type='ml.m4.xlarge',
                            accelerator_type='ml.eia2.medium')
```

**Use a Model Object**

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The model returns a predictor object, which we call its deploy method, as shown in this example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                         instance_type='ml.m4.xlarge',
                         accelerator_type='ml.eia2.medium')
```

**Use EI with Your Own Container**

To use EI with your own container that you build, use the low-level AWS SDK for Python (Boto 3). download and import the AWS EI-enabled versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks, and write your training script using those frameworks.

**Import the EI Version of TensorFlow, MXNet, or PyTorch into Your Docker Container**

To use EI with your own container, you need to import either the Amazon EI TensorFlow Serving library, the Amazon EI Apache MXNet library, or the Elastic Inference enabled PyTorch library into your container. The EI-enabled versions of TensorFlow and MXNet are currently available as binary files stored in Amazon S3 locations. You can download the EI-enabled binary for TensorFlow from the Amazon S3 bucket at `console.aws.amazon.com/s3/buckets/amazonei-tensorflow`. For information about building a container that uses the EI-enabled version of TensorFlow, see `https://github.com/aws/sagemaker-tensorflow-container#building-the-sagemaker-elastic-inference-tensorflow-serving-container`. You can download the EI-enabled binary for Apache MXNet from the public Amazon S3 bucket at `console.aws.amazon.com/s3/buckets/amazonei-apachemxnet`. For information about building a container that uses the EI-enabled version of MXNet, see `https://github.com/aws/sagemaker-mxnet-container#building-the-sagemaker-elastic-inference-mxnet-container`. You can download the Elastic Inference enabled binary for PyTorch from the public Amazon S3 bucket at `console.aws.amazon.com/s3/buckets/amazonei-pytorch`. For information about building a container that uses the Elastic Inference enabled version of PyTorch, see Building your image.

**Create an EI Endpoint with AWS SDK for Python (Boto 3)**

To create an endpoint by using AWS SDK for Python (Boto 3), you first create an endpoint configuration. The endpoint configuration specifies one or more models (called production variants) that you want to host at the endpoint. To attach EI to one or more of the production variants hosted at the endpoint, you
specify one of the EI instance types as the AcceleratorType field for that ProductionVariant. You then pass that endpoint configuration when you create the endpoint.

Create an Endpoint Configuration

To use EI, you need to specify an accelerator type in the endpoint configuration.

```python
# Create Endpoint Configuration
from time import gmtime, strftime
def create_endpoint_config_response(EndpointConfigName, model_name):
    return sagemaker.create_endpoint_config(EndpointConfigName=EndpointConfigName, ProductionVariants=[
        {'InstanceType': 'ml.m4.xlarge', 'InitialInstanceCount': 1, 'ModelName': model_name, 'VariantName': 'AllTraffic', 'AcceleratorType': 'ml.eia2.medium'}
    ]) 

print('Endpoint Config Arn: ' + create_endpoint_config_response('EndpointConfigArn'))
```

Create an Endpoint

After you create an endpoint configuration with an accelerator type, you can create an endpoint.

```python
def create_endpoint_response(EndpointName, endpoint_config_name):
    return sagemaker.create_endpoint(EndpointName=endpoint_name, EndpointConfigName=endpoint_config_name)

After creating the endpoint, you can invoke it using the invoke_endpoint method in a Boto3 runtime object, as you would any other endpoint.

Best practices to minimize interruptions during GPU driver upgrades

SageMaker Model Deployment upgrades GPU drivers on the ML instances for Real-time, Batch, and Asynchronous Inference options over time to provide customers access to improvements from the driver providers. Below you can see the GPU version supported for each Inference option. Different driver versions can change how your model interacts with the GPUs. Below are some strategies to help you understand how your application works with different driver versions.

Current versions and supported instance families

Amazon SageMaker Inference supports the following drivers and instance families:

<table>
<thead>
<tr>
<th>Service</th>
<th>GPU</th>
<th>Driver version</th>
<th>Instance types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real-time</td>
<td>NVIDIA</td>
<td>470.57.02</td>
<td>ml.p2.<em>, ml.p3.</em>, ml.p4d.<em>, ml.g4dn.</em>, ml.g5.*</td>
</tr>
</tbody>
</table>
### Troubleshoot your model container with GPU capabilities

If you encounter an issue when running your GPU workload, see the following guidance:

**GPU card detection failure or NVIDIA initialization error**

Run the `nvidia-smi` (NVIDIA System Management Interface) command from within the Docker container. If the NVIDIA System Management Interface detects a GPU detection error or NVIDIA initialization error, it will return the following error message:

`Failed to initialize NVML: Driver/library version mismatch`

Based on your use case, follow these best practices to resolve the failure or error:

- Follow the best practice recommendation described in the *If you bring your own (BYO) model containers* (p. 2992) dropdown.
- Follow the best practice recommendation described in the *If you use a CUDA compatibility layer* (p. 2992) dropdown.

Refer to the [NVIDIA System Management Interface page](https://nvidia.github.io/nvidia-smi/index.html) on the NVIDIA website for more information.

**Best practices for working with mismatched driver versions**

The following provides information on how to update your GPU driver:

**The driver my container depends on is lower than the version on the ML GPU instance**

No action is required. NVIDIA provides backwards compatibility.

**The driver my container depends on is greater than the version on the ML GPU instances**

If it is a minor version difference, no action is required. NVIDIA provides minor version forward compatibility.

If it is a major version difference, the CUDA Compatibility Package will need to be installed. Please refer to [CUDA Compatibility Package](https://drive.google.com/file/d/17tXfYl923y5n5m_oY7iAhkF8EOu3e5PI/view?usp=sharing) in the NVIDIA documentation.
Important

The CUDA Compatibility Package is not backwards compatible so it needs to be disabled if the driver version on the instance is greater than the CUDA Compatibility Package version.

If you bring your own (BYO) model containers

Ensure no NVIDIA driver packages are bundled in the image which could cause conflict with on host NVIDIA driver version.

If you use a CUDA compatibility layer

To verify if the platform Nvidia driver version supports the CUDA Compatibility Package version installed in the model container, see the CUDA documentation. If the platform Nvidia driver version does not support the CUDA Compatibility Package version, you can disable or remove the CUDA Compatibility Package from the model container image. If the CUDA compatibility libs version is supported by the latest Nvidia driver version, we suggest that you enable the CUDA Compatibility Package based on the detected Nvidia driver version for future compatibility by adding the code snippet below into the container start up shell script (at the ENTRYPOINT script).

The script demonstrates how to dynamically switch the use of the CUDA Compatibility Package based on the detected Nvidia driver version on the deployed host for your model container. When SageMaker releases a newer Nvidia driver version, the installed CUDA Compatibility Package can be turned off automatically if the CUDA application is supported natively on the new driver.

```bash
#!/bin/bash

verlte() {
    [ "$1" = "$2" ] && return 1 || [ "$2" = "\`echo -e "$1\n$2" | sort -V | head -n1\`" ]
}

if [ -f /usr/local/cuda/compat/libcuda.so.1 ]; then
    cat /usr/local/cuda/version.txt
    CUDA_COMPAT_MAX_DRIVER_VERSION=$(readlink /usr/local/cuda/compat/libcuda.so.1 | cut -d'.' -f 3-)
    echo "CUDA compat package requires Nvidia driver 
    NVIDIA_DRIVER_VERSION=$(sed -n 's/^NVRM.*Kernel Module \([0-9.]*\).*$/\1/p' /proc/driver/nvidia/version 2>/dev/null || true)
    echo "Current installed Nvidia driver version is 
    if [ $(verlte $CUDA_COMPAT_MAX_DRIVER_VERSION $NVIDIA_DRIVER_VERSION) ]; then
        echo "Setup CUDA compatibility libs path to LD_LIBRARY_PATH"
        export LD_LIBRARY_PATH=/usr/local/cuda/compat:$LD_LIBRARY_PATH
    echo $LD_LIBRARY_PATH
    else
        echo "Skip CUDA compat libs setup as newer Nvidia driver is installed"
    fi
    else
        echo "Skip CUDA compat libs setup as package not found"
    fi
```

Model Hosting FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Inference Hosting.

General Hosting

The following FAQ items answer common general questions for SageMaker Inference.
Q: What deployment options does Amazon SageMaker provide?

A: After you build and train models, Amazon SageMaker provides four options to deploy them so you can start making predictions. Real-Time Inference is suitable for workloads with millisecond latency requirements, payload sizes up to 6 MB, and processing times of up to 60 seconds. Batch Transform is ideal for offline predictions on large batches of data that are available up front. Asynchronous Inference is designed for workloads that do not have sub-second latency requirements, payload sizes up to 1 GB, and processing times of up to 15 minutes. With Serverless Inference, you can quickly deploy machine learning models for inference without having to configure or manage the underlying infrastructure, and you pay only for the compute capacity used to process inference requests, which is ideal for intermittent workloads.

Q: How do I choose a model deployment option in SageMaker?

A: The following diagram can help you choose a SageMaker Hosting model deployment option.

![Choosing Model Deployment Options](image)

The preceding diagram walks you through the following decision process. If you want to process requests in batches, you might want to choose Batch Transform. Otherwise, if you want to receive inference for each request to your model, you might want to choose Asynchronous Inference, Serverless Inference, or Real-Time Inference. You can choose Asynchronous Inference if you have long processing times or large payloads and want to queue requests. You can choose Serverless Inference if your workload has unpredictable or intermittent traffic. You can choose Real-Time Inference if you have sustained traffic and need lower and consistent latency for your requests.

Q: I've heard SageMaker Inference is expensive. What's the best way to optimize my cost when hosting models?

A: To optimize your costs with SageMaker Inference, you should choose the right hosting option for your use case. You can also use Inference features such as Amazon SageMaker Savings Plans, model optimization with SageMaker Neo, Multi-Model Endpoints and Multi-Container Endpoints, or autoscaling. For tips on how to optimize your Inference costs, see Inference cost optimization best practices (p. 2832).

Q: Why should I use Amazon SageMaker Inference Recommender?

A: You should use Amazon SageMaker Inference Recommender if you need recommendations for the right endpoint configuration to improve performance and reduce costs. Previously, data scientists who wanted to deploy their models had to run manual benchmarks to select the right endpoint configuration. First, they had to select the right machine learning instance type out of more than 70
available instance types based on the resource requirements of their models and sample payloads, and then optimize the model to account for differing hardware. Then, they had to conduct extensive load tests to validate that latency and throughput requirements were met and that the costs were low. Inference Recommender eliminates this complexity by helping you do the following:

- Get started in minutes with an instance recommendation.
- Conduct load tests across instance types to get recommendations on your endpoint configuration within hours.
- Automatically tune container and model server parameters as well as perform model optimizations for a given instance type.

Q: What is a model server?

A: SageMaker endpoints are HTTP REST endpoints that use a containerized web server, which includes a model server. These containers are responsible for loading up and serving requests for a machine learning model. They implement a web server that responds to /invocations and /ping on port 8080.

Common model servers include TensorFlow Serving, TorchServe and Multi Model Server. SageMaker framework containers have these model servers built in.

Q: What is Bring Your Own Container with Amazon SageMaker?

A: Everything in SageMaker Inference is containerized. SageMaker provides managed containers for popular frameworks such as TensorFlow, SKlearn, and HuggingFace. For a comprehensive updated list of those images, see Available Images.

Sometimes there are custom frameworks for which you might need to build a container. This approach is known as Bring Your Own Container or BYOC. With the BYOC approach, you provide the Docker image to set up your framework or library. Then, you push the image to Amazon Elastic Container Registry (Amazon ECR) so that you can use the image with SageMaker. For an example of a BYOC approach, see Overview of Containers for Amazon SageMaker.

Alternatively, instead of building an image from scratch, you can extend a container. You can take one of the base images that SageMaker provides and add your dependencies on top of it in your Dockerfile.

Q: Do I need to train my models on SageMaker to host them on SageMaker endpoints?

A: SageMaker offers the capacity to bring your own trained framework model that you've trained outside of SageMaker and deploy it on any of the SageMaker hosting options.

SageMaker requires you to package the model in a model.tar.gz file and have a specific directory structure. Each framework has its own model structure (see the following question for example structures). For more information, see the SageMaker Python SDK documentation for TensorFlow, PyTorch, and MXNet.

While you can choose from prebuilt framework images such as TensorFlow, PyTorch, and MXNet to host your trained model, you can also build your own container to host your trained models on SageMaker endpoints. For a walkthrough, see the example Jupyter notebook Building your own algorithm container.

Q: How should I structure my model if I want to deploy on SageMaker but not train on SageMaker?

A: SageMaker requires your model artifacts to be compressed in a .tar.gz file. SageMaker automatically extracts this .tar.gz file into the /opt/ml/model/ directory in your container. If you are
making use of one of the framework containers, such as TensorFlow, PyTorch, or MXNet, the container expects your TAR structure to be as follows:

**TensorFlow**

```
model.tar.gz/
    |--[model_version_number]/
    |    |--variables
    |    |    |--saved_model.pb
    |    
    |    code/
    |    |--inference.py
    |    |--requirements.txt
```

**PyTorch**

```
model.tar.gz/
    |-- model.pth
    |    |-- code/
    |    |    |-- inference.py
    |    |    |-- requirements.txt # only for versions 1.3.1 and higher
```

**MXNet**

```
model.tar.gz/
    |-- model-symbol.json
    |-- model-shapes.json
    |-- model-0000.params
    |    |-- code/
    |    |    |-- inference.py
    |    |    |-- requirements.txt # only for versions 1.6.0 and higher
```

**Q:** When invoking a SageMaker endpoint, I can provide a `ContentType` and `Accept` MIME Type. Which one is used to identify the data type being sent and received?

**A:** `ContentType` is the MIME type of the input data in the request body (the MIME type of the data you are sending to your endpoint). The model server uses the `ContentType` to determine if it can handle the type provided or not.

`Accept` is the MIME type of the inference response (the MIME type of the data your endpoint returns). The model server uses the `Accept` type to determine if it can handle returning the type provided or not.

Common MIME types include `text/csv`, `application/json`, and `application/jsonlines`.

**Q:** How do I invoke my endpoint with binary data such as videos or images?

Use the `Invoke Endpoint` API call to make inference against your endpoint.

When passing your input as a payload to the `InvokeEndpoint` API, you must provide the correct type of input data that your model expects. When passing a payload in the `InvokeEndpoint` API call, the request bytes are forwarded directly to the model container. For example, for an image, you may use `application/jpeg` for the `ContentType`, and make sure that your model can perform inference on this type of data. This applies for JSON, CSV, video, or any other type of input with which you may be dealing.

Another factor to consider is payload size limits. In terms of real-time and serverless endpoints, the payload limit is 6 MB. You can split your video into multiple frames and invoke the endpoint with each
frame individually. Alternatively, if your use case permits, you can send the whole video in the payload using an asynchronous endpoint, which supports up to 1 GB payloads.

For an example that showcases how to run computer vision inference on large videos with Asynchronous Inference, see this blog post.

### Real-Time Inference

The following FAQ items answer common questions for SageMaker Real-Time Inference.

**Q: How do I create a SageMaker endpoint?**

A: You can create a SageMaker endpoint through AWS-supported tooling such as the AWS SDKs, the SageMaker Python SDK, the AWS Management Console, AWS CloudFormation, and the AWS Cloud Development Kit (AWS CDK).

There are three key entities in endpoint creation: a SageMaker model, a SageMaker endpoint configuration, and a SageMaker endpoint. The SageMaker model points towards the model data and image you are using. The endpoint configuration defines your production variants, which might include the instance type and instance count. You can then use either the `create_endpoint` API call or the `deploy()` call for SageMaker to create an endpoint using the metadata from your model and endpoint configuration.

**Q: Do I need to use the SageMaker Python SDK to create/invoke endpoints?**

A: No, you can use the various AWS SDKs (see Invoke/Create for available SDKs) or even call the corresponding web APIs directly.

**Q: What is the difference between Multi-Model Endpoints (MME) and Multi Model Server (MMS)?**

A: A Multi-Model Endpoint is a Real-Time Inference option that SageMaker provides. With Multi-Model Endpoints, you can host thousands of models behind one endpoint. Multi Model Server is an open-source framework for serving machine learning models. It provides the HTTP front-end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and perform inference on a specified loaded model.

**Q: What are the different model deployment architectures supported by Real-Time Inference?**

A: SageMaker Real-Time Inference supports various model deployment architecture such as Multi-Model Endpoints, Multi-Container Endpoints, and Serial Inference Pipelines.

- **Multi-Model Endpoints (MME)** – MME allows customers to deploy 1000s of hyper-personalized models in a cost effective way. All the models are deployed on a shared-resource fleet. MME works best when the models are of similar size and latency and belong to the same ML framework. These endpoints are ideal for when you have don’t need to call the same model at all times. You can dynamically load respective models onto the SageMaker endpoint to serve your request.

- **Multi-Container Endpoints (MCE)** – MCE allows customers to deploy 15 different containers with diverse ML frameworks and functionalities with no cold starts while only using one SageMaker endpoint. You can directly invoke these containers. MCE is best for when you want to keep all the models in memory.

- **Serial Inference Pipelines (SIP)** – You can use SIP to chain together 2-15 containers on a single endpoint. SIP is mostly suitable for combining preprocessing and model inference in one endpoint and for low latency operations.
Serverless Inference

The following FAQ items answer common questions for Amazon SageMaker Serverless Inference.

**Q: What is Amazon SageMaker Serverless Inference?**

*A:* Serverless Inference *(p. 2776)* is a purpose-built serverless model serving option that makes it easy to deploy and scale ML models. Serverless Inference endpoints automatically start compute resources and scale them in and out depending on traffic, eliminating the need for you to choose instance type, run provisioned capacity, or manage scaling. You can optionally specify the memory requirements for your serverless endpoint. You pay only for the duration of running the inference code and the amount of data processed, not for idle periods.

**Q: Why should I use Serverless Inference?**

*A:* Serverless Inference simplifies the developer experience by eliminating the need to provision capacity up front and manage scaling policies. Serverless Inference can scale instantly from tens to thousands of inferences within seconds based on the usage patterns, making it ideal for ML applications with intermittent or unpredictable traffic. For example, a chatbot service used by a payroll processing company experiences an increase in inquiries at the end of the month while traffic is intermittent for rest of the month. Provisioning instances for the entire month in such scenarios is not cost-effective, as you end up paying for idle periods.

Serverless Inference helps address these types of use cases by providing you automatic and fast scaling out of the box without the need for you to forecast traffic up front or manage scaling policies. Additionally, you pay only for the compute time to run your inference code and for data processing, making it ideal for workloads with intermittent traffic.

**Q: How do I choose the right memory size for my serverless endpoint?**

*A:* Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs.

Choose your endpoint’s memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection for your model based on your latency SLAs. The memory size increments have different pricing; see the Amazon SageMaker pricing page for more information.

Batch Transform

The following FAQ items answer common questions for SageMaker Batch Transform.

**Q: How does Batch Transform split my data?**

*A:* For specific file formats such as CSV, RecordIO and TFRecord, SageMaker can split your data into single-record or multi-record mini batches and send this as a payload to your model container. When the value of **BatchStrategy** is **MultiRecord**, SageMaker sends the maximum number of records in each request, up to the **MaxPayloadInMB** limit. When the value of **BatchStrategy** is **SingleRecord**, SageMaker sends individual records in each request.

**Q: What is the maximum timeout for Batch Transform and payload limit for a single record?**

*A:* The maximum timeout for Batch Transform is 3600 seconds. The **maximum payload size** for a record (per mini batch) is 100 MB.
Q: How do I speed up a Batch Transform job?
A: If you are using the CreateTransformJob API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as MaxPayloadInMB, MaxConcurrentTransforms, or BatchStrategy. The ideal value for MaxConcurrentTransforms is equal to the number of compute workers in the batch transform job. If you are using the SageMaker console, you can specify these optimal parameter values in the Additional configuration section of the Batch transform job configuration page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

Q: What are the data formats natively supported in Batch Transform?
A: Batch Transform supports CVS and JSON.

Asynchronous Inference

The following FAQ items answer common general questions for SageMaker Asynchronous Inference.

Q: What is Amazon SageMaker Asynchronous Inference?
A: Asynchronous Inference queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes or long processing times that need to be processed as they arrive. Optionally, you can configure auto-scaling settings to scale down the instance count to zero when not actively processing requests.

Q: How do I scale my endpoints to 0 when there’s no traffic?
A: Amazon SageMaker supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models SageMaker supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up. For more information, see Autoscale an asynchronous endpoint.

Amazon SageMaker Serverless Inference also automatically scales down to zero. You won’t see this because SageMaker manages scaling your serverless endpoints, but if you are not experiencing any traffic, the same infrastructure applies.
Using Docker containers with SageMaker

Amazon SageMaker makes extensive use of Docker containers for build and runtime tasks. SageMaker provides prebuilt Docker images for its built-in algorithms and the supported deep learning frameworks used for training and inference. Using containers, you can train machine learning algorithms and deploy models quickly and reliably at any scale. The topics in this section show how to deploy these containers for your own use cases. For information on how to bring your own containers for use with Amazon SageMaker Studio, see Bring your own SageMaker image (p. 151).

Topics

• Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker (p. 2999)
• Docker Container Basics (p. 3000)
• Use Prebuilt SageMaker Docker images (p. 3000)
• Adapting Your Own Docker Container to Work with SageMaker (p. 3014)
• Create a container with your own algorithms and models (p. 3030)
• Example Notebooks: Use Your Own Algorithm or Model (p. 3046)
• Troubleshooting your Docker containers (p. 3048)

Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker

Amazon SageMaker always uses Docker containers when running scripts, training algorithms, and deploying models. However, your level of engagement with containers depends on your use case.

• **Use a built-in SageMaker algorithm or framework.** For most use cases, you can use the built-in algorithms and frameworks without worrying about containers. You can train and deploy these algorithms from the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the Amazon SageMaker Python SDK by specifying the algorithm or framework version when creating your Estimator. The built-in algorithms available are itemized and described in the Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1051) topic. For more information on the available frameworks, see ML Frameworks and Toolkits (p. 13). For an example of how to train and deploy a built-in algorithm using a Jupyter notebook running in a SageMaker notebook instance, see the Get Started with Amazon SageMaker (p. 33) topic.

• **Use prebuilt SageMaker container images.** Alternatively, you can use the built-in algorithms and frameworks using Docker containers. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. It also supports machine learning libraries such as scikit-learn and SparkML. If you use the Amazon SageMaker Python SDK, you can deploy the containers by passing the full container URI to their respective SageMaker SDK Estimator class. For the full list of deep learning frameworks currently supported by SageMaker, see Prebuilt SageMaker Docker Images for Deep Learning (p. 3001). For information on the scikit-learn and SparkML prebuilt container images, see Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 3001).
For more information about using frameworks with the Amazon SageMaker Python SDK, see their respective topics in *Use Machine Learning Frameworks, Python, and R with Amazon SageMaker* (p. 13).

- **Extend a prebuilt SageMaker container image.** If you would like to extend a prebuilt SageMaker algorithm or model Docker image, you can modify the SageMaker image to satisfy your needs. For an example, see *Extending our PyTorch containers*.

- **Adapt an existing container image:** If you would like to adapt a pre-existing container image to work with SageMaker, you need to modify the Docker container to enable either the SageMaker Training or Inference toolkit. For an example that shows how to build your own containers to train and host an algorithm, see *Bring Your Own R Algorithm*.

## Docker Container Basics

Docker is a program that performs operating system-level virtualization for installing, distributing, and managing software. It packages applications and their dependencies into virtual containers that provide isolation, portability, and security. With Docker, you can ship code faster, standardize application operations, seamlessly move code, and economize by improving resource utilization. For more general information about Docker, see *Docker overview*.

The following information outlines the most significant aspects of using Docker containers with Amazon SageMaker.

### SageMaker Functions

SageMaker uses Docker containers in the backend to manage training and inference processes. SageMaker abstracts away from this process, so it happens automatically when an estimator is used. While you don't need to use Docker containers explicitly with SageMaker for most use cases, you can use Docker containers to extend and customize SageMaker functionality.

### Containers with SageMaker Studio

SageMaker Studio runs from a Docker container and uses it to manage functionality. As a result, you must create your Docker container following the steps in *Bring your own SageMaker image* (p. 151).

## Use Prebuilt SageMaker Docker images

Amazon SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. It also supports machine learning libraries such as scikit-learn and SparkML.

You can use these images from your SageMaker notebook instance or SageMaker Studio. You can also extend the prebuilt SageMaker images to include libraries and needed functionality. The following topics give information about the available images and how to use them.

**Note**

For information on Docker images for developing reinforcement learning (RL) solutions in SageMaker, see *SageMaker RL Containers*.

### Topics

- [Prebuilt SageMaker Docker Images for Deep Learning](p. 3001)
- [Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML](p. 3001)
- [Train a Deep Graph Network](p. 3003)
- [Extend a Prebuilt Container](p. 3006)
Prebuilt SageMaker Docker Images for Deep Learning

SageMaker provides prebuilt Docker images that include deep learning framework libraries and other dependencies needed for training and inference. For a complete list of the available pre-built Docker images, see Deep Learning Containers Images.

If you are not using the Amazon SageMaker Python SDK and one of its estimators to retrieve the pre-built images, you have to retrieve them yourself.

Using the SageMaker Python SDK

With the SageMaker Python SDK, you can train and deploy models using these popular deep learning frameworks. For instructions on installing and using the SDK, see Amazon SageMaker Python SDK. The following table lists the available frameworks and instructions on how to use them with the SageMaker Python SDK:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>Using TensorFlow with the SageMaker Python SDK</td>
</tr>
<tr>
<td>MXNet</td>
<td>Using MXNet with the SageMaker Python SDK</td>
</tr>
<tr>
<td>PyTorch</td>
<td>Using PyTorch with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Chainer</td>
<td>Using Chainer with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Hugging Face</td>
<td>Using Hugging Face with the SageMaker Python SDK</td>
</tr>
</tbody>
</table>

Extending Prebuilt SageMaker Docker Images

You can customize these prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example, see Extending Our PyTorch Containers.

You can also use prebuilt containers to deploy your custom models or models that have been trained in a framework other than SageMaker. For an overview of the process of bringing the trained model artifacts into SageMaker and hosting them at an endpoint, see Bring Your Own Pretrained MXNet or TensorFlow Models into Amazon SageMaker.

Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML

SageMaker provides prebuilt Docker images that install the scikit-learn and Spark ML libraries. These libraries also include the dependencies needed to build Docker images that are compatible with SageMaker using the Amazon SageMaker Python SDK. With the SDK, you can use scikit-learn for machine learning tasks and use Spark ML to create and tune machine learning pipelines. For instructions on installing and using the SDK, see SageMaker Python SDK.

Using the SageMaker Python SDK

The following table contains links to the GitHub repositories with the source code for the scikit-learn and Spark ML containers. The table also contains links to instructions that show how use these containers with Python SDK estimators to run your own training algorithms and hosting your own models.
Specifying the Prebuilt Images Manually

If you are not using the SageMaker Python SDK and one of its estimators to manage the container, you have to retrieve the relevant prebuilt container manually. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). You can push or pull them using their fullname registry addresses. SageMaker uses the following Docker Image URL patterns for scikit-learn and Spark M:

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-scikit-learn:<SCIKIT-LEARN_VERSION>-cpu-py<PYTHON_VERSION>

  For example, 746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-scikit-learn:0.23-1-cpu-py3

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-sparkml-serving:<SPARK-ML_VERSION>

  For example, 341280168497.dkr.ecr.ca-central-1.amazonaws.com/sagemaker-sparkml-serving:2.4

The following table lists the supported values for account IDs and corresponding AWS Region names.

<table>
<thead>
<tr>
<th>ACCOUNT_ID</th>
<th>REGION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>746614075791</td>
<td>us-west-1</td>
</tr>
<tr>
<td>246618743249</td>
<td>us-west-2</td>
</tr>
<tr>
<td>683313688378</td>
<td>us-east-1</td>
</tr>
<tr>
<td>257758044811</td>
<td>us-east-2</td>
</tr>
<tr>
<td>354813040037</td>
<td>ap-northeast-1</td>
</tr>
<tr>
<td>366743142698</td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td>121021644041</td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td>783357654285</td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td>720646828776</td>
<td>ap-south-1</td>
</tr>
<tr>
<td>141502667606</td>
<td>eu-west-1</td>
</tr>
<tr>
<td>764974769150</td>
<td>eu-west-2</td>
</tr>
<tr>
<td>492215442770</td>
<td>eu-central-1</td>
</tr>
<tr>
<td>341280168497</td>
<td>ca-central-1</td>
</tr>
</tbody>
</table>
Finding Available Images

Use the following commands to find out which versions of the images are available. For example, use the following to find the available `sagemaker-sparkml-serving` image in the `ca-central-1` Region:

```
aws ecr describe-images \
  --region ca-central-1 \
  --registry-id 341280168497 \
  --repository-name sagemaker-sparkml-serving
```

Train a Deep Graph Network

In this overview, you learn how to get started with a deep graph network by using one of the DGL containers in Amazon Elastic Container Registry (Amazon ECR). You can also see links to practical examples for deep graph networks.

What Is a Deep Graph Network?

Deep graph networks refer to a type of neural network that is trained to solve graph problems. A deep graph network uses an underlying deep learning framework like PyTorch or MXNet. The potential for graph networks in practical AI applications is highlighted in the Amazon SageMaker tutorials for Deep Graph Library (DGL). Examples for training models on graph datasets include social networks, knowledge bases, biology, and chemistry.
Several examples are provided using Amazon SageMaker's deep learning containers that are preconfigured with DGL. If you have special modules you want to use with DGL, you can also build your own container. The examples involve heterographs, which are graphs that have multiple types of nodes and edges, and draw on a variety of applications across disparate scientific fields, such as bioinformatics and social network analysis. DGL provides a wide array of graph neural network implementations for different types models. Some of the highlights include:

- Graph convolutional network (GCN)
- Relational graph convolutional network (R-GCN)
- Graph attention network (GAT)
- Deep generative models of graphs (DGMG)
- Junction tree neural network (JTNN)

**Get Started**

DGL is available as a deep learning container in Amazon ECR. You can select deep learning containers when you write your estimator function in an Amazon SageMaker notebook. You can also craft your own custom container with DGL by following the Bring Your Own Container guide. The easiest way to get started with a deep graph network uses one of the DGL containers in Amazon ECR.

**Note**

Backend framework support is limited to PyTorch and MXNet.

**Setup**
If you are using Amazon SageMaker Studio, you need to clone the examples repository first. If you are using a notebook instance, you can find the examples by choosing the SageMaker icon at bottom of the left toolbar.

**To clone the Amazon SageMaker SDK and notebook examples repository**

1. From the JupyterLab view in Amazon SageMaker, go to the File Browser at the top of the left toolbar. From the File Browser panel, you can see a new navigation at the top of the panel.
2. Choose the icon on the far right to clone a Git repository.
3. Add the repository URL: https://github.com/awslabs/amazon-sagemaker-examples.git
4. Browse the newly added folder and its contents. The DGL examples are stored in the sagemaker-python-sdk folder.

**Run a Graph Network Training Example**

**To train a deep graph network**

1. From the JupyterLab view in Amazon SageMaker, browse the example notebooks and look for DGL folders. Several files may be included to support an example. Examine the README for any prerequisites.
2. Run the .ipynb notebook example.
3. Find the estimator function, and note the line where it is using an Amazon ECR container for DGL and a specific instance type. You may want to update this to use a container in your preferred Region.
4. Run the function to launch the instance and use the DGL container for training a graph network. Charges are incurred for launching this instance. The instance self-terminates when the training is complete.

**Examples**

An example of knowledge graph embedding (KGE) is provided. It uses the Freebase dataset, a knowledge base of general facts. An example use case would be to graph the relationships of persons and predict their nationality.

An example implementation of a graph convolutional network (GCN) shows how you can train a graph network to predict toxicity. A physiology dataset, Tox21, provides toxicity measurements for how substances affect biological responses.

Another GCN example shows you how to train a graph network on a scientific publications bibliography dataset, known as Cora. You can use it to find relationships between authors, topics, and conferences.

The last example is a recommender system for movie reviews. It uses a graph convolutional matrix completion (GCMC) network trained on the MovieLens datasets. These datasets consist of movie titles, genres, and ratings by users.

**Use a Deep Learning Container with DGL**

The following example uses preconfigured deep learning containers. This is the easiest to try since it works out of the box on Amazon SageMaker.

- Semi-supervised classification of a knowledge base using a GCN
Bring Your Own Container with DGL

The following examples enable you to bring your own container (BYOC). Read the BYOC guide and familiarize yourself with that process before trying these. Configuration is required.

- Molecular property prediction of toxicity using a GCN
- Recommender system for movies using a GCMC implementation

Extend a Prebuilt Container

If a prebuilt SageMaker container doesn't fulfill all of your requirements, you can extend the existing image to accommodate your needs. Even if there is direct support for your environment or framework, you may want to add additional functionality or configure your container environment differently. By extending a prebuilt image, you can leverage the included deep learning libraries and settings without having to create an image from scratch. You can extend the container to add libraries, modify settings, and install additional dependencies.

The following tutorial shows how to extend a prebuilt SageMaker image and publish it to Amazon ECR.

Topics
- Requirements to Extend a Prebuilt Container (p. 3006)
- Extend SageMaker Containers to Run a Python Script (p. 3006)

Requirements to Extend a Prebuilt Container

To extend a pre-built SageMaker image, you need to set the following environment variables within your Dockerfile. For more information on environment variables with SageMaker containers, see the SageMaker Training Toolkit GitHub repo.

- SAGEMAKER_SUBMIT_DIRECTORY: The directory within the container in which the Python script for training is located.
- SAGEMAKER_PROGRAM: The Python script that should be invoked and used as the entry point for training.

You can also install additional libraries by including the following in your Dockerfile:

```
RUN pip install <library>
```

The following tutorial shows how to use these environment variables.

Extend SageMaker Containers to Run a Python Script

In this tutorial, you learn how to extend the SageMaker PyTorch container with a Python file that uses the CIFAR-10 dataset. By extending the SageMaker PyTorch container, you utilize the existing training solution made to work with SageMaker. This tutorial extends a training image, but the same steps can be taken to extend an inference image. For a full list of the available images, see Available Deep Learning Containers Images.

To run your own training model using the SageMaker containers, build a Docker container through a SageMaker Notebook instance.

Step 1: Create an SageMaker Notebook Instance

1. Open the SageMaker console.
2. In the left navigation pane, choose Notebook, choose Notebook instances, and then choose Create
   notebook instance.
3. On the Create notebook instance page, provide the following information:
   a. For Notebook instance name, enter RunScriptNotebookInstance.
   b. For Notebook instance type, choose ml.t2.medium.
   c. In the Permissions and encryption section, do the following:
      i. For IAM role, choose Create a new role.
      ii. On the Create an IAM role page, choose Specific S3 buckets, specify an Amazon S3 bucket
         named sagemaker-run-script, and then choose Create role.
         SageMaker creates an IAM role named AmazonSageMaker-
         ExecutionRole-YYYYMMDDTHHmmSS, such as AmazonSageMaker-
         ExecutionRole-20190429T110788. Note that the execution role naming convention
         uses the date and time when the role was created, separated by a T.
   d. For Root Access, choose Enable.
   e. Choose Create notebook instance.
4. On the Notebook instances page, the Status is Pending. It can take a few minutes for Amazon
   SageMaker to launch a machine learning compute instance—in this case, it launches a notebook
   instance—and attach an ML storage volume to it. The notebook instance has a preconfigured
   Jupyter notebook server and a set of Anaconda libraries. For more information, see
   CreateNotebookInstance.
5. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into
   a notepad file to save it temporarily. You use this IAM role ARN number later to configure a
   local training estimator in the notebook instance. The IAM role ARN number looks like the
   following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-
   ExecutionRole-20190429T110788'
6. After the status of the notebook instance changes to InService, choose Open JupyterLab.

Step 2: Create and Upload the Dockerfile and Python Training Scripts

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-
   left corner, choose the New Folder icon, and then enter the folder name docker_test_folder.
2. Create a Dockerfile text file in the docker_test_folder directory.
   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-
ubuntu16.04
ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker PyTorch container to determine
our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code
subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py

# Defines cifar10.py as script entrypoint
```
### ENV SAGEMAKER_PROGRAM cifar10.py

The Dockerfile script performs the following tasks:

- **FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04** — Downloads the SageMaker PyTorch base image. You can replace this with any SageMaker base image you want to bring to build containers.

- **ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code** — Sets `/opt/ml/code` as the training script directory.

- **COPY cifar10.py /opt/ml/code/cifar10.py** — Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.

- **ENV SAGEMAKER_PROGRAM cifar10.py** — Sets your `cifar10.py` training script as the entrypoint script.

**d.** On the left directory navigation pane, the text file name might automatically be named `untitled.txt`. To rename the file, right-click the file, choose **Rename**, rename the file as `Dockerfile` without the `.txt` extension, and then press Ctrl+s or Command+s to save the file.

3. Create or upload a training script `cifar10.py` in the `docker_test_folder`. You can use the following example script for this exercise.

```python
import ast
import argparse
import logging
import os
import torch
import torch.distributed as dist
import torch.nn as nn
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision
import torchvision.models
import torchvision.transforms as transforms
import torch.nn.functional as F

logger=logging.getLogger(__name__)
logger.setLevel(logging.DEBUG)
classes=('plane', 'car', 'bird', 'cat', 'deer', 'dog', 'frog', 'horse', 'ship', 'truck')

# https://github.com/pytorch/tutorials/blob/master/beginner_source/blitz/cifar10_tutorial.py#L118
class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()

    parser.add_argument('--data-dir', type=str, default=os.environ['SM_CHANNEL_TRAINING'])
    parser.add_argument('--num-gpus', type=int, default=os.environ['SM_NUM_GPUS'])
Step 3: Build the Container

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the New Launch icon and then choose conda_pytorch_p36 in the Notebook section.
2. Run the following command in the first notebook cell to change to the docker_test_folder directory:

   ```
   % cd ~/SageMaker/docker_test_folder
   ```

   This returns your current directory as follows:

   ```
   ! pwd
   ```

   output: `/home/ec2-user/SageMaker/docker_test_folder`

3. Log in to Docker to access the base container:

   ```
   ! aws ecr get-login-password --region us-east-1 | docker login --username AWS -- password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
   ```

4. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

   ```
   ! docker build -t pytorch-extended-container-test .
   ```

   The Docker build command must be run from the Docker directory you created, in this case docker_test_folder.

   **Note**

   If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

   ```
   unable to prepare context: unable to evaluate symlinks in Dockerfile path: lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
   ```

   Remember that docker looks for a file specifically called Dockerfile without any extension within the current directory. If you named it something else, you can pass in the file name manually with the `-f` flag. For example, if you named your Dockerfile Dockerfile-text.txt, run the following command:

   ```
   ! docker build -t tf-custom-container-test -f Dockerfile-text.txt .
   ```

Step 4: Test the Container

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose New Launcher and choose Notebook in conda_pytorch_p36 framework. The rest of the code snippets must run from the Jupyter notebook instance.
2. Download the CIFAR-10 dataset.

   ```
   import torch
   ```
import torchvision
import torchvision.transforms as transforms

def _get_transform():
    return transforms.Compose(
        [transforms.ToTensor(),
         transforms.Normalize((0.5, 0.5, 0.5), (0.5, 0.5, 0.5))])

def get_train_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    trainset=torchvision.datasets.CIFAR10(root=data_dir, train=True,
                                           download=True, transform=transform)
    return torch.utils.data.DataLoader(trainset, batch_size=4,
                                        shuffle=True, num_workers=2)

def get_test_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
