### XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='ap-northeast-1', version='1.2-1')
```

### Docker Registry Paths and Example Code for Canada (Central) (ca-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.
Topics

- BlazingText (algorithm) (p. 1075)
- Chainer (DLC) (p. 1075)
- Clarify (algorithm) (p. 1075)
- Data Wrangler (algorithm) (p. 1076)
- Debugger (algorithm) (p. 1076)
- DeepAR Forecasting (algorithm) (p. 1076)
- Factorization Machines (algorithm) (p. 1077)
- Hugging Face (algorithm) (p. 1077)
- IP Insights (algorithm) (p. 1078)
- Image classification (algorithm) (p. 1078)
- Inferentia MXNet (DLC) (p. 1078)
- Inferentia PyTorch (DLC) (p. 1078)
- K-Means (algorithm) (p. 1079)
- KNN (algorithm) (p. 1079)
- LDA (algorithm) (p. 1079)
- Linear Learner (algorithm) (p. 1080)
- MXNet (DLC) (p. 1080)
- MXNet Coach (DLC) (p. 1082)
- Model Monitor (algorithm) (p. 1083)
- NTM (algorithm) (p. 1083)
- Neo Image Classification (algorithm) (p. 1083)
- Neo MXNet (DLC) (p. 1084)
- Neo PyTorch (DLC) (p. 1084)
- Neo Tensorflow (DLC) (p. 1085)
- Neo XGBoost (algorithm) (p. 1085)
- Object Detection (algorithm) (p. 1085)
- Object2Vec (algorithm) (p. 1086)
- PCA (algorithm) (p. 1086)
- PyTorch (DLC) (p. 1086)
- Random Cut Forest (algorithm) (p. 1088)

</tr>
</tbody>
</table>
### VW (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='vw', region='ca-central-1', version='8.7.0', image_scope='training')
```

### XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='ca-central-1', version='1.2-1')
```
<table>
<thead>
<tr>
<th>Registry path</th>

Docker Registry Paths and Example Code for China (Beijing) (cn-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- BlazingText (algorithm) (p. 1102)
- Chainer (DLC) (p. 1102)
- Clarify (algorithm) (p. 1103)
- Data Wrangler (algorithm) (p. 1103)
- Debugger (algorithm) (p. 1104)
- DeepAR Forecasting (algorithm) (p. 1104)
- Factorization Machines (algorithm) (p. 1104)
- Hugging Face (algorithm) (p. 1104)
- IP Insights (algorithm) (p. 1105)
- Image classification (algorithm) (p. 1105)
- Inferentia MXNet (DLC) (p. 1106)
- Inferentia PyTorch (DLC) (p. 1106)
- K-Means (algorithm) (p. 1106)
- KNN (algorithm) (p. 1106)
- Linear Learner (algorithm) (p. 1107)
- MXNet (DLC) (p. 1107)
- MXNet Coach (DLC) (p. 1110)
- Model Monitor (algorithm) (p. 1110)
- NTM (algorithm) (p. 1110)
- Neo Image Classification (algorithm) (p. 1111)
- Neo MXNet (DLC) (p. 1111)
- Neo PyTorch (DLC) (p. 1111)
- Neo Tensorflow (DLC) (p. 1112)
- Neo XGBoost (algorithm) (p. 1112)
- Object Detection (algorithm) (p. 1113)
- Object2Vec (algorithm) (p. 1113)
- PCA (algorithm) (p. 1113)
- PyTorch (DLC) (p. 1113)
- Random Cut Forest (algorithm) (p. 1116)
- Scikit-learn (algorithm) (p. 1116)
- Semantic Segmentation (algorithm) (p. 1116)
- Seq2Seq (algorithm) (p. 1117)
- Spark (algorithm) (p. 1117)
- SparkML Serving (algorithm) (p. 1117)
- Tensorflow (DLC) (p. 1118)
- Tensorflow Coach (DLC) (p. 1125)
- Tensorflow Inferentia (DLC) (p. 1126)
- Tensorflow Ray (DLC) (p. 1126)
- XGBoost (algorithm) (p. 1127)

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext',region='cn-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>390948362332.dkr.ecr.cn-north-1.amazonaws.com.cn/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
Use built-in algorithms

```
image_uris.retrieve(framework='chainer', region='cn-north-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>422961961927.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>422961961927.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>422961961927.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>

Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='cn-north-1', version='1.0', image_scope='processing')
```

| Registry path                                                                 | Version | Job types (image scope) | |
|------------------------------------------------------------------------------|---------|--------------------------||
| 122526803553.dkr.ecr.cn-1.0 north-1.amazonaws.com.cn/sagemaker-clarify-processing:<tag> |         | processing               | |

Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='cn-north-1')
```

| Registry path                                                                 | Version | Job types (image scope) | |
|------------------------------------------------------------------------------|---------|--------------------------||
| 24590911842.dkr.ecr.cn-1.x north-1.amazonaws.com.cn/sagemaker-data-wrangler-container:<tag> |         | processing               | |
**Debugger (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='cn-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>618459771430.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-debugger-rules:&lt;tag&gt;</td>
<td>latest</td>
<td>debugger</td>
</tr>
</tbody>
</table>

**DeepAR Forecasting (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='cn-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

<td></td>
<td>training</td>
</tr>
<tr>
<td>huggingface-tensorflow-training:&lt;tag&gt;</td>
<td></td>
<td>training</td>
</tr>
</tbody>
</table>

**IP Insights (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='cn-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ipinsights:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Image classification (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='cn-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

Use built-in algorithms

Tensorflow Inferentia (DLC)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow', region='cn-north-1', version='1.15.0', instance_type='ml.inf1.6xlarge')
```

Tensorflow Ray (DLC)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='cn-north-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```
XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost',region='cn-north-1',version='1.2-1')
```

### Docker Registry Paths and Example Code for China (Ningxia) (cn-northwest-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics
Use built-in algorithms

- BlazingText (algorithm) (p. 1128)
- Chainer (DLC) (p. 1129)
- Clarify (algorithm) (p. 1129)
- Data Wrangler (algorithm) (p. 1130)
- Debugger (algorithm) (p. 1130)
- DeepAR Forecasting (algorithm) (p. 1130)
- Factorization Machines (algorithm) (p. 1130)
- Hugging Face (algorithm) (p. 1131)
- IP Insights (algorithm) (p. 1131)
- Image classification (algorithm) (p. 1132)
- Inferentia MXNet (DLC) (p. 1132)
- Inferentia PyTorch (DLC) (p. 1132)
- K-Means (algorithm) (p. 1132)
- KNN (algorithm) (p. 1133)
- Linear Learner (algorithm) (p. 1133)
- MXNet (DLC) (p. 1133)
- MXNet Coach (DLC) (p. 1136)
- Model Monitor (algorithm) (p. 1136)
- NTM (algorithm) (p. 1137)
- Neo Image Classification (algorithm) (p. 1137)
- Neo MXNet (DLC) (p. 1137)
- Neo PyTorch (DLC) (p. 1138)
- Neo Tensorflow (DLC) (p. 1138)
- Neo XGBoost (algorithm) (p. 1139)
- Object Detection (algorithm) (p. 1139)
- Object2Vec (algorithm) (p. 1139)
- PCA (algorithm) (p. 1139)
- PyTorch (DLC) (p. 1140)
- Random Cut Forest (algorithm) (p. 1142)
- Scikit-learn (algorithm) (p. 1142)
- Semantic Segmentation (algorithm) (p. 1143)
- Seq2Seq (algorithm) (p. 1143)
- Spark (algorithm) (p. 1143)
- SparkML Serving (algorithm) (p. 1144)
- Tensorflow (DLC) (p. 1144)
- Tensorflow Coach (DLC) (p. 1151)
- Tensorflow Inferentia (DLC) (p. 1152)
- Tensorflow Ray (DLC) (p. 1152)
- XGBoost (algorithm) (p. 1153)

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.
```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext',region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer',region='cn-northwest-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>

**Clarify (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='cn-northwest-1',version='1.0',image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>122578899357.dkr.ecr.cn-1.0northwest-1.amazonaws.com.cn/sagemaker-clarify-processing:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>
Data Wrangler (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler',region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>249157047649.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-data-wrangler-container:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

Debugger (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>658757709296.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-debugger-rules:&lt;tag&gt;</td>
<td></td>
<td>debugger</td>
</tr>
</tbody>
</table>

DeepAR Forecasting (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar',region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/forecasting-deepar:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Factorization Machines (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines',region='cn-northwest-1')
```
### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='cn-northwest-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>

### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr-cn-1northwest-1.amazonaws.com.cn/ipinsights:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Image classification (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/image-classification:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Inferentia MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='cn-northwest-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td>1.5.1</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>

**Inferentia PyTorch (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='cn-northwest-1',version='1.5.1',py_version='py3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-neo-pytorch:&lt;tag&gt;</td>
<td>1.5.1</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>

**K-Means (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
### Use built-in algorithms

```python
image_uris.retrieve(framework='kmeans', region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/kmeans:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**KNN (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uri = image_uris.retrieve(framework='knn', region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/knn:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Linear Learner (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uri = image_uris.retrieve(framework='linear-learner', region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>

### Docker Registry Paths and Example Code for Europe (Frankfurt) (eu-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- BlazingText (algorithm) (p. 1155)
- Chainer (DLC) (p. 1155)
- Clarify (algorithm) (p. 1156)
- Data Wrangler (algorithm) (p. 1156)
- Debugger (algorithm) (p. 1156)
- DeepAR Forecasting (algorithm) (p. 1157)
- Factorization Machines (algorithm) (p. 1157)
- Hugging Face (algorithm) (p. 1157)
- IP Insights (algorithm) (p. 1158)
- Image classification (algorithm) (p. 1158)
- Inferentia MXNet (DLC) (p. 1159)
- Inferentia PyTorch (DLC) (p. 1159)
- K-Means (algorithm) (p. 1159)
- KNN (algorithm) (p. 1159)
- LDA (algorithm) (p. 1160)
- Linear Learner (algorithm) (p. 1160)
- MXNet (DLC) (p. 1160)
- MXNet Coach (DLC) (p. 1163)
- Model Monitor (algorithm) (p. 1163)
- NTM (algorithm) (p. 1164)
- Neo Image Classification (algorithm) (p. 1164)
- Neo MXNet (DLC) (p. 1164)
- Neo PyTorch (DLC) (p. 1165)
- Neo Tensorflow (DLC) (p. 1165)
- Neo XGBoost (algorithm) (p. 1166)
Use built-in algorithms

- Object Detection (algorithm) (p. 1166)
- Object2Vec (algorithm) (p. 1166)
- PCA (algorithm) (p. 1166)
- PyTorch (DLC) (p. 1167)
- Random Cut Forest (algorithm) (p. 1169)
- Ray PyTorch (DLC) (p. 1169)
- Scikit-learn (algorithm) (p. 1170)
- Semantic Segmentation (algorithm) (p. 1170)
- Seq2Seq (algorithm) (p. 1170)
- Spark (algorithm) (p. 1171)
- SparkML Serving (algorithm) (p. 1171)

Docker Registry Paths and Example Code for Europe (Ireland) (eu-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- BlazingText (algorithm) (p. 1183)
- Chainer (DLC) (p. 1183)
- Clarify (algorithm) (p. 1183)
- Data Wrangler (algorithm) (p. 1184)
- Debugger (algorithm) (p. 1184)
- DeepAR Forecasting (algorithm) (p. 1184)
- Factorization Machines (algorithm) (p. 1185)
- Hugging Face (algorithm) (p. 1185)
- IP Insights (algorithm) (p. 1186)
- Image classification (algorithm) (p. 1186)
- Inferentia MXNet (DLC) (p. 1186)
- Inferentia PyTorch (DLC) (p. 1187)
- K-Means (algorithm) (p. 1187)
- KNN (algorithm) (p. 1187)
- LDA (algorithm) (p. 1187)
- Linear Learner (algorithm) (p. 1188)
- MXNet (DLC) (p. 1188)
- MXNet Coach (DLC) (p. 1191)
- Model Monitor (algorithm) (p. 1191)
- NTM (algorithm) (p. 1191)
- Neo Image Classification (algorithm) (p. 1192)
- Neo MXNet (DLC) (p. 1192)
- Neo PyTorch (DLC) (p. 1192)
- Neo Tensorflow (DLC) (p. 1193)
- Neo XGBoost (algorithm) (p. 1193)
- Object Detection (algorithm) (p. 1194)
- Object2Vec (algorithm) (p. 1194)
- PCA (algorithm) (p. 1194)
- PyTorch (DLC) (p. 1194)
- Random Cut Forest (algorithm) (p. 1197)
- Ray PyTorch (DLC) (p. 1197)
- Scikit-learn (algorithm) (p. 1197)
- Semantic Segmentation (algorithm) (p. 1198)
- Seq2Seq (algorithm) (p. 1198)
• Spark (algorithm) (p. 1198)
• SparkML Serving (algorithm) (p. 1199)
• Tensorflow (DLC) (p. 1199)
• Tensorflow Coach (DLC) (p. 1206)
• Tensorflow Inherent (DLC) (p. 1207)
• Tensorflow Ray (DLC) (p. 1207)
• VW (algorithm) (p. 1208)
• XGBoost (algorithm) (p. 1209)

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
code here...
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>685385470294.dkr.ecr.eu-west-1.amazonaws.com/image-classification:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
code here...
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>802834080501.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>
**Inferentia PyTorch (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='eu-west-1', version='1.5.1', py_version='py3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>

<td>inference, training</td>
<td></td>
</tr>
</tbody>
</table>

**KNN (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='eu-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>438346466558.dkr.ecr.eu-west-1.amazonaws.com/knn:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td></td>
</tr>
</tbody>
</table>

**LDA (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='lda', region='eu-west-1')
```
Use built-in algorithms

**Docker Registry Paths and Example Code for Europe (London) (eu-west-2)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.
Topics

- BlazingText (algorithm) (p. 1211)
- Chainer (DLC) (p. 1211)
- Clarify (algorithm) (p. 1211)
- Data Wrangler (algorithm) (p. 1212)
- Debugger (algorithm) (p. 1212)
- DeepAR Forecasting (algorithm) (p. 1212)
- Factorization Machines (algorithm) (p. 1213)
- Hugging Face (algorithm) (p. 1213)
- IP Insights (algorithm) (p. 1214)
- Image classification (algorithm) (p. 1214)
- Inferentia MXNet (DLC) (p. 1214)
- Inferentia PyTorch (DLC) (p. 1214)
- K-Means (algorithm) (p. 1215)
- KNN (algorithm) (p. 1215)
- LDA (algorithm) (p. 1215)
- Linear Learner (algorithm) (p. 1216)
- MXNet (DLC) (p. 1216)
- MXNet Coach (DLC) (p. 1218)
- Model Monitor (algorithm) (p. 1219)
- NTM (algorithm) (p. 1219)
- Neo Image Classification (algorithm) (p. 1219)
- Neo MXNet (DLC) (p. 1220)
- Neo PyTorch (DLC) (p. 1220)
- Neo Tensorflow (DLC) (p. 1221)
- Neo XGBoost (algorithm) (p. 1221)
- Object Detection (algorithm) (p. 1221)
- Object2Vec (algorithm) (p. 1222)
- PCA (algorithm) (p. 1222)
- PyTorch (DLC) (p. 1222)
- Random Cut Forest (algorithm) (p. 1224)
- Ray PyTorch (DLC) (p. 1225)
- Scikit-learn (algorithm) (p. 1225)
- Semantic Segmentation (algorithm) (p. 1225)
- Seq2Seq (algorithm) (p. 1226)
- Spark (algorithm) (p. 1226)
- SparkML Serving (algorithm) (p. 1226)
- Tensorflow (DLC) (p. 1227)

Docker Registry Paths and Example Code for Europe (Paris) (eu-west-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- BlazingText (algorithm) (p. 1238)
- Chainer (DLC) (p. 1238)
- Clarify (algorithm) (p. 1239)
- Data Wrangler (algorithm) (p. 1239)
- Debugger (algorithm) (p. 1240)
- DeepAR Forecasting (algorithm) (p. 1240)
- Factorization Machines (algorithm) (p. 1240)
- Hugging Face (algorithm) (p. 1240)
- IP Insights (algorithm) (p. 1241)
- Image classification (algorithm) (p. 1241)
- Inferentia MXNet (DLC) (p. 1242)
- Inferentia PyTorch (DLC) (p. 1242)
- K-Means (algorithm) (p. 1242)
- KNN (algorithm) (p. 1242)
- Linear Learner (algorithm) (p. 1243)
- MXNet (DLC) (p. 1243)
- MXNet Coach (DLC) (p. 1246)
- Model Monitor (algorithm) (p. 1246)
- NTM (algorithm) (p. 1246)
- Neo Image Classification (algorithm) (p. 1247)
- Neo MXNet (DLC) (p. 1247)
- Neo PyTorch (DLC) (p. 1247)
- Neo Tensorflow (DLC) (p. 1248)
- Neo XGBoost (algorithm) (p. 1248)
- Object Detection (algorithm) (p. 1249)
- Object2Vec (algorithm) (p. 1249)
- PCA (algorithm) (p. 1249)
- PyTorch (DLC) (p. 1249)
- Random Cut Forest (algorithm) (p. 1252)
- Scikit-learn (algorithm) (p. 1252)
- Semantic Segmentation (algorithm) (p. 1252)
- Seq2Seq (algorithm) (p. 1253)
- Spark (algorithm) (p. 1253)
- SparkML Serving (algorithm) (p. 1253)
- Tensorflow (DLC) (p. 1254)
- Tensorflow Coach (DLC) (p. 1261)
- Tensorflow Inferentia (DLC) (p. 1262)
- Tensorflow Ray (DLC) (p. 1262)
- XGBoost (algorithm) (p. 1263)

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```
Use built-in algorithms

```python
image_uris.retrieve(framework='chainer', region='eu-west-3', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>520713654638.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
<td></td>
</tr>
<tr>
<td>520713654638.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
<td></td>
</tr>
<tr>
<td>520713654638.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
<td></td>
</tr>
</tbody>
</table>

**Clarify (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='eu-west-3', version='1.0', image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>341593696636.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-clarify-processing:&lt;tag&gt;</td>
<td>1.0</td>
<td>processing</td>
</tr>
</tbody>
</table>

**Data Wrangler (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>807237891255.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-data-wrangler-container:&lt;tag&gt;</td>
<td>1.x</td>
<td>processing</td>
</tr>
</tbody>
</table>
Debugger (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>447278800020.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-debugger-rules:&lt;tag&gt;</td>
<td></td>
<td>debugger</td>
</tr>
</tbody>
</table>

DeepAR Forecasting (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/forecasting-deepar:&lt;tag&gt;</td>
<td>1.0</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Factorization Machines (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/factorization-machines:&lt;tag&gt;</td>
<td>1.0</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Hugging Face (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-west-3', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```
### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/ipinsights:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/image-classification:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>
Inferentia MXNet (DLC)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='eu-west-3',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
<td></td>
</tr>
</tbody>
</table>

Inferentia PyTorch (DLC)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='eu-west-3',version='1.5.1',py_version='py3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-neo-pytorch:&lt;tag&gt;</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
<td></td>
</tr>
</tbody>
</table>

K-Means (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/kmeans:&lt;tag&gt;</td>
<td>inference, training</td>
<td></td>
</tr>
</tbody>
</table>

KNN (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='eu-west-3')
```
Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/knn:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Linear Learner (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/linear-learner:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='eu-west-3', version='1.4.1', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

### MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='eu-west-3', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>763104351884.dkr.ecr-west-3.amazonaws.com/mxnet-training:&lt;tag&gt;</td>
<td>1.8.0</td>
<td>training</td>
<td>CPU, GPU</td>
<td>py37</td>
</tr>
<tr>

<td></td>
<td>monitoring</td>
</tr>
</tbody>
</table>

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
Use built-in algorithms

```python
image_uris.retrieve(framework='ntm', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/ntm:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Neo Image Classification (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>254080097072.dkr.ecr.eu-west-3.amazonaws.com/image-classification-neo:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
</tr>
</tbody>
</table>

**Neo MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='eu-west-3', version='1.8', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
</table>

**Neo PyTorch (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='eu-west-3', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```
Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
</table>

**Neo Tensorflow (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow',region='eu-west-3',version='1.15.3',py_version='py3',instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
</table>

**Neo XGBoost (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo',region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>254080097072.dkr.ecr.eu-west-3.amazonaws.com/xgboost-neo:&lt;tag&gt;</td>
<td>inference</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris

Use built-in algorithms

**Tensorflow Inferentia (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow', region='eu-west-3', version='1.15.0', instance_type='ml.inf1.6xlarge')
```

**Tensorflow Ray (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='eu-west-3', version='0.8.5', instance_type='ml.c5.4xlarge')
```
### XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost',region='eu-west-3',version='1.2-1')
```

### Docker Registry Paths and Example Code for Europe (Stockholm) (eu-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
• BlazingText (algorithm) (p. 1264)
• Chainer (DLC) (p. 1265)
• Clarify (algorithm) (p. 1265)
• Data Wrangler (algorithm) (p. 1266)
• Debugger (algorithm) (p. 1266)
• DeepAR Forecasting (algorithm) (p. 1266)
• Factorization Machines (algorithm) (p. 1266)
• Hugging Face (algorithm) (p. 1267)
• IP Insights (algorithm) (p. 1267)
• Image classification (algorithm) (p. 1268)
• Inferentia MXNet (DLC) (p. 1268)
• Inferentia PyTorch (DLC) (p. 1268)
• K-Means (algorithm) (p. 1268)
• KNN (algorithm) (p. 1269)
• Linear Learner (algorithm) (p. 1269)
• MXNet (DLC) (p. 1269)
• MXNet Coach (DLC) (p. 1272)
• Model Monitor (algorithm) (p. 1272)
• NTM (algorithm) (p. 1273)
• Neo Image Classification (algorithm) (p. 1273)
• Neo MXNet (DLC) (p. 1273)
• Neo PyTorch (DLC) (p. 1274)
• Neo Tensorflow (DLC) (p. 1274)
• Neo XGBoost (algorithm) (p. 1275)
• Object Detection (algorithm) (p. 1275)
• Object2Vec (algorithm) (p. 1275)
• PCA (algorithm) (p. 1275)
• PyTorch (DLC) (p. 1276)
• Random Cut Forest (algorithm) (p. 1278)
• Scikit-learn (algorithm) (p. 1278)
• Semantic Segmentation (algorithm) (p. 1279)
• Seq2Seq (algorithm) (p. 1279)
• Spark (algorithm) (p. 1279)
• SparkML Serving (algorithm) (p. 1280)
• Tensorflow (DLC) (p. 1280)
• Tensorflow Coach (DLC) (p. 1287)
• Tensorflow Inferentia (DLC) (p. 1288)
• Tensorflow Ray (DLC) (p. 1288)
• XGBoost (algorithm) (p. 1289)

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-north-1')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-north-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>

**Clarify (algorithm)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='eu-north-1', version='1.0', image_scope='processing')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>763603941244.dkr.ecr.eu-1.amazonaws.com/sagemaker-clarify-processing:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>
**Data Wrangler (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>054986407534.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-data-wrangler-container:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

**Debugger (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>314864569078.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-debugger-rules:&lt;tag&gt;</td>
<td>latest</td>
<td>debugger</td>
</tr>
</tbody>
</table>

**DeepAR Forecasting (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/forecasting-deepar:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Factorization Machines (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-north-1')
```
<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

<td>training</td>
</tr>
<tr>
<td>763104351884.dkr.ecr.eu-4.5.0north-1.amazonaws.com/huggingface-tensorflow-training:&lt;tag&gt;</td>
<td></td>
<td>training</td>
</tr>
</tbody>
</table>

**IP Insights (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/ipinsights:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>
Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/image-classification:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='eu-north-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>

</thead>
<tbody>
<tr>
<td>601324751636.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td>1.5.1</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>

Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='eu-north-1', version='1.5.1', py_version='py3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>601324751636.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-neo-pytorch:&lt;tag&gt;</td>
<td>1.5.1</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>

K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
```python
image_uris.retrieve(framework='kmeans', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/kmeans:&lt;tag&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**KNN (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
drivers.retrieve(framework='knn', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

Docker Registry Paths and Example Code for Europe (Milan) (eu-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- BlazingText (algorithm) (p. 1291)
- Chainer (DLC) (p. 1291)
- Clarify (algorithm) (p. 1292)
- Data Wrangler (algorithm) (p. 1292)
- Debugger (algorithm) (p. 1292)
- DeepAR Forecasting (algorithm) (p. 1292)
- Factorization Machines (algorithm) (p. 1293)
- Hugging Face (algorithm) (p. 1293)
- IP Insights (algorithm) (p. 1294)
- Image classification (algorithm) (p. 1294)
- Inferentia MXNet (DLC) (p. 1294)
- Inferentia PyTorch (DLC) (p. 1295)
- K-Means (algorithm) (p. 1295)
- KNN (algorithm) (p. 1295)
- Linear Learner (algorithm) (p. 1295)
- MXNet (DLC) (p. 1296)
- MXNet Coach (DLC) (p. 1298)
- Model Monitor (algorithm) (p. 1299)
- NTM (algorithm) (p. 1299)
- Neo Image Classification (algorithm) (p. 1299)
- Neo MXNet (DLC) (p. 1300)
- Neo PyTorch (DLC) (p. 1300)
- Neo Tensorflow (DLC) (p. 1301)
- Neo XGBoost (algorithm) (p. 1301)
- Object Detection (algorithm) (p. 1301)
- Object2Vec (algorithm) (p. 1301)
- PCA (algorithm) (p. 1302)
- PyTorch (DLC) (p. 1302)
- Random Cut Forest (algorithm) (p. 1304)
- Scikit-learn (algorithm) (p. 1305)
- Semantic Segmentation (algorithm) (p. 1305)
- Seq2Seq (algorithm) (p. 1305)
- Spark (algorithm) (p. 1305)
- SparkML Serving (algorithm) (p. 1306)
- Tensorflow (DLC) (p. 1306)
- Tensorflow Coach (DLC) (p. 1313)
- Tensorflow Inferentia (DLC) (p. 1314)
- Tensorflow Ray (DLC) (p. 1314)
- XGBoost (algorithm) (p. 1315)

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext',region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>257386234256.dkr.ecr.eu-south-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer',region='eu-south-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>048378556238.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>

<td>1.0</td>
<td>processing</td>
</tr>
</tbody>
</table>

Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>488297956546.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-data-wrangler-container:&lt;tag&gt;</td>
<td>1.x</td>
<td>processing</td>
</tr>
</tbody>
</table>

Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>

<td>latest</td>
<td>debugger</td>
</tr>
</tbody>
</table>

DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```
image_uris.retrieve(framework='forecasting-deepar', region='eu-south-1')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>257386234256.dkr.ecr.eu-south-1.amazonaws.com/forecasting-deepar:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Factorization Machines (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>257386234256.dkr.ecr.eu-south-1.amazonaws.com/factorization-machines:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Hugging Face (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-south-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>692866216735.dkr.ecr.eu-south-1.amazonaws.com/huggingface-pytorch-training:&lt;tag&gt;</td>
<td>4.4.2</td>
<td>training</td>
</tr>
<tr>
<td>692866216735.dkr.ecr.eu-south-1.amazonaws.com/huggingface-pytorch-training:&lt;tag&gt;</td>

</tr>
<tr>
<td>692866216735.dkr.ecr.eu-south-1.amazonaws.com/huggingface-tensorflow-training:&lt;tag&gt;</td>
<td>4.5.0</td>
<td>training</td>
</tr>
</tbody>
</table>
**Use built-in algorithms**

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>huggingface-tensorflow-training:&lt;tag&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**IP Insights (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>257386234256.dkr.ecr.eu-south-1.amazonaws.com/ipinsights:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Image classification (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

Docker Registry Paths and Example Code for South America (São Paulo) (sa-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- BlazingText (algorithm) (p. 1344)
- Chainer (DLC) (p. 1344)
- Clarify (algorithm) (p. 1344)
- Data Wrangler (algorithm) (p. 1345)
- Debugger (algorithm) (p. 1345)
- DeepAR Forecasting (algorithm) (p. 1345)
- Factorization Machines (algorithm) (p. 1346)
- Hugging Face (algorithm) (p. 1346)
- IP Insights (algorithm) (p. 1346)
- Image classification (algorithm) (p. 1347)
- Inferentia MXNet (DLC) (p. 1347)
- Inferentia PyTorch (DLC) (p. 1347)
- K-Means (algorithm) (p. 1348)
- KNN (algorithm) (p. 1348)
- Linear Learner (algorithm) (p. 1348)
- MXNet (DLC) (p. 1348)
- MXNet Coach (DLC) (p. 1351)
- Model Monitor (algorithm) (p. 1352)
- NTM (algorithm) (p. 1352)
- Neo Image Classification (algorithm) (p. 1352)
- Neo MXNet (DLC) (p. 1352)
- Neo PyTorch (DLC) (p. 1353)
- Neo Tensorflow (DLC) (p. 1353)
- Neo XGBoost (algorithm) (p. 1354)
- Object Detection (algorithm) (p. 1354)
- Object2Vec (algorithm) (p. 1354)
- PCA (algorithm) (p. 1355)
- PyTorch (DLC) (p. 1355)
- Random Cut Forest (algorithm) (p. 1357)
- Scikit-learn (algorithm) (p. 1357)
- Semantic Segmentation (algorithm) (p. 1358)
- Seq2Seq (algorithm) (p. 1358)
- Spark (algorithm) (p. 1358)
- SparkML Serving (algorithm) (p. 1359)
- Tensorflow (DLC) (p. 1359)
- Tensorflow Coach (DLC) (p. 1366)
- Tensorflow Inferentia (DLC) (p. 1367)
- Tensorflow Ray (DLC) (p. 1367)
- XGBoost (algorithm) (p. 1368)
### BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='sa-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>855470959533.dkr.ecr.sa-east-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='sa-east-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>520713654638.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>520713654638.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>520713654638.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>

### Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='sa-east-1', version='1.0', image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>520018980103.dkr.ecr.sa-east-1.amazonaws.com/</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>
### Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-clarify-processing:&lt;tag&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler',region='sa-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>424196993095.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-data-wrangler-container:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

#### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='sa-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>818342061345.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-debugger-rules:&lt;tag&gt;</td>
<td></td>
<td>debugger</td>
</tr>
</tbody>
</table>

#### DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar',region='sa-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>855470959533.dkr.ecr.sa-east-1.amazonaws.com/forecasting-deepar:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>
Factorization Machines (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='sa-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>855470959533.dkr.ecr.sa-east-1.amazonaws.com/factorization-machines:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Hugging Face (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='sa-east-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>763104351884.dkr.ecr.sa-east-1.amazonaws.com/huggingface-pytorch-training:&lt;tag&gt;</td>
<td>4.4.2</td>
<td>training</td>
</tr>
<tr>
<td>763104351884.dkr.ecr.sa-east-1.amazonaws.com/huggingface-pytorch-training:&lt;tag&gt;</td>
<td>4.5.0</td>
<td>training</td>
</tr>
<tr>
<td>763104351884.dkr.ecr.sa-east-1.amazonaws.com/huggingface-tensorflow-training:&lt;tag&gt;</td>
<td>4.4.2</td>
<td>training</td>
</tr>
<tr>
<td>763104351884.dkr.ecr.sa-east-1.amazonaws.com/huggingface-tensorflow-training:&lt;tag&gt;</td>
<td>4.5.0</td>
<td>training</td>
</tr>
</tbody>
</table>

IP Insights (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='sa-east-1')
```
Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>855470959533.dkr.ecr.sa-east-1.amazonaws.com/ipinsights:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Image classification (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='sa-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>855470959533.dkr.ecr.sa-east-1.amazonaws.com/image-classification:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Inferentia MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='sa-east-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>756306329178.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td></td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>

**Inferentia PyTorch (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='sa-east-1',version='1.5.1',py_version='py3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

</tbody>
</table>
### K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans', region='sa-east-1')
```

### KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='sa-east-1')
```

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='sa-east-1')
```

### MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='sa-east-1', version='1.4.1', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')

### TensorFlow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow',region='sa-east-1',version='0.8.5',instance_type='ml.c5.4xlarge')
```
XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='sa-east-1', version='1.2-1')
```
Use built-in algorithms

### Docker Registry Paths and Example Code for AWS GovCloud (US-West) (us-gov-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- BlazingText (algorithm) (p. 1370)
- Chainer (DLC) (p. 1370)
- Debugger (algorithm) (p. 1371)
- DeepAR Forecasting (algorithm) (p. 1371)
- Factorization Machines (algorithm) (p. 1371)
- Hugging Face (algorithm) (p. 1372)
- IP Insights (algorithm) (p. 1372)
- Image classification (algorithm) (p. 1373)
- Inferentia MXNet (DLC) (p. 1373)
- Inferentia PyTorch (DLC) (p. 1373)
- K-Means (algorithm) (p. 1374)
- KNN (algorithm) (p. 1374)
- LDA (algorithm) (p. 1374)
- Linear Learner (algorithm) (p. 1375)
- MXNet (DLC) (p. 1375)
- MXNet Coach (DLC) (p. 1378)
- NTM (algorithm) (p. 1378)
- Neo Image Classification (algorithm) (p. 1379)
- Neo MXNet (DLC) (p. 1379)
- Neo PyTorch (DLC) (p. 1379)
- Neo Tensorflow (DLC) (p. 1380)
- Neo XGBoost (algorithm) (p. 1380)
- Object Detection (algorithm) (p. 1381)
- Object2Vec (algorithm) (p. 1381)
- PCA (algorithm) (p. 1381)
- PyTorch (DLC) (p. 1382)
- Random Cut Forest (algorithm) (p. 1384)
Use built-in algorithms

- Scikit-learn (algorithm) (p. 1385)
- Semantic Segmentation (algorithm) (p. 1385)
- Seq2Seq (algorithm) (p. 1385)
- Spark (algorithm) (p. 1386)
- SparkML Serving (algorithm) (p. 1386)
- Tensorflow (DLC) (p. 1387)
- Tensorflow Coach (DLC) (p. 1395)
- Tensorflow Inferentia (DLC) (p. 1396)
- Tensorflow Ray (DLC) (p. 1396)
- XGBoost (algorithm) (p. 1397)

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='us-gov-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>

</tbody>
</table>
**Image classification (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='us-gov-west-1')
```

---

**Inferentia MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='us-gov-west-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

---

**Inferentia PyTorch (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='us-gov-west-1', version='1.5.1', py_version='py3')
```
## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans', region='us-gov-west-1')
```

### LDA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='lda', region='us-gov-west-1')
```
Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='us-gov-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>

Common Data Formats for Built-in Algorithms

The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

Topics
- Common Data Formats for Training (p. 1398)
- Common Data Formats for Inference (p. 1402)

Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data need to go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

Topics
**Content Types Supported by Built-In Algorithms**

The following table lists some of the commonly supported `ContentType` values and the algorithms that use them:

<table>
<thead>
<tr>
<th>Content Type</th>
<th>Algorithm</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-image</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>application/x-recordio</td>
<td>Object Detection Algorithm</td>
</tr>
<tr>
<td>application/x-recordio-protobuf</td>
<td>Factorization Machines, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, Sequence-to-Sequence</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>BlazingText, DeepAR</td>
</tr>
<tr>
<td>image/jpeg</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>image/png</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>text/libsvm</td>
<td>XGBoost</td>
</tr>
</tbody>
</table>

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this table.

**Using Pipe Mode**

In *Pipe mode*, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to *File mode*, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the `AlgorithmSpecification` for additional details on the training input mode.

**Using CSV Format**

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify `text/csv` as the `ContentType`. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the number of label columns in the content type. For example, in this case `content_type=text/csv;label_size=0`. For a notebook example that uses CSV format, see Breast Cancer Prediction. For more information, see Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms.
Using RecordIO Format

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However, if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

**Note**
For an example that shows how to convert the commonly used numpy array into the protobuf recordIO format, see *An Introduction to Factorization Machines with MNIST*.

```proto2
syntax = "proto2";
package aialgs.data;

option java_package = "com.amazonaws.aialgorithms.proto";
option java_outer_classname = "RecordProtos";

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated float values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 20) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated double values = 1 [packed = true];

  // If this is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated int32 values = 1 [packed = true];

  // If this is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}
```
// An optional shape that allows the vector to represent a matrix.
// For example, if shape = [10, 20], floor(keys[i] / 10) gives the row,
// and keys[i] % 20 gives the column.
// This also supports n-dimensional tensors.
// Note: If the tensor is sparse, you must specify this value.
repeated uint64 shape = 3 [packed = true];

// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
  repeated bytes value = 1;
  // If the content type of the data is known, stores it.
  // This allows for the possibility of using decoders for common formats
  // in the future.
  optional string content_type = 2;
}

message Value {
  oneof value {
    // The numbering assumes the possible use of:
    // - float16, float128
    // - int8, int16, int32
    Float32Tensor float32_tensor = 2;
    Float64Tensor float64_tensor = 3;
    Int32Tensor int32_tensor = 7;
    Bytes bytes = 9;
  }
}

message Record {
  // Map from the name of the feature to the value.
  // For vectors and libsvm-like datasets,
  // a single feature with the name 'values'
  // should be specified.
  map<string, Value> features = 1;
  // An optional set of labels for this record.
  // Similar to the features field above, the key used for
  // generic scalar / vector labels should be 'values'.
  map<string, Value> label = 2;
  // A unique identifier for this record in the dataset.
  // Whilst not necessary, this allows better
  // debugging where there are data issues.
  // This is not used by the algorithm directly.
  optional string uid = 3;
  // Textual metadata describing the record.
  // This may include JSON-serialized information
  // about the source of the record.
  // This is not used by the algorithm directly.
  optional string metadata = 4;
  // An optional serialized JSON object that allows per-record
  // hyper-parameters/configuration/other information to be set.
  // The meaning/interpretation of this field is defined by
  // the algorithm author and may not be supported.
}
After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of InputDataConfig in create_training_job.

**Note**
For all Amazon SageMaker algorithms, the ChannelName in InputDataConfig must be set to train. Some algorithms also support a validation or test input channels. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

### Trained Model Deserialization

Amazon SageMaker models are stored as model.tar.gz in the S3 bucket specified in OutputDataConfig S3OutputPath parameter of the create_training_job call. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When model.tar.gz is untarred, it contains model_algo-1, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```python
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

### Common Data Formats for Inference

Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various AWS services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

### Topics

- Convert Data for Inference Request Serialization (p. 1402)
- Convert Data for Inference Response Deserialization (p. 1403)
- Common Request Formats for All Algorithms (p. 1405)
- Use Batch Transform with Built-in Algorithms (p. 1406)

### Convert Data for Inference Request Serialization

Content type options for Amazon SageMaker algorithm inference requests include: text/csv, application/json, and application/x-recordio-protobuf. Algorithms that don't support all of these types can support other types. XGBoost, for example, only supports text/csv from this list, but also supports text/libsvm.

For text/csv, the value for the Body argument to invoke_endpoint should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like 1.5,16.0,14,23.0. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.
application/json is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```javascript
let request = {
  // Instances might contain multiple rows that predictions are sought for.
  "instances": [
    {
      // Request and algorithm specific inference parameters.
      "configuration": {},
      // Data in the specific format required by the algorithm.
      "data": {
        "<field name>": dataElement
      }
    }
  ]
}
```

You have the following options for specifying the `dataElement`:

**Protocol buffers equivalent**

```javascript
// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
  "keys": [],
  "values": [],
  "shape": []
}
```

**Simple numeric vector**

```javascript
// An array containing numeric values is treated as an instance containing a
// single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
  "features": dataElement
}
```

**For multiple records**

```javascript
let request = {
  "instances": [
    // First instance.
    {
      "features": [1.5, 16.0, 14.0, 23.0]
    },
    // Second instance.
    {
      "features": [-2.0, 100.2, 15.2, 9.2]
    }
  ]
}
```

**Convert Data for Inference Response Deserialization**

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

```javascript
let response = {
```

1403
Use built-in algorithms

```json
"predictions": [{
// Fields in the response object are defined on a per algorithm-basis.
}]
}
```

The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

**Single-record inference**

```javascript
let response = {
"predictions": [{
  "closest_cluster": 5,
  "distance_to_cluster": 36.5
}]
}
```

**Multi-record inference**

```javascript
let response = {
  "predictions": [
  // First instance prediction.
  {
    "closest_cluster": 5,
    "distance_to_cluster": 36.5
  },
  // Second instance prediction.
  {
    "closest_cluster": 2,
    "distance_to_cluster": 90.3
  }
  ]
}
```

**Multi-record inference with protobuf input**

```javascript
{
  "features": [],
  "label": {
    "closest_cluster": {
      "values": [ 5.0 ] // e.g. the closest centroid/cluster was 1.0
    },
    "distance_to_cluster": {
      "values": [ 36.5 ]
    }
  },
  "uid": "abc123",
  "metadata": "{ "created_at": '2017-06-03' }"
}
```

SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```javascript
{"distance_to_cluster": 23.40593910217285, "closest_cluster": 0.0}
{"distance_to_cluster": 27.250282287597656, "closest_cluster": 0.0}
```

While running batch transform, we recommended using the jsonlines response type by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`. 
Common Request Formats for All Algorithms

Most algorithms use several of the following inference request formats.

**JSON Request Format**

**Content type:** application/JSON

### Dense format

```
let request = {
    "instances": [
        {
            "features": [1.5, 16.0, 14.0, 23.0]
        }
    ]
}
```

```
let request = {
    "instances": [
        {
            "data": {
                "features": {
                    "values": [1.5, 16.0, 14.0, 23.0]
                }
            }
        }
    ]
}
```

### Sparse format

```
{
    "instances": [
        {
            "data": {
                "features": {
                    "keys": [26, 182, 232, 243, 431],
                    "shape": [2000],
                    "values": [1, 1, 1, 4, 1]
                }
            }
        },
        {
            "data": {
                "features": {
                    "keys": [0, 182, 232, 243, 431],
                    "shape": [2000],
                    "values": [13, 1, 1, 4, 1]
                }
            },
        }
    ]
}
```

**JSONLINES Request Format**

**Content type:** application/JSONLINES

### Dense format

A single record in dense format can be represented as either:

```
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```
**Sparse Format**

A single record in sparse format is represented as:

```
{"data": { "features": { "keys": [26, 182, 232, 243, 431], "shape": [2000], "values": [1, 1, 1, 4, 1] } } }
```

Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```
{"data": { "features": { "keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } } }

{"data": { "features": { "values": [1.5, 16.0, 14.0, 23.0] } } }

{"features": [1.5, 16.0, 14.0, 23.0] }
```

**CSV Request Format**

Content type: text/CSV; label_size=0

*Note*

CSV support is not available for factorization machines.

**RECORDIO Request Format**

Content type: application/x-recordio-protobuf

**Use Batch Transform with Built-in Algorithms**

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the *Accept* field in the `CreateTransformJobRequest` to `application/jsonlines`.

When you create a transform job, the *SplitType* must be set according to the *ContentType* of the input data. Similarly, depending on the *Accept* field in the `CreateTransformJobRequest`, *AssembleWith* must be set accordingly. Please use the following table to help appropriately set these fields:

<table>
<thead>
<tr>
<th><em>ContentType</em></th>
<th>Recommended <em>SplitType</em></th>
<th><em>Accept</em></th>
<th>Recommended <em>AssembleWith</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>RecordIO</td>
<td>application/x-recordio-protobuf</td>
<td>None</td>
</tr>
<tr>
<td>text/csv</td>
<td>Line</td>
<td>application/jsonlines</td>
<td>Line</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>Line</td>
<td>application/json</td>
<td>None</td>
</tr>
<tr>
<td>application/x-image</td>
<td>None</td>
<td>application/x-image</td>
<td>None</td>
</tr>
<tr>
<td>image/*</td>
<td>None</td>
<td>image/*</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
For more information on response formats for specific algorithms, see the following:

- DeepAR Inference Formats (p. 1430)

- RCF Response Formats (p. 1544)

**Instance Types for Built-in Algorithms**

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.10xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution.

For more information on SageMaker hardware specifications, see Amazon SageMaker ML Instance Types.

**Logs for Built-in Algorithms**

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose CloudWatch, choose Logs, and then choose the /aws/sagemaker/TrainingJobs log group. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the TrainingJobName parameter when the job was created.

**Note**

If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm
Common Errors

If a training job fails, some details about the failure are provided by the FailureReason return value in the training job description, as follows:

```python
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

   **From the CloudWatch Log**

   ```text
   [10/16/2017 23:45:17 ERROR 139623806805824 train.py:48] Additional properties are not allowed (u'mini_batch_siz' was unexpected)
   ```

2. Specifying an invalid value for a hyperparameter.

   **FailureReason**

   ```text
   AlgorithmError: u'abc' is not valid under any of the given schemas\n   failed validating u'oneOf' in\n   schema[u'properties'][u'feature_dim']:\n   {u'oneOf':\n    [{u'pattern': u'^([1-9][0-9]*)$', u'type': u'string'},\n     {u'minimum': 1, u'type': u'integer'}]}\n   ```

3. Inaccurate protobuf file format.

   **From the CloudWatch log**

   ```text
   [10/16/2017 23:57:17 ERROR 140373086025536 train.py:48] u'abc' is not valid under any of the given schemas
   ```

BlazingText algorithm

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a word embedding. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained...
on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText’s implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see Docker Registry Paths for SageMaker Built-in Algorithms.

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.
- Enriched Word Vectors with Subword Information by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.
- A batch_skipgram mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The batch_skipgram mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see Parallelizing Word2Vec in Shared and Distributed Memory.

To summarize, the following modes are supported by BlazingText on different types instances:

<table>
<thead>
<tr>
<th>Modes</th>

<tr>
<td>Multiple CPU instances</td>
<td>Batch Skip-gram</td>
<td>None</td>
</tr>
</tbody>
</table>

For more information about the mathematics behind BlazingText, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.

Topics

- Input/Output Interface for the BlazingText Algorithm (p. 1410)
- EC2 Instance Recommendation for the BlazingText Algorithm (p. 1412)
- BlazingText Sample Notebooks (p. 1413)
- BlazingText Hyperparameters (p. 1413)
- Tune a BlazingText Model (p. 1417)
Input/Output Interface for the BlazingText Algorithm

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.

Training and Validation Data Format

Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the train channel. No other channels are supported. The file should contain a training sentence per line.

Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

Train with File Mode

For supervised mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string __label__. Here is an example of a training/validation file:

__label__4  linux ready for prime time , intel says , despite all the linux hype , the open-source movement has yet to make a huge splash in the desktop market . that may be about to change , thanks to chipmaking giant intel corp .

__label__2  bowled by the slower one again , kolkata , november 14 the past caught up with sourav ganguly as the indian skippers return to international cricket was short lived .

Note
The order of labels within the sentence doesn't matter.

Upload the training file under the train channel, and optionally upload the validation file under the validation channel.

Train with Augmented Manifest Text Format

The supervised mode also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in JSON Lines format in which each line represents one sample. The sentences are specified using the source tag and the label can be specified using the label tag. Both source and label tags should be provided under the AttributeNames parameter value as specified in the request.

```json
{"source":"linux ready for prime time , intel says , despite all the linux hype", "label":1}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up with sourav ganguly", "label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.

```json
{"source":"linux ready for prime time , intel says , despite all the linux hype", "label": [1, 3]}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up with sourav ganguly", "label": [2, 4, 5]}
```
For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1919).

Model Artifacts and Inference

Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of vectors.txt, which contains words-to-vectors mapping, and vectors.bin, a binary used by BlazingText for hosting, inference, or both. vectors.txt stores the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the vectors.txt file:

```python
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesnt_match("breakfast cereal dinner lunch".split())
```

If the evaluation parameter is set to True, an additional file, eval.json, is created. This file contains the similarity evaluation results (using Spearman's rank correlation coefficients) on WS-353 dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to True during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

Sample JSON Request

Mime-type: application/json

```
{
"instances": ["word1", "word2", "word3"]
}
```

Model Artifacts for the Text Classification Algorithm

Training with supervised outputs creates a model.bin file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

Sample JSON Request

Mime-type: application/json

```
{
"instances": ["the movie was excellent", "i did not like the plot ."]
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top k predictions, you can set k in the configuration, as follows:

```
{
"instances": ["the movie was excellent", "i did not like the plot ."],
"configuration":{"k": 2}
}
```

For BlazingText, the content-type and accept parameters must be equal. For batch transform, they both need to be application/jsonlines. If they differ, the Accept field is ignored. The format for input follows:
Amazon SageMaker Developer Guide
Use built-in algorithms

content-type: application/jsonlines
{"source": "source_0"}
{"source": "source_1"}
if you need to pass the value of k for top-k, then you can do it in the following way:
{"source": "source_0", "k": 2}
{"source": "source_1", "k": 3}

The format for output follows:
accept: application/jsonlines
{"prob": [prob_1], "label": ["__label__1"]}
{"prob": [prob_1], "label": ["__label__1"]}
If you have passed the value of k to be more than 1, then response will be in this format:
{"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]}
{"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]}

For both supervised (text classiﬁcation) and unsupervised (Word2Vec) modes, the binaries (*.bin)
produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries
produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText
using BlazingText.
Here is an example of how to use a model generated with BlazingText with fastText:

#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz
#Unzip the model archive
tar -xzf model.tar.gz
#Use the model archive with fastText
fasttext predict ./model.bin test.txt

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU
will not produce binaries.
For more details on dataset formats and model hosting, see the example notebooks Text Classiﬁcation
with the BlazingText Algorithm, FastText Models, and Generating Subword Embeddings with the
Word2Vec Algorithm.

EC2 Instance Recommendation for the BlazingText Algorithm
For cbow and skipgram modes, BlazingText supports single CPU and single GPU instances. Both
of these modes support learning of subwords embeddings. To achieve the highest speed without
compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.
For batch_skipgram mode, BlazingText supports single or multiple CPU instances. When training on
multiple instances, set the value of the S3DataDistributionType ﬁeld of the S3DataSource object
that you pass to CreateTrainingJob to FullyReplicated. BlazingText takes care of distributing
data across machines.
For the supervised text classiﬁcation mode, a C5 instance is recommended if the training dataset is less
than 2 GB. For larger datasets, use an instance with a single GPU (ml.p2.xlarge or ml.p3.2xlarge).

1412


BlazingText Sample Notebooks

For a sample notebook that uses the SageMaker BlazingText algorithm to train and deploy supervised binary and multiclass classification models, see Blazing Text classification on the DBPedia dataset. For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the Blazing Text are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab, then choose Create copy.

BlazingText Hyperparameters

When you start a training job with a CreateTrainingJob request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

Word2Vec Hyperparameters

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker.

<table>
<thead>
<tr>

| epochs         | The maximum number of complete passes through the training data.  
Optional  
Valid values: Positive integer  
Default value: 5 |
| learning_rate  | The step size used for parameter updates.  
Optional  
Valid values: Positive float  
Default value: 0.05 |
| min_count      | Words that appear less than min_count times are discarded.  
Optional  
Valid values: Non-negative integer  
Default value: 5 |
| min_epochs     | The minimum number of epochs to train before early stopping logic is invoked.  
Optional  
Valid values: Positive integer  
Default value: 5 |
| patience       | The number of epochs to wait before applying early stopping when no progress is made on the validation set. Used only when early_stopping is True.  
Optional  
Valid values: Positive integer  
Default: 4 |
| vector_dim     | The dimension of the embedding layer.  
Optional  
Valid values: Positive integer  
Default value: 100 |
| word_ngrams    | The number of word n-gram features to use.  
Optional  
Valid values: Positive integer  
Default value: 2 |
Tune a BlazingText Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

Metrics Computed by the BlazingText Algorithm

The BlazingText Word2Vec algorithm (skipgram, cbow, and batch_skipgram modes) reports on a single metric during training: \textit{train:mean_rho}. This metric is computed on WS-353 word similarity datasets. When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (supervised mode), also reports on a single metric during training: the \textit{validation:accuracy}. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

DeepAR Forecasting Algorithm

The Amazon SageMaker DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.

In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more target time series that have been generated by the same process or similar processes. Based on this input dataset, the algorithm trains a model that learns an approximation of this process/processes and uses it to predict how the target time series evolves. Each target time series can be optionally associated with a vector of static (time-independent) categorical features provided by the cat field and a vector of dynamic (time-dependent) time series provided by the dynamic_feat field. SageMaker trains the DeepAR model by randomly sampling training examples from each target time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To control how far in the past the network can see, use the context_length hyperparameter. To control how far in the future predictions can be made, use the prediction_length hyperparameter. For more information, see How the DeepAR Algorithm Works (p. 1422).

Topics

- Input/Output Interface for the DeepAR Algorithm (p. 1419)
Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required train channel describes the training dataset. The optional test channel describes a dataset that the algorithm uses to evaluate model accuracy after training. You can provide training and test datasets in JSON Lines format. Files can be in gzip or Parquet file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all files in the directory as inputs for the corresponding channel, except those that start with a period (.) and those named _SUCCESS. This ensures that you can directly use output folders produced by Spark jobs as input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (.json, .json.gz, or .parquet) in the specified input path. If the path does not end in one of these extensions, you must explicitly specify the format in the SDK for Python. Use the content_type parameter of the s3_input class.

The records in your input files should contain the following fields:

- **start**—A string with the format YYYY-MM-DD HH:MM:SS. The start timestamp can't contain time zone information.
- **target**—An array of floating-point values or integers that represent the time series. You can encode missing values as null literals, or as "NaN" strings in JSON, or as nan floating-point values in Parquet.
- **dynamic_feat** (optional)—An array of arrays of floating-point values or integers that represents the vector of custom feature time series (dynamic features). If you set this field, all records must have the same number of inner arrays (the same number of feature time series). In addition, each inner array must be the same length as the associated target value plus length of the context. Missing values are not supported in the features. For example, if target time series represents the demand of different products, an associated dynamic_feat might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

  ```json
  {"start": ... , "target": [1, 5, 10, 2], "dynamic_feat": [[0, 1, 0]]}
  ```

- **cat** (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain {R, G, B} can be encoded as {0, 1, 2}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the embedding_dimension hyperparameter. For more information, see DeepAR Hyperparameters (p. 1425).

If you use a JSON file, it must be in JSON Lines format. For example:

```json
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1], "dynamic_feat": [[1.1, 1.2, 0.5, ...]]}
```
In this example, each time series has two associated categorical features and one time series feature.

For Parquet, you use the same three fields as columns. In addition, "start" can be the datetime type. You can compress Parquet files using gzip (gzip) or the Snappy compression library (snappy).

If the algorithm is trained without cat and dynamic_feat fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the cat and dynamic_feat feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding cat features. For example, if the target time series represents the demand of clothing items, you can associate a two-dimensional cat vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:

```
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
```

At inference time, you can request predictions for targets with cat values that are combinations of the cat values observed in the training data, for example:

```
{ "start": ..., "target": ..., "cat": [0, 1], ... } # blue shoes
{ "start": ..., "target": ..., "cat": [1, 0], ... } # red dress
```

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
- Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
- Make sure to set the start field correctly. The algorithm uses the start timestamp to derive the internal features.
- If you use categorical features (cat), all time series must have the same number of categorical features. If the dataset contains the cat field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, cardinality is "auto". If the dataset contains the cat field, but you don't want to use it, you can disable it by setting cardinality to "". If a model was trained using a cat feature, you must include it for inference.
- If your dataset contains the dynamic_feat field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the dynamic_feat field should have the same length as the target. If the dataset contains the dynamic_feat field, but you don't want to use it, disable it by setting(num_dynamic_feat to ""). If the model was trained with the dynamic_feat field, you must provide this field for inference. In addition, each of the features has to have the length of the provided target plus the prediction_length. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:
Use built-in algorithms

\[
RMSE = \sqrt{\frac{1}{nT} \sum_{i,t} (\hat{y}_{i,t} - y_{i,t})^2}
\]

\(y_{i,t}\) is the true value of time series \(i\) at the time \(t\). \(\hat{y}_{i,t}\) is the mean prediction. The sum is over all \(n\) time series in the test set and over the last \(T\) time points for each time series, where \(T\) corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the `prediction_length` hyperparameter. For more information, see DeepAR Hyperparameters (p. 1425).

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range \([0, 1]\), the weighted quantile loss is defined as follows:

\[
w\text{QuantileLoss}[\tau] = 2 \frac{\sum_{i,t} Q_{i,t}^{(\tau)}}{\sum_{i,t} |y_{i,t}|}, \quad \text{with} \quad Q_{i,t}^{(\tau)} = \begin{cases} 
(1 - \tau)|q_{i,t}^{(\tau)} - y_{i,t}| & \text{if } q_{i,t}^{(\tau)} > y_{i,t} \\
\tau|q_{i,t}^{(\tau)} - y_{i,t}| & \text{otherwise}
\end{cases}
\]

\(q_{i,t}^{(\tau)}\) is the \(\tau\)-quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the `test_quantiles` hyperparameter. In addition to these, the average of the prescribed quantile losses is reported as part of the training logs. For information, see DeepAR Hyperparameters (p. 1425).

For inference, DeepAR accepts JSON format and the following fields:

- "instances", which includes one or more time series in JSON Lines format
- A name of "configuration", which includes parameters for generating the forecast

For more information, see DeepAR Inference Formats (p. 1430).

Best Practices for Using the DeepAR Algorithm

When preparing your time series data, follow these best practices to achieve the best results:

- Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set `context_length`, don’t break up the time series or provide only a part of it. The model uses data points further back than the value set in `context_length` for the lagged values feature.

- When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but on the future `prediction_length` time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last `prediction_length` points from each time series for training. During training, the model doesn’t see the target values for time points on which it is evaluated during testing. During testing, the algorithm withholds the last `prediction_length` points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see Tune a DeepAR Model (p. 1429).

- Avoid using very large values (>400) for the `prediction_length` because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use 5min instead of 1min.

- Because lags are used, a model can look further back in the time series than the value specified for `context_length`. Therefore, you don’t need to set this parameter to a large value. We recommend starting with the value that you used for `prediction_length`.

1421
• We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.

EC2 Instance Recommendations for the DeepAR Algorithm

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, ml.c4.2xlarge or ml.c4.4xlarge), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for context_length, prediction_length, num_cells, num_layers, or mini_batch_size can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

DeepAR Sample Notebooks

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker DeepAR algorithm and how to deploy the trained model for performing inferences, see Time series forecasting with DeepAR - Synthetic data as well as DeepAR demo on electricity dataset, which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all of the SageMaker examples. To open a notebook, choose its Use tab, and choose Create copy.

How the DeepAR Algorithm Works

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector of feature time series and a vector of categorical features. For more information, see Input/Output Interface for the DeepAR Algorithm (p. 1419).

For example, the following is an element of a training set indexed by \( i \) which consists of a target time series, \( Z_{i,t} \) and two associated feature time series, \( X_{i,1,t} \) and \( X_{i,2,t} \):
The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run "what if?" scenarios. What happens, for example, if I change the price of a product in some way?

Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

**How Feature Time Series Work in the DeepAR Algorithm**

To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. For example, DeepAR creates two feature time series (day of the month and day of the year) for a weekly time series frequency. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features: $u_{i,1,t}$ represents the hour of the day and $u_{i,2,t}$ the day of the week.

The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.

<table>
<thead>
<tr>
<th>Frequency of the Time Series</th>
<th>Derived Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minute</td>
<td>minute-of-hour, hour-of-day, day-of-week, day-of-month, day-of-year</td>
</tr>
</tbody>
</table>
DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The `context_length` hyperparameter controls how far in the past the network can see, and the `prediction_length` hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element $i$. For brevity, we've omitted the feature time series $x_{i,1,t}$ and $u_{i,2,t}$.

To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index, $t = T$, the model exposes the $z_{i,t}$ values, which occurred approximately one, two, and three days in the past.

For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next `prediction_length` values.
Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks.

**DeepAR Hyperparameters**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context_length</td>
<td>The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the prediction_length. The model also receives lagged inputs from the target, so context_length can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the time series. For example, lag values for daily frequency are previous week, 2 weeks, 3 weeks, 4 weeks, and year. Required Valid values: Positive integer</td>
</tr>
<tr>
<td>epochs</td>
<td>The maximum number of passes over the training data. The optimal value depends on your data size and learning rate. See also early_stopping_patience. Typical values range from 10 to 1000. Required Valid values: Positive integer</td>
</tr>
<tr>
<td>prediction_length</td>
<td>The number of time-steps that the model is trained to predict, also called the forecast horizon. The trained model always generates forecasts with this length. It can’t generate longer forecasts. The prediction_length is fixed when a model is trained and it cannot be changed later. Required Valid values: Positive integer</td>
</tr>
<tr>
<td>time_freq</td>
<td>The granularity of the time series in the dataset. Use time_freq to select appropriate date features and lags. The model supports the following basic frequencies. It also supports multiples of these basic frequencies. For example, 5min specifies a frequency of 5 minutes.</td>
</tr>

<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>cardinality</td>
<td>When using the categorical features (cat), cardinality is an array specifying the number of categories (groups) per categorical feature. Set this to auto to infer the cardinality from the data. The auto mode also works when no categorical features are used in the dataset. This is the recommended setting for the parameter. Set cardinality to ignore to force DeepAR to not use categorical features, even if they are present in the data. To perform additional data validation, it is possible to explicitly set this parameter to the actual value. For example, if two categorical features are provided where the first has 2 and the other has 3 possible values, set this to [2, 3]. For more information on how to use categorical feature, see the data-section on the main documentation page of DeepAR. <strong>Optional</strong> Valid values: auto, ignore, array of positive integers, empty string, or Default value: auto</td>
</tr>
<tr>
<td>dropout_rate</td>
<td>The dropout rate to use during training. The model uses zoneout regularization. For each iteration, a random subset of hidden neurons are not updated. Typical values are less than 0.2. <strong>Optional</strong> Valid values: float Default value: 0.1</td>
</tr>
<tr>
<td>early_stopping_patience</td>
<td>If this parameter is set, training stops when no progress is made within the specified number of epochs. The model that has the lowest loss is returned as the final model. <strong>Optional</strong> Valid values: integer</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>embedding_dimension</td>
<td>Size of embedding vector learned per categorical feature (same value is used for all categorical features). The DeepAR model can learn group-level time series patterns when a categorical grouping feature is provided. To do this, the model learns an embedding vector of size <code>embedding_dimension</code> for each group, capturing the common properties of all time series in the group. A larger <code>embedding_dimension</code> allows the model to capture more complex patterns. However, because increasing the <code>embedding_dimension</code> increases the number of parameters in the model, more training data is required to accurately learn these parameters. Typical values for this parameter are between 10-100.</td>

Use built-in algorithms

Parameter Name | Description
--- | ---
num_layers | The number of hidden layers in the RNN. Typical values range from 1 to 4.
| Optional
| Valid values: positive integer
| Default value: 2

test_quantiles | Quantiles for which to calculate quantile loss on the test channel.
| Optional
| Valid values: array of floats
| Default value: [0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9]

Tune a DeepAR Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1797).

Metrics Computed by the DeepAR Algorithm

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see [Best Practices for Using the DeepAR Algorithm](p. 1421).

<table>

### DeepAR Inference Formats

#### DeepAR JSON Request Formats

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the `instances` field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a `cat` for each instance. If the model was trained without the `cat` field, it should be omitted.

If the model was trained with a custom feature time series (`dynamic_feat`), you have to provide the same number of `dynamic_feat` values for each instance. Each of them should have a length given by `length(target) + prediction_length`, where the last `prediction_length` values correspond to the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```json
{
    "instances": [
        {
            "start": "2009-11-01 00:00:00",
            "target": [4.0, 10.0, "NaN", 100.0, 113.0],
            "cat": [0, 1],
            "dynamic_feat": [[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
        },
        {
            "start": "2012-01-30",
            "target": [1.0],
            "cat": [2, 1],
            "dynamic_feat": [[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
        },
        {
            "start": "1999-01-30",
```
The `configuration` field is optional. `configuration.num_samples` sets the number of sample paths that the model generates to estimate the mean and quantiles. `configuration.output_types` describes the information that will be returned in the request. Valid values are "mean", "quantiles", and "samples". If you specify "quantiles", each of the quantile values in `configuration.quantiles` is returned as a time series. If you specify "samples", the model also returns the raw samples used to calculate the other outputs.

### DeepAR JSON Response Formats

The following is the format of a response, where `[...]` are arrays of numbers:

```json
{
  "predictions": [
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    }
  ]
}
```

DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request, the forecasts are generated sequentially. Because the forecast for each time series typically takes about 300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a single request can cause time outs. It's better to send fewer time series per request and send more requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much higher throughput by sending multiple requests in parallel.

By default, DeepAR uses one worker per CPU for inference, if there is sufficient memory per CPU. If the model is large and there isn't enough memory to run a model on each CPU, the number of workers is reduced. The number of workers used for inference can be overwritten using the environment variable.
Amazon SageMaker Developer Guide
Use built-in algorithms

MODEL_SERVER_WORKERS For example, by setting MODEL_SERVER_WORKERS=1) when calling the
SageMaker CreateModel API.

Batch Transform with the DeepAR Algorithm
DeepAR forecasting supports getting inferences by using batch transform from data using the JSON
Lines format. In this format, each record is represented on a single line as a JSON object, and lines
are separated by newline characters. The format is identical to the JSON Lines format used for model
training. For information, see Input/Output Interface for the DeepAR Algorithm (p. 1419). For example:
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
"dynamic_feat": [[1.1, 1.2, 0.5, ..]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat":
[[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
[[1.3, 0.4]]}

Note

When creating the transformation job with CreateTransformJob, set the BatchStrategy
value to SingleRecord and set the SplitType value in the TransformInput conﬁguration
to Line, as the default values currently cause runtime failures.
Similar to the hosted endpoint inference request format, the cat and the dynamic_feat ﬁelds for each
instance are required if both of the following are true:
• The model is trained on a dataset that contained both the cat and the dynamic_feat ﬁelds.
• The corresponding cardinality and num_dynamic_feat values used in the training job are not set
to "".
Unlike hosted endpoint inference, the conﬁguration ﬁeld is set once for the entire batch
inference job using an environment variable named DEEPAR_INFERENCE_CONFIG. The
value of DEEPAR_INFERENCE_CONFIG can be passed when the model is created by calling
CreateTransformJob API. If DEEPAR_INFERENCE_CONFIG is missing in the container environment,
the inference container uses the following default:
{

}

"num_samples": 100,
"output_types": ["mean", "quantiles"],
"quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]

The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance
order in the corresponding input ﬁle. Predictions are encoded as objects identical to the ones returned by
responses in online inference mode. For example:
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }

Note that in the TransformInput conﬁguration of the SageMaker CreateTransformJob request
clients must explicitly set the AssembleWith value to Line, as the default value None concatenates all
JSON objects on the same line.
For example, here is a SageMaker CreateTransformJob request for a DeepAR job with a custom
DEEPAR_INFERENCE_CONFIG:
{

"BatchStrategy": "SingleRecord",
"Environment": {
"DEEPAR_INFERENCE_CONFIG" : "{ \"num_samples\": 200, \"output_types\": [\"mean\"] }",

1432


Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.

**Note**
The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

**Topics**
- Input/Output Interface for the Factorization Machines Algorithm (p. 1433)
- EC2 Instance Recommendation for the Factorization Machines Algorithm (p. 1434)
- Factorization Machines Sample Notebooks (p. 1434)
- How Factorization Machines Work (p. 1434)
- Factorization Machines Hyperparameters (p. 1435)
- Tune a Factorization Machines Model (p. 1440)
- Factorization Machines Response Formats (p. 1441)

**Input/Output Interface for the Factorization Machines Algorithm**

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the test channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For training, the Factorization Machines algorithm currently supports only the recordIO-protobuf format with Float32 tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For inference, the Factorization Machines algorithm supports the application/json and x-recordio-protobuf formats.

- For the **binary classification** problem, the algorithm predicts a score and a label. The label is a number and can be either 0 or 1. The score is a number that indicates how strongly the algorithm believes that the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.
- For the **regression** problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.
Please see Factorization Machines Sample Notebooks (p. 1434) for more details on training and inference file formats.

EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data.

Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function ŷ from a feature set xᵢ to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset (xᵢ, yⱼ) available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

\[ \hat{y} = w₀ + \sum_i wᵢ xᵢ + \sum_i \sum_{j>i} <vᵢ, vⱼ> xᵢ xⱼ \]

The three terms in this equation correspond respectively to the three components of the model:

- The \( w₀ \) term represents the global bias.
- The \( wᵢ \) linear terms model the strength of the \( i^{th} \) variable.
- The \( <vᵢ, vⱼ> \) factorization terms model the pairwise interaction between the \( i^{th} \) and \( j^{th} \) variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see Factorization Machines.

For regression tasks, the model is trained by minimizing the squared error between the model prediction \( \hat{y}_n \) and the target value \( y_n \). This is known as the square loss:

\[ L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2 \]

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

\[ L = \frac{1}{N} \sum_n [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)] \]
where:
\[ \hat{p}_n = \frac{1}{1 + e^{-\theta_n}} \]

For more information about loss functions for classification, see Loss functions for classification.

**Factorization Machines Hyperparameters**

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

Tune a Factorization Machines Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

Metrics Computed by the Factorization Machines Algorithm

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a test:rmse regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: uniform, normal, and constant. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is uniform, then only the scale parameters are tunable. Specifically, if bias_init_method==uniform, then bias_init_scale, linear_init_scale, and factors_init_scale are tunable. Similarly, if the initialization method is normal, then only sigma parameters are tunable. If the initialization method is constant, then only value parameters are tunable. These dependencies are listed in the following table.

**Factorization Machines Response Formats**

**JSON Response Format**

**Binary classification**

```javascript
let response = {
    "predictions": [
        {
            "score": 0.4,
            "predicted_label": 0
        }
    ]
```

1441
Regression

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

**JSONLINES Response Format**

Binary classification

```json
{"score": 0.4, "predicted_label": 0}
```

Regression

```json
{"score": 0.4}
```

**RECORDIO Response Format**

Binary classification

```json
[  Record = {
      features = {},
      label = {
        'score': {
          keys: [],
          values: [0.4]  # float32
        },
        'predicted_label': {
          keys: [],
          values: [0.0]  # float32
        }
      }
  }
]
```

Regression

```json
[  Record = {
      features = {},
      label = {
        'score': {
          keys: [],
          values: [0.4]  # float32
        }
      }
  }
]
```
Image Classification Algorithm

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network (ResNet) that can be trained from scratch or trained using transfer learning when a large number of training images are not available.

The recommended input format for the Amazon SageMaker image classification algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. Refer to this discussion for a broad overview of efficient data preparation and loading for machine learning systems.

Note
To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

For more information on convolutional networks, see:
• Deep residual learning for image recognition Kaiming He, et al., 2016 IEEE Conference on Computer Vision and Pattern Recognition
• ImageNet image database
• Image classification with Gluon-CV and MXNet

• Image Classification Hyperparameters (p. 1446)
• Tune an Image Classification Model (p. 1453)

Input/Output Interface for the Image Classification Algorithm

The SageMaker Image Classification algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode, and supports the RecordIO (application/x-recordio) content type for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format.

Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the S3DataDistributionType of the S3DataSource to FullyReplicated. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports image/png, image/jpeg, and application/x-image for inference.

Train with RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio.

Train with Image Format

If you use the Image format for training, specify train, validation, train_lst, and validation_lst channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify the individual image data (.jpg or .png files) for the train
and validation channels. Specify one .lst file in each of the train_lst and validation_lst channels. Set the content type for all four channels to application/x-image.

**Note**

SageMaker reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A .lst file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a .lst file:

```
5      1   your_image_directory/train_img_dog1.jpg
1000   0   your_image_directory/train_img_cat1.jpg
22     1   your_image_directory/train_img_dog2.jpg
```

For example, if your training images are stored in s3://<your_bucket>/train/class_dog, s3://<your_bucket>/train/class_cat, and so on, specify the path for your train channel as s3://<your_bucket>/train, which is the top-level directory for your data. In the .lst file, specify the relative path for an individual file named train_image_dog1.jpg in the class_dog class directory as class_dog/train_image_dog1.jpg. You can also store all your image files under one subdirectory inside the train directory. In that case, use that subdirectory for the relative path. For example, s3://<your_bucket>/train/your_image_directory.

**Train with Augmented Manifest Image Format**

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames" are contained in the list of image and annotation references ["source-ref", "class"]. The corresponding label value is "0" for the first image and "1" for the second image:

```
{"source-ref" :"s3://image/filename1.jpg", "class":0}
{"source-ref" :"s3://image/filename2.jpg", "class":1, "class-metadata": {"class-name" : "cat", "type" : "groundtruth/image-classification"}}
```

The order of "AttributeNames" in the input files matters when training the ImageClassification algorithm. It accepts piped data in a specific order, with image first, followed by label. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "class". When using the ImageClassification algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO".

Multi-label training is also supported by specifying a JSON array of values. The num_classes hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:
Amazon SageMaker Developer Guide
Use built-in algorithms

{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[1, 0, 1]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[0, 0, 1]"}

In the class-id format, each label is a list of the class ids, from [0, num_classes), which apply to the data
point. The previous example would instead look like this:
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[0, 2]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[2]"}

The multi-hot format is the default, but can be explicitly set in the content type with the label-format
parameter: "application/x-recordio; label-format=multi-hot". The class-id format, which
is the format outputted by GroundTruth, must be set explicitly: "application/x-recordio; labelformat=class-id".
For more information on augmented manifest ﬁles, see Provide Dataset Metadata to Training Jobs with
an Augmented Manifest File (p. 1919).

Incremental Training
You can also seed the training of a new model with the artifacts from a model that you trained
previously with SageMaker. Incremental training saves training time when you want to train a new model
with the same or similar data. SageMaker image classiﬁcation models can be seeded only with another
To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model"
in the InputDataConfig parameter. Set the ContentType for the model channel to application/xsagemaker-model. The input hyperparameters of both the new model and the pretrained model that
you upload to the model channel must have the same settings for the num_layers, image_shape and
num_classes input parameters. These parameters deﬁne the network architecture. For the pretrained
model ﬁle, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use
either RecordIO or image formats for input data.
For a sample notebook that shows how to use incremental training with the SageMaker image
classiﬁcation algorithm, see the End-to-End Incremental Training Image Classiﬁcation Example. For more
information on incremental training and for instructions on how to use it, see Incremental Training in
Amazon SageMaker (p. 1909).

Inference with the Image Classiﬁcation Algorithm
The generated models can be hosted for inference and support encoded .jpg and .png image formats
as image/png, image/jpeg, and application/x-image content-type. The input image is resized
automatically. The output is the probability values for all classes encoded in JSON format, or in JSON
Lines text format for batch transform. The image classiﬁcation model processes a single image per
request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a
response in JSON Lines format:
accept: application/jsonlines
{"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}

For more details on training and inference, see the image classiﬁcation sample notebook instances
referenced in the introduction.

EC2 Instance Recommendation for the Image Classiﬁcation Algorithm
For image classiﬁcation, we support the following GPU instances for training: ml.p2.xlarge,
ml.p2.8xlarge, ml.p2.16xlarge, ml.p3.2xlarge, ml.p3.8xlargeand ml.p3.16xlarge. We
recommend using GPU instances with more memory for training with large batch sizes. However, both

1445


CPU (such as C4) and GPU (such as P2 and P3) instances can be used for the inference. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training.

Both P2 and P3 instances are supported in the image classification algorithm.

### Image Classification Sample Notebooks

For a sample notebook that uses the SageMaker image classification algorithm to train a model on the caltech-256 dataset and then to deploy it to perform inferences, see the End-to-End Multiclass Image Classification Example. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The example image classification notebooks are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

### How Image Classification Works

The image classification algorithm takes an image as input and classifies it into one of the output categories. Deep learning has revolutionized the image classification domain and has achieved great performance. Various deep learning networks such as ResNet [1], DenseNet, inception, and so on, have been developed to be highly accurate for image classification. At the same time, there have been efforts to collect labeled image data that are essential for training these networks. ImageNet[2] is one such large dataset that has more than 11 million images with about 11,000 categories. Once a network is trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a different dataset.

Image classification in Amazon SageMaker can be run in two modes: full training and transfer learning. In full training mode, the network is initialized with random weights and trained on user data from scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new data. In this mode, training can be achieved even with a smaller dataset. This is because the network is already trained and therefore can be used in cases without sufficient training data.

### Image Classification Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification algorithm. See Tune an Image Classification Model (p. 1453) for information on image classification hyperparameter tuning.

<table>
<thead>

</tbody>
</table>
| epochs         | Number of training epochs.  
Optional  
Valid values: positive integer  
Default value: 30 |
| eps            | The epsilon for adam and rmsprop. It is usually set to a small value to avoid division by 0.  
Optional  
Valid values: float. Range in [0, 1].  
Default value: 1e-8 |
| gamma          | The gamma for rmsprop, the decay factor for the moving average of the squared gradient.  
Optional  
Valid values: float. Range in [0, 1].  
Default value: 0.9 |
| image_shape    | The input image dimensions, which is the same size as the input layer of the network. The format is defined as 'num_channels, height, width'. The image dimension can take on any value as the network can handle varied dimensions of the input. However, there may be memory constraints if a larger image dimension is used. Pretrained models can use only a fixed 224 x 224 image size. Typical image dimensions for image classification are '3, 224, 224'. This is similar to the ImageNet dataset.  
For training, if any input image is smaller than this parameter in any dimension, training fails. If an image is larger, a portion of the image is cropped, with the cropped area specified by this parameter. If hyperparameter augmentation_type is set, random crop is taken; otherwise, central crop is taken.  
At inference, input images are resized to the image_shape that was used during training. Aspect ratio is not preserved, and images are not cropped.  
Optional  
Valid values: string  
Default value: ‘3, 224, 224’ |

| kv_store          | Weight update synchronization mode during distributed training. The weight updates can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See distributed training in MXNet for more details.  
This parameter is not applicable to single machine training.                                                                                                                                                                                                                      |
|                   | • dist_sync: The gradients are synchronized after every batch with all the workers. With dist_sync, batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like local with batch size n*b  
• dist_async: Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed.                                                                                                                                 |
|                   | **Optional**                                                                                                                                                                                                                                                                                                                               |
|                   | Valid values: dist_sync or dist_async                                                                                                                                                                                                                                                                                                     |
|                   | Default value: no default value                                                                                                                                                                                                                                                                                                            |
| learning_rate     | Initial learning rate.                                                                                                                                                                                                                                                                                                                      |
|                   | **Optional**                                                                                                                                                                                                                                                                                                                               |
|                   | Valid values: float. Range in [0, 1].                                                                                                                                                                                                                                                                                                     |
|                   | Default value: 0.1                                                                                                                                                                                                                                                                                                                         |
| lr_scheduler_factor | The ratio to reduce learning rate used in conjunction with the lr_scheduler_step parameter, defined as lr_new = lr_old * lr_scheduler_factor.                                                                                                                                                                                                 |
|                   | **Optional**                                                                                                                                                                                                                                                                                                                               |
|                   | Valid values: float. Range in [0, 1].                                                                                                                                                                                                                                                                                                     |
|                   | Default value: 0.1                                                                                                                                                                                                                                                                                                                         |
| lr_scheduler_step  | The epochs at which to reduce the learning rate. As explained in the lr_scheduler_factor parameter, the learning rate is reduced by lr_scheduler_factor at these epochs. For example, if the value is set to "10, 20", then the learning rate is reduced by lr_scheduler_factor after 10th epoch and again by lr_scheduler_factor after 20th epoch. The epochs are delimited by ".".  
**Optional**                                                                                                                                                                                                                                                                 |
<p>|                   | Valid values: string                                                                                                                                                                                                                                                                                                                          |
|                   | Default value: no default value                                                                                                                                                                                                                                                                                                             |</p>
<table>
<thead>
<tr>

</table>
| optimizer      | The optimizer type. For more details of the parameters for the optimizers, please refer to MXNet's API.  
   **Optional**  
   Valid values: One of `sgd`, `adam`, `rmsprop`, or `nag`.  
   - `sgd`: Stochastic gradient descent  
   - `adam`: Adaptive momentum estimation  
   - `rmsprop`: Root mean square propagation  
   - `nag`: Nesterov accelerated gradient  
   Default value: `sgd` |
| precision_dtype | The precision of the weights used for training. The algorithm can use either single precision (`float32`) or half precision (`float16`) for the weights. Using half-precision for weights results in reduced memory consumption.  
   **Optional**  
   Valid values: `float32` or `float16`  
   Default value: `float32` |
| resize         | The number of pixels in the shortest side of an image after resizing it for training. If the parameter is not set, then the training data is used without resizing. The parameter should be larger than both the width and height components of `image_shape` to prevent training failure.  
   **Required** when using image content types  
   **Optional** when using the RecordIO content type  
   Valid values: positive integer  
   Default value: no default value |
| top_k          | Reports the top-k accuracy during training. This parameter has to be greater than 1, since the top-1 training accuracy is the same as the regular training accuracy that has already been reported.  
   **Optional**  
   Valid values: positive integer larger than 1.  
   Default value: no default value |

Tune an Image Classification Model

Automated model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automated model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automated Model Tuning with SageMaker (p. 1797).

Metrics Computed by the Image Classification Algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

Tunable Image Classification Hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: mini_batch_size, learning_rate,
and optimizer. Tune the optimizer-related hyperparameters, such as momentum, weight_decay, beta_1, beta_2, eps, and gamma, based on the selected optimizer. For example, use beta_1 and beta_2 only when adam is the optimizer.

For more information about which hyperparameters are used in each optimizer, see Image Classification Hyperparameters (p. 1446).

**IP Insights**

Amazon SageMaker IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from Amazon GuardDuty.

The SageMaker IP Insights algorithm can also learn vector representations of IP addresses, known as *embeddings*. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.
Input/Output Interface for the IP Insights Algorithm

Training and Validation

The SageMaker IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in text/csv format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see IP Insights Training Data Formats (p. 1461).

Inference

For inference, IP Insights supports text/csv, application/json, and application/jsonlines data content types. For more information about the common data formats for inference provided by SageMaker, see Common Data Formats for Inference (p. 1402). IP Insights inference returns output formatted as either application/json or application/jsonlines. Each record in the output data contains the corresponding dot_product (or compatibility score) for each input data point. For more information and some examples, see IP Insights Inference Data Formats (p. 1462).

EC2 Instance Recommendation for the IP Insights Algorithm

The SageMaker IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances.

GPU Instances for the IP Insights Algorithm

IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as ml.p3.2xlarge, and then moving to a multi-GPU environment, such as ml.p3.8xlarge and ml.p3.16xlarge. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the mini_batch_size is divided equally into the number of GPUs used. You may want to increase the value of the mini_batch_size to compensate for this.

CPU Instances for the IP Insights Algorithm

The type of CPU instance that we recommend depends largely on the instance's available memory and the model size. The model size is determined by two hyperparameters: vector_dim and num_entity_vectors. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for vector_dim in the first column range from 32 to 2048 and the values for num_entity_vectors in the first row range from 10,000 to 50,000,000.
The values for the `mini_batch_size`, `num_ip_encoder_layers`, `random_negative_sampling_rate`, and `shuffled_negative_sampling_rate` hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.

### IP Insights Sample Notebooks

For a sample notebook that shows how to train the SageMaker IP Insights algorithm and perform inferences with it, see [An Introduction to the SageMaker IP Insights Algorithm](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances](#) (p. 139). After creating a notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. To open a notebook, choose its **Use** tab and choose **Create copy**.

## How IP Insights Works

Amazon SageMaker IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to insure that the number of collisions, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see [Feature Hashing for Large Scale Multitask Learning](#). For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the cross entropy, also known as the **log loss**, defined as follows:

</tbody>
</table>
$L = \frac{1}{N} \sum_n[y_n \log p_n + (1 - y_n) \log (1 - p_n)]$

$y_n$ is the label that indicates whether the sample is from the real distribution governing observed data ($y_n=1$) or from the distribution generating negative samples ($y_n=0$). $p_n$ is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the `random_negative_sampling_rate` and `shuffled_negative_sampling_rate` hyperparameters.

Given an nth (entity, IP address pair), the IP Insights model outputs a score, $S_n$, that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given (entity, IP address) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

$$S_n = \log \left( \frac{P_{\text{real}}(n)}{P_{\text{neg}}(n)} \right)$$

The score is essentially a measure of the similarity between the vector representations of the nth entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution, $p_n$, to use in the cross entropy minimization, where:

$$p_n = \frac{1}{1 + e^{-S_n}}$$

### IP Insights Hyperparameters

In the `CreateTransformJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker IP Insights algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>num_entity_vectors</code></td>
<td>The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers.</td>
</tr>
<tr>
<td><strong>Required</strong></td>
<td></td>
</tr>
<tr>
<td>Valid values: $1 \leq \text{positive integer} \leq 250,000,000</td>
<td></td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>vector_dim</td>
<td>The size of embedding vectors to represent entities and IP addresses. The larger the value, the more information that can be encoded using these representations. In practice, model size scales linearly with this parameter and limits how large the dimension can be. In addition, using vector representations that are too large can cause the model to overfit, especially for small training datasets. Overfitting occurs when a model doesn't learn any pattern in the data but effectively memorizes the training data and, therefore, cannot generalize well and performs poorly during inference. The recommended value is 128.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $4 \leq \text{positive integer} \leq 4096$</td>
</tr>
<tr>
<td>batch_metrics_publish_interval</td>
<td>The interval (every X batches) at which the Apache MXNet Speedometer function prints the training speed of the network (samples/second).</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: positive integer $\geq 1$</td>
</tr>
<tr>
<td></td>
<td>Default value: 1,000</td>
</tr>
<tr>
<td>epochs</td>
<td>The number of passes over the training data. The optimal value depends on your data size and learning rate. Typical values range from 5 to 100.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: positive integer $\geq 1$</td>
</tr>
<tr>
<td></td>
<td>Default value: 10</td>
</tr>
<tr>
<td>learning_rate</td>
<td>The learning rate for the optimizer. IP Insights use a gradient-descent-based Adam optimizer. The learning rate effectively controls the step size to update model parameters at each iteration. Too large a learning rate can cause the model to diverge because the training is likely to overshoot a minima. On the other hand, too small a learning rate slows down convergence. Typical values range from $1e^{-4}$ to $1e^{-1}$.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $1e^{-6} \leq \text{float} \leq 10.0$</td>
</tr>
<tr>

</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mini_batch_size</td>
<td>The number of examples in each mini batch. The training procedure processes data in mini batches. The optimal value depends on the number of unique account identifiers in the dataset. In general, the larger the mini_batch_size, the faster the training and the greater the number of possible shuffled-negative-sample combinations. However, with a large mini_batch_size, the training is more likely to converge to a poor local minimum and perform relatively worse for inference.</td>
</tr>
<tr>
<td>num_ip_encoder_layers</td>
<td>The number of fully connected layers used to encode the IP address embedding. The larger the number of layers, the greater the model's capacity to capture patterns among IP addresses. However, using a large number of layers increases the chance of overfitting.</td>
</tr>
<tr>
<td>random_negative_sampling_rate</td>
<td>The number of random negative samples, R, to generate per input example. The training procedure relies on negative samples to prevent the vector representations of the model collapsing to a single point. Random negative sampling generates R random IP addresses for each input account in the mini batch. The sum of the random_negative_sampling_rate (R) and shuffled_negative_sampling_rate (S) must be in the interval: 1 ≤ R + S ≤ 500.</td>
</tr>
</tbody>
</table>
### Use built-in algorithms

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
<th>Optional</th>
<th>Valid values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>shuffled_negative_sampling_rate</td>
<td>The number of shuffled negative samples, ( S ), to generate per input example. In some cases, it helps to use more realistic negative samples that are randomly picked from the training data itself. This kind of negative sampling is achieved by shuffling the data within a mini batch. Shuffled negative sampling generates ( S ) negative IP addresses by shuffling the IP address and account pairings within a mini batch. The sum of the random_negative_sampling_rate ( (R) ) and shuffled_negative_sampling_rate ( (S) ) must be in the interval: ( 1 \leq R + S \leq 500 ).</td>
<td>Optional</td>
<td>( 0 \leq \text{positive integer} \leq 500 )</td>
<td>1</td>
</tr>
<tr>
<td>weight_decay</td>
<td>The weight decay coefficient. This parameter adds an L2 regularization factor that is required to prevent the model from overfitting the training data.</td>
<td>Optional</td>
<td>( 0.0 \leq \text{float} \leq 10.0 )</td>
<td>0.00001</td>
</tr>
</tbody>
</table>

### Tune an IP Insights Model

*Automatic model tuning*, also called hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker (p. 1797)](https://docs.aws.amazon.com/sagemaker/latest/dg/perform-automatic-model-tuning.html).

### Metrics Computed by the IP Insights Algorithm

The Amazon SageMaker IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model, which learns to separate observed data points (*positive samples*) from randomly generated data points (*negative samples*). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This *validation:discriminator_auc* metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a *validation:discriminator_auc* metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.
**Metric Name** | **Description** | **Optimization Direction**
--- | --- | ---
validation:discriminator_auc | Area under the receiver operating characteristic curve on the validation dataset. The validation dataset is not labeled. Area Under the Curve (AUC) is a metric that describes the model's ability to discriminate validation data points from randomly generated data points. | Maximize

**Tunable IP Insights Hyperparameters**

**IP Insights Data Formats**

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

**Topics**
- IP Insights Training Data Formats (p. 1461)
- IP Insights Inference Data Formats (p. 1462)

**IP Insights Training Data Formats**

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input training format described in Common Data Formats for
Training (p. 1398). However, the SageMaker IP Insights algorithm currently supports only the CSV data input format.

**IP Insights Training Data Input Formats**

**INPUT: CSV**

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

**IP Insights Inference Data Formats**

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats for Inference (p. 1402). However, the SageMaker IP Insights algorithm does not currently support RecordIO format.

**IP Insights Input Request Formats**

**INPUT: CSV Format**

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

**INPUT: JSON Format**

JSON data can be provided in different formats. IP Insights follows the common SageMaker formats. For more information about inference formats, see Common Data Formats for Inference (p. 1402).

content-type: application/json

```
{
  "instances": [
    {
      "data": {
        "attributes": {
          "values": [
            "entity_id_1", "192.168.1.2"
          ]
        }
      }
    },
    {
      "features": {
        "values": [
          "entity_id_2", "10.10.1.2"
        ]
      }
    }
  ]
}
```

**INPUT: JSONLINES Format**

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker inference formats, see Common Data Formats for Inference (p. 1402). For more information on running batch transform jobs, see Get Inferences for an Entire Dataset with Batch Transform (p. 11).
IP Insights Output Response Formats

OUTPUT: JSON Response Format

The default output of the SageMaker IP Insights algorithm is the dot_product between the input entity and IP address. The dot_product signifies how compatible the model considers the entity and IP address. The dot_product is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the dot_product for anomaly detection, see the An Introduction to the SageMakerIP Insights Algorithm.

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter verbose=True to the Accept heading. You can use the entity_embedding and ip_embedding for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

OUTPUT: JSONLINES Response Format

1463
K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see Web-scale k-means Clustering.

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The \( n \) attributes in each row represent a point in \( n \)-dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker, see How K-Means Clustering Works (p. 1465).

Topics

- Input/Output Interface for the K-Means Algorithm (p. 1464)
- EC2 Instance Recommendation for the K-Means Algorithm (p. 1464)
- K-Means Sample Notebooks (p. 1464)
- How K-Means Clustering Works (p. 1465)
- K-Means Hyperparameters (p. 1467)
- Tune a K-Means Model (p. 1470)
- K-Means Response Formats (p. 1471)

Input/Output Interface for the K-Means Algorithm

For training, the k-means algorithm expects data to be provided in the train channel (recommended S3DataDistributionType=ShardedByS3Key), with an optional test channel (recommended S3DataDistributionType=FullyReplicated) to score the data on. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, text/csv, application/json, and application/x-recordio-protobuf are supported. k-means returns a closest_cluster label and the distance_to_cluster for each observation.

For more information on input and output file formats, see K-Means Response Formats (p. 1471) for inference and the K-Means Sample Notebooks (p. 1464). The k-means algorithm does not support multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

EC2 Instance Recommendation for the K-Means Algorithm

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to p*.xlarge instances because only one GPU per instance is used.

K-Means Sample Notebooks

For a sample notebook that uses the SageMaker K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see Analyze US census data for population segmentation using Amazon SageMaker. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon
SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

**How K-Means Clustering Works**

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the \( n \)-dimensional space (where \( n \) is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points \((t, h)\) in 2-dimensional space.

**Note**
Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters (\( k \)) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit (0, 1, ..., 9). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space \((x,y)\). To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

**Note**
Amazon SageMaker uses a customized version of the algorithm where, instead of specifying that the algorithm create \( k \) clusters, you might choose to improve model accuracy by specifying extra cluster centers \((K = k \times x)\). However, the algorithm ultimately reduces these to \( k \) clusters.

In SageMaker, you specify the number of clusters when creating a training job. For more information, see CreateTrainingJob. In the request body, you add the HyperParameters string map to specify the \( k \) and extra_center_factor strings.

The following is a summary of how k-means works for model training in SageMaker:

1. It determines the initial \( K \) cluster centers.

   **Note**
   In the following topics, \( K \) clusters refer to \( k \times x \), where you specify \( k \) and \( x \) when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.
3. It reduces resulting clusters to \( k \) (if the data scientist specified the creation of \( k \times x \) clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the HyperParameters string map.

**Topics**
- Step 1: Determine the Initial Cluster Centers (p. 1466)
- Step 2: Iterate over the Training Dataset and Calculate Cluster Centers (p. 1466)
- Step 3: Reduce the Clusters from \( K \) to \( k \) (p. 1467)
Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

- **The random approach**—Randomly choose \( K \) observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.

- **The k-means++ approach**, which works as follows:
  
  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.
  
  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:
     
     - For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
     
     - Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.
  
  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.
  
  4. Repeat the process until you have the \( K \) cluster centers.

To train a model in SageMaker, you create a training job. In the request, you provide configuration information by specifying the following `HyperParameters` string maps:

- To specify the number of clusters to create, add the `k` string.
- For greater accuracy, add the optional `extra_center_factor` string.
- To specify the strategy that you want to use to determine the initial cluster centers, add the `init_method` string and set its value to `random` or `k-means++`.

For more information about the SageMaker k-means estimator, see K-means in the Amazon SageMaker Python SDK documentation.

You now have an initial set of cluster centers.

Step 2: Iterate over the Training Dataset and Calculate Cluster Centers

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the \( K \) cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

   **Note**
   
   When creating a model training job, you specify the batch size in the `mini_batch_size` string in the `HyperParameters` string map.
a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.
b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

For example, consider the following clusters:

Cluster c1 = 100 previously assigned points. You added 25 points from the mini-batch in this step.

Cluster c2 = 150 previously assigned points. You added 40 points from the mini-batch in this step.

Cluster c3 = 450 previously assigned points. You added 5 points from the mini-batch in this step.

Calculate the proportion of new points assigned to each of clusters as follows:

\[ p_1 = \text{proportion of points assigned to c1} = \frac{25}{100+25} \]
\[ p_2 = \text{proportion of points assigned to c2} = \frac{40}{150+40} \]
\[ p_3 = \text{proportion of points assigned to c3} = \frac{5}{450+5} \]

c. Compute the center of the new points added to each cluster:

\[ d_1 = \text{center of the new points added to cluster 1} \]
\[ d_2 = \text{center of the new points added to cluster 2} \]
\[ d_3 = \text{center of the new points added to cluster 3} \]

d. Compute the weighted average to find the updated cluster centers as follows:

\[ \text{Center of cluster 1} = ((1 - p_1) \times \text{center of cluster 1}) + (p_1 \times d_1) \]
\[ \text{Center of cluster 2} = ((1 - p_2) \times \text{center of cluster 2}) + (p_2 \times d_2) \]
\[ \text{Center of cluster 3} = ((1 - p_3) \times \text{center of cluster 3}) + (p_3 \times d_3) \]

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.
3. For more information about mini-batch k-means, see Web-Scale k-means Clustering).

Step 3: Reduce the Clusters from K to k

If the algorithm created K clusters—(K = k\*x) where x is greater than 1—then it reduces the K clusters to k clusters. (For more information, see extra_center_factor in the preceding discussion.) It does this by applying Lloyd's method with kmeans++ initialization to the K cluster centers. For more information about Lloyd's method, see k-means clustering.

K-Means Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker. For more information about how k-means clustering works, see How K-Means Clustering Works (p. 1465).

Tune a K-Means Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn't use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

Metrics Computed by the K-Means Algorithm

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:msd</td>
<td>Mean squared distances between each record in the test set and the closest center of the model.</td>
<td>Minimize</td>
</tr>
<tr>
<td>test:ssd</td>
<td>Sum of the squared distances between each record in the test set and the closest center of the model.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

Tunable K-Means Hyperparameters

Tune the Amazon SageMaker k-means model with the following hyperparameters. The hyperparameters that have the greatest impact on k-means objective metrics are: mini_batch_size, extra_center_factor, and init_method. Tuning the hyperparameter epochs generally results in minor improvements.

<table>

### K-Means Response Formats

All SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-means algorithm.

**JSON Response Format**

```json
{
  "predictions": [
    {
      "closest_cluster": 1.0,
      "distance_to_cluster": 3.0,
    },
    {
      "closest_cluster": 2.0,
      "distance_to_cluster": 5.0,
    },
    ...
  ]
}
```

**JSONLINES Response Format**

```json
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

**RECORDIO Response Format**

```json
[ Record = {
    features = {},
    label = {
        'closest_cluster': {
            keys: [],
            values: [1.0, 2.0] # float32
        },
        'distance_to_cluster': {
            keys: [],
            values: [3.0, 5.0] # float32
        }
    }
}
```

**CSV Response Format**

The first value in each line corresponds to closest_cluster.
The second value in each line corresponds to `distance_to_cluster`.

| 1.0,3.0 | 2.0,5.0 |

**K-Nearest Neighbors (k-NN) Algorithm**

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the $k$ points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the $k$ closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional (d > 1000) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN's training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the k nearest points to use for inference.

**Input/Output Interface for the k-NN Algorithm**

SageMaker k-NN supports train and test data channels.

- Use a **train channel** for data that you want to sample and construct into the k-NN index.
- Use a **test channel** to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for classifier, mean-squared error (mse) for regressor for score.

For training inputs, k-NN supports `text/csv` and `application/x-recordio-protobuf` data formats. For input type `text/csv`, the first `label_size` columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference inputs, k-NN supports the `application/json`, `application/x-recordio-protobuf`, and `text/csv` data formats. The `text/csv` format accepts a `label_size` and encoding parameter. It assumes a `label_size` of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the `application/json` and `application/x-recordio-protobuf` data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.
For batch transform, k-NN supports the application/jsonlines data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines

{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

An example output is as follows:

```
accept: application/jsonlines

{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see Data Formats for k-NN Training Input (p. 1477) for training, k-NN Request and Response Formats (p. 1478) for inference, and the k-NN Sample Notebooks (p. 1473).

### k-NN Sample Notebooks

For a sample notebook that uses the SageMaker k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the K-Nearest Neighbor Covertyte.

Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

### How the k-NN Algorithm Works

#### Step 1: Sample

To specify the total number of data points to be sampled from the training dataset, use the `sample_size` parameter. For example, if the initial dataset has 1,000 data points and the `sample_size` is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

#### Step 2: Perform Dimension Reduction

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the `dimension_reduction_type` hyperparameter. The `sign` method specifies a random projection, which uses a linear projection using a matrix of random signs, and the `fjlt` method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The `fjlt` method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The `sign` method requires $O(ndk)$ time to reduce the dimension of a batch of $n$ points of dimension $d$ into a target dimension $k$. The `fjlt` method requires $O(nd \log(d))$ time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

#### Step 3: Build an Index

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the `index_type` parameter.
Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- `model_algo-1`: Contains the serialized index for computing the nearest neighbors.
- `model_algo-1.labels`: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
- `model_algo-1.json`: Contains the JSON-formatted model metadata which stores the $k$ and `predictor_type` hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change $k$ to 10 or change `predictor_type` to `regressor`.

```json
{
    "k": 5,
    "predictor_type": "classifier",
    "dimension_reduction": {
        "type": "sign",
        "seed": 3,
        "target_dim": 10,
        "input_dim": 20,
        "normalize": False,
        "version": "1.0"
    }
}
```

EC2 Instance Recommendation for the k-NN Algorithm

**Instance Recommendation for Training with the k-NN Algorithm**

To start, try running training on a CPU, using, for example, an ml.m5.2xlarge instance, or on a GPU using, for example, an ml.p2.xlarge instance.

**Instance Recommendation for Inference with the k-NN Algorithm**

Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

**k-NN Hyperparameters**

</table>
## Tune a k-NN Model

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1797).

### Metrics Computed by the k-NN Algorithm

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the `predictor_type` hyper-parameter.

- `classifier` specifies a classification task and computes `test:accuracy`
- `regressor` specifies a regression task and computes `test:mse`.

Choose the `predictor_type` value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

### Metric Name | Description | Optimization Direction
--- | --- | ---
test:mse | When predictor_type is set to regressor, k-NN compares the predicted label, based on the average of the k-nearest neighbors’ labels, to the ground truth label provided in the test channel data. The mean squared error is computed by comparing the two labels. | Minimize

### Tunable k-NN Hyperparameters
Tune the Amazon SageMaker k-nearest neighbor model with the following hyperparameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Recommended Ranges</th>
</tr>
</thead>
</table>
k | IntegerParameterRanges | MinValue: 1, MaxValue: 1024 |
sample_size | IntegerParameterRanges | MinValue: 256, MaxValue: 2000000 |

### Data Formats for k-NN Training Input
All Amazon SageMaker built-in algorithms adhere to the common input training formats described in Common Data Formats - Training. This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

#### CSV Data Format

<table>
<thead>
<tr>
<th>content-type: text/csv; label_size=1</th>
</tr>
</thead>
<tbody>
<tr>
<td>4,1.2,1.3,9.6,20.3</td>
</tr>
</tbody>
</table>

The first label_size columns are interpreted as the label vector for that row.

#### RECORDIO Data Format

<table>
<thead>
<tr>
<th>content-type: application/x-recordio-protobuf</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ Record = { features = { 'values': { values: [1.2, 1.3, 9.6, 20.3] # float32 } }, label = { 'values': { values: [4] # float32 } } } ]</td>
</tr>
</tbody>
</table>
k-NN Request and Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats – Inference. This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

**INPUT: CSV Request Format**

```
content-type: text/csv

1.2,1.3,9.6,20.3
```

This accepts a label_size or encoding parameter. It assumes a label_size of 0 and a utf-8 encoding.

**INPUT: JSON Request Format**

```
content-type: application/json

{
  "instances": [
    {
      "data": {
        "features": {
          "values": [-3, -1, -4, 2]
        }
      }
    },
    {
      "features": [3.0, 0.1, 0.04, 0.002]
    }
  ]
}
```

**INPUT: JSONLINES Request Format**

```
content-type: application/jsonlines

{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}
```

**INPUT: RECORDIO Request Format**

```
content-type: application/x-recordio-protobuf

[ Record = {
  features = {
    'values': {
      values: [-3, -1, -4, 2]  # float32
    }
  },
  label = {}
}, Record = {
  features = {
    'values': {
      values: [3.0, 0.1, 0.04, 0.002]  # float32
    }
  },
  label = {}
}
```

**OUTPUT: JSON Response Format**

```

```

**Latent Dirichlet Allocation (LDA) Algorithm**

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use
them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: *eat, sleep, play, meow, and bark*, LDA might produce topics like the following:

<table>
<thead>
<tr>
<th>Topic</th>
<th><em>eat</em></th>
<th><em>sleep</em></th>
<th><em>play</em></th>
<th><em>meow</em></th>
<th><em>bark</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic 1</td>
<td>0.1</td>
<td>0.3</td>
<td>0.2</td>
<td>0.4</td>
<td>0.0</td>
</tr>
<tr>
<td>Topic 2</td>
<td>0.2</td>
<td>0.1</td>
<td>0.4</td>
<td>0.0</td>
<td>0.3</td>
</tr>
</tbody>
</table>

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to *meow* and *sleep*), and documents that fall into Topic 2 are about dogs (who prefer to *play* and *bark*). These topics can be found even though the words dog and cat never appear in any of the texts.

**Topics**
- Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM) (p. 1481)

- LDA Hyperparameters (p. 1484)
- Tune an LDA Model (p. 1485)

**Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)**

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.

Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to number of records * vocabulary size. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, text/csv, application/json, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. LDA inference returns application/json or application/x-recordio-protobuf predictions, which include the topic mixture vector for each observation.

Please see the LDA Sample Notebooks (p. 1482) for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.

LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the An Introduction to SageMaker LDA. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How LDA Works

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

Note

Lemmatization significantly increases algorithm performance and accuracy. Consider preprocessing any input text data.

An LDA model is defined by two parameters:

- \( \alpha \) — A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- \( \beta \) — A collection of \( k \) topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a "topic-word distribution."

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture \( \theta \sim \text{Dirichlet}(\alpha) \).
For each word in the document:

- Choose a topic \( z \sim \text{Multinomial}(\theta) \)
- Choose the corresponding topic-word distribution \( \beta_z \).
- Draw a word \( w \sim \text{Multinomial}(\beta_z) \).

When training the model, the goal is to find parameters \( \alpha \) and \( \beta \), which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This provides several advantages:

- **Theoretical guarantees on results.** The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
- **Embarrassingly parallelizable.** The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
- **Fast.** Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a \( V \times V \times V \) tensor, which summarizes the moments of the documents in our corpus. \( V \) is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters \( \alpha \) and \( \beta \), which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this \( V \times V \times V \) tensor is prohibitively large to store in memory.
2. Instead, it uses a \( V \times V \) moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension \( V \times k \). This matrix can be used to convert the \( V \times V \) moment matrix into a \( k \times k \) identity matrix. \( k \) is the number of topics in the model.
3. This same whitening matrix can then be used to find a smaller \( k \times k \times k \) tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the \( V \times V \times V \) tensor.
4. **Alternating Least Squares** is used to decompose the smaller \( k \times k \times k \) tensor. This provides a substantial improvement in memory consumption and speed. The parameters \( \alpha \) and \( \beta \) can be found by "unwhitening" these outputs in the spectral decomposition.

After the LDA model's parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```python
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

For more information about algorithms for LDA and the SageMaker implementation, see the following:

**LDA Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see *How LDA Works* (p. 1482).

<table>

**Optional**  
Valid values: Positive float  
Default value: 1e-8 |

### Tune an LDA Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The "per-word log-likelihood" (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

### Metrics Computed by the LDA Algorithm

The LDA algorithm reports on a single metric during training: test:pwll. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>test:pwll</strong></td>
<td>Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.</td>
</tr>
</tbody>
</table>

### Tunable LDA Hyperparameters

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, alpha0 and num_topics, can affect the LDA objective metric (test:pwll). If you don’t already know the optimal
values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

**Linear Learner Algorithm**

*Linear models* are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples \((x, y)\). \(x\) is a high-dimensional vector and \(y\) is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to \(\text{num\_classes} - 1\). For regression problems, \(y\) is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector \(x\) to an approximation of the label \(y\).

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see `CreateTrainingJob`. You can specify additional parameters in the `HyperParameters` string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you’re using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

**Topics**

- EC2 instance recommendation for the linear learner algorithm (p. 1487)
- Linear learner sample notebooks (p. 1487)
- How linear learner works (p. 1488)
- Linear learner hyperparameters (p. 1489)
- Tune a linear learner model (p. 1498)
- Linear learner response formats (p. 1500)
Input/Output interface for the linear learner algorithm

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the S3DataDistributionType should be FullyReplicated. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

For training, the linear learner algorithm supports both recordIO-wrapped protobuf and CSV formats. For the application/x-recordio-protobuf input type, only Float32 tensors are supported. For the text/csv input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, the linear learner algorithm supports the application/json, application/x-recordio-protobuf, and text/csv formats. When you make predictions on new data, the format of the response depends on the type of model. For regression (predictor_type='regressor'), the score is the prediction produced by the model. For classification (predictor_type='binary_classifier' or predictor_type='multiclass_classifier'), the model returns a score and also a predicted_label. The predicted_label is the class predicted by the model and the score measures the strength of that prediction.

- For binary classification, predicted_label is 0 or 1, and score is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- For multiclass classification, the predicted_class will be an integer from 0 to num_classes-1, and score will be a list of one floating point number per class.

To interpret the score in classification problems, you have to consider the loss function used. If the loss hyperparameter value is logistic for binary classification or softmax_loss for multiclass classification, then the score can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the loss value is auto default value. But if the loss is set to hinge_loss, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats (p. 1500). For more information on inference formats, and the Linear learner sample notebooks (p. 1487).

EC2 instance recommendation for the linear learner algorithm

You can train the linear learner algorithm on single- or multi-machine CPU and GPU instances. During testing, we have not found substantial evidence that multi-GPU computers are faster than single-GPU computers. Results can vary, depending on your specific use case.

Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>An Introduction with the MNIST dataset</td>
<td>Using the MNIST dataset, we train a binary classifier to predict a single digit.</td>
</tr>
<tr>
<td>Predict Breast Cancer</td>
<td>Using UCI’s Breast Cancer dataset, we train a model to predict Breast Cancer.</td>
</tr>
</tbody>
</table>
How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate. Step 4 provides example code that shows how to deploy a trained model.

Step 1: Preprocess

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

Note
For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the `normalize_data` and `normalize_label` hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

Step 2: Train

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

Step 3: Validate and set the threshold

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.
**Note**
If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

**Step 4: Deploy a trained linear model**

Here is an example of Python code that you can use to deploy a model in MXNet that has been trained with SageMaker linear learner

```python
import mxnet as mx
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

# Load the mxnet module from the model files
mod = mx.module.Module.load('mx-mod', 0)
# model's weights
mod._arg_params['fc0_weight'].asnumpy().flatten()

# model bias
mod._arg_params['fc0_bias'].asnumpy().flatten()
mod.bind(data_shapes=data_iter.provide_data) #data_iter is an iterator configured with your test data
#perform inference
result = mod.predict(data_iter)
```

**Linear learner hyperparameters**

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to auto, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>The number of classes for the response variable. The algorithm assumes that classes are labeled 0, ..., num_classes - 1. Required when predictor_type is multiclass_classifier. Otherwise, the algorithm ignores it. Valid values: Integers from 3 to 1,000,000</td>
</tr>
<tr>
<td>predictor_type</td>
<td>Specifies the type of target variable as a binary classification, multiclass classification, or regression. Required</td>
</tr>
<tr>
<td>accuracy_top_k</td>
<td>When computing the top-k accuracy metric for multiclass classification, the value of k. If the model assigns one of the top-k scores to the true label, an example is scored as correct. Optional</td>

</tbody>
</table>
| binary_classifier_model_selection_criteria | When predictor_type is set to binary_classifier, the model evaluation criteria for the validation dataset (or for the training dataset if you don’t provide a validation dataset). Criteria include:

- accuracy—The model with the highest accuracy.
- f_beta—The model with the highest F1 score. The default is F1.
- precision_at_target_recall—The model with the highest precision at a given recall target.
- recall_at_target_precision—The model with the highest recall at a given precision target.
- loss_function—The model with the lowest value of the loss function used in training.

Optional
Valid values: accuracy, f_beta, precision_at_target_recall, recall_at_target_precision, or loss_function
Default value: accuracy                                                                                                                                                                                                                                           |
| early_stopping_patience | If no improvement is made in the relevant metric, the number of epochs to wait before ending training. If you have provided a value for binary_classifier_model_selection_criteria, the metric is that value. Otherwise, the metric is the same as the value specified for the loss hyperparameter. The metric is evaluated on the validation data. If you haven’t provided validation data, the metric is always the same as the value specified for the loss hyperparameter and is evaluated on the training data. To disable early stopping, set early_stopping_patience to a value greater than the value specified for epochs.

Optional
Valid values: Positive integer
Default value: 3                                                                                                                                                                                                                                                                                       |
| early_stopping_tolerance | The relative tolerance to measure an improvement in loss. If the ratio of the improvement in loss divided by the previous best loss is smaller than this value, early stopping considers the improvement to be zero.

Optional
Valid values: Positive floating-point integer
Default value: 0.001                                                                                                                                                                                                                                                                                      |
| epochs | The maximum number of passes over the training data.

Optional
Valid values: Positive integer
Default value: 15                                                                                                                                                                                                                                                                                         |

</table>
| `f_beta`       | The value of beta to use when calculating F score metrics for binary or multiclass classification. Also used if the value specified for `binary_classifier_model_selection_criteria` is `f_beta`.  
Optional  
Valid values: Positive floating-point integers  
Default value: 1.0 |
| `feature_dim`  | The number of features in the input data.  
Optional  
Valid values: auto or positive integer  
Default values: auto |
| `huber_delta`  | The parameter for Huber loss. During training and metric evaluation, compute L2 loss for errors smaller than delta and L1 loss for errors larger than delta.  
Optional  
Valid values: Positive floating-point integer  
Default value: 1.0 |
| `init_bias`    | Initial weight for the bias term.  
Optional  
Valid values: Floating-point integer  
Default value: 0 |
| `init_method`  | Sets the initial distribution function used for model weights. Functions include:  
- `uniform`—Uniformly distributed between (-scale, +scale)  
- `normal`—Normal distribution, with mean 0 and sigma  
Optional  
Valid values: uniform or normal  
Default value: uniform |
| `init_scale`   | Scales an initial uniform distribution for model weights. Applies only when the `init_method` hyperparameter is set to uniform.  
Optional  
Valid values: Positive floating-point integer  
Default value: 0.07 |

Tune a linear learner model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, num_models, to 1. The algorithm ignores any value that you set for num_models.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

Metrics computed by the linear learner algorithm

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:objective_loss</td>
<td>The mean value of the objective loss function on the test dataset after the model is trained. By default, the loss is logistic loss for binary classification and squared loss for regression. To set the loss to other types, use the loss hyperparameter.</td>
<td>Minimize</td>
</tr>
<tr>
<td>test:binary_classification_accuracy</td>
<td>The accuracy of the final model on the test dataset.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:binary_f_beta</td>
<td>The F_beta score of the final model on the test dataset. By default, it is the F1 score, which is the harmonic mean of precision and recall.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:precision</td>
<td>The precision of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the binary_classifier_model_selection hyperparameter to precision_at_target_recall and setting the value for the target_recall hyperparameter.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:recall</td>
<td>The recall of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the binary_classifier_model_selection hyperparameter to recall_at_target_precision and setting the value for the target_precision hyperparameter.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:objective_loss</td>
<td>The mean value of the objective loss function on the validation dataset every epoch. By default,</td>
<td>Minimize</td>
</tr>
</tbody>
</table>
### Use built-in algorithms

#### Metric Name
- `validation:binary_classification_accuracy`: the accuracy of the final model on the validation dataset. **Maximize**
- `validation:binary_f_beta`: the F_beta score of the final model on the validation dataset. By default, the F_beta score is the F1 score, which is the harmonic mean of the validation:precision and validation:recall metrics. **Maximize**
- `validation:precision`: the precision of the final model on the validation dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the `binary_classifier_model_selection` hyperparameter to `precision_at_target_recall` and setting the value for the `target_recall` hyperparameter. **Maximize**
- `validation:recall`: the recall of the final model on the validation dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the `binary_classifier_model_selection` hyperparameter to `recall_at_target_precision` and setting the value for the `target_precision` hyperparameter. **Maximize**

### Tuning linear learner hyperparameters

You can tune a linear learner model with the following hyperparameters.

<table>
<thead>

Linear learner response formats

JSON response formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. The following are the available output formats for the SageMaker linear learner algorithm.

Binary Classification

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

Multiclass Classification

```javascript
let response = {
  "predictions": [
    {
      "score": [0.1, 0.2, 0.4, 0.3],
      "predicted_label": 2
    }
  ]
}
```

Regression

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

JSONLINES response formats

Binary Classification

```javascript
{"score": 0.4, "predicted_label": 0}
```

Multiclass Classification

```javascript
{"score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2}
```

Regression

```javascript
{"score": 0.4}
```

RECORDIO response formats

Binary Classification

```
1500
```
Multiclass Classification

```
Record = {
    "features": [],
    "label": {
        "score": {
            "values": [0.1, 0.2, 0.3, 0.4]
        },
        "predicted_label": {
            "values": [3]
        }
    },
    "uid": "abc123",
    "metadata": "{created_at: '2017-06-03'}"
}
```

Regression

```
Record = {
    features = {},
    label = {
        'score': {
            keys: [],
            values: [0.4]  # float32
        }
    }
}
```

Neural Topic Model (NTM) Algorithm

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into topics that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on topic similarities. The topics from documents that NTM learns are characterized as a latent representation because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.
Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see Neural Variational Inference for Text Processing.

Input/Output Interface for the NTM Algorithm

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the S3DataDistributionType parameter for them to FullyReplicated. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to: (number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The ContentType for the auxiliary channel is text/plain, with each line containing a single word, in the order corresponding to the integer IDs provided in the data. The vocabulary file must be named vocab.txt and currently only UTF-8 encoding is supported.

For inference, text/csv, application/json, application/jsonlines, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. NTM inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_weights vector for each observation.

See the blog post and the companion notebook for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker Neural Topic Model.
For more information on input and output file formats, see NTM Response Formats (p. 1506) for inference and the NTM Sample Notebooks (p. 1503).

**EC2 Instance Recommendation for the NTM Algorithm**

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference.

**NTM Sample Notebooks**

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality of NTM. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**NTM Hyperparameters**

### Parameter Name | Description
--- | ---
encoder_layers_activation | The activation function to use in the encoder layers.
epochs | The maximum number of passes over the training data.
learning_rate | The learning rate for the optimizer.
mini_batch_size | The number of examples in each mini batch.
num_patience_epochs | The number of successive epochs over which early stopping criterion is evaluated. Early stopping is triggered when the change in the loss function drops below the specified tolerance within the last num_patience_epochs number of epochs. To disable early stopping, set num_patience_epochs to a value larger than epochs.

**Optional**

- Valid values:
  - sigmoid: Sigmoid function
  - tanh: Hyperbolic tangent
  - relu: Rectified linear unit

Default value: sigmoid

Optional

- Valid values: Positive integer (min: 1)

Default value: 50

Optional

- Valid values: Float (min: 1e-6, max: 1.0)

Default value: 0.001

Optional

- Valid values: Positive integer (min: 1, max: 10000)

Default value: 256

Optional

- Valid values: Positive integer (min: 1)

Default value: 3

Tune an NTM Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.
Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. **Training loss** measures how well the model fits the training data. **Validation loss** measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which it has not been trained. Usually, it's preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

**Metrics Computed by the NTM Algorithm**

The NTM algorithm reports a single metric that is computed during training: `validation:total_loss`. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

</tbody>
</table>

**Tunable NTM Hyperparameters**

You can tune the following hyperparameters for the NTM algorithm. Usually setting low `mini_batch_size` and small `learning_rate` values results in lower validation losses, although it might take longer to train. Low validation losses don't necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see NTM Hyperparameters (p. 1503).

**NTM Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker NTM algorithm.
Object2Vec Algorithm

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker BlazingText algorithm (p. 1408). For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker Object2Vec.

### I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

<table>
<thead>
<tr>
<th>Input Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentence-sentence pairs</td>
<td>&quot;A soccer game with multiple males playing.&quot; and &quot;Some men are playing a sport.&quot;</td>
</tr>
<tr>
<td>Labels-sequence pairs</td>
<td>The genre tags of the movie &quot;Titanic&quot;, such as &quot;Romance&quot; and &quot;Drama&quot;, and its short description: &quot;James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912.&quot;</td>
</tr>
<tr>
<td>Customer-customer pairs</td>
<td>The customer ID of Jane and customer ID of Jackie.</td>
</tr>
<tr>
<td>Product-product pairs</td>
<td>The product ID of football and product ID of basketball.</td>
</tr>
<tr>
<td>Item review user-item pairs</td>
<td>A user's ID and the items she has bought, such as apple, pear, and orange.</td>
</tr>
</tbody>
</table>

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single integer-id. For example, [10].
- A sequences of discrete tokens, which is represented as a list of integer-ids. For example, [0, 12, 10, 13].

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss.
function. Specify these loss functions with the `output_layer` hyperparameter when you create the model training job.

**EC2 Instance Recommendation for the Object2Vec Algorithm**

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inferences.

**Instance Recommendation for Training**

When training a model using the Object2Vec algorithm on a CPU, start with an `ml.m5.2xlarge` instance. For training on a GPU, start with an `ml.p2.xlarge` instance. If the training takes too long on this instance, you can use a larger instance, such as an `ml.m5.4xlarge` or an `ml.m5.12xlarge` instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs.

**Instance Recommendation for Inference**

For inference with a trained Object2Vec model that has a deep neural network, we recommend using `ml.p3.2xlarge` GPU instance. Due to GPU memory scarcity, the `INFERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the section called “GPU optimization: Classification or Regression” (p. 1521) or the section called “GPU optimization: Encoder Embeddings” (p. 1522) inference network is loaded into GPU.

**Object2Vec Sample Notebooks**

- Using Object2Vec to Encode Sentences into Fixed Length Embeddings
- Using Object2Vec to learn document embeddings

**Note**

To run the notebooks on a notebook instance, see Example Notebooks (p. 152). To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 70).

**How Object2Vec Works**

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

**Topics**

- Step 1: Process Data (p. 1509)
- Step 2: Train a Model (p. 1509)
- Step 3: Produce Inferences (p. 1510)

**Step 1: Process Data**

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training (p. 1521). To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For python, you could use `np.random.shuffle`; for Unix, `shuf`.

**Step 2: Train a Model**

The SageMaker Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.
• **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.

• **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.

During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to True when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.

**Architecture of the Object2Vec Algorithm from Data Inputs to Scores**

**Step 3: Produce Inferences**

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

• To convert singleton input objects into fixed-length embeddings using the corresponding encoder
• To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.

Object2Vec Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enc0_max_seq_len</td>
<td>The maximum sequence length for the enc0 encoder.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $1 \leq \text{integer} \leq 5000$</td>
</tr>
<tr>
<td>enc0_vocab_size</td>
<td>The vocabulary size of enc0 tokens.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $2 \leq \text{integer} \leq 3000000$</td>
</tr>
<tr>
<td>bucket_width</td>
<td>The allowed difference between data sequence length when bucketing is enabled.</td>
</tr>
<tr>
<td></td>
<td>To enable bucketing, specify a non-zero value for this parameter.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $0 \leq \text{integer} \leq 100$</td>
</tr>
<tr>
<td></td>
<td>Default value: 0 (no bucketing)</td>
</tr>
<tr>
<td>comparator_list</td>
<td>A list used to customize the way in which two embeddings are compared.</td>
</tr>
<tr>
<td></td>
<td>The Object2Vec comparator operator layer takes the encodings from both encoders as inputs and outputs a single vector. This vector is a concatenation of subvectors. The string values passed to the comparator_list and the order in which they are passed determine how these subvectors are assembled. For example, if comparator_list=&quot;hadamard, concat&quot;, then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two encodings. If, on the other hand, comparator_list=&quot;hadamard&quot;, then the comparator operator constructs the vector as the hadamard product of only two encodings.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: A string that contains any combination of the names of the three binary operators: hadamard, concat, or abs_diff. The Object2Vec algorithm currently requires that the two vector encodings have the same dimension. These operators produce the subvectors as follows:</td>
</tr>
<tr>
<td></td>
<td>• hadamard: Constructs a vector as the <strong>Hadamard (element-wise) product</strong> of two encodings.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>

</tr>
</tbody>
</table>
|                        | • *concat*: Constructs a vector as the concatenation of two encodings.  
|                        | • *abs_diff*: Constructs a vector as the absolute difference between two encodings.                                                                                                                                                                                                                                                                   |
|                        | Default value: "hadamard, concat, abs_diff"                                                                                                                                                                                                                                                                                                           |
| dropout                | The dropout probability for network layers. *Dropout* is a form of regularization used in neural networks that reduces overfitting by trimming codependent neurons.                                                                                                                                                                                                                                                 |
|                        | **Optional**                                                                                                                                                                                                                                                                                                                                        |
|                        | Valid values: $0.0 \leq \text{float} \leq 1.0$                                                                                                                                                                                                                                                                                                        |
|                        | Default value: 0.0                                                                                                                                                                                                                                                                                                                                |
| early_stopping_patience| The number of consecutive epochs without improvement allowed before early stopping is applied. Improvement is defined by with the early_stopping_tolerance hyperparameter.                                                                                                                                                                                                                                  |
|                        | **Optional**                                                                                                                                                                                                                                                                                                                                        |
|                        | Valid values: $1 \leq \text{integer} \leq 5$                                                                                                                                                                                                                                                                                                      |
|                        | Default value: 3                                                                                                                                                                                                                                                                                                                                  |
| early_stopping_tolerance| The reduction in the loss function that an algorithm must achieve between consecutive epochs to avoid early stopping after the number of consecutive epochs specified in the early_stopping_patience hyperparameter concludes.                                                                                                                                                                      |
|                        | **Optional**                                                                                                                                                                                                                                                                                                                                        |
|                        | Valid values: $0.000001 \leq \text{float} \leq 0.1$                                                                                                                                                                                                                                                                                                  |
|                        | Default value: 0.01                                                                                                                                                                                                                                                                                                                                |
| enc_dim                | The dimension of the output of the embedding layer.                                                                                                                                                                                                                                                                                                  |
|                        | **Optional**                                                                                                                                                                                                                                                                                                                                        |
|                        | Valid values: $4 \leq \text{integer} \leq 10000$                                                                                                                                                                                                                                                                                                   |
|                        | Default value: 4096                                                                                                                                                                                                                                                                                                                                |
### Parameter Name | Description
---|---
enc0_network | The network model for the enc0 encoder.  
**Optional**  
Valid values: `hcnn`, `bilstm`, or `pooled_embedding`  
- `hcnn`: A hierarchical convolutional neural network.  
- `bilstm`: A bidirectional long short-term memory network (biLSTM), in which the signal propagates backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks.  
- `pooled_embedding`: Averages the embeddings of all of the tokens in the input.  
Default value: `hcnn`

enc0_cnn_filter_width | The filter width of the convolutional neural network (CNN) enc0 encoder.  
**Conditional**  
Valid values: 1 ≤ integer ≤ 9  
Default value: 3

enc0_freeze_pretrained_embedding | Whether to freeze enc0 pretrained embedding weights.  
**Conditional**  
Valid values: `True` or `False`  
Default value: `True`

enc0_layers | The number of layers in the enc0 encoder.  
**Conditional**  
Valid values: `auto` or 1 ≤ integer ≤ 4  
- For `hcnn`, `auto` means 4.  
- For `bilstm`, `auto` means 1.  
- For `pooled_embedding`, `auto` ignores the number of layers.  
Default value: `auto`

enc0_pretrained_embedding_file | The filename of the pretrained enc0 token embedding file in the auxiliary data channel.  
**Conditional**  
Valid values: String with alphanumeric characters, underscore, or period. `[A-Za-z0-9\._]`  
Default value: `""` (empty string)

<tbody>
<tr>
<td>negative_sampling_rate</td>
<td>The ratio of negative samples, generated to assist in training the algorithm, to positive samples that are provided by users. Negative samples represent data that is unlikely to occur in reality and are labelled negatively for training. They facilitate training a model to discriminate between the positive samples observed and the negative samples that are not. To specify the ratio of negative samples to positive samples used for training, set the value to a positive integer. For example, if you train the algorithm on input data in which all of the samples are positive and set negative_sampling_rate to 2, the Object2Vec algorithm internally generates two negative samples per positive sample. If you don't want to generate or use negative samples during training, set the value to 0. Optional Valid values: 0 ≤ integer Default value: 0 (off)</td>
</tr>
<tr>

Tune an Object2Vec Model

*Automatic model tuning* also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

**Metrics Computed by the Object2Vec Algorithm**

The Object2Vec algorithm has both classification and regression metrics. The `output_layer` type determines which metric you can use for automatic model tuning.

**Regressor Metrics Computed by the Object2Vec Algorithm**

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.

<td>test:mean_squared_error</td>
<td>The Mean Square Error</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:mean_squared_error</td>
<td>The Mean Square Error</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

**Classification Metrics Computed by the Object2Vec Algorithm**

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

**Data Formats for Object2Vec Training**

**Input: JSON Lines Request Format**

Content-type: application/jsonlines

```
{"label": 0, "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"label": 1, "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"label": 1, "in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

The "in0" and "in1" are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field "label" can accept real valued inputs.

**Data Formats for Object2Vec Inference**

**GPU optimization: Classification or Regression**

Due to GPU memory scarcity, the INFERENC...E_MODE environment variable can be specified to optimize on whether the classification/regression or the the section called “Output: Encoder Embeddings” (p. 1523) inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify INFE...E_MODE=classification. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for classification/regression inference:

```python
transformer = o2v.transformer(instance_count=4,
                             instance_type="ml.p2.xlarge",
                             max_concurrent_transforms=2,
                             max_payload=1,  # 1MB
                             strategy='MultiRecord',
                             env={'INFERENCE_PREFERRED_MODE': 'classification'},  # only useful with GPU
                             output_path=output_s3_path)
```

**Input: Classification or Regression Request Format**

Content-type: application/json

```
{
    "instances" : [ 
        {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]},
        {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]},
        {"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
    ]
}
```

Content-type: application/jsonlines

```
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```
For classification problems, the length of the scores vector corresponds to \texttt{num_classes}. For regression problems, the length is 1.

**Output: Classification or Regression Response Format**

Accept: application/json

```json
{
  "predictions": [
    {
      "scores": [
        0.6533935070037842,
        0.07582679390907288,
        0.2707797586917877
      ]
    },
    {
      "scores": [
        0.026291321963071823,
        0.6577019095420837,
        0.31600672006607056
      ]
    }
  ]
}
```

Accept: application/jsonlines

```json
{"scores":[0.195667684078216,0.395351558923721,0.408980727195739]}
{"scores":[0.251988261938095,0.258233487606048,0.489778339862823]}
{"scores":[0.280087798833847,0.368331134319305,0.351581096649169]}
```

In both the classification and regression formats, the scores apply to individual labels.

**Encoder Embeddings for Object2Vec**

**GPU optimization: Encoder Embeddings**

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the \texttt{INFEERENCE\_PREFERRED\_MODE} environment variable can be specified to optimize on whether the the section called "Inference Formats: Scoring" (p. 1521) or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify \texttt{INFEERENCE\_PREFERRED\_MODE=embedding}. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```python
transformer = o2v.transformer(instance_count=4,
    instance_type="ml.p2.xlarge",
    max_concurrent_transforms=2,
    max_payload=1,  # 1MB
    strategy='MultiRecord',
    env={'INFEERENCE\_PREFERRED\_MODE': 'embedding'},  # only useful with GPU
    output_path=output_s3_path)
```

**Input: Encoder Embeddings**

Content-type: application/json; infer_max_seqlen=<FWD-LENGTH>,<BCK-LENGTH>

Where \texttt{<FWD-LENGTH>} and \texttt{<BCK-LENGTH>} are integers in the range \([1,5000]\) and define the maximum sequence lengths for the forward and backward encoder.
Use built-in algorithms

```
{
  "instances" : [
    {"in0" : [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]},
    {"in0" : [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]},
    {"in0" : [774, 14, 21, 206]}
  ]
}
```

Content-type: application/jsonlines; infer_max_seq_lens=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```
{"in0" : [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]}
{"in0" : [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]}
{"in0" : [774, 14, 21, 206]}
```

In both of these formats, you specify only one input type: “in0” or “in1.” The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

**Output: Encoder Embeddings**

Content-type: application/json

```
{
  "predictions": [
    {"embeddings":
      [0.057368703186511, 0.030703511089086, 0.099890425801277, 0.063688032329082, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.007419463712722]
    },
    {"embeddings":
      [0.150190666317939, 0.05145975202322, 0.098204270005226, 0.064249359071254, 0.056249320507049, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.008508535102009]
    }
  ]
}
```

Content-type: application/jsonlines

```
{"embeddings":
  [0.057368703186511, 0.030703511089086, 0.099890425801277, 0.063688032329082, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.007419463712722]
}{"embeddings":
  [0.150190666317939, 0.05145975202322, 0.098204270005226, 0.064249359071254, 0.056249320507049, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.008508535102009]
}
```

The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: `enc0_token_embedding_dim`, `enc1_token_embedding_dim`, or `enc_dim`.

**Object Detection Algorithm**

The Amazon SageMaker Object Detection algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the Single Shot multibox Detector (SSD) framework and supports two base networks: VGG and ResNet. The network can be trained from scratch, or trained with models that have been pre-trained on the ImageNet dataset.

**Topics**

- Input/Output Interface for the Object Detection Algorithm (p. 1524)
- EC2 Instance Recommendation for the Object Detection Algorithm (p. 1526)
Input/Output Interface for the Object Detection Algorithm

The SageMaker Object Detection algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode and supports RecordIO (application/x-recordio) for training in pipe mode. However you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker object detection algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. The algorithm supports only application/x-image for inference.

**Note**

To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

See the Object Detection Sample Notebooks (p. 1526) for more details on data formats.

### Train with the RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the MXNet's GluonCV to generate RecordIO files for popular datasets like the PASCAL Visual Object Classes and Common Objects in Context (COCO).

### Train with the Image Format

If you use the image format for training, specify train, validation, train_annotation, and validation_annotation channels as values for the InputDataConfig parameter of CreateTrainingJob request. Specify the individual image data (.jpg or .png) files for the train and validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the train_annotation and validation_annotation channels. Set the content type for all four channels to image/png or image/jpeg based on the image type. You can also use the content type application/x-image when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```json
{
  "file": "your_image_directory/sample_image1.jpg",
  "image_size": [
    {
      "width": 500,
      "height": 400,
      "depth": 3
    }
  ],
  "annotations": [
    {
      "class_id": 0,
      "left": 111,
      "top": 134,
      "width": 61,
      "height": 128
    }
  ]
}
```
Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://your_bucket/train/sample_image and s3://your_bucket/train_annotation, specify the path for your train and train_annotation channels as s3://your_bucket/train and s3://your_bucket/train_annotation, respectively.

In the .json file, the relative path for an image named sample_image1.jpg should be sample_image/sample_image1.jpg. The "image_size" property specifies the overall image dimensions. The SageMaker object detection algorithm currently only supports 3-channel images. The "annotations" property specifies the categories and bounding boxes for objects within the image. Each object is annotated by a "class_id" index and by four bounding box coordinates ("left", "top", "width", "height"). The "left" (x-coordinate) and "top" (y-coordinate) values represent the upper-left corner of the bounding box. The "width" (x-coordinate) and "height" (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The "categories" property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The "categories" property is optional for the annotation .json file.

**Train with Augmented Manifest Image Format**

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames" are contained in the list ['"source-ref", "bounding-box"']:
The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with image first, followed by annotations. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter recordwrapperType must be set as "RecordIO".

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1919).

**Incremental Training**

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker object detection models can be seeded only with another built-in object detection model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the base_network and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For a sample notebook that shows how to use incremental training with the SageMaker object detection algorithm, see SageMaker Object Detection Incremental Training sample notebook. For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 1909).

**EC2 Instance Recommendation for the Object Detection Algorithm**

For object detection, we support the following GPU instances for training: ml.p2.xlarge, ml.p2.8xlarge, ml.p2.16xlarge, ml.p3.2xlarge, ml.p3.8xlarge and ml.p3.16xlarge. We recommend using GPU instances with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training. However, both CPU (such as C5 and M5) and GPU (such as P2 and P3) instances can be used for the inference. All the supported instance types for inference are itemized on Amazon SageMaker ML Instance Types.

**Object Detection Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Object Detection algorithm to train and host a model on the COCO dataset using the Single Shot multibox Detector algorithm, see Object Detection using the Image and JSON format. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The object detection example notebook using the Object Detection algorithm is located in the Introduction to Amazon Algorithms section. To open a notebook, click on its Use tab and select Create copy.
How Object Detection Works

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object's location and scale with a rectangular bounding box. Amazon SageMaker Object Detection uses the Single Shot multibox Detector (SSD) algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as VGG and ResNet have achieved great performance on the image classification task. Object detection in Amazon SageMaker supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

Object Detection Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker for training the object detection algorithm. For more information about how object training works, see How Object Detection Works (p. 1527).

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>The number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. Required Valid values: positive integer</td>
</tr>
<tr>
<td>num_training_samples</td>
<td>The number of training examples in the input dataset. Note: If there is a mismatch between this value and the number of samples in the training set, then the behavior of the lr_scheduler_step parameter will be undefined and distributed training accuracy may be affected. Required Valid values: positive integer</td>
</tr>
<tr>
<td>base_network</td>
<td>The base network architecture to use. Optional Valid values: 'vgg-16' or 'resnet-50' Default value: 'vgg-16'</td>
</tr>
<tr>
<td>early_stopping</td>
<td>True to use early stopping logic during training. False not to use it.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: True or False</td>
</tr>
<tr>
<td>early_stopping_min_epochs</td>
<td>The minimum number of epochs that must be run before the early stopping logic can be invoked. It is used only when early_stopping = True.</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td>early_stopping_patience</td>
<td>The number of epochs to wait before ending training if no improvement, as defined by the early_stopping_tolerance hyperparameter, is made in the relevant metric. It is used only when early_stopping = True.</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td>early_stopping_tolerance</td>
<td>The tolerance value that the relative improvement in validation:mAP, the mean average precision (mAP), is required to exceed to avoid early stopping. If the ratio of the change in the mAP divided by the previous best mAP is smaller than the early_stopping_tolerance value set, early stopping considers that there is no improvement. It is used only when early_stopping = True.</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: $0 \leq \text{float} \leq 1$</td>
</tr>
<tr>
<td>image_shape</td>
<td>The image size for input images. We rescale the input image to a square image with this size. We recommend using 300 and 512 for better performance.</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: positive integer $\geq 300$</td>
</tr>
<tr>
<td>epochs</td>
<td>The number of training epochs.</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td></td>
<td>Default: 30</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>freeze_layer_pattern</td>
<td>The regular expression (regex) for freezing layers in the base network. For example, if we set `freeze_layer_pattern = &quot;^(conv1_</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: string</td>
</tr>
<tr>
<td></td>
<td>Default: No layers frozen.</td>
</tr>
<tr>
<td>kv_store</td>
<td>The weight update synchronization mode used for distributed training. The weights can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See the Distributed Training MXNet tutorial for details. Note This parameter is not applicable to single machine training.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 'dist_sync' or 'dist_async'</td>
</tr>
<tr>
<td></td>
<td>• 'dist_sync': The gradients are synchronized after every batch with all the workers. With 'dist_sync', batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like a single machine with batch size n*b.</td>
</tr>
<tr>
<td></td>
<td>• 'dist_async': Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed.</td>
</tr>
<tr>
<td></td>
<td>Default: -</td>
</tr>
<tr>

Tune an Object Detection Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

Metrics Computed by the Object Detection Algorithm

The object detection algorithm reports on a single metric during training: validation:mAP. When tuning a model, choose this metric as the objective metric.

Tunable Object Detection Hyperparameters

Tune the Amazon SageMaker object detection model with the following hyperparameters. The hyperparameters that have the greatest impact on the object detection objective metric are: mini_batch_size, learning_rate, and optimizer.

### Object Detection Request and Response Formats

#### Request Format

Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats with `image/jpeg` and `image/png` content-types.

#### Response Formats

The response is the class index with a confidence score and bounding box coordinates for all objects within the image encoded in JSON format. The following is an example of response .json file:

```
{"prediction":
  [[4.0, 0.8641945540949988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244],
   [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571, 0.9712159633636475],
   [4.0, 0.32643985450267792, 0.3677481412887573, 0.03488332031573486, 0.6318609714508057, 0.5967587828636169],
   [8.0, 0.22552496790859295, 0.6152569651603699, 0.572278261846924, 0.882301390171051, 0.8985623121261597],
   [3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702, 0.39093565940856934, 0.9574796557426453]]
}
```

Each row in this .json file contains an array that represents a detected object. Each of these object arrays consists of a list of six numbers. The first number is the predicted class label. The second number is the associated confidence score for the detection. The last four numbers represent the bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices are normalized by the overall image size. Note that this encoding is different than that use by the input .json format. For example, in the first entry of the detection result, 0.3088374733924866 is the left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of lower-right corner) of the bounding box as a ratio of the overall image width, and 0.9345266819000244 is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the overall image height.

To avoid unreliable detection results, you might want to filter out the detection results with low confidence scores. In the object detection sample notebook, we provide scripts to remove the low confidence detections. Scripts are also provided to plot the bounding boxes on the original image.

For batch transform, the response is in JSON format, where the format is identical to the JSON format described above. The detection results of each image is represented as a JSON file. For example:

```
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id, confidence_score, xmin, ymin, xmax, ymax]]}
```
Principal Component Analysis (PCA) Algorithm

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by finding a new set of features called components, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker, PCA operates in two modes, depending on the scenario:

- **regular**: For datasets with sparse data and a moderate number of observations and features.
- **randomized**: For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data.

The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the
covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

**Topics**

- How PCA Works (p. 1535)
- PCA Hyperparameters (p. 1536)
- PCA Response Formats (p. 1537)

**Input/Output Interface for the PCA Algorithm**

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, PCA supports text/csv, application/json, and application/x-recordio-protobuf. Results are returned in either application/json or application/x-recordio-protobuf format with a vector of “projections.”

For more information on input and output file formats, see PCA Response Formats (p. 1537) for inference and the PCA Sample Notebooks (p. 1535).

**EC2 Instance Recommendation for the PCA Algorithm**

PCA supports both GPU and CPU computation. Which instance type is most performant depends heavily on the specifics of the input data.

**PCA Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to PCA with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**How PCA Works**

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called components, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren’t used.

Given the input of a matrix with rows $x_1, \ldots, x_n$ each of dimension $1 \times d$, the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.
Modes

The Amazon SageMaker PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm’s last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

Mode 1: Regular

The workers jointly compute both \( \sum x_i^T x_i \) and \( \sum x_i \).

**Note**

Because \( x_i \) are \( 1 \times d \) row vectors, \( x_i^T x_i \) is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.

The covariance matrix is computed as \( \sum x_i^T x_i - \frac{1}{n} (\sum x_i)^T \sum x_i \), and its top \( \text{num\_components} \) singular vectors form the model.

**Note**

If \( \text{subtract\_mean} \) is False, we avoid computing and subtracting \( \sum x_i \).

Use this algorithm when the dimension \( d \) of the vectors is small enough so that \( d^3 \) can fit in memory.

Mode 2: Randomized

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch \( X_t \) of dimension \( b \times d \), we randomly initialize a \( (\text{num\_components} + \text{extra\_components}) \times b \) matrix that we multiply by each mini-batch, to create a \( (\text{num\_components} + \text{extra\_components}) \times d \) matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final \( (\text{num\_components} + \text{extra\_components}) \times d \) matrix. The top right \( \text{num\_components} \) singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let \( \ell = \text{num\_components} + \text{extra\_components} \). Given a mini-batch \( X_t \), of dimension \( b \times d \), the worker draws a random matrix \( H_t \) of dimension \( \ell \times b \). Depending on whether the environment uses a GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is \( \pm 1 \) or a FJLT (fast Johnson Lindenstrauss transform; for information, see FJLT Transforms and the follow-up papers). The worker then computes \( H_t X_t \), and maintains \( B = \sum H_t X_t \). The worker also maintains \( h^T \), the sum of columns of \( H_1, \ldots, H_T \) (\( T \) being the total number of mini-batches), and \( s \), the sum of all input rows. After processing the entire shard of data, the worker sends the server \( B, h, s, \) and \( n \) (the number of input rows).

Denote the different inputs to the server as \( B^i, h^i, s^i, n^i \). The server computes \( b, h, s, n \) the sums of the respective inputs. It then computes \( C = B - \frac{1}{n} h^T s \), and finds its singular value decomposition. The top-right singular vectors and singular values of \( C \) are used as the approximate solution to the problem.

PCA Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker. For more information about how PCA works, see How PCA Works (p. 1535).

**PCA Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker PCA algorithm.

**JSON Response Format**

Accept—application/json

```json
{
```
Random Cut Forest (RCF) Algorithm

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the “regular” data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the “regular” data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-
dimensional input. Amazon SageMaker RCF scales well with respect to number of features, data set size, and number of instances.

Topics

- Instance Recommendations for the RCF Algorithm (p. 1540)
- RCF Sample Notebooks (p. 1540)
- How RCF Works (p. 1540)
- RCF Hyperparameters (p. 1543)
- Tune an RCF Model (p. 1543)
- RCF Response Formats (p. 1544)

Input/Output Interface for the RCF Algorithm

Amazon SageMaker Random Cut Forest supports the train and test data channels. The optional test channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and test data content types can be either application/x-recordio-protobuf or text/csv formats. For the test data, when using text/csv format, the content must be specified as text/csv;label_size=1 where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

Also note that the train channel only supports S3DataDistributionType=ShardedByS3Key and the test channel only supports S3DataDistributionType=FullyReplicated. The S3 distribution type can be specified using the Amazon SageMaker Python SDK as follows:

```python
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
rcf = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.s3_input(
    s3_data=s3_training_data_location,
    content_type='text/csv;label_size=0',
    distribution='ShardedByS3Key')

# run the training job on input data stored in S3
rcf.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, AmazonSageMakerFullAccess and AmazonEC2ContainerRegistryFullAccess. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger than the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different AWS account's Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the ECR repository permissions for more information on setting a repository policy statement.

See the S3DataSource for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports application/x-recordio-protobuf, text/csv and application/json input data content types. See the Common Data Formats for Built-in Algorithms (p. 1398).
documentation for more information. RCF inference returns application/x-recordio-protobuf or application/json formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See Common Data Formats--Inference for more information.

For more information on input and output file formats, see RCF Response Formats (p. 1544) for inference and the RCF Sample Notebooks (p. 1540).

Instance Recommendations for the RCF Algorithm

For training, we recommend the ml.m4, ml.c4, and ml.c5 instance families. For inference we recommend using a ml.c5.xl instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

RCF Sample Notebooks

For an example of how to train an RCF model and perform inferences with it, see the An Introduction to SageMaker Random Cut Forests notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

How RCF Works

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the “regular” data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the “regular” data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

Sample Data Randomly

The first step in the RCF algorithm is to obtain a random sample of the training data. In particular, suppose we want a sample of size $\kappa$ from $N$ total data points. If the training data is small enough, the entire dataset can be used, and we could randomly draw $\kappa$ elements from this set. However, frequently the training data is too large to fit all at once, and this approach isn't feasible. Instead, we use a technique called reservoir sampling.

Reservoir sampling is an algorithm for efficiently drawing random samples from a dataset $S = \{S_1, \ldots, S_N\}$ where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when $N$ is not known a priori. If only one sample is requested, such as when $\kappa = 1$, the algorithm is like this:

**Algorithm: Reservoir Sampling**
• Input: dataset or data stream $S = \{S_1, \ldots, S_N\}$
• Initialize the random sample $X = S_1$
• For each observed sample $S_n, n = 2, \ldots, N$:
  • Pick a uniform random number $\xi \in [0, 1]$
  • If $\xi < 1/n$
    • Set $X = S_n$
  • Return $X$

This algorithm selects a random sample such that $P(X = S_n) = 1/N$ for all $n = 1, \ldots, N$. When $K > 1$ the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

**Train a RCF Model and Produce Inferences**

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest. Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:

A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher “variance”), and then randomly determining the position of a hyperplane “cut” through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.
A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

Choose Hyperparameters

The primary hyperparameters used to tune the RCF model are `num_trees` and `num_samples_per_tree`. Increasing `num_trees` has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm described above.

The parameter `num_samples_per_tree` is related to the expected density of anomalies in the dataset. In particular, `num_samples_per_tree` should be chosen such that $1/\text{num_samples_per_tree}$ approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies $1/256$ or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

**Tune an RCF Model**

*Automatic model tuning*, also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset.
You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test datapoints and then labels the datapoints as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

**Metrics Computed by the RCF Algorithm**

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:f1</td>
<td>F1-score on the test dataset, based on the difference between calculated labels and actual labels.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

**Tunable RCF Hyperparameters**

You can tune a RCF model with the following hyperparameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Recommended Ranges</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_samples_per_tree</td>
<td>IntegerParameterRanges</td>

**RCF Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. Note that SageMaker Random Cut Forest supports both dense and sparse JSON and RecordIO formats. This topic contains a list of the available output formats for the SageMaker RCF algorithm.

**JSON Response Format**

ACCEPT: application/json.

```json
{
}
```
"scores": [
    {"score": 0.02},
    {"score": 0.25}
]

**JSONLINES Response Format**

**ACCEPT**: application/jsonlines.

```
{"score": 0.02},
{"score": 0.25}
```

**RECORDIO Response Format**

**ACCEPT**: application/x-recordio-protobuf.

```
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.25]  # float32
            }
        }
    }
]
```
Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker Image Classification Algorithm (p. 1443) is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The Object Detection Algorithm (p. 1523) is a supervised learning algorithm that detects and classifies all instances of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is represented as a grayscale image, called a segmentation mask. A segmentation mask is a grayscale image with the same shape as the input image.
The SageMaker semantic segmentation algorithm is built using the **MXNet Gluon framework and the Gluon CV toolkit**, and provides you with a choice of three build-in algorithms to train a deep neural network. You can use the **Fully-Convolutional Network (FCN) algorithm**, **Pyramid Scene Parsing (PSP) algorithm**, or **DeepLabV3**.

Each of the three algorithms has two distinct components:

- **The *backbone* (or *encoder*)**—A network that produces reliable activation maps of features.
- **The *decoder***—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: **ResNet50** or **ResNet101**. These backbones include pretrained artifacts that were originally trained on the ImageNet classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

**Semantic Segmentation Sample Notebooks**

For a sample Jupyter notebook that uses the SageMaker semantic segmentation algorithm to train a model and deploy it to perform inferences, see the **Semantic Segmentation Example**. For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see **Use Amazon SageMaker Notebook Instances (p. 139)**.

To see a list of all of the SageMaker samples, create and open a notebook instance, and choose the **SageMaker Examples** tab. The example semantic segmentation notebooks are located under **Introduction to Amazon algorithms**. To open a notebook, choose its **Use** tab, and choose **Create copy**.

**Input/Output Interface for the Semantic Segmentation Algorithm**

SageMaker semantic segmentation expects the customer's training dataset to be on **Amazon Simple Storage Service (Amazon S3)**. Once trained, it produces the resulting model artifacts on Amazon S3. The input interface format for the SageMaker semantic segmentation is similar to that of most standardized semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented in two channels, one for `train` and one for `validation` using four directories, two for images and two for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have a label map that describes how the annotation mappings are established. If not, the algorithm uses a default. It also supports the augmented manifest image format (**application/x-image**) for training in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an **image/jpeg** content type.

**How Training Works**

The training data is split into four directories: `train`, `train_annotation`, `validation`, and `validation_annotation`. There is a channel for each of these directories. The dataset also expected
to have one label_map.json file per channel for train_annotation and validation_annotation respectively. If you don’t provide these JSON files, SageMaker provides the default set label map.

The dataset specifying these files should look similar to the following example:

```
s3://bucket_name
  |-
  |  train
  |   |-
  |   0000.jpg
  |   coffee.jpg
  |-
  |  validation
  |   |-
  |   00a0.jpg
  |   bananna.jpg
  |-
  |  train_annotation
  |   |-
  |   0000.png
  |   coffee.png
  |-
  |  validation_annotation
  |   |-
  |   00a0.png
  |   bananna.png
  |-
  |  label_map
  |   |-
  |   train_label_map.json
  |   validation_label_map.json
```

Every JPG image in the train and validation directories has a corresponding PNG label image with the same name in the train_annotation and validation_annotation directories. This naming convention helps the algorithm to associate a label with its corresponding image during training. The train, train_annotation, validation, and validation_annotation channels are mandatory. The annotations are single-channel PNG images. The format works as long as the metadata (modes) in the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer. For more information on our support for modes, see the Python Image Library documentation. We recommend using the 8-bit pixel, true color P mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a map of a label, the algorithm uses one mapping file per channel, called the label map. The label map is used to map the values in the image with actual label indices. In the default label map, which is provided by default if you don’t provide one, the pixel value in an annotation matrix (image) directly index the label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the unscaled default case is the following:

```
{
  "scale": "1"
}
```

To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn’t convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```
{
  "scale": "3"
}
```

The following example shows how this "scale" value is used to rescale the encoded_label values of the input annotation image when they are mapped to the mapped_label values to be used in training.
The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```plaintext
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a `label_map` file:

```json
{
  "map": {
    "0": 5,
    "1": 0,
    "2": 2
  }
}
```

This label mapping for this example is:

```plaintext
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]
```

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the `label_map` channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

**Training with the Augmented Manifest Format**

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be in JSON Lines format, as described in the `CreateTrainingJob` request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a `source-ref` key. The `source-ref` key should contain the value of the Amazon S3 URI to the image. The labels are provided under the `AttributeNames` parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the example below, the `AttributeNames` are contained in the list of image and annotation references ["source-ref", "city-streets-ref"]. These names must have -ref appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the `RecordWrapperType` parameter must be "RecordIO" and value of the `ContentType` parameter must be application/x-recordio.

```json
{"source-ref": "S3 bucket location", "city-streets-ref": "S3 bucket location", "city-streets-metadata": {"job-name": "label-city-streets", }}
```

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1919).

**Incremental Training**

You can also seed the training of a new model with a model that you trained previously using SageMaker. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker Semantic Segmentation.
To use your own pre-trained model, specify the ChannelName as "model" in the InputDataConfig for the CreateTrainingJob request. Set the ContentType for the model channel to application/x-sagemaker-model. The backbone, algorithm, crop_size, and num_classes input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker outputs. You can only use image formats for input data. For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 1909).

Produce Inferences

To query a trained model that is deployed to an endpoint, you need to provide an image and an AcceptType that denotes the type of output required. The endpoint takes JPEG images with an image/jpeg content type. If you request an AcceptType of image/png, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of application/x-recordio-protobuf, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.

EC2 Instance Recommendation for the Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using P2/P3 EC2 Amazon Elastic Compute Cloud (Amazon EC2) instances in single machine configurations. It supports the following GPU instances for training:

- ml.p2.xlarge
- ml.p2.8xlarge
- ml.p2.16xlarge
- ml.p3.2xlarge
- ml.p3.8xlarge
- ml.p3.16xlarge

For inference, you can use either CPU instances (such as c5 and m5) and GPU instances (such as p2 and p3) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see Amazon SageMaker ML Instance Types.

Semantic Segmentation Hyperparameters

The following tables list the hyperparameters supported by the Amazon SageMaker semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the AlgorithmName of the CreateTrainingJob request.

Network Architecture Hyperparameters

<table>

</tr>
</thead>
</table>
| **mini_batch_size** | The batch size for training. Using a large `mini_batch_size` usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the `mini_batch_size` and `image_shape` parameters, and the backbone architecture.  
  **Optional**  
  Valid values: positive integer  
  Default value: 16 |
| **momentum** | The momentum for the `sgd` optimizer. When you use other optimizers, the semantic segmentation algorithm ignores this parameter.  
  **Optional**  
  Valid values: $0 < \text{float} \leq 1$  
  Default value: 0.9 |
| **optimizer** | The type of optimizer. For more information about an optimizer, choose the appropriate link:  
  - `adam`: Adaptive momentum estimation  
  - `adagrad`: Adaptive gradient descent  
  - `nag`: Nesterov accelerated gradient  
  - `rmsprop`: Root mean square propagation  
  - `sgd`: Stochastic gradient descent  
  **Optional**  
  Valid values: `adam, adagrad, nag, rmsprop, sgd`  
  Default value: `sgd` |
| **syncbn** | If set to `True`, the batch normalization mean and variance are computed over all the samples processed across the GPUs.  
  **Optional**  
  Valid values: `True, False`  
  Default value: `False` |
Parameter Name | Description
--- | ---
validation_mini_batch_size | The batch size for validation. A large mini_batch_size usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the mini_batch_size and image_shape parameters, and the backbone architecture.
- To score the validation on the entire image without cropping the images, set this parameter to 1. Use this option if you want to measure performance on the entire image as a whole.
  **Note**
  Setting the validation_mini_batch_size parameter to 1 causes the algorithm to create a new network model for every image. This might slow validation and training.
- To crop images to the size specified in the crop_size parameter, even during evaluation, set this parameter to a value greater than 1.

Optional
Valid values: positive integer
Default value: 16

weight_decay | The weight decay coefficient for the sgd optimizer. When you use other optimizers, the algorithm ignores this parameter.

Optional
Valid values: 0 < float < 1
Default value: 0.0001

### Tuning a Semantic Segmentation Model

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

### Metrics Computed by the Semantic Segmentation Algorithm

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:mIOU</td>
<td>The area of the intersection of the predicted segmentation and the ground truth divided by the area of union between them for images in the validation set. Also known as the Jaccard Index.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:pixel_acc</td>
<td>The percentage of pixels that are correctly classified in images from the validation set.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>
Tunable Semantic Segmentation Hyperparameters

You can tune the following hyperparameters for the semantic segmentation algorithm.

Sequence-to-Sequence Algorithm

Amazon SageMaker Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

- Sequence-to-Sequence Hyperparameters (p. 1558)
- Tune a Sequence-to-Sequence Model (p. 1566)

Input/Output Interface for the Sequence-to-Sequence Algorithm

Training

SageMaker seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in the seq2seq example notebook. In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:
- **train**: It should contain the training data (for example, the train.rec file generated by the preprocessing script).
• **validation**: It should contain the validation data (for example, the val.rec file generated by the preprocessing script).

• **vocab**: It should contain two vocabulary files (`vocab.src.json` and `vocab.trg.json`)

If the algorithm doesn't find data in any of these three channels, training results in an error.

**Inference**

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the application/json format. Otherwise, use the recordio-protobuf format to work with the integer encoded data. Both modes support batching of input data. application/json format also allows you to visualize the attention matrix.

• **application/json**: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be application/json. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:

  - `configuration`: {
    `attention_matrix`: true
  }

  Returns the attention matrix for the particular input sequence.

• **application/x-recordio-protobuf**: Expects the input in recordio-protobuf format and returns the output in recordio-protobuf format. Both content and accept types should be application/x-recordio-protobuf. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be application/jsonlines. The format for input is as follows:

```json
content-type: application/jsonlines

{"source": "source_sequence_0"}
{"source": "source_sequence_1"}
```

The format for response is as follows:

```json
accept: application/jsonlines

{"target": "predicted_sequence_0"}
{"target": "predicted_sequence_1"}
```

For additional details on how to serialize and deserialize the inputs and outputs to specific formats for inference, see the Sequence-to-Sequence Sample Notebooks (p. 1557).

**EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm**

Currently Amazon SageMaker seq2seq is only supported on GPU instance types and is only set up to train on a single machine. But it does also offer support for multiple GPUs.

**Sequence-to-Sequence Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Sequence to Sequence algorithm to train a English-German translation model, see Machine Translation English-German Example Using SageMaker Seq2Seq. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the
SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Sequence-to-Sequence Works

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:

- **An embedding layer.** In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like FastText or Glove or to initialize it randomly and learn the parameters during training.

- **An encoder layer.** After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). (Colah's blog explains LSTM in a great detail.)

- **A decoder layer.** The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by Sutskever et al. in 2014.

**Attention mechanism.** The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the attention mechanism. In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.

For more in details, see the whitepaper Effective Approaches to Attention-based Neural Machine Translation by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper Google's Neural Machine Translation System: Bridging the Gap between Human and Machine Translation by Wu, et al. describes Google's architecture for machine translation, which uses skip connections between encoder and decoder layers.

**Tune a Sequence-to-Sequence Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.
For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

**Metrics Computed by the Sequence-to-Sequence Algorithm**

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:accuracy</td>
<td>Accuracy computed on the validation dataset.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:bleu</td>
<td><strong>Bleu</strong> score computed on the validation dataset. Because BLEU computation is expensive, you can choose to compute BLEU on a random subsample of the validation dataset to speed up the overall training process. Use the bleu_sample_size parameter to specify the subsample.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:perplexity</td>
<td><strong>Perplexity</strong>, is a loss function computed on the validation dataset. Perplexity measures the cross-entropy between an empirical sample and the distribution predicted by a model and so provides a measure of how well a model predicts the sample values, Models that are good at predicting a sample have a low perplexity.</td>
<td>Minimize</td>
</tr>
</tbody>

**Tunable Sequence-to-Sequence Hyperparameters**

You can tune the following hyperparameters for the SageMaker Sequence to Sequence algorithm. The hyperparameters that have the greatest impact on sequence to sequence objective metrics are: `batch_size`, `optimizer_type`, `learning_rate`, `num_layers_encoder`, and `num_layers_decoder`.

<table>

### XGBoost Algorithm

The XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as an Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost estimator that executes a training script in a

</tbody>
</table>
managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 0.90, 1.0, 1.2, and 1.3.

**Supported versions**

- Framework (open source) mode: 0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-2, 1.3-1
- Algorithm mode: 0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-2, 1.3-1

**Warning**
The XGBoost 0.90 version will be deprecated on December 31, 2021. Supports for security updates or bug fixes for XGBoost 0.90 will be discontinued after this date. It is highly recommended to upgrade the XGBoost version to one of the newer versions (1.0-1 or later) before the deprecation.

**Note**
XGBoost 1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost 1.2. Consider using SageMaker XGBoost 1.2-2 or later.

**How to Use SageMaker XGBoost**

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts.

- **Use XGBoost as a framework**

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import s3_input, Session

# initialize hyperparameters
hyperparameters = {
    "max_depth":"5",
    "eta":"0.2",
    "gamma":"4",
    "min_child_weight":"6",
    "subsample":"0.7",
    "verbosity":"1",
    "objective":"reg:linear",
    "num_round":"50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}/output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
    framework_version='1.2-2',
    hyperparameters=hyperparameters,
    role=sagemaker.get_execution_role(),
    instance_count=1,
    output_path=output_path)
```
Use built-in algorithms

```python
instance_type='ml.m5.2xlarge',
output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = s3_input("s3:///{}/{}".format(bucket, prefix, 'train'),
    content_type=content_type)
validation_input = s3_input("s3:///{}/{}".format(bucket, prefix, 'validation'),
    content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

SageMaker Python SDK v2

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "verbosity": "1",
    "objective": "reg:linear",
    "num_round": "50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}/output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
    framework_version='1.2-2',
    hyperparameters=hyperparameters,
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.m5.2xlarge',
    output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3:///{}/{}".format(bucket, prefix, 'train'),
    content_type=content_type)
validation_input = TrainingInput("s3:///{}/{}".format(bucket, prefix, 'validation'),
    content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

For an end-to-end example of using SageMaker XGBoost as a framework, see Regression with Amazon SageMaker XGBoost

- **Use XGBoost as a built-in algorithm**

  Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the

1570
Use built-in algorithms

SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the image_uris.retrieve API finds the correct URI, see Common parameters for built-in algorithms and look up xgboost from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

SageMaker Python SDK v1

```python
import sagemaker
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
from sagemaker.session import s3_input, Session

# initialize hyperparameters
hyperparameters = {
    "max_depth":"5",
    "eta":"0.2",
    "gamma":"4",
    "min_child_weight":"6",
    "subsample":"0.7",
    "objective":"reg:squarederror",
    "num_round":"50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = get_image_uri(boto3.Session().region_name, 'xgboost', repo_version='1.2-2')

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_name=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           train_volume_size=5, # 5 GB
                                           output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = s3_input("s3://{}/{}/{}").format(bucket, prefix, 'train'),
validation_input = s3_input("s3://{}/{}/{}").format(bucket, prefix, 'validation'),

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

SageMaker Python SDK v2

```python
import sagemaker
import boto3
from sagemaker import image_uris
```

1571
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "objective": "reg:squarederror",
    "num_round": "50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.2-2")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          role=sagemaker.get_execution_role(),
                                          instance_count=1,
                                          instance_type='ml.m5.2xlarge',
                                          volume_size=5, # 5 GB
                                          output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/train/".format(bucket, prefix),
                            content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/validation/".format(bucket, prefix),
                                 content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.

- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker XGBoost (Parquet input)

Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm (default) or text/csv.
Note
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.
For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: `<label> <index0>:<value0> <index1>:<value1> ...` Inference requests for libsvm might not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it’s not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

To use a model trained with SageMaker XGBoost in open source XGBoost

- Use the following Python code:

```python
import pickle as pkl
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = pkl.load(open(model_file_path, 'rb'))
# prediction with test data
pred = model.predict(dtest)
```

To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For text/csv input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

EC2 Instance Recommendation for the XGBoost Algorithm

SageMaker XGBoost 1.0-1 or earlier currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

SageMaker XGBoost version 1.2 or later supports single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script. SageMaker currently does not support multi-GPU training.
XGBoost Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.

<table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

How XGBoost Works

XGBoost is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using gradient boosting for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leafs that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It's called
Gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.

\[
F_m(X) = F_{m-1}(X) + \alpha_m h_m(X, r_{m-1}),
\]

where \(\alpha_m\) and \(r_i\) are the regularization parameters and residuals computed with the \(i^{th}\) tree respectively, and \(h_i\) is a function that is trained to predict residuals, \(r_i\) using \(X\) for the \(i^{th}\) tree. To compute \(\alpha_i\) we use the residuals computed, \(r_i\) and compute the following:

\[
\arg\min_{\alpha} \sum_{i=1}^{m} L(Y_i, F_{i-1}(X_i) + \alpha h_i(X_i, r_{i-1}))
\]

where \(L(Y, F(X))\) is a differentiable loss function.

- Gradient Tree Boosting
- Introduction to Boosted Trees

**XGBoost Hyperparameters**

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. Currently SageMaker supports version 1.2-2. For details about full set of hyperparameter that can be configured for this version of XGBoost, see XGBoost Parameters.

Tune an XGBoost Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning *objective* function to optimize during model training
- an *eval_metric* to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

**Note**

Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1797).

Evaluation Metrics Computed by the XGBoost Algorithm

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid *eval_metric* values, refer to [XGBoost Learning Task Parameters](#).

<table>
<thead>
<tr>

**Deprecated Versions of XGBoost and their Upgrades**

This topic contains documentation for previous versions of Amazon SageMaker XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.

**Topics**
- Upgrade XGBoost Version 0.90 to Version 1.2 (p. 1584)
- XGBoost Version 0.72 (p. 1586)

**Upgrade XGBoost Version 0.90 to Version 1.2**

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.2, you must have version 2.x of the SDK installed and change the XGBoost `version` and `framework_version` parameters to 1.2-2. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.
Topics
• Upgrade SageMaker Python SDK Version 1.x to Version 2.x (p. 1585)
• Change the image tag to 1.2-2 (p. 1585)
• Change Docker Image for Boto3 (p. 1585)
• Update Hyperparameters and Learning Objectives (p. 1586)

Upgrade SageMaker Python SDK Version 1.x to Version 2.x
If you are still using Version 1.x of the SageMaker Python SDK, you must to upgrade version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see Use Version 2.x of the SageMaker Python SDK. To install the latest version, run:

```bash
python -m pip install --upgrade sagemaker
```

Change the image tag to 1.2-2
If you are using the SageMaker Python SDK and using the XGBoost build-in algorithm, change the version parameter in `image_uris.retrieve`.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.2-2")
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
hyperparameters=hyperparameters,
role=sagemaker.get_execution_role(),
instance_count=1,
instante_type='ml.m5.2xlarge',
train_volume_size=5, # 5 GB
output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```python
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
framework_version='1.2-2',
hyperparameters=hyperparameters,
role=sagemaker.get_execution_role(),
instance_count=1,
instante_type='ml.m5.2xlarge',
output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.

```python
content_type = "libsvm"
train_input = TrainingInput("s3://{{}}/{{}}/{{}}/train",
content_type=content_type)
validation_input = TrainingInput("s3://{{}}/{{}}/{{}}/validation",
content_type=content_type)
```

For the full list of SageMaker Python SDK version 2.x changes, see Use Version 2.x of the SageMaker Python SDK.

Change Docker Image for Boto3
If you are using Boto3 to train or deploy your model, change the docker image tag (0.90-1 or 0.90-2) to 1.2-2.
Use built-in algorithms

```json
{
    "AlgorithmSpecification": {
        "TrainingImage": "746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-xgboost:1.2-2"
    }
}
```

If you are using the SageMaker Python SDK to retrieve registry path, change the `version` parameter in `image_uris.retrieve`.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.2-2")
```

Update Hyperparameters and Learning Objectives

The `silent` parameter has been deprecated and is no longer available in XGBoost 1.2 and later versions. Use `verbosity` instead. If you were using the `reg:linear` learning objective, it has been deprecated as well in favor of `reg:squarederror`. Use `reg:squarederror` instead.

```python
hyperparameters = {
    "verbosity": "2",
    "objective": "reg:squarederror",
    "num_round": "50",
    ...
}
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           ...
)
```

XGBoost Version 0.72

**Important**

The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with `:1` is for the old version.

**SageMaker Python SDK v1**

```python
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",
                            repo_version="1")
```

**SageMaker Python SDK v2**

```python
import boto3
from sagemaker import image_uris
xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name, "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see Supported versions (p. 1569)).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of
the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost Algorithm (p. 1568). They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

Input/Output Interface for the XGBoost Release 0.72

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm or (the default) text/csv.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: 

\(<label> <index0>:<value0> <index1>:<value1> ...\) ... Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

**To use a model trained with SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
```
pred = model.predict(dtest)

**To differentiate the importance of labelled data points use Instance Weight Supports**

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For `text/libsvm` input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For `text/csv` input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

**EC2 Instance Recommendation for the XGBoost Release 0.72**

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

**XGBoost Release 0.72 Sample Notebooks**

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see [Regression with Amazon SageMaker XGBoost algorithm](https://docs.aws.amazon.com/sagemaker/latest/dg/regression-with-xgboost.html). To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances](https://docs.aws.amazon.com/sagemaker/latest/dg/notebook-instances.html) (p. 139). Once you have created a notebook instance and opened it, select the [SageMaker Examples](https://docs.aws.amazon.com/sagemaker/latest/dg/examples.html) tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the [Introduction to Amazon algorithms](https://docs.aws.amazon.com/sagemaker/latest/dg/algorithms.html) section. To open a notebook, click on its [Use](https://docs.aws.amazon.com/sagemaker/latest/dg/notebook-instances.html) tab and select [Create copy](https://docs.aws.amazon.com/sagemaker/latest/dg/notebook-instances.html).

**XGBoost Release 0.72 Hyperparameters**

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see [XGBoost Parameters](https://xgboost.readthedocs.io/en/stable/parameter.html).

**Tune an XGBoost Release 0.72 Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning **objective function** to optimize during model training
- an **eval_metric** to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically
You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1797).

**Metrics Computed by the XGBoost Release 0.72 Algorithm**

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to XGBoost Learning Task Parameters.

<table>

Use Reinforcement Learning with Amazon SageMaker

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent's current state. Furthermore, the learning agent's goals should correlate strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

What are the differences between reinforcement, supervised, and unsupervised learning paradigms?

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.

Topics
- Why is Reinforcement Learning Important? (p. 1597)
Why is Reinforcement Learning Important?

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles. Because RL models learn by a continuous process of receiving rewards and punishments for every action taken by the agent, it is possible to train systems to make decisions under uncertainty and in dynamic environments.

Markov Decision Process (MDP)

RL is based on models called Markov Decision Processes (MDPs). An MDP consists of a series of time steps. Each time step consists of the following:

Environment

Defines the space in which the RL model operates. This can be either a real-world environment or a simulator. For example, if you train a physical autonomous vehicle on a physical road, that would be a real-world environment. If you train a computer program that models an autonomous vehicle driving on a road, that would be a simulator.

State

Specifies all information about the environment and past steps that is relevant to the future. For example, in an RL model in which a robot can move in any direction at any time step, the position of the robot at the current time step is the state, because if we know where the robot is, it isn’t necessary to know the steps it took to get there.

Action

What the agent does. For example, the robot takes a step forward.

Reward

A number that represents the value of the state that resulted from the last action that the agent took. For example, if the goal is for a robot to find treasure, the reward for finding treasure might be 5, and the reward for not finding treasure might be 0. The RL model attempts to find a strategy that optimizes the cumulative reward over the long term. This strategy is called a policy.

Observation

Information about the state of the environment that is available to the agent at each step. This might be the entire state, or it might be just a part of the state. For example, the agent in a chess-playing model would be able to observe the entire state of the board at any step, but a robot in a maze might only be able to observe a small portion of the maze that it currently occupies.

Typically, training in RL consists of many episodes. An episode consists of all of the time steps in an MDP from the initial state until the environment reaches the terminal state.
Key Features of Amazon SageMaker RL

To train RL models in SageMaker RL, use the following components:

- An RL environment. You can use custom environments, open-source environments, or commercial environments. For information, see RL Environments in Amazon SageMaker (p. 1601).

The following diagram shows the RL components that are supported in SageMaker RL.
Reinforcement Learning Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker reinforcement learning.

<table>

Sample RL Workflow Using Amazon SageMaker RL

The following example describes the steps for developing RL models using Amazon SageMaker RL.

For complete code examples, see the sample notebooks at https://github.com/awslabs/amazon-sagemaker-examples/tree/master/reinforcement-learning.

1. **Formulate the RL problem**—First, formulate the business problem into an RL problem. For example, auto scaling enables services to dynamically increase or decrease capacity depending on conditions that you define. Currently, this requires setting up alarms, scaling policies, thresholds, and other manual steps. To solve this with RL, we define the components of the Markov Decision Process:
   - **Objective**—Scale instance capacity so that it matches the desired load profile.
   - **Environment**—A custom environment that includes the load profile. It generates a simulated load with daily and weekly variations and occasional spikes. The simulated system has a delay between when new resources are requested and when they become available for serving requests.
   - **State**—The current load, number of failed jobs, and number of active machines.
   - **Action**—Remove, add, or keep the same number of instances.
   - **Reward**—A positive reward for successful transactions and a high penalty for failing transactions beyond a specified threshold.

2. **Define the RL environment**—The RL environment can be the real world where the RL agent interacts or a simulation of the real world. You can connect open source and custom environments developed using Gym interfaces and commercial simulation environments such as MATLAB and Simulink.

3. **Define the presets**—The presets configure the RL training jobs and define the hyperparameters for the RL algorithms.

4. **Write the training code**—Write training code as a Python script and pass the script to a SageMaker training job. In your training code, import the environment files and the preset files, and then define the main() function.

5. **Train the RL Model**—Use the SageMaker RLEstimator in the Amazon SageMaker Python SDK to start an RL training job. If you are using local mode, the training job runs on the notebook instance.
When you use SageMaker for training, you can select GPU or CPU instances. Store the output from the training job in a local directory if you train in local mode, or on Amazon S3 if you use SageMaker training.

The `RLEstimator` requires the following information as parameters.

- The source directory where the environment, presets, and training code are uploaded.
- The path to the training script.
- The RL toolkit and deep learning framework you want to use. This automatically resolves to the Amazon ECR path for the RL container.
- The training parameters, such as the instance count, job name, and S3 path for output.
- Metric definitions that you want to capture in your logs. These can also be visualized in CloudWatch and in SageMaker notebooks.

6. **Visualize training metrics and output**—After a training job that uses an RL model completes, you can view the metrics you defined in the training jobs in CloudWatch. You can also plot the metrics in a notebook by using the Amazon SageMaker Python SDK analytics library. Visualizing metrics helps you understand how the performance of the model as measured by the reward improves over time.

   **Note**
   If you train in local mode, you can't visualize metrics in CloudWatch.

7. **Evaluate the model**—Checkpointed data from the previously trained models can be passed on for evaluation and inference in the checkpoint channel. In local mode, use the local directory. In SageMaker training mode, you need to upload the data to S3 first.

8. **Deploy RL models**—Finally, deploy the trained model on an endpoint hosted on SageMaker containers or on an edge device by using AWS IoT Greengrass.

For more information on RL with SageMaker, see [Using RL with the SageMaker Python SDK](#).

### RL Environments in Amazon SageMaker

Amazon SageMaker RL uses environments to mimic real-world scenarios. Given the current state of the environment and an action taken by the agent or agents, the simulator processes the impact of the action, and returns the next state and a reward. Simulators are useful in cases where it is not safe to train an agent in the real world (for example, flying a drone) or if the RL algorithm takes a long time to converge (for example, when playing chess).

The following diagram shows an example of the interactions with a simulator for a car racing game.
The simulation environment consists of an agent and a simulator. Here, a convolutional neural network (CNN) consumes images from the simulator and generates actions to control the game controller. With multiple simulations, this environment generates training data of the form \( \text{state}_t, \text{action}, \text{state}_{t+1}, \text{reward}_{t+1} \). Defining the reward is not trivial and impacts the RL model quality. We want to provide a few examples of reward functions, but would like to make it user-configurable.

**Topics**

- Use OpenAI Gym Interface for Environments in SageMaker RL (p. 1602)
- Use Open-Source Environments (p. 1603)
- Use Commercial Environments (p. 1603)

**Use OpenAI Gym Interface for Environments in SageMaker RL**

To use OpenAI Gym environments in SageMaker RL, use the following API elements. For more information about OpenAI Gym, see [https://gym.openai.com/docs/](https://gym.openai.com/docs/).

- `env.action_space`—Defines the actions the agent can take, specifies whether each action is continuous or discrete, and specifies the minimum and maximum if the action is continuous.
- `env.observation_space`—Defines the observations the agent receives from the environment, as well as minimum and maximum for continuous observations.
- `env.reset()`—Initializes a training episode. The `reset()` function returns the initial state of the environment, and the agent uses the initial state to take its first action. The action is then sent to `step()` repeatedly until the episode reaches a terminal state. When `step()` returns `done = True`, the episode ends. The RL toolkit re-initializes the environment by calling `reset()`.
- `step()`—Takes the agent action as input and outputs the next state of the environment, the reward, whether the episode has terminated, and an `info` dictionary to communicate debugging information. It is the responsibility of the environment to validate the inputs.
- `env.render()`—Used for environments that have visualization. The RL toolkit calls this function to capture visualizations of the environment after each call to the `step()` function.
Use Open-Source Environments

You can use open-source environments, such as EnergyPlus and RoboSchool, in SageMaker RL by building your own container. For more information about EnergyPlus, see https://energyplus.net/. For more information about RoboSchool, see https://github.com/openai/roboschool. The HVAC and RoboSchool examples in the SageMaker examples repository show how to build a custom container to use with SageMaker RL:

Use Commercial Environments

You can use commercial environments, such as MATLAB and Simulink, in SageMaker RL by building your own container. You need to manage your own licenses.

Distributed Training with Amazon SageMaker RL

Amazon SageMaker RL supports multi-core and multi-instance distributed training. Depending on your use case, training and/or environment rollout can be distributed. For example, SageMaker RL works for the following distributed scenarios:

- Single training instance and multiple rollout instances of the same instance type. For an example, see the Neural Network Compression example in the SageMaker examples repository.
- Single trainer instance and multiple rollout instances, where different instance types for training and rollouts. For an example, see the AWS DeepRacer / AWS RoboMaker example in the SageMaker examples repository.
- Single trainer instance that uses multiple cores for rollout. For an example, see the Roboschool example in the SageMaker examples repository. This is useful if the simulation environment is lightweight and can run on a single thread.
- Multiple instances for training and rollouts. For an example, see the Roboschool example in the SageMaker examples repository.

Hyperparameter Tuning with Amazon SageMaker RL

You can run a hyperparameter tuning job to optimize hyperparameters for Amazon SageMaker RL. The Roboschool example in the sample notebooks in the SageMaker examples repository shows how you can do this with RL Coach. The launcher script shows how you can abstract parameters from the Coach preset file and optimize them.

Manage Machine Learning with Amazon SageMaker Experiments

Amazon SageMaker Experiments is a capability of Amazon SageMaker that lets you organize, track, compare, and evaluate your machine learning experiments.

Machine learning is an iterative process. You need to experiment with multiple combinations of data, algorithm and parameters, all the while observing the impact of incremental changes on model accuracy. Over time this iterative experimentation can result in thousands of model training runs and model versions. This makes it hard to track the best performing models and their input configurations. It’s also difficult to compare active experiments with past experiments to identify opportunities for further incremental improvements.

SageMaker Experiments automatically tracks the inputs, parameters, configurations, and results of your iterations as trials. You can assign, group, and organize these trials into experiments. SageMaker
Experiments is integrated with Amazon SageMaker Studio providing a visual interface to browse your active and past experiments, compare trials on key performance metrics, and identify the best performing models.

SageMaker Experiments comes with its own Experiments Python SDK which makes the analytics capabilities easily accessible in Amazon SageMaker Notebooks. Because SageMaker Experiments enables tracking of all the steps and artifacts that went into creating a model, you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

SageMaker Experiments Features

The following sections provide a brief overview of the features provided by SageMaker Experiments.

Topics
- Organize Experiments (p. 1604)
- Track Experiments (p. 1604)
- Compare and Evaluate Experiments (p. 1605)
- Amazon SageMaker Autopilot (p. 1605)

Organize Experiments

Amazon SageMaker Experiments offers a structured organization scheme to help users group and organize their machine learning iterations. The top level entity, an experiment, is a collection of trials that are observed, compared, and evaluated as a group. A trial is a set of steps called trial components. Each trial component can include a combination of inputs such as datasets, algorithms, and parameters, and produce specific outputs such as models, metrics, datasets, and checkpoints. Examples of trial components are data pre-processing jobs, training jobs, and batch transform jobs.

The goal of an experiment is to determine the trial that produces the best model. Multiple trials are performed, each one isolating and measuring the impact of a change to one or more inputs, while keeping the remaining inputs constant. By analyzing the trials, you can determine which features have the most effect on the model.

Track Experiments

Amazon SageMaker Experiments enables tracking of experiments.

Automated Tracking

SageMaker Experiments automatically tracks Amazon SageMaker Autopilot jobs as experiments with their underlying training jobs tracked as trials. SageMaker Experiments also automatically tracks
SageMaker independently executed training, batch transform, and processing jobs as trial components, whether assigned to a trial or left unassigned. Unassigned trial components can be associated with a trial at a later time. All experiment artifacts including datasets, algorithms, hyperparameters, and model metrics are tracked and recorded. This data allows customers to trace the complete lineage of a model which helps with model governance, auditing, and compliance verifications.

**Manual Tracking**

SageMaker Experiments provides tracking APIs for recording and tracking machine learning workflows running locally on SageMaker Studio notebooks, including classic SageMaker notebooks. These experiments must be part of a SageMaker training, batch transform, or processing job.

**Compare and Evaluate Experiments**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Studio. When you use SageMaker Studio, SageMaker Experiments automatically tracks your experiments and trials, and presents visualizations of the tracked data and an interface to search the data.

SageMaker Experiments automatically organizes, ranks, and sorts trials based on a chosen metric using the concept of a trial leaderboard. SageMaker Studio produces real-time data visualizations, such as metric charts and graphs, to quickly compare and identify the best performing models. These are updated in real-time as the experiment progresses.

**Amazon SageMaker Autopilot**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Autopilot. When you perform an Autopilot job, SageMaker Experiments creates an experiment for the job, and trials for each of the different combinations of the available trial components, parameters, and artifacts. You can visually drill into all trials and components using SageMaker Studio.

**Create an Amazon SageMaker Experiment**

Create an Amazon SageMaker experiment to track your SageMaker training, processing, and transform jobs.

The following procedure shows you how to create a SageMaker experiment for a SageMaker training, processing, or transform job. Steps labeled as (Studio) describe how to view the experiment in Amazon SageMaker Studio. You don't have to run the experiment in Studio to view the experiment in Studio.

For a tutorial that shows this functionality in an existing SageMaker Studio notebook, see Track and Compare Tutorial (p. 1612).

1. Import the `sys` module to install the SDKs.

   ```python
   import sys
   ```

2. (Optional) The Amazon SageMaker Python SDK, comes preinstalled in SageMaker Studio. If you plan to run your code outside Studio, install the SageMaker Python SDK.

   ```sh
   !{sys.executable} -m pip install sagemaker
   ```

3. Install the SageMaker Experiments Python SDK.

   ```sh
   !{sys.executable} -m pip install sagemaker-experiments
   ```

4. Import modules.
import time
from time import strftime
import sagemaker
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker

5. Get the execution role and create the SageMaker session.

    role = sagemaker.get_execution_role()
    sm_sess = sagemaker.session.Session()

6. Create a SageMaker experiment. The experiment name must be unique in your account.

    Note
    The tags parameter is optional. You can search for the tag using Studio, the SageMaker console, and the SDK. Tags can also be applied to trials and trial components. For information on how to search tags using Studio, see Search by Tag (p. 1622).

    create_date = strftime("%Y-%m-%d-%H-%M-%S")
    demo_experiment = Experiment.create(experiment_name = "DEMO-{}".format(create_date),
                                        description = "Demo experiment",
                                        tags = [{"Key": 'demo-experiments', 'Value': 'demo1'}])

7. (Studio) To view the experiment in SageMaker Studio, in the left sidebar, choose the Components and registries icon (perms). In the drop-down menu, select Experiments and trials to display the experiments browser.

    After the code runs, the experiment list contains the new experiment. It might take a moment for the list to refresh and display the experiment. The filter on the experiment tag is also displayed. Only experiments that have a matching tag are displayed. Your list should look similar to the following:
8. Create a trial for the experiment. The trial name must be unique in your account.

```python
demo_trial = Trial.create(trial_name = "DEMO-{}".format(create_date),
                        experiment_name = demo_experiment.experiment_name,
                        tags = [{'Key': 'demo-trials', 'Value': 'demo1'}])
```

9. (Studio) In the experiment list, double-click the experiment to display a list of the trials in the experiment (this example has one trial). Your list should look similar to the following:
10. Create a trial component as part of the trial. The trial component is the SageMaker job.

Add the `ExperimentConfig` parameter to the appropriate method. The SageMaker jobs listed in the following table are supported.

<table>
<thead>
<tr>
<th>Job</th>
<th>SageMaker Python SDK method</th>
<th>Boto3 method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training</td>
<td><code>Estimator.fit</code></td>
<td><code>CreateTrainingJob</code></td>
</tr>
<tr>
<td>Processing</td>
<td><code>Processor.run</code></td>
<td><code>CreateProcessingJob</code></td>
</tr>
<tr>
<td>Transform</td>
<td><code>Transformer.transform</code></td>
<td><code>CreateTransformJob</code></td>
</tr>
</tbody>
</table>

The following examples are for a training job. The `Tags` parameter adds a tag to the trial component. `ExperimentName` isn't specified because the trial was associated with the experiment when the trial was created in an earlier step.

**Using the SageMaker Python SDK**

```python
sagemaker.estimator.Estimator(
    ...
    sagemaker_session = sm_sess,
    tags = [{'Key': 'demo-jobs', 'Value': 'demo2'}])

estimator.fit(
    ...,
    experiment_config = {
        # "ExperimentName"
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    })
```

**Using Boto3**

```python
```
create_training_job(
    ...
    "ExperimentConfig": {
        "TrialName": demo_trial.trial_name,
        "TrialComponentDisplayName": "TrainingJob",
        "Tags": [{"Key": 'demo-jobs', 'Value': 'demo2'}])

11. (Studio) In the trial list, double-click the trial to display a list of the components in the trial (this example has one trial). Your list should look similar to the following:

![List of components](image)

12. (Studio) To view information about the experiment, trial, and job (trial component), see View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 1609).

To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources (p. 1623).

**View and Compare Amazon SageMaker Experiments, Trials, and Trial Components**

An Amazon SageMaker experiment consists of multiple trials with a related objective. A trial consists of one or more trial components, such as a data preprocessing job and a training job.

You use the experiments browser to display a list of these entities. You can filter the list by entity name, type, and tags. The entities are presented in a hierarchical view (that is, experiments > trials > trial components). Double-click an entity to see other entities that are at a lower level in the hierarchy. Use the breadcrumbs above the list to move to a higher level in the hierarchy.

For a tutorial using a SageMaker example notebook, see Track and Compare Tutorial (p. 1612). For an overview of the Studio user interface, see Amazon SageMaker Studio UI Overview (p. 59).

**Topics**

- View Experiments, Trials, and Trial Components (p. 1610)
- Compare Experiments, Trials, and Trial Components (p. 1611)
View Experiments, Trials, and Trial Components

Amazon SageMaker Studio provides an experiments browser that you can use to view lists of experiments, trials, and trial components. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison.

To view experiments, trials, and trial components

1. In the left sidebar of Studio, choose the Components and registries icon ( ). In the drop-down menu, select Experiments and trials to display the experiments browser.

A list of experiments and their properties is displayed. The list includes all the SageMaker experiments in your account, including experiments created outside of SageMaker Studio.

Note
To view all the properties, you might have to expand the width of the experiments browser by dragging the right border.

2. In the experiments list, double-click an experiment to display a list of the trials in the experiment.

3. Double-click a trial to display a list of the components in the trial.
4. Double-click one of the components to open the Describe Trial Component tab.

5. On the Describe Trial Component tab, choose any of the following column headings to see available information about each trial component:
   - **Charts** – Build your own charts.
   - **Metrics** – Metrics that are logged by a Tracker during a trial run.
   - **Parameters** – Hyperparameter values and instance information.
   - **Artifacts** – Amazon S3 bucket storage locations for the input dataset and the output model.
   - **AWS Settings** – Job name, ARN, status, creation time, training time, billable time, instance information, and others.
   - **Debugger** – A list of debugger rules and any issues found.
   - **Trial Mappings**

For information about comparing Experiments entities, see View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 1609).

**Compare Experiments, Trials, and Trial Components**

You can compare experiments, trials, and trial components by selecting the entities and opening them in the trial components list. The trial components list is referred to as the Studio Leaderboard. In the Leaderboard you can do the following:

- View detailed information about the entities
- Compare entities
• Stop a training job
• Deploy a model

To compare experiments, trials, and trial components

1. In the left sidebar of SageMaker Studio, choose the SageMaker Experiment List icon ( ).
2. In the Experiments browser, choose either the experiment or trial list. For more information, see View Experiments, Trials, and Trial Components (p. 1610).
3. Choose the experiments or trials that you want to compare, right-click the selection, and then choose Open in trial component list. The Leaderboard opens and lists the associated Experiments entities as shown in the following screenshot.

The Leaderboard has a TABLE PROPERTIES pane on the right side. Use the Settings icon ( ) to open and close the pane. You can hide or display properties by category or by individual columns. When you display a chart, the pane changes to display chart properties.

For information on searching the Experiments entities, see Search Experiments Using Amazon SageMaker Studio (p. 1618).

Track and Compare Tutorial

This tutorial demonstrates how to visually track and compare trials in a model training experiment using Amazon SageMaker Studio. The basis of the tutorial is the MNIST Handwritten Digits Classification Experiment notebook.

It is intended that this topic be viewed alongside Studio with the MNIST notebook open. As you run through the cells, the sections in this document highlight the relevant code and show you how to observe the results in Studio. Some of the code snippets have been edited for brevity.

To clean up the resources created by the notebook, see Clean Up Amazon SageMaker Experiment Resources (p. 1623).

For a tutorial that showcases additional features of Studio, see Amazon SageMaker Studio Tour (p. 69).

Prerequisites
• A local copy of the MNIST example notebook and the companion mnist.py file. Both files are available from the sagemaker_experiments/mnist-handwritten-digits-classification-experiment folder in the aws/amazon-sagemaker-examples repository. To download the files, choose each link, right-click on the Raw button, and then choose Save as.
• An AWS SSO or IAM account to sign-on to SageMaker Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 34).

Topics
• Open the Notebook in Studio (p. 1613)
• Install the Experiments SDK and Import Modules (p. 1613)
• Transform and Track the Input Data (p. 1614)
• Create and Track an Experiment (p. 1614)
• Compare and Analyze Trials (p. 1616)

Open the Notebook in Studio

To open the notebook

1. Sign-on to Studio.
2. In the left sidebar, choose the File Browser icon ( ).
3. At the top of the file browser pane, choose the Up arrow icon and then a File Upload dialog opens. Browse to and choose your local versions of the mnist-handwritten-digits-classification-experiment.ipynb and mnist.py files, and then choose Open.
4. The two files are listed in the file browser. Double-click the uploaded notebook file to open the notebook in a new tab.
5. At the top right of the notebook, make sure the kernel is Python 3 (Data Science). If not, choose the current kernel name to open the Select Kernel dropdown. Choose Python 3 (Data Science) and then choose Select.

Install the Experiments SDK and Import Modules

The Amazon SageMaker Experiments Python SDK is separate from the Amazon SageMaker Python SDK, which comes preinstalled in SageMaker Studio. Run the first few cells in the notebook to install the Experiments SDK and import the Experiments modules. The relevant sections of the notebook cells are displayed below.

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments
```

```python
import sagemaker
from sagemaker import get_execution_role
from sagemaker.session import Session
from sagemaker.analytics import ExperimentAnalytics
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker
```
Transform and Track the Input Data

The next few cells create an Amazon S3 bucket and a folder in the bucket named `mnist`. In Studio, the file browser displays the `mnist` folder. The input data is downloaded to the `mnist/MNIST/raw` folder, normalized, and then the transformed data is uploaded to the `mnist/MNIST/processed` folder. You can drill down into the `mnist` folder to display, but not open, the data files.

Your screen should look similar to the following:

![Image of Amazon SageMaker Studio with folders and files]

The last cell in the Dataset section creates a Tracker for the transform job. The tracker logs the normalization parameters and the URI of the Amazon S3 bucket where the transformed dataset is stored. In a later section, we show how to find this information in Studio. In the next section, the tracker is used to track the experiment and trial runs.

```python
with Tracker.create(display_name="Preprocessing", sagemaker_boto_client=sm) as tracker:
    tracker.log_parameters({
        "normalization_mean": 0.1307,
        "normalization_std": 0.3081,
    })
    tracker.log_input(name="mnist-dataset", media_type="s3/uri", value=inputs)
```

Create and Track an Experiment

The following procedure creates and tracks an experiment to determine the effect of the model's `num_hidden_channel` hyperparameter. As part of the experiment, five trials are created inside a loop, one for each value of the `num_hidden_channel` hyperparameter. Later in the notebook, you'll compare the results of these five trials.

1. In the left sidebar of Studio, choose the SageMaker Components and registries icon (教你). In the dropdown menu, choose Experiments and trials to display the list of experiments in your account.
2. Run the following cell.

```python
mnist_experiment = Experiment.create(
    experiment_name=f"mnist-hand-written-digits-classification-{int(time.time())}",
    description="Classification of mnist hand-written digits",
    sagemaker_boto_client=sm)
print(mnist_experiment)
```

Output:

```
Experiment(sagemaker_boto_client=<botocore.client.SageMaker object at 0x7f7152b326d0>,
    experiment_name='mnist-hand-written-digits-classification-1575947870',
    description='Classification of mnist hand-written digits',
```

After the code runs, the experiments list contains an entry for the experiment. It might take a moment to display and you might have to refresh the experiments list. Your screen should look similar to the following:
3. Run the following cell.

```python
preprocessing_trial_component = tracker.trial_component
```

After the code runs, the experiments list contains an entry labeled **Unassigned trial components**. The trial component entry is the data preprocessing step previously created. Double-click the trial component for verification. The trial component isn’t associated with an experiment at this time.

Your screen should look similar to the following:

4. Choose the **Home** icon in the navigation breadcrumb at the top on the experiments browser. From there, double-click on your experiment to display a list of the trials in the experiment.

5. The following code create trials for the experiment. Each trial trains a model using a different number for the `num_hidden_channel` hyperparameter. The preprocessing trial component is added to each trial for complete tracking (for example, for auditing purposes). The code also specifies definitions for the following metrics:

- Train loss
- Test loss
- Test accuracy

The definitions tell SageMaker to capture those metrics from the algorithm’s log output. The metrics are used later to evaluate and compare the models.

```python
preprocessing_trial_component = tracker.trial_component

for i, num_hidden_channel in enumerate([2, 5, 10, 20, 32]):
    trial_name = f"cnn-training-job-{num_hidden_channel}-hidden-channels-{int(time.time())}"

    cnn_trial = Trial.create(
        trial_name=trial_name,
        experiment_name=mnist_experiment.experiment_name,
        sagemaker_boto_client=sm,
    )

    hidden_channel_trial_name_map[num_hidden_channel] = trial_name

    cnn_trial.add_trial_component(preprocessing_trial_component)
```
estimator = PyTorch(
    py_version='py3',
    framework_version='1.1.0',
    ...
    hyperparameters={
        'hidden_channels': num_hidden_channel,
        ...
    },
    metric_definitions=[
        {'Name': 'train:loss', 'Regex': 'Train Loss: (.*)'},
        {'Name': 'test:loss', 'Regex': 'Test Average loss: (.*)'},
        {'Name': 'test:accuracy', 'Regex': 'Test Accuracy: (.*%)'}
    ],
    enable_sagemaker_metrics=True,
)

cnn_training_job_name = "cnn-training-job-{}.format(int(time.time()))
estimator.fit(
    inputs={'training': inputs},
    job_name=cnn_training_job_name,
    experiment_config=
        "TrialName": cnn_trial.trial_name,
        "TrialComponentDisplayName": "Training",
    )
)

The trial list automatically updates as each training job runs. It takes a few minutes for each trial to be displayed. Your screen should look similar to the following:

**Compare and Analyze Trials**

This section deviates from the notebook and shows you how to compare and analyze the trained models using the SageMaker Studio UI.

**To view the details of a trial**

1. Double-click one of the trials to display a list of the trial components associated with the trial. There's a preprocessing job and training job for each trial. Double-click one of the components to open a new tab that displays information about each component.

2. Under **Trial stages**, choose **Preprocessing**. On the **Describe Trial Component** menu, choose **Parameters** to display the normalization parameters that were previously logged. Next, choose **Artifacts** to display the URI of the Amazon S3 bucket where the transformed dataset was stored.

3. Under **Trial stages**, choose **Training**. On the **Describe Trial Component** menu, choose the following items to display information about the training job trial component.
• **Metrics** – test:loss, test:accuracy, and train:loss
• **Parameters** – hyperparameter values and instance information
• **Artifacts** – Amazon S3 storage for the input dataset and the output model
• **AWS Settings** – job name, ARN, status, creation time, training time, billable time, instance information, and others

**To view a list of trials ordered by test:accuracy**

1. Choose the experiment name on the navigation breadcrumb above **TRIAL COMPONENTS** to display the trial list.
2. Choose all five trials. Hold down the CTRL/CMD key and select each trial. Right-click the selection and then choose **Open in trial component list**. A new tab opens that displays each trial and trial component.
3. If the **TABLE PROPERTIES** pane isn't open, choose the **Settings** icon (🔧) in the upper right corner to open it. Deselect everything except **Trial**, **Metrics**, and **Training job**. Choose the **Settings** icon to close the pane.
4. Choose the **test:accuracy** column header to sort the list by decreasing maximum test accuracy. Your screen should look similar to the following:

![Table of trials](image)

**To view a chart of test:loss versus num_hidden_channel**

1. In the **TRIAL COMPONENTS** pane, choose all five trials and then choose **Add chart**. Select inside the chart area to open the preferences pane for **CHART PROPERTIES**.
2. In **CHART PROPERTIES**, choose the following:
   - **Data type** - Summary statistics
   - **Chart type** - Line
   - **X-axis** - hidden-channels
   - **Y-axis** - test:loss_last
Search Experiments Using Amazon SageMaker Studio

You can search your experiments, trials, and trial components using the experiments browser. After choosing the entities, you can search on properties of these entities on the Amazon SageMaker Leaderboard.

Topics
- Search Experiments, Trials, and Trial Components (p. 1618)
- Search the SageMaker Studio Leaderboard (p. 1619)
- Search by Tag (p. 1622)

Search Experiments, Trials, and Trial Components

You can search and create multiple filters to display a subset of experiments, trials, and trial components in the experiments browser. After you search and filter your list, you can open the entities in the Leaderboard and search on additional properties.

To search for experiments, trials, and trial components, and apply filters

For more information about the following steps, along with screenshots, see Search the SageMaker Studio Leaderboard (p. 1619).

1. In the experiments browser, navigate to the entity type you want to search for: experiment, trial, or trial component.
2. Place your cursor in the search box to display the list of column that are searchable.
3. Choose the column that you want to search on and one of the following dialog boxes opens that's specific to the column you chose:
• **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.

• **Discrete values** – Choose one or more property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values.

• **Date** – Enter a date in **From Date** and **To Date**, or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.

• **Tag** – In **Search tag key**, start entering the tag's key. A list of tag keys is filtered to only those keys with a name that starts with the text string that you enter. Choose the tag key that you want to search on from the list. In **Search tag value**, enter the complete tag value, and then choose **Apply**.

4. To create the filter, choose **Apply**.

5. To apply additional filters, repeat the preceding steps. You can have a maximum of 20 filters. An entity must match all filters to be displayed.

**Search the SageMaker Studio Leaderboard**

The Amazon SageMaker Studio trial components list is referred to as the Leaderboard. You can use the Leaderboard to compare your trials and experiments. The Leaderboard lists properties of the trials, such as the trial status, debugger status, tags, metrics, hyperparameters, and input and output artifacts.

You can search the Leaderboard to find specific trial components. You apply the results of a search to create a filter that displays only those components that satisfy the filter. You can apply up to 20 filters. A component is displayed only if it matches all filters. To remove a filter, choose the **X** that displays to the right of the filter.

**To search the Leaderboard and apply filters**

1. If the **TABLE PROPERTIES** pane isn't open in SageMaker Studio, choose the **Settings** icon (⚙️) in the upper-right corner to open it.

2. In the **Settings** pane, select the check boxes for the columns that you want to view, and then choose the **Settings** icon to close the pane.

3. Place your cursor in the **Search column name** box to display the following list of **TABLE PROPERTIES** column names that are searchable:

   **Summary section**
   - Trial component name
   - Trial component type
   - Created
   - Last modified
   - Created by
   - Tags

   **Detail sections** (all columns)
   - Metrics
   - Parameters
   - Input artifacts
   - Output artifacts
4. To limit the column names when you search the detail sections, start typing the column name. The list displays only those columns with a name that starts with the text string that you enter.

5. Choose the column that you want to search on. This opens a dialog that's specific to the type of data in that column.

6. Enter your search criteria in the dialog for the appropriate data type:

   - **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.

   ![Image of a search dialog box with a text field labeled 'Search trial component name' and a list of trial components.]

   - **Discrete values** – Choose one or more of the property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values. For the **Trial component type** column, **Others** matches components with no value in the column.

   ![Image of a trial component list with a filter menu opened and a column for **Trial component type** showing the option **Others**.

   ![Image of a second trial component list with a text field labeled 'Search column name to start' and a list of trial components.]

• **Date** – Enter a date in **From Date** and **To Date** or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.

• **Created by** – Select **Me** or **Everyone else**. This filter limits the list to those components that were created by the currently signed-in user or everyone but the currently signed-in user.

• **Tag** – Choose the tag to search. For more information, see Search by Tag (p. 1622).

• **Detail columns** – Specify the conditions that the component’s property value must satisfy.
7. To create the filter, choose Apply.
8. To apply additional filters, repeat the preceding steps. A component must match all filters to be displayed. You can have a maximum of 20 filters.

**Search by Tag**

You can add searchable tags to experiments, trials, and trial components when the entities are created or afterwards using the AddTags API. A tag consists of a unique case-sensitive key and an optional value. Multiple tags can be added to an entity. You can add the same tag to multiple entities.

**To search by tag and apply filters**

1. If the **TABLE PROPERTIES** pane isn't open in SageMaker Studio, choose the **Settings** icon (⚙️) in the upper-right corner to open it.
2. In the **Settings** pane, select **Tags** if it isn't selected, and then choose the **Settings** icon to close the pane.
3. Place your cursor in the **Search column name** box and then choose **Tags**.
4. In **Search tag key**, start entering the tag's key. A list of tag keys displays only those keys with a name that starts with the text string that you enter.
5. Choose the tag key that you want to search on from the list.

6. In Search tag value, enter the complete tag value, and then choose Apply.

7. The trial component list displays only those components that have tags that match the key-value pair you chose.

8. To add more tag filters, repeat the previous steps. A tag must match all filters for the component to be displayed.

Clean Up Amazon SageMaker Experiment Resources

To avoid incurring unnecessary charges, delete the Amazon SageMaker Experiment resources you no longer need. You can't delete Experiment resources through the SageMaker Management Console or the Amazon SageMaker Studio UI. This topic shows you how to clean up these resources using Boto3 and the Experiments SDK. For more information about the Experiments SDK, see sagemaker-experiments.

To delete the experiment, you must delete all trials in the experiment. To delete a trial, you must remove all trial components from the trial. To delete a trial component, you must remove the component from all trials.

Note

Trial components can exist independent of trials and experiments. You do not have to delete them. If you want to reuse them, comment out `tc.delete()` in the code.
Clean Up Using the Experiments SDK

To clean up using the Experiments SDK

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments

import time
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent

def cleanup_sme_sdk(experiment):
    for trial_summary in experiment.list_trials():
        trial = Trial.load(trial_name=trial_summary.trial_name)
        for trial_component_summary in trial.list_trial_components():
            tc = TrialComponent.load(trial_component_name=trial_component_summary.trial_component_name)
            trial.remove_trial_component(tc)
            try:
                # comment out to keep trial components
                tc.delete()
            except:
                # tc is associated with another trial
                continue
            # to prevent throttling
            time.sleep(.5)
        trial.delete()
        experiment_name = experiment.experiment_name
        experiment.delete()
        print(f"\nExperiment {experiment_name} deleted")

Call cleanup_sme_sdk

experiment_to_cleanup = Experiment.load(
    # Use experiment name not display name
    experiment_name="experiment-name")
cleanup_sme_sdk(experiment_to_cleanup)
```

Clean Up Using the Python SDK (Boto3)

To clean up using Boto 3

```python
import boto3
sm = boto3.Session().client('sagemaker')

Define cleanup_boto3
```
def cleanup_boto3(experiment_name):
    trials = sm.list_trials(ExperimentName=experiment_name)['TrialSummaries']
    print('TrialNames:
    for trial in trials:
        trial_name = trial['TrialName']
        print(f"n{trial_name}"),
    components_in_trial = sm.list_trial_components(TrialName=trial_name)
    print('
TrialComponentNames:
    for component in components_in_trial['TrialComponentSummaries']:
        component_name = component['TrialComponentName']
        print(f"t{component_name}"),
        sm.disassociate_trial_component(TrialComponentName=component_name, TrialName=trial_name)
        try:
            # comment out to keep trial components
            sm.delete_trial_component(TrialComponentName=component_name)
        except:
            # component is associated with another trial
            continue
    # to prevent throttling
    time.sleep(.5)
    sm.delete_trial(TrialName=trial_name)
    sm.delete_experiment(ExperimentName=experiment_name)
    print(f"nExperiment {experiment_name} deleted")

Call cleanup_boto3

# Use experiment name not display name
experiment_name = "experiment-name"
cleanup_boto3(experiment_name)

Search Using the Amazon SageMaker Console and API

Developing a machine learning model typically requires extensive experimenting with different datasets, algorithms, and hyperparameter values. To manage up to thousands of machine learning model experiments, use the search capabilities in SageMaker.

You can use SageMaker search to:

- Organize, find, and evaluate training jobs using properties, hyperparameters, performance metrics, or any metadata.
- Find the best performing model by reviewing training job and model metrics, such as training loss or validation accuracy.
- Trace a model's lineage to the training job and its related resources, such as the training datasets.

This topic covers searching from the SageMaker console and the SageMaker API. For information on searching in Amazon SageMaker Studio, see Search Experiments Using Studio (p. 1618).

Topics

- Sample Notebooks for Managing ML Experiments (p. 1626)
- Organize, Find, and Evaluate Training Jobs (Console) (p. 1626)
- Find and Evaluate Training Jobs (API) (p. 1628)
- Verify the Datasets Used by Your Training Jobs (p. 1629)
Sample Notebooks for Managing ML Experiments

For a sample notebook that uses Amazon SageMaker model tracking capability to manage ML experiments, see Managing ML Experimentation using Amazon SageMaker Model Tracking Capability.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The notebook for managing ML experiments is located in the Advanced Functionality section. To open a notebook, choose its Use tab, and choose Create copy. If you have questions, post them on the Amazon Machine Learning Developer Forum.

Organize, Find, and Evaluate Training Jobs (Console)

To organize training jobs, assign one or more tags to them.

To find a specific training job, model, or resource, use model tracking to search on keywords assigned to any searchable items. Searchable items include training jobs, models, hyperparameters, metadata, tags, and URLs. To refine your tracking results, you can search using multiple criteria.

To choose the best model for deployment, evaluate how all models performed against one or more metrics. You can use model tracking results to list, sort, and evaluate the performance of the models in your experiments.

Topics
- Use Tags to Track Training Jobs (Console) (p. 1626)
- Find Training Jobs (Console) (p. 1627)
- Evaluate Models (Console) (p. 1627)

Use Tags to Track Training Jobs (Console)

To group training jobs, create tags with descriptive keys and a value. For example, create tag keys for: project, owner, customer, and industry.

Add tags to training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Training jobs and Create training job.
3. Scroll to the bottom of the page and enter a key and value for the tag.
4. To add another tag, choose Add tag, and add another key-value pair.
Find Training Jobs (Console)

You can search for training jobs using a variety of job attributes. Note that some search parameters appear only if you have created a training job with that attribute. For example, Tags appears only if you have added a tag for a training job.

To find training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search.
3. Add Parameters.
   a. In the search box, enter a parameter and choose a parameter type, for example TrainingJobName.
   b. Choose a conditional operation. For numeric values, use operators such as is equals to, lesser than, or or greater than. For text-based values, use operators such as equals to or contains.
   c. Enter a value for the parameter.
4. (Optional) To refine your search, add additional search criteria. Choose Add row and enter the parameter values.
5. Choose Search.

Evaluate Models (Console)

To evaluate a model’s performance, review its metadata, hyperparameters, and metrics. To highlight metrics, adjust the view to show only metrics and important hyperparameters.

To evaluate a model (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search and search for training jobs by specifying relevant parameters. The results are displayed in a table.

   Results: Training jobs

<table>
<thead>
<tr>
<th>HyperParameter</th>
<th>HyperParameter</th>
<th>Metric</th>
<th>Metric</th>
<th>Metric</th>
</tr>
</thead>
<tbody>
<tr>
<td>mini_batch_size</td>
<td>predictor_type</td>
<td>train.binary_f_beta</td>
<td>train:progress</td>
<td>train:objective_loss</td>
</tr>
<tr>
<td>300</td>
<td>binary_classifier</td>
<td>0.966639518737793</td>
<td>100</td>
<td>0.02381423674523</td>
</tr>
<tr>
<td>100</td>
<td>binary_classifier</td>
<td>0.9652714133262634</td>
<td>100</td>
<td>0.02350491285324</td>
</tr>
<tr>
<td>200</td>
<td>binary_classifier</td>
<td>0.9647442698478699</td>
<td>100</td>
<td>0.02325980737805</td>
</tr>
</tbody>
</table>

3. Open the preferences window by choosing the settings icon in the search results table.
4. To show or hide a hyperparameter or metric, turn it on or off by choosing **Hyperparameter** or **Metric**.
5. Make necessary changes, then choose **Update view**.
6. After viewing metrics and important hyperparameters, you can compare and contrast the result. Then, you can choose the best model to host or investigate the models that are performing poorly.

**Find and Evaluate Training Jobs (API)**

To find and evaluate training jobs or to get suggestions for items used in experiments that are searchable, you can use the **Search API**.

**Topics**
- **Find Training Jobs (API) (p. 1628)**
- **Evaluate Models (API) (p. 1628)**
- **Get Suggestions for a Search (API) (p. 1629)**

**Find Training Jobs (API)**

To find training jobs, create a search parameter using the `search_params` parameter. Then use the search function in the `smclient` subprocess in the AWS SDK for Python (Boto3).

The following example shows how to use the **Search API** to find training jobs.

```python
import boto3

search_params={
    "MaxResults": 10,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [{
            "Name": "Tags.Project",
            "Operator": "Equals",
            "Value": "Project_Binary_Classifier"
        }],
        "SortBy": "Metrics.train:binary_classification_accuracy",
        "SortOrder": "Descending"
    }
}

smclient = boto3.client(service_name='sagemaker')
results = smclient.search(**search_params)
```

**Evaluate Models (API)**

To evaluate models, run a search as described in **Find Training Jobs (API) (p. 1628)**, review model metrics, then, use the AWS SDK for Python (Boto3) to create a table and plot it.

The following example shows how to evaluate models and to display the results in a table.

```python
import pandas

headers=['Training Job Name', 'Training Job Status', 'Batch Size', 'Binary Classification Accuracy']
rows=[]
for result in results['Results']:
    trainingJob = result['TrainingJob']
    metrics = trainingJob['FinalMetricDataList']
    rows.append([trainingJob['TrainingJobName'],
```

1628
Get Suggestions for a Search (API)

To get suggestions for a search, use the GetSearchSuggestions API.

The following example for AWS SDK for Python (Boto3) is a get_search_suggestions request for items containing linear.

```python
search_suggestion_params={
    "Resource": "TrainingJob",
    "SuggestionQuery": {
        "PropertyNameQuery": {
            "PropertyNameHint": "linear"
        }
    }
}
```

The following is an example response for a get_search_suggestions request.

```json
{
    'PropertyNameSuggestions': [{'PropertyName': 'hyperparameters.linear_init_method'},
                                {'PropertyName': 'hyperparameters.linear_init_value'},
                                {'PropertyName': 'hyperparameters.linear_init_sigma'},
                                {'PropertyName': 'hyperparameters.linear_l1'},
                                {'PropertyName': 'hyperparameters.linear_wd'}]
}
```

After getting search suggestions, you can use one of the property names in a search.

Verify the Datasets Used by Your Training Jobs

You can use model tracking capability to verify which datasets were used in training, where holdout datasets were used, and other details about training jobs. For example, use model tracking capability to verify that a specific dataset was used in a training job for an audit or to verify compliance.

To check whether a specific dataset was used in a training job, you search for the URL to its location in Amazon Simple Storage Service (Amazon S3). Model tracking capability returns the training jobs that used the dataset that you specify. If your search doesn't return the dataset (the result is empty), the dataset wasn't used in a training job. An empty result confirms, for example, that a holdout dataset wasn't used.

Trace Model Lineage

You can use model tracking capability to get information about the lineage of training jobs and the model resources that were used for them, including the dataset, algorithm, hyperparameters, and metrics. For example, if you find that the performance of a hosted model has declined, you can review its training job and the resources it used to determine what's causing the problem.
• Trace Model Lineage (Console) (p. 1630)
• Trace Model Lineage (API) (p. 1630)

Trace Model Lineage (Console)

To trace a model’s lineage (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Endpoints, and choose the relevant endpoint.
3. Scroll to the Endpoint configuration settings section. This section lists all of the model versions deployed at the endpoint, with a hyperlink to the training job that created each.

Trace Model Lineage (API)

To trace a model’s lineage, get the model’s name, then use it to search for training jobs.

The following example shows how to trace a model’s lineage using the API.

```python
# Get the name of model deployed at endpoint
endpoint_config = smclient.describe_endpoint_config(EndpointConfigName=endpointName)
model_name = endpoint_config['ProductionVariants'][0]['ModelName']

# Get the model's name
model = smclient.describe_model(ModelName=model_name)

# Search the training job by the location of model artifacts in Amazon S3
search_params={
    "MaxResults": 1,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [
            {
                "Name": "ModelArtifacts.S3ModelArtifacts",
                "Operator": "Equals",
                "Value": model['PrimaryContainer']['ModelDataUrl']
            }
        ]
    }
}
results = smclient.search(**search_params)
```

After finding the training job, you can review the resources used to train the model.

Amazon SageMaker Debugger

Debug, monitor, and profile training jobs in real time, detect non-converging conditions, optimize resource utilization by eliminating bottlenecks, improve training time, and reduce costs of your machine learning models using Amazon SageMaker Debugger.

Amazon SageMaker Debugger Features

A machine learning (ML) training job can have problems such as system bottlenecks, overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.

SageMaker Debugger profiles and debugs training jobs to help resolve such problems and improve your ML model’s compute resource utilization and performance. Debugger offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.
SageMaker Debugger supports Apache MXNet, TensorFlow, PyTorch, and XGBoost. For more information about available frameworks and versions, see Supported Frameworks and Algorithms (p. 1632).

The high-level Debugger workflow is as follows:

1. Configure a SageMaker training job with Debugger.
   - Configure using the SageMaker `Estimator` API (for Python SDK).
   - Configure using the SageMaker `CreateTrainingJob` request (for Boto3 or CLI).
   - Configure custom training containers (p. 1723) with Debugger.

2. Start a training job and monitor training issues in real time.
   - SageMaker Studio Debugger dashboards in Studio Experiments and trials (p. 1736).
   - List of Debugger Built-in Rules (p. 1677).

3. Get alerts and take prompt actions against the training issues.
   - Receive texts and emails and stop training jobs when training issues are found using Debugger Built-in Actions for Rules (p. 1727).
   - Set up your own actions using Amazon CloudWatch Events and AWS Lambda (p. 1731).

4. Receive training reports, suggestions to fix the issues, and insights into your training jobs.
   - Studio Debugger Insights dashboard for deep learning frameworks
   - Deep learning framework profiling report
   - SageMaker XGBoost training report

5. Explore deep analysis of the training issues and bottlenecks.
   - For profiling training jobs, see Analyze Data Using the SMDebug Client Library (p. 1775).
   - For debugging model parameters, see Visualize Debugger Output Tensors in TensorBoard (p. ).

6. Fix the issues, considering the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

**Topics**

- Supported Frameworks and Algorithms (p. 1632)

</tr>
</tbody>
</table>

• **Monitoring system bottlenecks** – Monitor the system utilization rate for resources such as CPU, GPU, memories, network, and data I/O metrics. This is a framework and model agnostic feature and available for any training jobs in SageMaker.

• **Profiling deep learning framework operations** – Profile the deep learning operations of the TensorFlow and PyTorch frameworks, such as step durations, data loaders, forward and backward operations, Python profiling metrics, and framework-specific metrics.

• **Debugging output tensors** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.
Important
For the TensorFlow framework with Keras, SageMaker Debugger deprecates the zero code change support for debugging models built using the `tf.keras` modules of TensorFlow 2.6 and later. This is due to breaking changes announced in the TensorFlow 2.6.0 release note. SageMaker Debugger continues to support the zero code change experience for the native TensorFlow (which excludes the `tf.keras` modules).

If the framework or algorithm that you want to train and debug is not listed in the table, go to the AWS Discussion Forum and leave feedback on SageMaker Debugger.

Use Debugger with Custom Training Containers

Bring your training containers to SageMaker and gain insights into your training jobs using Debugger. Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.

For more information about how to build your training container with the SMDebug client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see Use Debugger with Custom Training Containers (p. 1723).

Debugger Open-Source GitHub Repositories

Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker `CreateTrainingJob` and `DescribeTrainingJob` API operations. The SMDebug client library provides tools to register hooks and access the training data through its `trial` feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and SMDebug API operations, see the following links:

- The Amazon SageMaker Python SDK documentation
- The Amazon SageMaker Debugger APIs
- The SMDebug open source client library
- The SMDebug PyPI

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:

- Amazon SageMaker Debugger API Operations (p. 1789)
- Configure Debugger Using Amazon SageMaker API (p. 1666)

Amazon SageMaker Debugger Architecture

This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for *performance optimization* to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger's debugging functionality for *model optimization* is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.
Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **System metrics** – Hardware resource utilization data, such as CPU, GPU, CPU and GPU memory, network, and data input and output (I/O) metrics.
- **Framework metrics** – Metrics to track each framework operation per call or sampling, such as convolutional layer operations in the forward pass, batch normalization operations in the backward pass, data loader processes between steps, and gradient descent algorithm operations to calculate and update the loss function.
- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

**Note**
By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics
every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured Amazon S3 bucket.

The Debugger built-in rules run on processing containers, which are designed to evaluate machine learning models by processing the training data collected in your S3 bucket (see Process Data and Evaluate Models). The built-in rules are fully managed by Debugger. You can also create your own rules customized to your model to watch for any issues you want to monitor.

See the following topics for best practices to improve the performance of your model using SageMaker Debugger.

Get Started with Debugger Tutorials

The following topics walk you through tutorials from the basics to advanced use cases of monitoring, profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and learn how you can debug and improve your machine learning models efficiently by using Debugger.

Topics

- Debugger Tutorial Videos (p. 1635)
- Debugger Example Notebooks (p. 1636)
- Debugger Advanced Demos and Visualization (p. 1638)

Debugger Tutorial Videos

The following videos provide a tour of Amazon SageMaker Debugger capabilities using SageMaker Studio and SageMaker notebook instances.

Topics

- Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger (p. 1635)
- Debug Models with Amazon SageMaker Debugger in Studio (p. 1635)
- Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor (p. 1636)

Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger

Emily Webber, AWS Machine Learning Specialist | Length: 13 minutes 54 seconds

This tutorial video gives you a tour of Amazon SageMaker Debugger to capture, debug, and visualize model output data from a training model with MXNet. Learn how Amazon SageMaker Debugger makes the training process transparent by automatically capturing metrics, analyzing training runs, and detecting problems.

Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger

You can find the example notebook in this video at Visualizing Debugging Tensors of MXNet training in the Amazon SageMaker Examples GitHub repository.

Debug Models with Amazon SageMaker Debugger in Studio

Julien Simon, AWS Technical Evangelist | Length: 14 minutes 17 seconds
This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect debugging information from a training model. The example training model used in this video is a simple convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker in a TensorFlow framework and Debugger enable you to build an estimator directly using the training script and debug the training job.

**Debug Models with Amazon SageMaker Debugger (part 1)**

You can find the example notebook in the video in this Studio Demo repository provided by the author. You need to clone the debugger.ipynb notebook file and the mnist_keras_tf.py training script to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the path keras_script_path to the mnist_keras_tf.py file inside the debugger.ipynb notebook. For example, if you cloned the two files in the same directory, set it as keras_script_path = "mnist_keras_tf.py".

**Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor**

*Julien Simon, AWS Technical Evangelist | Length: 44 minutes 34 seconds*

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

**Debug Models with Debugger (part 2)**

You can find the example notebook in the video in this AWS Dev Days 2020 repository offered by the author.

**Debugger Example Notebooks**

*SageMaker Debugger example notebooks are provided in the aws/amazon-sagemaker-examples repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.*

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at Amazon SageMaker Studio Tour.

To find the examples in a SageMaker Notebook instance, follow the instructions at SageMaker Notebook Instance Example Notebooks.

**Important**

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Debugger Example Notebooks for Profiling Training Jobs**

The following list shows Debugger example notebooks introducing Debugger's adaptability to monitor and profile training jobs for various machine learning models, datasets, and frameworks.

To find advanced visualizations of model parameters and use cases, see the next topic at Debugger Advanced Demos and Visualization (p. 1638).

**Debugger Advanced Demos and Visualization**

The following demos walk you through advanced use cases and visualization scripts using Debugger.

**Topics**

- Train and Tune Your Models with Amazon SageMaker Experiments and Debugger (p. 1638)
- Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training (p. 1641)
- Using SageMaker Debugger to Monitor Attentions in BERT Model Training (p. 1641)
- Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs) (p. 1644)

**Train and Tune Your Models with Amazon SageMaker Experiments and Debugger**

*Dr. Nathalie Rauschmayr, AWS Applied Scientist | Length: 49 minutes 26 seconds*

**Train and Prune Models with SageMaker Experiments and Debugger**

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as trials through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a *model pruning* technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.
SageMaker Estimator trains those algorithms supplied from the PyTorch model zoo in an AWS Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an AWS Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.

Learning objectives are as follows:

- Learn how to use SageMaker to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from SageMaker Debugger PyTorch Iterative Model Pruning.

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

Pruning iteration: 0

Trainable params: 50,883,321
Non-trainable params: 0

Input size (MB): 0.57
Forward/backward pass size (MB): 7.27
Params size (MB): 194.19
Estimated Total Size (MB): 201.95
You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.

In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

**Note**
To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the `train` function in the `train.py` script.

```
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
    print('acc:{:.4f}'.format(correct/total))
    hook.save_scalar("accuracy", correct/total, sm_metric=True)

    # Add the following code to line 128 of the train.py script to save the pruned models
    # under the current SageMaker Studio model directory
    torch.save(model.state_dict(), os.environ['SM_MODEL_DIR'] + '/model.pt')
```
Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size (1, 20) from an original input image of size (28, 28) and significantly reduces the size of data for training by 40 times.

The decoder has two deconvolutional layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.

Using SageMaker Debugger to Monitor Attentions in BERT Model Training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on transfer learning and the Transformer model for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple example, the BERT model can give a high attention to appropriate verb tokens or pronoun tokens from a subject token.
The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.

Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called attention.

This notebook demonstrates how to use the pre-trained BERT model from the GluonNLP model zoo on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting attention scores and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker Debugger, you can retrieve the tensors and plot the attention-head view in real time as training progresses and understand what the model is learning.

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.
Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a convolutional neural network (CNN or ConvNet) is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on the German Traffic Sign Dataset, which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.

During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a saliency map) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

Configure Debugger Using Amazon SageMaker Python SDK

To configure Debugger, use Amazon SageMaker Python SDK and specify Debugger-specific parameters while constructing SageMaker estimators. There are three parameters you need to configure: profiler_config, debugger_hook_config, and rules.

Note

By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured S3 bucket.
Important
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Construct a SageMaker Estimator with Debugger

The following example codes show how to construct a SageMaker estimator with the Debugger-specific parameters depending on a framework of your choice. Throughout the documentation in the following topics, you can find more information about how to configure the Debugger-specific parameters that you can mix and match as you want.

Note
The following example codes are not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

TensorFlow

To access the deep profiling feature for TensorFlow, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```python
# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"
        # Debugger-specific parameters
        profiler_config=profiler_config,
        debugger_hook_config=debugger_hook_config,
        rules=rules
)

estimator.fit(wait=False)
```
PyTorch

To access the deep profiling feature for PyTorch, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```python
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)

rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04",
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

MXNet

```python
# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)

rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",
)```
# Debugger-specific parameters
proposer_config=profiler_config,
deprecated_hook_config=debugger_hook_config,
rules=rules)

estimator.fit(wait=False)

Note
For MXNet, when configuring the profiler_config parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for MXNet.

XGBoost

# An example of constructing a SageMaker XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

profiler_config=ProfilerConfig(...)
deprecated_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.2-1",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    deprecated_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)

Note
For XGBoost, when configuring the profiler_config parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

Generic estimator

# An example of constructing a SageMaker generic estimator using the XGBoost algorithm
base image
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

profiler_config=ProfilerConfig(...)
deprecated_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")
estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)
estimator.fit(wait=False)

Where you configure the following parameters:

- **profiler_config** parameter – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the profiler_config parameter, see Configure Debugger Monitoring Hardware System Resource Utilization (p. 1649) and Configure Debugger Framework Profiling (p. 1649).

- **debugger_hook_config** parameter – Configure Debugger to collect output tensors from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the debugger_hook_config parameter, see Configure Debugger Hook to Save Tensors (p. 1653).

- **rules** parameter – Configure this parameter to enable Debugger built-in rules that you want to run in parallel. The rules automatically analyze your training job and find training issues. The ProfilerReport rule saves the Debugger profiling reports in your secured S3 bucket URI. To learn how to configure the rules parameter, see Configure Debugger Built-in Rules (p. 1659).

**Note**
Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/ There are three subfolders created by Debugger: debug-output, profiler-output, and rule-output. You can also retrieve the default S3 bucket URIs using the SageMaker estimator classmethods (p. 1665).

See the following topics to find out how to configure the Debugger-specific parameters in detail.

**Topics**

- Configure Debugger Monitoring Hardware System Resource Utilization (p. 1649)
- Configure Debugger Framework Profiling (p. 1649)
- Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 1653)
- Configure Debugger Hook to Save Tensors (p. 1653)
- Configure Debugger Built-in Rules (p. 1659)
- Turn Off Debugger (p. 1665)
- Useful SageMaker Estimator Classmethods for Debugger (p. 1665)
Configure Debugger Monitoring Hardware System Resource Utilization

To adjust Debugger system monitoring time intervals, use the `ProfilerConfig` API operation to create a parameter object while constructing a SageMaker framework or generic estimator depending on your preference.

**Note**
By default, for all SageMaker training jobs, Debugger collects hardware system utilization data from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the system metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

The following example code shows how to set up the `profiler_config` parameter with a system monitoring time interval of 1000 milliseconds.

```python
from sagemaker.debugger import ProfilerConfig

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

- `system_monitor_interval_millis` (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see Open Amazon SageMaker Debugger Insights Dashboard (p. 1737).

**Configure Debugger Framework Profiling**

To enable Debugger framework profiling, configure the `framework_profile_params` parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the `FrameworkProfile` class, you can configure custom framework profiling options.

**Note**
Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see Supported Frameworks and Algorithms (p. 1632).

Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

**Start a Training Job with the Default System Monitoring and Framework Profiling**

The following example code is the simplest `profiler_config` parameter setting to start the default system monitoring and the default framework profiling. The `FrameworkProfile` class in the following example code initiates the default framework profiling when a training job starts. Debugger framework profiling includes the following options: detailed profiling, data loader profiling, and Python profiling.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
```
profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile()
)

With this profiler_config parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options (p. 1651) and SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

If you want to change the system monitoring interval and enable the default framework profiling, you can specify the system_monitor_interval_millis parameter explicitly with the framework_profile_params parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile()
)
```

For more information about the FrameworkProfile class, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

Start a Training Job with the Default System Monitoring and Customized Framework Profiling for Target Steps or a Target Time Range

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the FrameworkProfile class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile

  profiler_config=ProfilerConfig(
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile

  profiler_config=ProfilerConfig(
      system_monitor_interval_millis=1000,
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

- **For a target time range**
With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()), duration=600)
)
```

With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()), duration=600)
)
```

The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

The next section shows you how to script the available profiling options.

### Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options

You can use the following profiling configuration classes to manage the framework profiling options:

- **DetailedProfilingConfig** – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.
  
  **Note**
  
  Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

- **DataloaderProfilingConfig** – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.
  
  **Note**
  
  Data loader profiling might lower the training performance while collecting information from data loaders. We don't recommend enabling data loader profiling for more than a couple of steps. Debugger is preconfigured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes from any other custom or external training containers.

- **PythonProfilingConfig** – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.
• **cProfile** – The standard Python profiler. cProfile collects information for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation for each function call, providing complete detail about Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function call executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

• **Pyinstrument** – Pyinstrument is a low-overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wall-clock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noise (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

**Note**

Enabling Python profiling might slow down the overall training time. cProfile profiles the most frequently called Python operators at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling options with specified values.

```python
import time
from sagemaker.debugger import (ProfilerConfig,
                                 FrameworkProfile,
                                 DetailedProfilingConfig,
                                 DataloaderProfilingConfig,
                                 PythonProfilingConfig,
                                 PythonProfiler, cProfileTimer)

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloder_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
        python_profiling_config=PythonProfilingConfig(
            start_step=9,
            num_steps=1,
            python_profiler=PythonProfiler.CPROFILE,
            cprofile_timer=cProfileTimer.TOTAL_TIME
        )
    )
)
```

For more information about available profiling options, see DetailedProfilingConfig, DataloaderProfilingConfig, and PythonProfilingConfig in the Amazon SageMaker Python SDK.
Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running

If you want to enable or update the Debugger monitoring and profiling configuration for a training job that is currently running, use the following SageMaker estimator extension methods:

- To enable Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:

```python
estimator.enable_default_profiling()
```

When you use the `enable_default_profiling` method, Debugger initiates the default system monitoring and the `ProfileReport` built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

For more information, see `estimator.enable_default_profiling` in the Amazon SageMaker Python SDK.

- To enable Debugger built-in rules, system monitoring, and framework profiling with customizable configuration parameters, use the following:

```python
estimator.update_profiler(
    rules=[ProfilerRule.sagemaker(rule_configs.BuiltinRule()),
          system_monitor_interval_millis=500,
          framework_profile_params=FrameworkProfile()
    )
```

For more information, see `estimator.update_profiler` in the Amazon SageMaker Python SDK.

Configure Debugger Hook to Save Tensors

*Tensors* are data collections of updated parameters from the backward and forward pass of each training iteration, and Debugger collects output tensors to analyze the state of a training job. The Amazon SageMaker Debugger `CollectionConfig` and `DebuggerHookConfig` API operations provide methods for grouping tensors into *collections* and saving them to a target S3 bucket.

**Note**

By default, for all SageMaker training jobs, Debugger collects loss and accuracy output scalars from the training jobs every 500 steps, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the output data in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

While constructing a SageMaker estimator, enable Debugger by specifying the hook configuration parameter, `debugger_hook_config`. The following steps include examples of how to set up the `debugger_hook_config` using the `CollectionConfig` and `DebuggerHookConfig` API operations to pull tensors out of your training jobs and save them. If you use Debugger-supported AWS containers for zero script change, you can simply run the training job without changing your training script. You can also use Debugger for training jobs running in any other Debugger-supported AWS containers with script mode, making minimal changes to your training script.

Configure Debugger Tensor Collections Using the `CollectionConfig` API Operation

Use the `CollectionConfig` API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-
supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients")
]
```

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default "save_interval" value.

**For a full list of available Debugger built-in collections, see Debugger Built-in Collections.**

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following `CollectionConfig` template to adjust parameters.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(
        name="tensor_collection",
        parameters={
            "key_1": "value_1",
            "key_2": "value_2",
            ...
            "key_n": "value_n"
        }
    )
]
```

For more information about available parameter keys, see `CollectionConfig` in the Amazon SageMaker Python SDK. For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={
            "train.save_interval": "100",
            "eval.save_interval": "10"
        }
    )
]
```

**Tip**

This tensor collection configuration object can be used for both `DebuggerHookConfig` and Rule API operations.

**Configure Debugger Hook to Save Tensors**

Use the `DebuggerHookConfig` class to create a `debugger_hook_config` object using the `collection_configs` object you created in the previous step.

```python
from sagemaker.debugger import DebuggerHookConfig
```
Configure Debugger Using SageMaker Python SDK

```python
debuger_hook_config=DebuggerHookConfig(
    collection_configs=collection_configs
)
```

Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```python
from sagemaker.debugger import DebuggerHookConfig
debuger_hook_config=DebuggerHookConfig(
    s3_output_path="specify-your-s3-bucket-uri",
    collection_configs=collection_configs
)
```

For more information, see `DebuggerHookConfig` in the Amazon SageMaker Python SDK.

Example Notebooks and Code Samples to Configure Debugger Hook

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

**Topics**
- Tensor Visualization Example Notebooks (p. 1655)
- Save Tensors Using Debugger Built-in Collections (p. 1657)
- Save Tensors Using Debugger Modified Built-in Collections (p. 1658)
- Save Tensors Using Debugger Custom Collections (p. 1658)

Tensor Visualization Example Notebooks

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

- Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet

  This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.
This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

- **Visualizing and Debugging Tensors from MXNet Model Training**

This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLu activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLu activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.

In this notebook, the TensorPlot class imported from tensor_plot.py is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The tensor_plot.py script provided with the notebook retrieves tensors using Debugger and visualizes
the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- **Real-time Tensor Analysis in a SageMaker Notebook with MXNet**

  This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

**Save Tensors Using Debugger Built-in Collections**

You can use built-in collections of tensors using the `CollectionConfig` API and save them using the `DebuggerHookConfig` API. The following example shows how to use the default settings of Debugger hook configurations to construct a SageMaker TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

**Note**

In the following example code, the `s3_output_path` parameter for `DebuggerHookConfig` is optional. If you do not specify it, Debugger saves the tensors at `s3://<output_path>/debug-output/`, where the `<output_path>` is the default output path of SageMaker training jobs. For example:

```
"s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"
```

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs = [
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients"),
    CollectionConfig(name="losses"),
    CollectionConfig(name="biases"),
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session = sagemaker.Session()
BUCKET_NAME = sagemaker_session.default_bucket()
LOCATION_IN_BUCKET = 'debugger-built-in-collections-hook'

hook_config = DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                                                                 LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator = TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",
)```
`# debugger-specific hook argument below`

deprecated

deprecated

sagemaker_estimator.fit()

To see a list of Debugger built-in collections, see Debugger Built-in Collections.

Save Tensors Using Debugger Modified Built-in Collections

You can modify the Debugger built-in collections using the `CollectionConfig` API operation. The following example shows how to tweak the built-in `losses` collection and construct a SageMaker TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs = [
    CollectionConfig(
        name="losses",
        parameters={"save_interval": "50"})
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session = sagemaker.Session()
BUCKET_NAME = sagemaker_session.default_bucket()
LOCATION_IN_BUCKET = 'debugger-modified-collections-hook'

hook_config = DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME, LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator = TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",
    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of `CollectionConfig` parameters, see Debugger CollectionConfig API.

Save Tensors Using Debugger Custom Collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs = [
    CollectionConfig(
        name="losses",
        parameters={"save_interval": "50"})
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session = sagemaker.Session()
BUCKET_NAME = sagemaker_session.default_bucket()
LOCATION_IN_BUCKET = 'debugger-modified-collections-hook'

hook_config = DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME, LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator = TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",
    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of `CollectionConfig` parameters, see Debugger CollectionConfig API.

Save Tensors Using Debugger Custom Collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection
collection_configs=[
    CollectionConfig(
        name="custom_activations_collection",
        parameters={
            "include_regex": "relu|tanh", # Required
            "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
        }
    )
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-custom-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME, LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of CollectionConfig parameters, see Debugger CollectionConfig.

Configure Debugger Built-in Rules

Amazon SageMaker Debugger rules analyze tensors emitted during the training of a model. Debugger offers the Rule API operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger Built-in Rules (p. 1677).

Note
The built-in rules are prepared in Amazon SageMaker processing containers and fully managed by SageMaker Debugger. By default, Debugger initiates the ProfilerReport (p. 1679) rule for all SageMaker training jobs, without any Debugger-specific rule parameter specified to the SageMaker estimators. The ProfilerReport rule invokes all of the following built-in rules for monitoring system bottlenecks and profiling framework metrics:

- BatchSize (p. 1680)
Debugger saves the profiling report in a default S3 bucket. The format of the default S3 bucket URI is \texttt{s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/rule-output/}. For more information about how to download the profiling report, see \texttt{SageMaker Debugger Profiling Report (p. 1752)}. SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the \texttt{Amazon SageMaker Studio is available at no additional charge} section of the \texttt{Amazon SageMaker Pricing} page.

In the following topics, learn how to use the Debugger built-in rules.

Topics
- Use Debugger Built-in Rules with the Default Parameter Settings (p. 1660)
- Use Debugger Built-in Rules with Custom Parameter Values (p. 1661)
- Example Notebooks and Code Samples to Configure Debugger Rules (p. 1662)

Use Debugger Built-in Rules with the Default Parameter Settings

To specify Debugger built-in rules in an estimator, you need to configure a \texttt{rules} list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_n()),
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n())
]
```

For more information about default parameter values and descriptions of the built-in rule, see \texttt{List of Debugger Built-in Rules (p. 1677)}.

For example, to inspect the overall training performance and progress of your model, construct a \texttt{SageMaker} estimator with the following built-in rule configuration:

```python
from sagemaker.debugger import Rule, rule_configs

rules=[
```
ProfilerRule.sagemaker(rule_configs.ProfilerReport()),
Rule.sagemaker(rule_configs.loss_not_decreasing()),
Rule.sagemaker(rule_configs.overfit()),
Rule.sagemaker(rule_configs.overtraining()),
Rule.sagemaker(rule_configs.stalled_training_rule())
]

When you start the training job, Debugger collects system resource utilization data every
500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger
analyzes the resource utilization to identify if your model is having bottleneck problems. The
loss_not_decreasing, overfit, overtraining, and stalled_training_rule monitors if your
model is optimizing the loss function without those training issues. If the rules detect training anomalies,
the rule evaluation status changes to IssueFound. You can set up automated actions, such as notifying
training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more
information, see Action on Amazon SageMaker Debugger Rules (p. 1726).

Use Debugger Built-in Rules with Custom Parameter Values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure
the base_config and rule_parameters parameters for the ProfilerRule.sagemaker and
Rule.sagemaker class methods. In case of the Rule.sagemaker class methods, you can also customize
tensor collections through the collections_to_save parameter. The instruction of how to use
the CollectionConfig class is provided at Configure Debugger Tensor Collections Using the
CollectionConfig API Operation (p. 1653).

Use the following configuration template for built-in rules to customize parameter values. By changing
the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The base_config argument is where you call the built-in rule methods.
- The rule_parameters argument is to adjust the default key values of the built-in rules listed in List
  of Debugger Built-in Rules (p. 1677).
- The collections_to_save argument takes in a tensor configuration through the CollectionConfig API, which requires name and parameters arguments.
  - To find available tensor collections for name, see Debugger Built-in Tensor Collections.
  - For a full list of adjustable parameters, see Debugger CollectionConfig API.

For more information about the Debugger rule class, methods, and parameters, see SageMaker
Debugger Rule class in the Amazon SageMaker Python SDK.

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig
rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInProfilerRuleName(),
        rule_parameters={
            "key": "value"
        }
    ),
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
            "key": "value"
        }
    ),
    collections_to_save=[
        CollectionConfig(
            name="tensor_collection_name",
            parameters={
```
The parameter descriptions and value customization examples are provided for each rule at List of Debugger Built-in Rules (p. 1677).

Example Notebooks and Code Samples to Configure Debugger Rules

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

Topics
- Debugger Built-in Rules Example Notebooks (p. 1662)
- Debugger Built-in Rules Example Code (p. 1663)
- Use Debugger Built-in Rules with Parameter Modifications (p. 1664)

Debugger Built-in Rules Example Notebooks

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker:

- Using a SageMaker Debugger built-in rule with TensorFlow
- Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet
- Using a SageMaker Debugger built-in rule with XGBoost
- Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost

While running the example notebooks in SageMaker Studio, you can find the training job trial created on the Studio Experiment List tab. For example, as shown in the following screenshot, you can find and open a Describe Trial Component window of your current training job. On the Debugger tab, you can check if the Debugger rules, `vanishing_gradient()` and `loss_not_decreasing()`, are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see SageMaker Studio - View Experiments, Trials, and Trial Components.
There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

**Debugger Built-in Rules Example Code**

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see [List of Debugger Built-in Rules](p. 1677).

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call built-in rules that you want to use.
built_in_rules = [
    Rule.sagemaker(rule_configs.vanishing_gradient()),
    Rule.sagemaker(rule_configs.loss_not_decreasing())
]

# construct a SageMaker estimator with the Debugger built-in rules
sagemaker_estimator = TensorFlow(  
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    rules=built_in_rules
)
```

There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

**Debugger Built-in Rules Example Code**

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see [List of Debugger Built-in Rules](p. 1677).

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call built-in rules that you want to use.
built_in_rules = [
    Rule.sagemaker(rule_configs.vanishing_gradient()),
    Rule.sagemaker(rule_configs.loss_not_decreasing())
]

# construct a SageMaker estimator with the Debugger built-in rules
sagemaker_estimator = TensorFlow(  
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
)```
instance_count=1,
instance_type="ml.m4.xlarge",
framework_version="2.1.0",
py_version="py3",

# debugger-specific arguments below
rules=built_in_rules
}
sagemaker_estimator.fit()

Note
The Debugger built-in rules run in parallel with your training job. The maximum number of built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

To find an example of how to adjust the Debugger rule parameters, see the following Use Debugger Built-in Rules with Parameter Modifications (p. 1664) section.

Use Debugger Built-in Rules with Parameter Modifications

The following code example shows the structure of built-in rules to adjust parameters. In this example, the stalled_training_rule collects the losses tensor collection from a training job at every 50 steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting tensor outputs for 120 seconds, the stalled_training_rule stops the training job.

import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters
base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))
built_in_rules_modified=[
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            'threshold': '120',
            'training_job_name_prefix': base_job_name_prefix,
            'stop_training_on_fire': 'True'
        }
    )
    collections_to_save=[
        CollectionConfig(
            name="losses",
            parameters={
                "train.save_interval": "50"
                "eval.save_interval": "10"
            }
        )
    ]
]

# construct a SageMaker estimator with the modified Debugger built-in rule
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name=base_job_name_prefix,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.1.0",
    py_version="py3",
)
# debugger-specific arguments below
rules=built_in_rules_modified
}
sagemaker_estimator.fit()

For an advanced configuration of the Debugger built-in rules using the CreateTrainingJob API, see Configure Debugger Using Amazon SageMaker API (p. 1666).

**Turn Off Debugger**

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:
  
  To disable both monitoring and profiling, include the disable_profiler parameter to your estimator and set it to True.

    **Warning**
    If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To disable debugging, set the debugger_hook_config parameter to False.

    **Warning**
    If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

```python
estimator=Estimator(
    ...
    disable_profiler=True
disable_debugger_hook_config=False
)
```

For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:
  
  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

```python
estimator.disable_profiling()
```

To disable framework profiling only and keep system monitoring, use the update_profiler method:

```python
estimator.update_profiler(disable_framework_metrics=true)
```

For more information about the estimator extension methods, see the estimator.disable_profiling and estimator.update_profiler classmethods in the Amazon SageMaker Python SDK documentation.

**Useful SageMaker Estimator Classmethods for Debugger**

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the estimator.fit() method.
• To check the base S3 bucket URI of a SageMaker training job:

```python
estimator.output_path
```

• To check the base job name of a SageMaker training job:

```python
estimator.latest_training_job.job_name
```

• To see a full `CreateTrainingJob` API operation configuration of a SageMaker training job:

```python
estimator.latest_training_job.describe()
```

• To check a full list of the Debugger rules while a SageMaker training job is running:

```python
estimator.latest_training_job.rule_job_summary()
```

• To check the S3 bucket URI where the model parameter data (output tensors) are saved:

```python
estimator.latest_job_debugger_artifacts_path()
```

• To check the S3 bucket URI at where the model performance data (system and framework metrics) are saved:

```python
estimator.latest_job_profiler_artifacts_path()
```

• To check the Debugger rule configuration for debugging output tensors:

```python
estimator.debugger_rule_configs
```

• To check the list of the Debugger rules for debugging while a SageMaker training job is running:

```python
estimator.debugger_rules
```

• To check the Debugger rule configuration for monitoring and profiling system and framework metrics:

```python
estimator.profiler_rule_configs
```

• To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:

```python
estimator.profiler_rules
```

For more information about the SageMaker estimator class and its methods, see Estimator API in the Amazon SageMaker Python SDK.

**Configure Debugger Using Amazon SageMaker API**

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This offers a high-level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this guide covers how to configure `CreateTrainingJob`, `UpdateTrainingJob`, Debugger configuration APIs, and their parameters to use the Debugger built-in and custom rules.

**Topics**
Configure Debugger Using SageMaker API

- JSON (AWS CLI) (p. 1667)
- AWS Boto3 (p. 1671)

### JSON (AWS CLI)

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `DebugHookConfig`, `DebugRuleConfiguration`, `ProfilerConfig`, and `ProfilerRuleConfiguration` objects through the SageMaker `CreateTrainingJob` API operation. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the JSON strings to request `CreateTrainingJob`.

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using AWS CLI. For example, save the following code as `debugger-training-job-cli.json`.

**Note**

Ensure that you use the correct Docker container images. To find AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1790).

```json

  "DebugRuleConfigurations": [
    {
      "RuleConfigurationName": "LossNotDecreasing",
      "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
      debugger-rules:latest",
      "RuleParameters": {"rule_to_invoke": "LossNotDecreasing"}
    }
  ],
  "ProfilerConfig": {
```
Configure Debugger Using SageMaker API

```json
"S3OutputPath": "s3://sagemaker-us-west-2-111122223333/debugger-aws-cli-test",
"ProfilingIntervalInMilliseconds": 500,
"ProfilingParameters": {
  "DataloaderProfilingConfig": "{{"StartStep": 5, "NumSteps": 3, "MetricsRegex ": "\."","}},
  "DetailedProfilingConfig": "{{"StartStep": 5, "NumSteps": 3, }}",
  "PythonProfilingConfig": "{{"StartStep": 5, "NumSteps": 3, "ProfilerName": \"cprofile\", \"cProfileTimer\": \"total_time\" },
  "LocalPath": "/opt/ml/output/profiler/"
},
"ProfilerRuleConfigurations": [
  {"RuleConfigurationName": "ProfilerReport",
  "RuleParameters": {"rule_to_invoke": "ProfilerReport"}
  },
  "ResourceConfig": {
    "InstanceType": "ml.p3.8xlarge",
    "InstanceCount": 1,
    "VolumeSizeInGB": 30,
  },
  "StoppingCondition": {
    "MaxRuntimeInSeconds": 86400
  }
}
```

After saving the JSON file, run the following command in your terminal. (Use ! at the beginning of the line if you use a Jupyter notebook.)

```
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-cli.json
```

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```json
"DebugHookConfig": {
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
  "CollectionConfigurations": [
    {"CollectionName": "gradients",
     "CollectionParameters": {
       "save_interval": "500"
     }
    }
  ]
}
```

This will make the training job save the tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available CollectionParameters parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the SageMaker Python SDK documentation.
To enable Debugger rules for debugging the output tensors

The following `DebugRuleConfigurations` API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
"DebugRuleConfigurations": [
  {
    "RuleConfigurationName": "VanishingGradient",
    "RuleEvaluatorImage": "50385931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",
    "RuleParameters": {
      "rule_to_invoke": "VanishingGradient",
      "threshold": "20.0"
    }
  }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1790). To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules (p. 1677).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the `ProfilerConfig` API operation to enable collecting system and framework metrics.

```
Target Step

"ProfilerConfig": {
  // Optional. Path to an S3 bucket to save profiling outputs
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
  // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
  "ProfilingIntervalInMilliseconds": 500,
  "ProfilingParameters": {
    "DataloaderProfilingConfig": "{ "StartStep": 5, "NumSteps": 3, "MetricsRegex": ".*" }",
    "DetailedProfilingConfig": "{ "StartStep": 5, "NumSteps": 3 }",
    // For PythonProfilingConfig,
    // available ProfilerName options: cProfile, Pyinstrument
    // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
    "PythonProfilingConfig": "{ "StartStep": 5, "NumSteps": 3, "ProfilerName": "cProfile", "cProfileTimer": "total_time" }",
    // Optional. Local path for profiling outputs
    "LocalPath": "/opt/ml/output/profiler/"
  }
}
```

```
Target Time Duration

"ProfilerConfig": {
  // Optional. Path to an S3 bucket to save profiling outputs
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
  // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
}
```
To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

```
"ProfilerRuleConfigurations": [
  {
    "RuleConfigurationName": "ProfilerReport",
    "RuleParameters": {
      "rule_to_invoke": "ProfilerReport",
      "CPUBottleneck_cpu_threshold": "90",
      "IOBottleneck_threshold": "90"
    }
  }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1790). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1677).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

```
{
  "ProfilerConfig": {
    "DisableProfiler": boolean,
    "ProfilingIntervalInMilliseconds": number,
    "ProfilingParameters": {
      "string" : "string"
    }
  },
  "ProfilerRuleConfigurations": [
    {
      "RuleConfigurationName": "string",
      "RuleEvaluatorImage": "string",
      "RuleParameters": {
        "string" : "string"
      }
    }
  ]
}
```
Configure Debugger Using SageMaker API Operation

A custom rule can be configured for a training job using the `DebugHookConfig` and `DebugRuleConfiguration` objects in the `CreateTrainingJob` API operation. The following code sample shows how to configure a custom `ImproperActivation` rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1791). You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```json
"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "relu_activations",
            "CollectionParameters": {
                "include_regex": "relu",
                "save_interval": "500",
                "end_step": "5000"
            }
        }
    ],
    "DebugRulesConfigurations": [
        {
            "RuleConfigurationName": "improper_activation_job",
            "InstanceType": "ml.c4.xlarge",
            "VolumeSizeInGB": 400,
            "RuleParameters": {
                "source_s3_uri": "s3://bucket/custom_rules.py",
                "rule_to_invoke": "ImproperActivation",
                "collection_names": "relu_activations"
            }
        }
    ]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1790). To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules (p. 1677).

**AWS Boto3**

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `create_training_job()` function of the AWS Boto3 SageMaker client. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the request body for the `create_training_job()` function.

The following code shows a complete example of how to configure Debugger for the `create_training_job()` request body and start a training job in `us-west-2`, assuming that a
training script `entry_point/train.py` is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

**Note**
Ensure that you use the correct Docker container images. To find available AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1790).

```python
import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()

# Upload a training script to a default Amazon S3 bucket of the current SageMaker session
source = 'source.tar.gz'
project = 'debugger-boto3-test'
tar = tarfile.open(source, 'w:gz')
tar.add ('entry_point/train.py') # Specify the directory and name of your training script
tar.close()

s3 = boto3.client('s3')
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    TrainingJobName='debugger-boto3-\'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/'+source,
        'sagemaker_program': '/entry_point/train.py' # training script file location and name under the sagemaker_submit_directory
    },
    # Specify a training container image URI (Deep Learning Container or your own training container) to TrainingImage.
    AlgorithmSpecification={
        'TrainingInputMode': 'File',
        'EnableSageMakerMetricsTimeSeries': False
    },
    RoleArn='arn:aws:iam::111122233333:role/service-role/AmazonSageMaker-ExecutionRole-20201014T161125',
    OutputDataConfig={'S3OutputPath': 's3://'+bucket+'/'+project+'/output'},
    ResourceConfig={
        'InstanceType': 'ml.p3.8xlarge',
        'InstanceCount': 1,
        'VolumeSizeInGB': 30
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 86400
    },
    DebugHookConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/debug-output',
        'CollectionConfigurations': [
            {
                'CollectionName': 'losses',
            }
        ]
    }
)
```
To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```python
DebugHookConfig={
    'S3OutputPath': 's3:///<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'gradients',
            'CollectionParameters': {
                'train.save_interval': '500',
                'eval.save_interval': '50'
            }
        }
    ]
}
```

This will make the training job save a tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client.
library documentation. To find available CollectionParameters parameter keys and values, see the sagemaker.debugger.CollectionConfig class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
DebugRuleConfigurations=[
    {
        'RuleConfigurationName': 'VanishingGradient',
        'RuleParameters': {
            'rule_to_invoke': 'VanishingGradient',
            'threshold': '20.0'
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1790). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1677).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output',  # Optional. Path to an S3 bucket to save profiling outputs
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "MetricsRegex": ".*"
        }',
        'DetailedProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3
        }',
        'PythonProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "ProfilerName": "cprofile",  # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time"  # Include only when using cprofile.
        }',
        'LocalPath': '/opt/ml/output/profiler/'  # Optional. Local path for profiling outputs
    }
}
```
Target Time Duration

ProfilerConfig={
  'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output',  # Optional. Path to an S3 bucket to save profiling outputs
  'ProfilerIntervalInMilliseconds': 500,  # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
  'ProfilerParameters': {
    'DataloaderProfilingConfig': '{
      "StartTimeInSecSinceEpoch": 1234567789,
      "DurationInSeconds": 10,
      "MetricsRegex": ".*"
    },
    'DetailedProfilingConfig': '{
      "StartTimeInSecSinceEpoch": 1234567789,
      "DurationInSeconds": 10
    },
    'PythonProfilingConfig': '{
      "StartTimeInSecSinceEpoch": 1234567789,
      "DurationInSeconds": 10,
      "ProfilerName": "cprofile",  # Available options: cprofile, pyinstrument
      "CPUBottleneck_cpu_threshold": '90',  # Include only when using cprofile.
      "cProfileTimer": "total_time"  # Include only when using cprofile.
    },
    'LocalPath': '/opt/ml/output/profiler/'  # Optional. Local path for profiling outputs
  }
}

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

ProfilerRuleConfigurations=[
  {
    'RuleConfigurationName': 'ProfilerReport',
    'RuleParameters': {
      'rule_to_invoke': 'ProfilerReport',
      'CPUBottleneck_cpu_threshold': '90',
      'IOBottleneck_threshold': '90'
    }
  }
]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1790). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1677).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the update_training_job() function of the AWS Boto3 SageMaker client. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.
ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string' : 'string'
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'string',
        'RuleEvaluatorImage': 'string',
        'RuleParameters': {
            'string' : 'string'
        }
    }
],
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'

Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the `DebugHookConfig` and `DebugRuleConfiguration` objects using the AWS Boto3 SageMaker client's `create_training_job()` function. The following code sample shows how to configure a custom `ImproperActivation` rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1791). You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'relu_activations',
            'CollectionParameters': {
                'include_regex': 'relu',
                'save_interval': '500',
                'end_step': '5000'
            }
        }
    ],
},
DebugRulesConfigurations=[
    {
        'RuleConfigurationName': 'ImproperActivation_job',
        'InstanceType': 'ml.c4.xlarge',
        'VolumeSizeInGB': 400,
        'RuleParameters': {
            'source_s3_uri': 's3://bucket/custom_rules.py',
            'rule_to_invoke': 'ImproperActivation',
            'collection_names': 'relu_activations'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1790). To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules (p. 1677).
List of Debugger Built-in Rules

Use the Debugger built-in rules provided by Amazon SageMaker Debugger and analyze tensors emitted while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. Depending on deep learning frameworks of your choice, there are four scopes of validity for the built-in rules as shown in the following table.

Note
The maximum numbers of built-in rules for a training job are 20 for ProfilerRule and 20 for Rule. SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the Amazon SageMaker Studio is available at no additional charge section of the Amazon SageMaker Pricing page.

Important
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Debugger ProfilerRule

The following rules are the Debugger built-in rules that are callable using the ProfilerRule.sagemaker classmethod.

### Debugger Built-in Rules for Generating Profiling Reports

<table>
<thead>
<tr>
<th>Scope of Validity</th>
<th>Built-in Rules</th>

</tbody>
</table>

### To use the built-in rules with default parameter values

To use the built-in rules with default parameter values – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),
    ...
```
ProfilerRule.sagemaker(rule_configs.BuiltinRuleName_n()),
Rule.sagemaker(rule_configs.built_in_rule_name_1()),
Rule.sagemaker(rule_configs.built_in_rule_name_2()),
...
Rule.sagemaker(rule_configs.built_in_rule_name_n())
]

To use the built-in rules with customizing the parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
rules = [
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltinRuleName(),
        rule_parameters={
            "key": "value"
        }
    )
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
            "key": "value"
        }
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    )
]
```

To find available keys for the rule_parameters parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger Built-in Rules Example Code (p. 1663).
- For a full instruction of using the built-in rules with the low-level SageMaker API operations, see Configure Debugger Using Amazon SageMaker API (p. 1666).

**ProfilerReport**

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            <BuiltInRuleName>._<parameter_name> = value
        )
    )
]
```
If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```python
rules=[ProfilerRule.sagemaker(rule_configs.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's `cpu_threshold` parameter and the IOBottleneck rule's `threshold` parameter.

```python
rules=[
    ProfilerRule.sagemaker(        
        rule_configs.ProfilerReport(          
            CPUBottleneck_cpu_threshold = 90, 
            IOBottleneck_threshold = 90          
        )                               
    )                                 
]
```

**Parameter Descriptions for the OverallSystemUsage Rule**

<table>
<thead>
<tr>

<td>Customizable parameter to adjust thresholds of other built-in monitoring and profiling rules.</td>
</tr>
<tr>
<td></td>
<td>Optional</td>
</tr>
<tr>
<td></td>
<td>Default value: None</td>
</tr>
</tbody>
</table>

**BatchSize**

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

**Parameter Descriptions for the BatchSize Rule**

</tbody>
</table>
LowGPUUtilization

The LowGPUUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below threshold_p95 which indicates underutilization. Rule returns true if 95th quantile is above threshold_p95 and 5th quantile is below threshold_p5 which indicates fluctuations.

Parameter Descriptions for the LowGPUUtilization Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

<td></td>
</tr>
</tbody>
</table>
OverallSystemUsage

The OverallSystemUsage rule measures overall system usage per worker node. The rule currently only aggregates values per node and computes their percentiles.

Parameter Descriptions for the OverallSystemUsage Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. <strong>Required</strong> Valid values: String</td>
</tr>
<tr>
<td>scan_interval_us</td>
<td>Time interval to scan timeline files. <strong>Optional</strong> Valid values: Integer Default values: 60000000 (in microseconds)</td>
</tr>
</tbody>
</table>

MaxInitializationTime

The MaxInitializationTime rule helps detect if the training initialization is taking too much time. The rule waits until the first step is available.

Parameter Descriptions for the MaxInitializationTime Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. <strong>Required</strong> Valid values: String</td>
</tr>
<tr>

### CreateXgboostReport

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerates a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- **hyperparameters** – Saves at the first step
- **metrics** – Saves loss and accuracy every 5 steps
- **feature_importance** – Saves every 5 steps
- **predictions** – Saves every 5 steps
- **labels** – Saves every 5 steps

---

## DeadRelu

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the threshold_layer value of inactive ReLUs, the rule returns True.

### Parameter Descriptions for the DeadRelu Rule

            parameters={
                "include_regex": ".*relu_output|.*ReLU_output",
                "save_interval": "500"
            }
        )
    ]
]
```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](#).

**Note**
This rule is not available for the XGBoost algorithm.

### ExplodingTensor

This rule detects whether the tensors emitted during training have non-finite values, either infinite or NaN (not a number). If a non-finite value is detected, the rule returns True.

#### Parameter Descriptions for the ExplodingTensor Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>

</tr>
<tr>
<td>only_nan</td>
<td>True to monitor the base_trial tensors only for NaN values and not for infinity. False to treat both NaN and infinity as exploding values and to monitor for both.</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.exploding_tensor(),
        rule_parameters={
            "tensor_regex": ".*gradient",
            "only_nan": "False"
        }
    ),
    CollectionConfig(name="gradients",
        parameters={
            "save_interval": "500"
        }
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

**Note**
This rule is not available for the XGBoost algorithm.

**PoorWeightInitialization**

This rule detects if your model parameters have been poorly initialized.
Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

**Parameter Descriptions for the PoorWeightInitialization Rule**

<table>
<thead>

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](#).  

**Note**  
This rule is not available for the XGBoost algorithm.

### SaturatedActivation

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective min_threshold and max_thresholds values. If the activity of a node drops below the threshold_inactivity percentage, it is considered saturated. If more than a threshold_layer percent of the nodes are saturated, the rule returns True.

        parameters={
            "include_regex": ".*tanh_input|.*sigmoid_input"
            "save_interval": 500
        }
    )
]

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

Note
This rule is not available for the XGBoost algorithm.

**VanishingGradient**

This rule detects if the gradients in a trial become extremely small or drop to a zero magnitude. If the mean of the absolute values of the gradients drops below a specified threshold, the rule returns True.

**Parameters Descriptions for the VanishingGradient Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.vanishing_gradient(),
        rule_parameters={
            "threshold": 0.0000001
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
            )
        ]
    )
]
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

**Note**
This rule is not available for the XGBoost algorithm.

## WeightUpdateRatio

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the `large_threshold` value or if this ratio is smaller than `small_threshold`, the rule returns True.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and `train.save_interval` needs to be set equal to `num_steps`.

### Parameter Descriptions for the WeightUpdateRatio Rule

<table>
<thead>
<tr>
<th>Parameter Name, Description</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. <strong>Required</strong> Valid values: String</td>
</tr>
<tr>
<td>num_steps</td>
<td>The number of steps across which the rule checks to determine if the tensor has changed. The number of steps across which you want to compare the weight ratios. If you pass no value, the rule runs by default against the current step and the immediately previous saved step. If you override the default by passing a value for this parameter, the comparison is done between weights at step ( s ) and at a step ( &gt;= s - num_steps ). <strong>Optional</strong> Valid values: Integer Default value: None</td>
</tr>
<tr>

                }
            )
        ]
    )
]```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

**Note**

This rule is not available for the XGBoost algorithm.

**AllZero**

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the collection_names or tensor_regex parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

### Parameters Descriptions for the AllZero Rule

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.all_zero(),
        rule_parameters={
            "tensor_regex": ".*",
            "threshold": "100"
        },
        collections_to_save=[
            CollectionConfig(name="all",
                            parameters={
```
ClassImbalance

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.

Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the threshold_imbalance, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above threshold_misprediction, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

```
LossNotDecreasing

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

Parameter Descriptions for the LossNotDecreasing Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

Overfit

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

**Note**
A standard way to prevent overfitting is to regularize your model.

### Parameter Descriptions for the Overfit Rule

## List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| start_step     | The step from which to start comparing the validation and training loss.  
                | Optional  
                | Valid values: Integer  
                | Default value: 0 |
| patience       | The number of steps for which the ratio_threshold is allowed to exceed the value set before the model is considered to be overfit.  
                | Optional  
                | Valid values: Integer  
                | Default value: 1 |
| ratio_threshold| The maximum ratio of the difference between the mean validation loss and mean training loss to the mean training loss. If this threshold is exceeded for a patience number of steps, the model is being overfit and the rule returns True.  
                | Optional  
                | Valid values: Float  
                | Default value: 0.1 |

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overfit(),
        rule_parameters={
            "tensor_regex": ".*",
            "start_step": "0",
            "patience": "1",
            "ratio_threshold": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "train.save_interval": "100",
                    "eval.save_interval": "10"
                }
            )
        ]
    )
]
```

### Overtraining

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum of the loss function and does not improve anymore. If the model continues training it can happen that validation
loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to
determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet,
and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in
Rules (p. 1659).

Note
Overtraining can be avoided by early stopping. For information on early stopping, see Stop
Training Jobs Early (p. 1816). For an example that shows how to use spot training with
Debugger, see Enable Spot Training with Amazon SageMaker Debugger.

Parameter Descriptions for the Overtraining Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
<tr>
<td>patience_train</td>
<td>The number of steps to wait before the training loss is considered to not to be improving anymore. Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 5</td>
</tr>
<tr>
<td>patience_validation</td>
<td>The number of steps to wait before the validation loss is considered to not to be improving anymore. Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 10</td>
</tr>
<tr>
<td>delta</td>
<td>The minimum threshold by how much the error should improve before it is considered as a new optimum. Optional</td>
</tr>

<td>Default value: 0.01</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overtraining(),
        rule_parameters={
            "patience_train": "5",
            "patience_validation": "10",
```
```
    "delta": "0.01"
},
collections_to_save=[
    CollectionConfig(
        name="losses",
        parameters={
            "save_interval": "500"
        }
    )
]
```

## SimilarAcrossRuns

This rule compares tensors gathered from a base trial with tensors from another trial.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

### Parameter Descriptions for the SimilarAcrossRuns Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| base_trial         | The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. **Required**  
Valid values: String |
| other_trial        | A completed training job name whose tensors you want to compare to those tensors gathered from the current base_trial. **Required**  
Valid values: String |
| collection_names   | The list of collection names whose tensors the rule inspects. **Optional**  
Valid values: List of strings or a comma-separated string  
Default value: None |
| tensor_regex       | A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. |
### Parameter Descriptions for the StalledTrainingRule Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td>threshold</td>
<td>A threshold that defines by how much time in seconds the rule waits for a tensor output until it fires a stalled training issue. Default value is 1800 seconds. Optional</td>
</tr>
<tr>
<td>stop_training_on_fire</td>
<td>If set to True, watches if the base training job outputs tensors in &quot;threshold&quot; seconds.</td>
</tr>
</tbody>
</table>

**StalledTrainingRule**

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its threshold parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.
## List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Valid values: Boolean</td>
</tr>
<tr>
<td>Default value: False</td>
<td></td>
</tr>
<tr>
<td><strong>training_job_name_prefix</strong></td>
<td>The prefix of base training job name. If <code>stop_training_on_fire</code> is true, the rule searches for SageMaker training jobs with this prefix in the same account. If there is an inactivity found, the rule takes a <code>StopTrainingJob</code> action. Note if there are multiple jobs found with same prefix, the rule skips termination. It is important that the prefix is set unique per each training job. Optional Valid values: String</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            "threshold": "1800",
            "stop_training_on_fire": "True",
            "training_job_name_prefix": "<specify-training-base-job-name>"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

### TensorVariance

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](p. 1659).

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tensor_variance(),
        rule_parameters={
            "collection_names": "weights",
```

UnchangedTensor

This rule detects whether a tensor is no longer changing across steps.

This rule runs the `numpy.allclose` method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.unchanged_tensor(),
        rule_parameters={
            "collection_names": "losses",
            "tensor_regex": ",",
            "num_steps": "3",
            "rtol": "1e-05",
```
CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

Parameter Descriptions for the CheckInputImages Rule

<table>
<thead>
<tr>

</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.check_input_images(),
        rule_parameters={
            "threshold_mean": "0.2",
            "threshold_samples": "500",
            "regex": ".*hybridsequential0_input_0",
            "channel": "1"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*hybridsequential0_input_0",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

### NLPSequenceRatio

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

### Parameter Descriptions for the NLPSequenceRatio Rule

<table>
<thead>

                }
            )
        ]
    )
]```
Confusion

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size category_no*category_no and populates it with data coming from (labels, predictions) pairs. For each (labels, predictions) pair, the count in confusion[labels][predictions] is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: confusion[i][i]/sum_j(confusion[j][j])>=min_diag
- For elements off the diagonal: confusion[j][i]/sum_j(confusion[j][i])<=max_off_diag

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.confusion(),
        rule_parameters={
            "category_no": "10",
            "labels": "labels",
            "predictions": "predictions",
            "labels_collection": "labels",
            "predictions_collection": "predictions",
            "min_diag": "0.9",
            "max_off_diag": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="labels",
                parameters={
                    "save_interval": "500"
                }
            ),
            CollectionConfig(
                name="predictions",
                parameters={
                    "include_regex": "500"
                }
            )
        ]
    )
]`
```
**Note**
This rule infers default values for the optional parameters if their values aren't specified.

**FeatureImportanceOverweight**

This rule accumulates the weights of the $n$ largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](p. 1659).

**Parameter Descriptions for the FeatureImportanceOverweight Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>

</thead>
</table>
| base_trial     | The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  
*Required*  
Valid values: String |
| threshold      | Defines the threshold for the proportion of the cumulative sum of the $n$ largest features. The number $n$ is defined by the nfeatures parameter.  
*Optional*  
Valid values: Float  
Default value: 0.8 |
| nfeatures      | The number of largest features.  
*Optional*  
Valid values: Integer  
Default value: 3 |
| tensor_regex   | Regular expression (regex) of tensor names the rule to analyze.  
*Optional*  
Valid values: String  
Default value: ".*feature_importance/weight" |

```python
built_in_rules = [
```
List of Built-in Rules

TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the `depth` parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1659).

Create Debugger Custom Rules for Training Job Analysis

You can create custom rules to monitor your training job using the Debugger Rule APIs and the open source smdebug Python library that provide tools to build your own rule containers.

Topics
- Prerequisites for Creating Debugger Custom Rules (p. 1721)
- Use the Debugger Client Library smdebug to Create a Custom Rule Python Script (p. 1721)
- Use the Debugger APIs to Run Your Own Custom Rules (p. 1722)

Prerequisites for Creating Debugger Custom Rules

To create Debugger custom rules, you need the following prerequisites.

- SageMaker Debugger Rule.custom API
- The open source smdebug Python library
- Your own custom rule python script
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1791)

Use the Debugger Client Library smdebug to Create a Custom Rule Python Script

The smdebug Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, CustomGradientRule. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker estimator when it initiates training job.

```python
from smdebug.rules.rule import Rule

class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):  
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False
```

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.
Use the Debugger APIs to Run Your Own Custom Rules

The following code sample shows how to configure a custom rule with the Amazon SageMaker Python SDK. This example assumes that the custom rule script you created in the previous step is located at 'path/to/my_custom_rule.py'.

```python
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
    rule_to_invoke='CustomGradientRule',
    collections_to_save=[CollectionConfig("gradients")],
    rule_parameters={"threshold": "20.0"}
)
```

The following list explains the Debugger `Rule.custom` API arguments.

- **name (str)**: Specify a custom rule name as you want.
- **image_uri (str)**: This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job. You can find the list of open source SageMaker rule evaluator images from Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1791).
- **instance_type (str)**: You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- **source (str)**: This is the local path or the Amazon S3 URI to your custom rule script.
- **rule_to_invoke (str)**: This specifies the particular Rule class implementation in your custom rule script. SageMaker supports only one rule to be evaluated at a time in a rule job.
- **collections_to_save (str)**: This specifies which tensor collections you will save for the rule to run.
- **rule_parameters (dictionary)**: This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the custom_rule object, you can use it for building a SageMaker estimator for any training jobs. Specify the `entry_point` to your training script. You do not need to make any change of your training script.

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    role=sagemaker.get_execution_role(),
    base_job_name='smdebug-custom-rule-demo-tf-keras',
    entry_point='path/to/your_training_script.py',
    train_instance_type='ml.p2.xlarge',

    rules = [custom_rule]
)

estimator.fit()
```

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.
Use Debugger with Custom Training Containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The AWS CLI, SageMaker Estimator API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger.

- Amazon SageMaker Python SDK
- The SMDebug open source client library
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger Hook to Your Training Script (p. 1723).

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- Build a Custom Training Container and Debug Training Jobs with Debugger

**Tip**

This custom container with Debugger guide is an extension of the Adapting Your Own Training Container (p. 2225) guide which walks you thorough how to build and push your custom training container to Amazon ECR.

Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

```bash
### debugger_custom_container_test_notebook.ipynb  # a notebook to run python snippet codes
### debugger_custom_container_test_folder       # this is a docker folder
  ### your-training-script.py            # your training script with Debugger hook
  ### Dockerfile                           # a Dockerfile to build your own container
```

Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

**Note**

This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the debugger_hook_config parameter when constructing an estimator.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.
# An example of training script (your-training-script.py)

```python
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):
    ...  
    model.fit(X_train, Y_train,
              batch_size=batch_size,
              epochs=epoch,
              validation_data=(X_valid, Y_valid),
              shuffle=True,
              callbacks=[hook])  

def main():
    parser=argparse.ArgumentParser(description="Train resnet50 cifar10")
    # hyperparameter settings
    parser.add_argument(...)  
    args = parser.parse_args()
    model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)
    hook=smd.KerasHook.create_from_json_file()
    # Add the following line to register the Debugger hook for Keras.
    # Start the training.
    train(args.batch_size, args.epoch, model, hook)
if __name__ == '__main__':
    main()
```

For more information about registering the Debugger hook for the supported frameworks and algorithm, see the following links in the SMDebug client library:

- SMDebug TensorFlow hook
- SMDebug PyTorch hook
- SMDebug MXNet hook
- SMDebug XGBoost hook

In the following example notebooks’ training scripts, you can find more examples about how to add the Debugger hooks to training scripts and collect output tensors in detail:

- Debugger in script mode with the TensorFlow 2.1 framework

To see the difference between using Debugger in a Deep Learning Container and in script mode, open this notebook and put it and the previous Debugger in a Deep Learning Container TensorFlow v2.1 notebook example side by side.

In script mode, the hook configuration part is removed from the script in which you set the estimator. Instead, the Debugger hook feature is merged into the training script, TensorFlow Keras ResNet training script in script mode. The training script imports the smdebug library in the required TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also manually implements the smdebug hook functionality by adding the callbacks=[hook] argument
inside the `train` function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.

This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example. The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by AWS Deep Learning Containers.

- **Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode**

This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker containers, and this example shows details of how to modify a training script.

The SageMaker PyTorch estimator is already in script mode by default. In the notebook, the line to activate `script_mode` is not included in the estimator configuration.

This notebook shows detailed steps to change an original PyTorch training script to a modified version with Debugger enabled. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and Dockerfile. The following code example is a Dockerfile that includes essential docker build commands. Paste the following code into the Dockerfile text file and save it. Upload your training script to the same folder.

```bash
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf
# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug
CMD ["bin/bash"]
```

If you want to use a pre-built AWS Deep Learning Container image, see Available AWS Deep Learning Containers Images.

Build and Push the Custom Training Container to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```python
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'
region = boto3.session.Session().region_name

uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
```
byoc_image_uri = '{}.dkr.ecr.{}.{}'\'\'.format(account_id, region, uri_suffix, ecr_repository + tag)

docker build -t $ecr_repository docker

aws ecr get-login --region $region --no-include-email

aws ecr create-repository --repository-name $ecr_repository

docker tag {ecr_repository + tag} $byoc_image_uri

docker push $byoc_image_uri

Tip
If you use one of the AWS Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.

aws ecr get-login-password --region {region} | docker login --username AWS --password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com

Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the estimator.fit(), Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the smdebug core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

import sagemaker
from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...) rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltinRule())
]
estimator=Estimator(
    image_uri=byoc_image_uri,
    entry_point='./debugger_custom_container_test_folder/your-training-script.py'
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-custom-container-test-',
    instance_count=1,
    instance_type='ml.p3.2xlarge',

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

# start training
estimator.fit()

Action on Amazon SageMaker Debugger Rules

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can
also create your own actions using Amazon CloudWatch Events and AWS Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

Topics
- Debugger Built-in Actions for Rules (p. 1727)
- Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 1731)

Debugger Built-in Actions for Rules

Use Debugger built-in actions to respond to issues found by Debugger Rule (p. 1678). The Debugger rule_configs class provides tools to configure a list of actions, including automatically stopping training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues.

Step 1: Set Up Amazon SNS, Create an SMDebugRules Topic, and Subscribe to the Topic

This section walks you through how to set up an Amazon SNS SMDebugRules topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

Note
For more information about billing for Amazon SNS, see Amazon SNS pricing and Amazon SNS FAQs.

To create a SMDebugRules topic
2. In the left navigation pane, choose Topics.
3. On the Topics page, choose Create topic.
4. On the Create topic page, in the Details section, do the following:
   a. For Type, choose Standard for topic type.
   b. In Name, enter SMDebugRules.
5. Skip all other optional settings and choose Create topic. If you want to learn more about the optional settings, see Creating an Amazon SNS topic.

To subscribe to the SMDebugRules topic
2. In the left navigation pane, choose Subscriptions.
3. On the Subscriptions page, choose Create subscription.
4. On the Create subscription page, in the Details section, do the following:
   b. For Protocol, choose Email or SMS.
   c. For Endpoint, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.

Note
Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.
5. Skip all other optional settings and choose **Create subscription**. If you want to learn more about the optional settings, see **Subscribing to an Amazon SNS topic**.

After you subscribe to the **SMDebugRules** topic, you receive the following confirmation message in email or by phone:

**AWS Notification - Subscription Confirmation**

![SNS Subscription](image)

You have chosen to subscribe to the topic:

`arn:aws:sns:*:111122223333:SMDebugRules`

To confirm this subscription, click or visit the link below (If this was in error no action is necessary):

[Confirm subscription](link)

Please do not reply directly to this email. If you wish to remove yourself from receiving all future SNS subscription confirmation requests please send an email to [sns-opt-out](mailto:sns-opt-out)

For more information about Amazon SNS, see **Mobile text messaging (SMS)** and **Email notifications** in the **Amazon SNS Developer Guide**.

**Step 2: Set Up Your IAM Role to Attach Required Policies**

In this step, you add the required policies to your IAM role.

**To add the required policies to your IAM role**

1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
2. In the left navigation pane, choose **Policies**, and choose **Create policy**.
3. On the **Create policy** page, do the following to create a new sns-access policy:
   
   a. Choose the **JSON** tab.
   b. Paste the JSON strings formatted in bold in the following code into the "Statement", replacing the 12-digit AWS account ID with your AWS account ID:

   ```json
   ```
   c. At the bottom of the page, choose **Review policy**.
   d. On the **Review policy** page, for Name, enter *sns-access*.
   e. At the bottom of the page, choose **Create policy**.
4. Go back to the IAM console, and choose **Roles** in the left navigation pane.

1728
5. Look up the IAM role that you use for SageMaker model training and choose that IAM role.
6. On the Permissions tab of the Summary page, choose Attach policies.
7. Search for the sns-access policy, select the check box next to the policy, and then choose Attach policy.

For more examples of setting up IAM policies for Amazon SNS, see Example cases for Amazon SNS access control.

**Step 3: Configure Debugger Rules with the Built-in Actions**

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the actions list object. The rule_configs is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- `rule_configs.StopTraining()` – Stops a training job when the Debugger rule finds an issue.
- `rule_configs.Email("abc@abc.com")` – Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- `rule_configs.SMS("+1234567890")` – Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

**Note**
Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.

You can use all of the built-in actions or a subset of actions by wrapping up using the `rule_configs.ActionList()` method, which takes the built-in actions and configures a list of actions.

**To add all of the three built-in actions to a single rule**

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```python
from sagemaker.debugger import Rule, rule_configs

# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule(), # Required
        rule_parameters={"paramter_key": value }, # Optional
        actions=actions
    )
]

estimator = Estimator(
    ...
```

1729
To create multiple built-in action objects to assign different actions to a single rule

If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules' name attribute) as shown in the following example script template. This example shows how to set up StalledTrainingRule (p. 1709) to take two different actions: send an email to abc@abc.com when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```python
from sagemaker.debugger import Rule, rule_configs
import time
base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)

# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

# Configure a rule with the Email built-in action to trigger if a training job stalls for 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "60",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_email
)
stalled_training_job_rule_email_text.name="StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "120",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_stop_training
)
stalled_training_job_rule.name="StalledTrainingJobRuleStopTraining"

estimator = Estimator(
    ...
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)
estimator.fit(wait=False)
```

While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.
The following screenshot shows an example text notification that Debugger sends when the rule finds a StalledTraining issue.

Considerations for Using the Debugger Built-in Actions

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker or Amazon VPC.
- The built-in actions cannot be used for Debugger ProfilerRule (p. 1677).
- The built-in actions cannot be used on training jobs with spot training interruptions.
- In email or text notifications, None appears at the end of messages. This does not have any meaning, so you can disregard the text None.

Create Actions on Rules Using Amazon CloudWatch and AWS Lambda

Amazon CloudWatch collects Amazon SageMaker model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and AWS Lambda to take action based on Debugger rule evaluation status.

CloudWatch Logs for Debugger Rules and Training Jobs

To find training job logs and Debugger rule job logs

2. In the left navigation pane under the Log node, choose Log Groups.
3. In the log groups list, do the following:
   - Choose /aws/sagemaker/TrainingJobs for training job logs.
• Choose `/aws/sagemaker/ProcessingJobs` for Debugger rule job logs.

You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues.

For more information about monitoring training jobs using CloudWatch, see [Monitor Amazon SageMaker](https://console.aws.amazon.com/sagemaker/).  

**Set Up Debugger for Automated Training Job Termination Using CloudWatch and Lambda**

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status.

**Step 1: Create a Lambda Function**

**To create a Lambda function**

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose **Functions** and then choose **Create function**.
3. On the **Create function** page, choose **Author from scratch** option.
4. In the **Basic information** section, enter a **Function name** (for example, `debugger-rule-stop-training-job`).
5. For **Runtime**, choose **Python 3.7**.
6. For **Permissions**, expand the drop down option, and choose **Change default execution role**.
7. For **Execution role**, choose **Use an existing role** and choose the IAM role that you use for training jobs on SageMaker.
   **Note**
   Make sure you use the execution role with `AmazonSageMakerFullAccess` and `AWSLambdaBasicExecutionRole` attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:

   ```python
   import sagemaker
   sagemaker.get_execution_role()
   ```

8. At the bottom of the page, choose **Create function**.

The following figure shows an example of the **Create function** page with the input fields and selections completed.
Step 2: Configure the Lambda function

To configure the Lambda function

1. In the **Function code** section of the configuration page, paste the following Python script in the Lambda code editor pane. The `lambda_handler` function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the `StopTrainingJob` API operation. The AWS SDK for Python (Boto3) `client` for SageMaker provides a high-level method, `stop_training_job`, which triggers the `StopTrainingJob` API operation.

```python
import json
import boto3
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)

def lambda_handler(event, context):
    training_job_name = event.get("detail").get("TrainingJobName")
    logging.info(f' Evaluating Debugger rules for training job: {training_job_name}')
```
eval_statuses = event.get("detail").get("DebugRuleEvaluationStatuses", None)

if eval_statuses is None or len(eval_statuses) == 0:
    logging.info("Couldn't find any debug rule statuses, skipping...")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

# should only attempt stopping jobs with InProgress status
training_job_status = event.get("detail").get("TrainingJobStatus", None)
if training_job_status != 'InProgress':
    logging.debug(f"Current Training job status({training_job_status}) is not 'InProgress'. Exiting")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

client = boto3.client('sagemaker')
for status in eval_statuses:
    logging.info(status.get("RuleEvaluationStatus") + ', RuleEvaluationStatus=' + str(status))
    if status.get("RuleEvaluationStatus") == "IssuesFound":
        secondary_status = event.get("detail").get("SecondaryStatus", None)
        logging.info(f'About to stop training job, since evaluation of rule configuration {status.get("RuleConfigurationName")} resulted in "IssuesFound". ' + f'\n\ntraining job "{training_job_name}" status is "{training_job_status}", secondary status is "{secondary_status}"' + f'\n\nAttempting to stop training job "{training_job_name}"'
    )
    try:
        client.stop_training_job(
            TrainingJobName=training_job_name
        )
    except Exception as e:
        logging.error("Encountered error while trying to " + "stop training job {}": {}.format( 
            training_job_name, str(e)
        )
    }
return None

For more information about the Lambda code editor interface, see Creating functions using the AWS Lambda console editor.

2. Skip all other settings and choose Save at the top of the configuration page.

**Step 3: Create a CloudWatch Events Rule and Link to the Lambda Function for Debugger**

**To create a CloudWatch Events rule and link to the Lambda function for Debugger**

2. In the left navigation pane, choose Rules under the Events node.
3. Choose Create rule.
4. In the **Event Source** section of the **Step 1: Create rule** page, choose **SageMaker** for **Service Name**, and choose **SageMaker Training Job State Change** for **Event Type**. The Event Pattern Preview should look like the following example JSON strings:

```json
{
    "source": [
        "aws.sagemaker"
    ],
    "detail-type": [
        "SageMaker Training Job State Change"
    ]
}
```

5. In the **Targets** section, choose **Add target***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.

6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.

7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.

8. Choose **Create rule** to finish.

9. Go back to the Lambda function configuration page and refresh the page. Confirm that it’s configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:

![Configuration panel with CloudWatch Events trigger configured](image)

**Run Example Notebooks to Test Automated Training Job Termination**

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using Debugger’s built-in rules.

- Amazon SageMaker Debugger - Reacting to CloudWatch Events from Debugger rules
This example notebook runs a training job that has a vanishing gradient issue. The Debugger VanishingGradient (p. 1697) built-in rule is used while constructing the SageMaker TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.

- Detect stalled training and stop training job using Debugger rule

This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger StalledTrainingRule (p. 1709) built-in rule invokes issues and stops the training job.

Disable the CloudWatch Events Rule to Stop Using the Automated Training Job Termination

If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda Designer panel, choose the EventBridge (CloudWatch Events) block linked to the Lambda function. This shows an EventBridge panel below the Designer panel (for example, see the previous screen shot). Select the check box next to EventBridge (CloudWatch Events): debugger-cw-event-rule, and then choose Disable. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

SageMaker Debugger on Studio

Use Debugger dashboards on Studio to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, CPU and GPU memory, Network, and data I/O) every 500 milliseconds and basic output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio UI or using the Amazon SageMaker Python SDK.

Important
If using existing SageMaker Studio apps, you need to restart them to use the new features. For instructions on how to restart and update your Studio environment, see Update Amazon SageMaker Studio.

Topics
- Open Amazon SageMaker Debugger Insights Dashboard (p. 1737)
Open Amazon SageMaker Debugger Insights Dashboard

Open the Debugger insights dashboard on Studio to see profiling progress and results of resource utilization and system bottlenecks of your training job running on EC2 instances.

**Note**

Studio Debugger insights dashboard runs a Studio app on an \texttt{ml.m5.4xlarge} instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the \texttt{ml.m5.4xlarge} instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

**Important**

When you are done using the Debugger insights dashboard, you must shut down the \texttt{ml.m5.4xlarge} instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the SageMaker Debugger Insights Instance (p. 1748).

**To open the Debugger insights dashboard**

1. Choose the SageMakerComponents and registries icon ( ).
2. Open the drop down menu, and choose Experiments and trials.
3. Look up your training job name. If you have not assigned a SageMaker Experiments trial component to the training job, the job is collected under the Unassigned trial components list.
4. **Right-click** (or an equivalent UI interaction) to open the context menu of the training job trial component. There are two menu items to access the Debugger features on Studio: Open Debugger for insights and Open in trial details.
5. Choose **Open Debugger for insights**. This opens a **Debug [your-training-job-name]** tab. In this tab, Debugger provides an overview of your model training performance on EC2 instances and identifies system bottleneck problems. While **monitoring** the system resource utilization, you can also enable **profiling** to capture framework metrics that consist of data from neural network operations executed during forward and backward pass and data loading. For more information about how to enable **profiling** using the Debugger insights dashboard controller, see **Enable and Configure Debugger Profiling for Detailed Insights** (p. 1739).

Debugger correlates the system resource utilization metrics with the framework metrics and helps identify resource-intensive operators that might be the root cause of the system bottlenecks. You can also download an aggregated Debugger profiling report. For more information, see **SageMaker Debugger Insights Dashboard Controller** (p. 1738).

### SageMaker Debugger Insights Dashboard Controller

There are different components of the Debugger Controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

**Note**

Studio Debugger insights dashboard runs a Studio app on an **ml.m5.4xlarge** instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the **ml.m5.4xlarge** instance usage. For information about pricing, see the **Amazon SageMaker Pricing** page.

**Important**

When you are done using the Debugger insights dashboard, you must shut down the **ml.m5.4xlarge** instance to avoid accruing charges. For instructions on how to shut down the instance, see **Shut Down the SageMaker Debugger Insights Instance** (p. 1748).

### SageMaker Debugger Insights Controller UI

Using the Debugger controller located at the upper-left corner of the insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics and profiling framework metrics, stop training job, and download Debugger profiling report.

- If you want to manually refresh the **Debug [your-training-job-name]** page, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceeding screenshot.

- **Monitoring** is on by default for any SageMaker training job. By monitoring your training job, Debugger only collects system metrics to detect resource utilization problems, such as CPU bottlenecks and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see **Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics)** (p. 1677).
• To download a comprehensive Debugger profiling report with details and analysis of a training job, choose **Download report**. For more information about the Debugger profiling report, see SageMaker Debugger Profiling Report (p. 1752).

**Enable and Configure Debugger Profiling for Detailed Insights**

When you enable **Profiling**, Debugger starts collecting framework metrics. Framework metrics are model data collected from ML framework operations of your model, such as forward pass, backward pass, batch normalization, and data loader processes. Debugger correlates system performance bottlenecks with the framework operations and runs the **Debugger Built-in Rules for Profiling Framework Metrics** (p. 1677).

**Note**

After you've enabled profiling, Debugger collects every framework operation call that's executed in each step: operations for convolving down input layers during forward pass, updating weights of millions of neurons during backward pass, and data loader processes. While profiling enables you to understand model performance at a deeper level, collecting framework metrics might impact your training time and performance. We recommend that you enable profiling to inspect your model up to two steps at a time. For more information about how to configure Debugger for framework profiling using Amazon SageMaker Python SDK, see Configure Debugger Framework Profiling (p. 1649) and Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 1653).

If you want to enable profiling while your training job is running, use the following steps to start profiling.

1. In SageMaker Studio, turn on **Profiling** to enable Debugger framework profiling. This opens a Debugger monitoring and profiling configuration page.

![Debugger monitoring and profiling configuration page](image)

2. In **Configure Debugger monitoring and profiling**, S3 bucket URI and **Collect monitoring data every** are already set to the default values.

   You can choose to change the monitoring interval using the drop down menu and selecting among the following available options: 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.
The following fields need to be specified:

- **S3 bucket URI** – Specify the base S3 bucket URI.
- **Collect monitoring data every** – Select a time interval to collect system metrics.

**Note**
If you choose one of the lower time intervals, you increase the granularity of monitoring system metrics. It allows you to capture spikes and anomalies with a higher time resolution. However, as the size of system metrics to process proportionally increases, it might impact the overall training and processing time.

3. **In Advanced settings for profiling**, configure framework metrics profiling options. Specify **Start step** (or **Start time**) and **Number of steps to profile** (or **Time duration to profile**) to profile. You can also leave the input fields blank. The default values will be automatically configured to use the current step and for 1 step duration.
• **Detailed profiling** – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

**Note**
The detailed profiling might significantly increase GPU memory consumption. It is not recommended to enable the detailed profiling for more than a couple of steps.

• **Python profiling** – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.

  • cProfile – The standard Python profiler. cProfile collects for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation of each function call, providing a complete detail of Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function calls executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

  • Pyinstrument – Pyinstrument is a low overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wallclock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noises (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

**Note**
Enabling Python profiling might result in slowing down the overall training time. In case of cProfile, Python operators that are the most frequently called are profiled at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

• **Dataloader profiling** – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.
Note
The data loader profiling can lower the training performance while collecting information from data loaders. We don't recommend that you enable the data loader profiling for more than a couple of steps. Debugger is pre-configured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes on any other custom or external containers.

4. Choose Confirm to finish your profiling configuration. When the configuration is successfully updated, you should be able to see the following confirmation message.

Image: Debugger configuration updated successfully

SageMaker Debugger Insights Dashboard Walkthrough

When you initiate a SageMaker training job, Debugger starts monitoring hardware system resource utilization of EC2 instances by default. You can track the system utilization rate, statistics overview, and bottleneck detection status and results through the Studio. This guide walks you through every component of the Studio Debugger insights dashboard.

Note
Studio Debugger insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important
When you are done using the Debugger insights dashboard, you must shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the SageMaker Debugger Insights Instance (p. 1748).

Topics
- Debugger Insights – Overview (p. 1742)
- Debugger Insights – Nodes (p. 1745)

Debugger Insights – Overview

On the Overview tab, you can find a training job summary, resource utilization summary, resource intensive operations, and insights.

Training job summary

The Training job summary section shows the overall training time spent on different phases of training: initialization, training loop, and finalization. The pie chart shows the time usage percentage and absolute time amount spent on the different training phases. For example, you can have a high-level overview of how long it takes for initializing a training job, check if the initialization is taking too long due to data downloading, leaving the GPUs idle.
This section has the following features:

- The **Training progress over time** chart shows the timeline of the different training phase over time. If using spot training, you can also find the spot interruptions in the timeline chart.

- The **Training job details** panel shows the exact time stamps and utilization rate percentage numbers.
  - **Start time** – The exact time when the training job started.
  - **End time** – The exact time when the training job finished.
  - **Job duration** – The total training time from the **Start time** to the **End time**.
  - **Training loop start** – The exact time when the first step of the first epoch has started.
  - **Training loop end** – The exact time when the last step of the last epoch has finished.
  - **Training loop duration** – The total time between the Training loop start time and the Training loop end time.
  - **Initialization** – Time spent on initializing the training job, such as compiling the training script, initiating EC2 instances, and downloading training data.
  - **Finalization** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances.
  - **Initialization (%)** – The percentage of time spent on **Initialization** over the total **Job duration**.
  - **Training loop (%)** – The percentage of time spent on **Training loop** over the total **Job duration**.
  - **Finalization (%)** – The percentage of time spent on **Finalization** over the total **Job duration**.

**Resource utilization summary**

This summary table shows hardware system resource utilization statistics of all workers (algo-n). System metrics include total CPU utilization, total GPU utilization, total CPU memory utilization, total GPU memory utilization, total I/O wait time, and total Network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.
Resource intensive operations

The Resource intensive operations section provides more detailed profiling results that show what operations of the training job were compute intensive. In the following example, it shows that the convolutional neural network backward pass operators were the most resource intensive on the GPUs.

| Node  | Type      | Max   | p90  | p50  | p10  | Max
|-------|-----------|-------|------|------|------|------
| algo-1| Network   | 2439946715.3 | 0    | 0    | 0    | 0
| algo-2| Network   | 0     | 0    | 0    | 0    | 0
| algo-1| GPU       | 75    | 74.25| 68.75| 0    | 0
| algo-2| GPU       | 75    | 74.25| 68    | 0    | 0
| algo-1| CPU       | 54.62 | 22.19| 15.11| 0    | 0
| algo-2| CPU       | 51.8  | 22.89| 15.43| 0.8  | 0
| algo-1| CPU memory| 5.04  | 5.05 | 4.92 | 0.87 | 0.55
| algo-2| CPU memory| 5     | 5    | 4.95 | 0.87 | 0.55
| algo-1| GPU memory| 56.75 | 24.82| 18.25| 0    | 0
| algo-2| GPU memory| 51.75 | 22.75| 14.5 | 0    | 0
| algo-1| I/O       | 22.16 | 6.25 | 0.57 | 0    | 0
| algo-2| I/O       | 21.88 | 6.25 | 0.62 | 0    | 0

Insights

In the Insights pane, you can find training issues detected by Debugger built-in rules. You can expand each of the list to find useful insights, suggestions, a description of the rule, and criteria of triggering the rule.

For more information about the Debugger built-in rules, see List of Debugger Built-in Rules (p. 1677).
Debugger Insights – Nodes

On the Studio Debugger Insight Nodes tab, Debugger provides detailed graphs that track each compute node on which your training jobs are running.

CPU and Network utilization

The first two graphs show CPU utilization and network utilization over time. By default, the graphs show the mean values: the average of CPU and network utilization over the total number of CPU cores. You can select one or more CPU cores, by selecting on the labels, to graph them on single chart and compare utilization across cores. The timeline graphs are interactive, and the two graphs are synced up. You can drag and zoom in and out to see specific time windows that you want to have a closer look.
The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of EC2 instance. The following figure shows an example training job on an ml.p3.16xlarge instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.
Overall system utilization over time

The following heatmap shows the entire system utilization over time projected onto the two-dimensional plot. Every CPU and GPU cores are listed in the vertical axis, and the utilization is recorded over time with colors. See the labeled colorbar on the right side of the plot to find out what color level corresponds to what utilization rate. For example, in the following heatmap, after initialization phase has ended around Sun 23:18, you can find that the training job fully utilizes an ml.p3.16xlarge instance: the GPU cores are fully utilized and the CPUs are moderately used for processing Python operations. There were several CPU bottleneck problems scattered across the CPUs at different times.

System resource utilization over time and framework event phase

The System metrics over time graph shows the overall CPU, GPU, and data I/O utilization. The Framework metrics over time graph shows the framework metrics, which are the framework event phases that you can correlate with the System metrics over time graph.

You can select a time interval of interest in the system resource usage timeline, and the framework event phase spots the interval to show what events happened during the selected time interval. In each event phase block, you can find what time interval was actually spent for training loop, and break the training loop into backward pass and forward pass events. Overall, you can see that actual training time intervals are occupying only a small percentage over the entire training time.
Time spent in training

In the following graph, framework metrics from the last 30 steps of the last training loop are captured. This graph shows cumulative time spent by different events in each step.

Shut Down the SageMaker Debugger Insights Instance

When you are not using the Debugger insights dashboard, it is important to shut down the instance on which it runs to avoid incurring additional fees.

To shut down the Debugger insights instance in Studio
1. In Studio, select the **Running Instances and Kernels** icon ( ).

2. Under the **RUNNING APPS** list, look for the **sagemaker-debugger-1.0** app. Select the shut down icon ( ) next to the app. The Debugger insights dashboards run on an **ml.m5.4xlarge** instance. This instance also disappears from the **RUNNING INSTANCES** when you shut down the **sagemaker-debugger-1.0** app.

## SageMaker Debugger on Studio Experiments

In this section, you learn how to use the Debugger in Studio Experiments. You can select any training jobs from the Experiment trial list to see the model output data graphs, such as accuracy and loss curves, debugging built-in rule status, and Debugger configuration information for debugging.

### Visualize Tensors Using SageMaker Debugger and Studio

SageMaker Studio provides visualizations to interpret tensor outputs that are captured by Debugger.

### Loss Curves While Training Is in Progress

The following screenshot shows visualizations of loss curves for training. The training is in progress.
Analyzing Training Jobs: Comparing Loss Curves Across Multiple Jobs

SageMaker Studio enables you to compare across multiple jobs (in this case, the loss). This helps you identify the best-performing training jobs.

Rules Triggering and Logs from Jobs

When rules are triggered for anomalous conditions, SageMaker Studio presents logs for the failing rule. This enables you to analyze the causes of the condition.
SageMaker Debugger Interactive Reports

Receive training and profiling reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see SageMaker Debugger Profiling Report (p. 1752).

**Note**

You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

**Topics**

- SageMaker Debugger Profiling Report (p. 1752)
- SageMaker Debugger XGBoost Training Report (p. 1763)
SageMaker Debugger Profiling Report

For any SageMaker training jobs, the Debugger ProfilerReport (p. 1679) rule invokes all of the monitoring and profiling rules (p. 1677) and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the Amazon SageMaker Python SDK or the S3 console, and learn what you can interpret from the profiling results.

Topics

- Download a Debugger Profiling Report (p. 1752)
- Debugger Profiling Report Walkthrough (p. 1755)

Download a Debugger Profiling Report

Download the Debugger profiling report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

Tip

You can also download the report with one click and no additional scripting through the SageMaker Studio Debugger insights dashboard. To find out how to download the report from Studio, see Open Amazon SageMaker Debugger Insights Dashboard (p. 1737).

Download using SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.

   \[\texttt{estimator.output\_path}\]

2. Check the current job name.

   \[\texttt{estimator.latest\_training\_job\_job\_name}\]
3. The Debugger profiling report is stored under `<default-s3-output-base-uri>/training-job-name/rule-output`. Configure the rule output path as follows:

```python
rule_output_path = estimator.output_path + estimator.latest_training_job.job_name + "/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

```bash
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under an autogenerated folder that's named as `ProfilerReport-1234567890`. The folder name is a combination of strings: `ProfilerReport` and a unique 10-digit tag based on the Unix timestamp when the `ProfilerReport` rule is initiated.

The `profiler-report.html` is an autogenerated profiling report by Debugger. The remaining files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are used to aggregate them into the report.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```bash
! aws s3 cp {rule_output_path} ./ --recursive
```

**Tip**
If using a Jupyter notebook server, run `!pwd` to double check the current working directory.

6. Under the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.html`. If using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger profiling report.

7. Open the `profiler-report.ipynb` file to explore how the report is generated. You can also customize and extend the profiling report using the Jupyter notebook file.

---

**Download using Amazon S3 Console**

1. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).

2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the **Find bucket by name** field.
3. In the base S3 bucket, look up the training job name by specifying your job name prefix into the Find objects by prefix input field. Choose the training job name.

4. In the training job's S3 bucket, there must be three subfolders for training data collected by Debugger: `debug-output/`, `profiler-output/`, and `rule-output/`. Choose `rule-output/`.

5. In the `rule-output/` folder, choose `ProfilerReport-1234567890`, and choose `profiler-output/` folder. The `profiler-output/` folder contains `profiler-report.html` (the autogenerated profiling report in html), `profiler-report.ipynb` (a Jupyter notebook with scripts that are used for generating the report), and a `profiler-report/` folder (contains rule analysis JSON files that are used as components of the report).

6. Select the `profiler-report.html` file, choose Actions, and Download.
7. Open the downloaded `profiler-report.html` file in a web browser.

**Note**
If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics profiling and receive an extended Debugger profiling report, configure the `profiler_config` parameter when constructing or updating SageMaker estimators. To learn how to configure the `profiler_config` parameter before starting a training job, see Configure Debugger Framework Profiling (p. 1649). To update the current training job and enable framework metrics profiling, see Update Debugger Framework Profiling Configuration (p. 1653).

**Debugger Profiling Report Walkthrough**
This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

**Topics**
- Training Job Summary (p. 1756)
- System Usage Statistics (p. 1757)
- Framework metrics summary (p. 1757)
- Rules Summary (p. 1759)
- Analyzing the Training Loop – Step Durations (p. 1760)
- GPU Utilization Analysis (p. 1760)
Training Job Summary

At the beginning of the report, Debugger provides a summary of your training job. In this section, you can overview the time durations and timestamps at different training phases.

The following table gives a summary about the training job. The table includes information about when the training job started and ended, how much time initialization, training loop and finalization took. Your training job started on 11/09/2020 at 20:12:42 and ran for 707 seconds.

<table>
<thead>
<tr>
<th>#</th>
<th>Job Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>start_time 20:12:42 11/09/2020</td>
</tr>
<tr>
<td>1</td>
<td>end_time 20:24:59 11/09/2020</td>
</tr>
<tr>
<td>2</td>
<td>job_duration_in_seconds 757 seconds</td>
</tr>
<tr>
<td>3</td>
<td>training_loop_start 20:17:31 11/09/2020</td>
</tr>
<tr>
<td>4</td>
<td>training_loop_end 20:44:59 11/09/2020</td>
</tr>
<tr>
<td>5</td>
<td>training_loop_duration 448 seconds</td>
</tr>
<tr>
<td>6</td>
<td>initialization_time 288 seconds</td>
</tr>
<tr>
<td>7</td>
<td>finalization_time 9 seconds</td>
</tr>
<tr>
<td>8</td>
<td>initialization 39 %</td>
</tr>
<tr>
<td>9</td>
<td>training_loop 50 %</td>
</tr>
<tr>
<td>10</td>
<td>finalization 0 %</td>
</tr>
</tbody>
</table>

The summary table contains the following information:

- **start_time** – The exact time when the training job started.
- **end_time** – The exact time when the training job finished.
- **job_duration_in_seconds** – The total training time from the start_time to the end_time.
- **training_loop_start** – The exact time when the first step of the first epoch has started.
- **training_loop_end** – The exact time when the last step of the last epoch has finished.
- **training_loop_duration_in_seconds** – The total time between the training loop start time and the training loop end time.
- **initialization_in_seconds** – Time spent on initializing the training job. The initialization phase covers the period from the start_time to the training_loop_start time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
- **finalization_in_seconds** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the training_loop_end time to the end_time.
- **initialization (%)** – The percentage of time spent on initialization over the total job_duration_in_seconds.
- **training loop (%)** – The percentage of time spent on training loop over the total job_duration_in_seconds.
- **finalization (%)** – The percentage of time spent on finalization over the total job_duration_in_seconds.
System Usage Statistics

In this section, you can see an overview of system utilization statistics.

### System usage statistics

The 95th quantile of the total GPU utilization on node algo-2 is 74%. GPUs on node algo-2 are well utilized.

The following table shows usage statistics per worker node such as total CPU and GPU utilization, total CPU and memory footprint. The table also include total IO wait time and total sent/received bytes. The table shows min and max values as well as p99, p95 and p50 percentiles.

<table>

</tr>
</tbody>
</table>

The Debugger profiling report includes the following information:

- **node** – Lists the name of nodes. If using distributed training on multi nodes (multiple EC2 instances), the node names are in format of algo-n.
- **metric** – The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.
- **unit** – The unit of the system metrics.
- **max** – The maximum value of each system metric.
- **p99** – The 99th percentile of each system utilization.
- **p95** – The 95th percentile of each system utilization.
- **p50** – The 50th percentile (median) of each system utilization.
- **min** – The minimum value of each system metric.

**Framework metrics summary**

In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.
Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.
- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.

**Overview: CPU Operators**

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.
Overview: GPU Operators

This section provides information of the GPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called GPU operators.

## Overview: GPU operators

The following table shows a list of operators that your training job run on GPU. The most expensive operator on GPU was "CudnnConvolutionBackward" with 54%.

<table>

### Rules Summary

In this section, Debugger aggregates all of the rule evaluation results, analysis, rule descriptions, and suggestions.

#### Rules summary

The following table shows a summary of the executed profiler rules. The table is sorted by the rules that triggered most frequently. In your training job this was the case for rule `LoadBalancing`. It has processed 9,476 data points and triggered 263 times.

<table>
<thead>
<tr>

</tbody>
</table>
Analyzing the Training Loop – Step Durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that's causing step duration outliers.

GPU Utilization Analysis

This section shows the detailed statistics about GPU core utilization based on LowGPUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

Batch Size

This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.
CPU Bottlenecks

In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above \( \text{cpu\_threshold} \) (90% by default) and also if the GPU utilization is below \( \text{gpu\_threshold} \) (10% by default).

- **Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.

The pie charts show the following information:

- **Low GPU usage caused by CPU bottlenecks**
- **Ratio between TRAIN/EVAL phase and others**
- **Ratio between forward and backward pass**

The following pie chart shows a breakdown of the CPU/GPU operations that happened during CPU bottlenecks. It shows that 24% of the time was spent in executing operations on CPU functions.
• **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.

• **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

### I/O Bottlenecks

In this section, you can find a summary of I/O bottlenecks. The rule evaluates the I/O wait time and GPU utilization rates and monitors if the time spent on the I/O requests exceeds a threshold percent of the total training time. It might indicate I/O bottlenecks where GPUs are waiting for data to arrive from storage.

### LoadBalancing in Multi-GPU Training

In this section, you can identify workload balancing issue across GPUs.

![Workloads on node algo-1](image)

### GPU Memory Analysis

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.

![Node algo-1](image)
SageMaker Debugger XGBoost Training Report

For SageMaker XGBoost training jobs, use the Debugger CreateXgboostReport (p. 1689) rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the CreateXgboostReport (p. 1689) rule while constructing an XGBoost estimator, download the report using the Amazon SageMaker Python SDK or the Amazon S3 console, and then you can interpret the profiling results.

Topics

- Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule (p. 1763)
- Download the Debugger XGBoost Training Report (p. 1764)
- Debugger XGBoost Training Report Walkthrough (p. 1766)

Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule

When you construct a SageMaker estimator for an XGBoost training job, specify the rule as shown in the following example code.

The CreateXgboostReport (p. 1689) rule collects the following output tensors from your training job:

- hyperparameters – Saves at the first step.
- metrics – Saves loss and accuracy every 5 steps.
- feature_importance – Saves every 5 steps.
- predictions – Saves every 5 steps.
- labels – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/.

Using the SageMaker generic estimator

```python
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.create_xgboost_report())
]

region = boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-xgboost-report-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",
    # Add the Debugger XGBoost report rule
    rules=rules
)

estimator.fit(wait=False)
```

1763
Download the Debugger XGBoost Training Report

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

Download using the SageMaker Python SDK and AWS CLI

1. Check the current job’s default S3 output base URI.

   ```python
   estimator.output_path
   ```

2. Check the current job name.

   ```python
   estimator.latest_training_job.job_name
   ```

3. The Debugger XGBoost report is stored under `<default-s3-output-base-uri>/training-job-name>/rule-output`. Configure the rule output path as follows:

   ```python
   rule_output_path = estimator.output_path + "/" + estimator.latest_training_job.job_name + "/rule-output"
   ```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

   ```bash
   ! aws s3 ls {rule_output_path} --recursive
   ```

This should return a complete list of files under autogenerated folders that are named `CreateXgboostReport` and `ProfilerReport-1234567890`. The XGBoost training report is stored in the `CreateXgboostReport`, and the profiling report is stored in the `ProfilerReport-1234567890` folder. To learn more about the profiling report generated by default with the XGBoost training job, see SageMaker Debugger Profiling Report (p. 1752).

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

   ```bash
   ! aws s3 cp {rule_output_path} ./ --recursive
   ```

   **Tip**
   If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger training report.

The `xgboost_report.html` is an autogenerated XGBoost training report by Debugger. The `xgboost_report.ipynb` is a Jupyter notebook that’s used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

   ```bash
   ! aws s3 cp {rule_output_path} ./ --recursive
   ```

   **Tip**
   If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger training report.
7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Search for the base S3 bucket. For example, if you haven’t specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the `Find bucket by name` field.

3. In the base S3 bucket, look up the training job name by entering your job name prefix in `Find objects by prefix` and then choosing the training job name.

4. In the training job’s S3 bucket, choose `rule-output/` subfolder. There must be three subfolders for training data collected by Debugger: `debug-output/`, `profiler-output/`, and `rule-output/`. 
5. In the `rule-output/` folder, choose the `CreateXgboostReport/` folder. The folder contains `xbgoost_report.html` (the autogenerated report in html) and `xbgoost_report.ipynb` (a Jupyter notebook with scripts that are used for generating the report).

6. Choose the `xbgoost_report.html` file, choose **Download actions**, and then choose **Download**.

7. Open the downloaded `xbgoost_report.html` file in a web browser.

**Debugger XGBoost Training Report Walkthrough**

This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.

**Topics**
- Distribution of True Labels of the Dataset (p. 1767)
- Loss versus Step Graph (p. 1767)
• Feature Importance (p. 1768)
• Confusion Matrix (p. 1769)
• Evaluation of the Confusion Matrix (p. 1770)
• Accuracy Rate of Each Diagonal Element Over Iteration (p. 1771)
• Receiver Operating Characteristic Curve (p. 1772)
• Distribution of Residuals at the Last Saved Step (p. 1773)
• Absolute Validation Error per Label Bin Over Iteration (p. 1774)

Distribution of True Labels of the Dataset

This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.

Loss versus Step Graph

This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.
Feature Importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.
Confusion Matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it's also important to know the false positive rate and false negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.
Evaluation of the Confusion Matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.
Accuracy Rate of Each Diagonal Element Over Iteration

This visualization is only applicable to binary classification and multiclass classification models. This is a line chart that plots the diagonal values in the confusion matrix throughout the training steps for each class. This plot shows you how the accuracy of each class progresses throughout the training steps. You can identify the under-performing classes from this plot.
Receiver Operating Characteristic Curve

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPF) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).
Distribution of Residuals at the Last Saved Step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that’s centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.
Absolute Validation Error per Label Bin Over Iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.
## Analyze Data Using the SMDebug Client Library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the Amazon SageMaker Python SDK and the SMDebug client library. The SMDebug library provides analysis and visualization tools that enable you to drill down into your training job data.

### To install the library and use the SMDebug analysis tools (in a JupyterLab notebook or an iPython kernel)

```bash
! pip install -U smdebug
```

The following topics walk you through how to use the SMDebug tools to visualize and analyze the training data collected by Debugger.

### Analyze system and framework metrics

- Access the Monitoring and Profiling Data (p. 1775)
- Plot the System Metrics and Framework Metrics Data (p. 1776)
- Access the Profiling Data Using the Pandas Data Parsing Tool (p. 1777)
- Access the Python Profiling Stats Data (p. 1778)
- Merge Timelines of Different Profiling Trace Files (p. 1780)
- Profiling Data Loader (p. 1782)

### Access the Monitoring and Profiling Data

The SMDebug `TrainingJob` class reads data from the S3 bucket where the system and framework metrics are saved.

#### To set up a `TrainingJob` object and retrieve profiling event files of a training job

```python
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob
tj = TrainingJob(training_job_name, region)
```

**Tip**

You need to specify the `training_job_name` and `region` parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.

```python
import sagemaker
training_job_name=estimator.latest_training_job.job_name
region=sagemaker.Session().boto_region_name
```

- Pass strings directly.

```python
training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
region="us-west-2"
```

**Note**

By default, SageMaker Debugger collects system metrics to monitor hardware resource utilization and system bottlenecks. Running the following functions, you might receive error messages regarding unavailability of framework metrics. To retrieve framework profiling data and gain insights into framework operations, you must enable framework profiling.
• If you use SageMaker Python SDK to manipulate your training job request, pass the `framework_profile_params` to the `profiler_config` argument of your estimator. To learn more, see Configure SageMaker Debugger Framework Profiling.

• If you use Studio, turn on profiling using the Profiling toggle button in the Debugger insights dashboard. To learn more, see SageMaker Debugger Insights Dashboard Controller.

To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved

```python
tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()
```

To check if the system and framework metrics are available from the S3 URI

```python
tj.wait_for_sys_profiling_data_to_be_available()
tj.wait_for_framework_profiling_data_to_be_available()
```

To create system and framework reader objects after the metric data become available

```python
system_metrics_reader = tj.get_systems_metrics_reader()
framework_metrics_reader = tj.get_framework_metrics_reader()
```

To refresh and retrieve the latest training event files

The reader objects have an extended method, `refresh_event_file_list()`, to retrieve the latest training event files.

```python
system_metrics_reader.refresh_event_file_list()
framework_metrics_reader.refresh_event_file_list()
```

Plot the System Metrics and Framework Metrics Data

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

**Note**

To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify `select_dimensions` and `select_events` parameters. For example, if you specify `select_dimensions=\["GPU"\]`, the plot methods filter the metrics that include the "GPU" keyword. If you specify `select_events=\["total"\]`, the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

- The `MetricsHistogram` class

```python
from smdebug.profiler.analysis.notebook_utils.metrics_histogram import MetricsHistogram

metrics_histogram = MetricsHistogram(system_metrics_reader)
metrics_histogram.plot(
    starttime=0,
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),
    select_dimensions=\["CPU", "GPU", "I/O"\], # optional
    select_events=\["total"\] # optional
)
```
• The **StepTimelineChart** class

```python
from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import StepTimelineChart
view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)
```

• The **StepHistogram** class

```python
from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram
step_histogram = StepHistogram(framework_metrics_reader)
step_histogram.plot(
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
    endtime=step_histogram.last_timestamp,
    show_workers=True
)
```

• The **TimelineCharts** class

```python
from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts
view_timeline_charts = TimelineCharts(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=['CPU', 'GPU', 'I/O'], # optional
    select_events=['total']                  # optional
)
view_timeline_charts.plot_detailed_profiler_data([700, 710])
```

• The **Heatmap** class

```python
from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap
view_heatmap = Heatmap(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=['CPU', 'GPU', 'I/O'], # optional
    select_events=['total'],                 # optional
    plot_height=450
)
```

---

**Access the Profiling Data Using the Pandas Data Parsing Tool**

The following **PandasFrame** class provides tools to convert the collected profiling data to Pandas data frame.

```python
from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame
```

The **PandasFrame** class takes the *tj* object's S3 bucket output path, and its methods

- `get_all_system_metrics()` return system metrics and
- `get_all_framework_metrics()` return framework metrics in the Pandas data format.

```python
pf = PandasFrame(tj.profiler_s3_output_path)
system_metrics_df = pf.get_all_system_metrics()
framework_metrics_df = pf.get_all_framework_metrics(
    selected_framework_metrics=[
        'Step:ModeKeys.TRAIN',
    ]
)```

Access the Python Profiling Stats Data

The Python profiling provides framework metrics related to Python functions and operators in your training scripts and the SageMaker deep learning frameworks.

Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger provides tools to set modes and phases.

For training modes, use the following `PythonProfileModes` class:

```python
from smdebug.profiler.python_profile_utils import PythonProfileModes
```

This class provides the following options:

- `PythonProfileModes.TRAIN` – Use if you want to profile the target steps in the training phase. This mode option available only for TensorFlow.
- `PythonProfileModes.EVAL` – Use if you want to profile the target steps in the evaluation phase. This mode option available only for TensorFlow.
- `PythonProfileModes.PREDICT` – Use if you want to profile the target steps in the prediction phase. This mode option available only for TensorFlow.
- `PythonProfileModes.GLOBAL` – Use if you want to profile the target steps in the global phase, which includes the previous three phases. This mode option available only for PyTorch.
- `PythonProfileModes.PRE_STEP_ZERO` – Use if you want to profile the target steps in the initialization stage before the first training step of the first epoch starts. This phase includes the initial job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and downloading input data. This mode option available for both TensorFlow and PyTorch.
- `PythonProfileModes.POST_HOOK_CLOSE` – Use if you want to profile the target steps in the finalization stage after the training job has done and the Debugger hook is closed. This phase includes profiling data while the training jobs are finalized and completed. This mode option available for both TensorFlow and PyTorch.

For training phases, use the following `StepPhase` class:

```python
from smdebug.profiler.analysis.utils.python_profile_analysis_utils import StepPhase
```

This class provides the following options:

- `StepPhase.START` – Use to specify the start point of the initialization phase.
- `StepPhase.STEP_START` – Use to specify the start step of the training phase.
- `StepPhase.FORWARD_PASS_END` – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- `StepPhase.STEP_END` – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- `StepPhase.END` – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

Python Profiling Analysis Tools
Debugger supports the Python profiling with two profiling tools:

- cProfile – The standard python profiler. cProfile collects framework metrics on CPU time for every function called when profiling was enabled.
- Pyinstrument – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options (p. 1651).

The following methods of the PythonProfileAnalysis, cProfileAnalysis, PyinstrumentAnalysis classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.

```python
from smdebug.profiler.analysis.python_profile_analysis import PythonProfileAnalysis, cProfileAnalysis, PyinstrumentAnalysis
```

To set Python profiling objects for analysis, use the cProfileAnalysis or PyinstrumentAnalysis classes as shown in the following example code. It shows how to set a cProfileAnalysis object, and if you want to use PyinstrumentAnalysis, replace the class name.

```python
python_analysis = cProfileAnalysis(
    local_profile_dir=tf_python_stats_dir,
    s3_path=tj.profiler_s3_output_path
)
```

The following methods are available for the cProfileAnalysis and PyinstrumentAnalysis classes to fetch the Python profiling stats data:

- `python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_secs, end_time_since_epoch_in_secs)` – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.
- `python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)` – Takes in a start step and end step and returns the function stats of all step stats whose profiled step satisfies `start_step <= step < end_step`.
  - `start_step` and `end_step` (str) – Specify the start step and end step to fetch the Python profiling stats data.
  - `mode` (str) – Specify the mode of training job using the PythonProfileModes enumerator class. The default is PythonProfileModes.TRAIN. Available options are provided in the Training Modes and Phases for Python Profiling (p. 1778) section.
  - `start_phase` (str) – Specify the start phase in the target step(s) using the StepPhase enumerator class. This parameter enables profiling between different phases of training. The default is StepPhase.STEP_START. Available options are provided in the Training Modes and Phases for Python Profiling (p. 1778) section.
  - `end_phase` (str) – Specify the end phase in the target step(s) using the StepPhase enumerator class. This parameter sets up the end phase of training. Available options are as same as the ones for the `start_phase` parameter. The default is StepPhase.STEP_END. Available options are provided in the Training Modes and Phases for Python Profiling (p. 1778) section.
- `python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)` – Fetches stats from the Python profiling between the start and end modes.
- `python_analysis.fetch_pre_step_zero_profile_stats()` – Fetches the stats from the Python profiling until step 0.
- `python_analysis.fetch_post_hook_close_profile_stats()` – Fetches stats from the Python profiling after the hook is closed.
Analyze Data Using the SMDebug Client Library

- `python_analysis.list_profile_stats()` — Returns a DataFrame of the Python profiling stats. Each row holds the metadata for each instance of profiling and the corresponding stats file (one per step).
- `python_analysis.list_available_node_ids()` — Returns a list the available node IDs for the Python profiling stats.

The `cProfileAnalysis` class specific methods:

- `fetch_profile_stats_by_training_phase()` — Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are `(PRE_STEP_ZERO, TRAIN), (TRAIN, TRAIN), (TRAIN, EVAL), (EVAL, EVAL), and (EVAL, POST_HOOK_CLOSE)`. All stats files within each of these combinations are aggregated.
- `fetch_profile_stats_by_job_phase()` — Fetches and aggregates the Python profiling stats by job phase. The job phases are initialization (profiling until step 0), training_loop (training and validation), and finalization (profiling after the hook is closed).

Merge Timelines of Different Profiling Trace Files

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

**Tip**
Before proceeding, you need to set a TrainingJob object that will be utilized throughout the examples in this page. For more information about setting up a TrainingJob object, see Access the Monitoring and Profiling Data (p. 1775).

The `MergedTimeline` class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default `tracefolder` directory.

- For annotations in the Python layers, the trace files are saved in `*pythontimeline.json`.
- For annotations in the TensorFlow C++ layers, the trace files are saved in `*model_timeline.json`.
- Tensorflow profiler saves events in a `*trace.json.gz` file.

**Tip**
If you want to list all of the JSON trace files, use the following AWS CLI command:

```
aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '.json$'
```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.
Tip
To interact with the merged timeline on the tracing app using a keyboard, use the W key for
zooming in, the A key for shifting to the left, the S key for zooming out, and the D key for
shifting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file
using the following MergedTimeline API operation and class method from the
smdebug.profiler.analysis.utils.merge_timelines module.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The MergedTimeline API operation passes the following parameters:

- **path** (str) – Specify a root folder (/profiler-output) that contains system and framework profiling
  trace files. You can locate the profiler-output using the SageMaker estimator classmethod or the TrainingJob object. For example, estimator.latest_job_profiler_artifacts_path() or
tj.profiler_s3_output_path.
- **file_suffix_filter** (list) – Specify a list of file suffix filters to merge timelines. Available suffix
c filters are ["model_timeline.json", "pythontimeline.json", "trace.json.gz"]. If this
parameter is not manually specified, all of the trace files are merged by default.
- **output_directory** (str) – Specify a path to save the merged timeline JSON file. The default is to the
directory specified for the path parameter.

The merge_timeline() classmethod passes the following parameters to execute the merging process:

- **start** (int) – Specify start time (in microseconds and in Unix time format) or start step to merge
timelines.
- **end** (int) – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
• unit (str) – Choose between "time" and "step". The default is "time".

Using the following example codes, execute the merge_timeline() method and download the merged JSON file.

• Merge timeline with the "time" unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```python
import time
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

• Merge timeline with the "step" unit option. The following example code merges all available timelines between step 3 and step 9.

```python
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(3, 9, unit="step")
```

Open the Chrome tracing app at chrome://tracing on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

### Profiling Data Loader

In PyTorch, data loader iterators, such as SingleProcessingDataLoaderIter and MultiProcessingDataLoaderIter, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and pin_memory threads.

To use the PyTorch data loader profiling analysis tool, import the following PT_dataloader_analysis class:

```python
from smdebug.profiler.profiler_analysis.utils.pytorch_dataloader_analysis import PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the Access the Profiling Data Using the Pandas Data Parsing Tool (p. 1777) section:

```python
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the pt_analysis object:

- `pt_analysis.analyze_dataloaderIter_initialization()`

  The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e duration is greater than 2 * median), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.
The following list shows what analysis is available from this class method:
- Which type of data loader iterators were initialized.
- The number of workers per iterator.
- Inspect whether the iterator was initialized with or without pin\_memory.
- Number of times the iterators were initialized during training.

```
pt_analysis.analyze_dataloaderWorkers()
```

The following list shows what analysis is available from this class method:
- The number of worker processes that were spun off during the entire training.
- Median and maximum duration for the worker processes.
- Start and end time for the worker processes that are outliers.

```
pt_analysis.analyze_dataloader\_getnext()
```

The following list shows what analysis is available from this class method:
- Number of GetNext calls made during the training.
- Median and maximum duration in microseconds for GetNext calls.
- Start time, End time, duration and worker id for the outlier GetNext call duration.

```
pt_analysis.analyze\_batchtime(start\_timestamp, end\_timestamp,
select\_events="\.*", select\_dimensions="\.*")
```

Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.

The following list shows what analysis is available from this class method:
- Profile time spent on each data batch, BatchTime\_in\_seconds, by finding the difference between start times of current and subsequent GetNext calls.
- Find the outliers in BatchTime\_in\_seconds and start and end time for those outliers.
- Obtain the system and framework metrics during those BatchTime\_in\_seconds timestamps. This indicates where the time was spent.

```
pt_analysis.plot\_the\_window()
```

Plots a timeline charts between a start timestamp and the end timestamp.

**Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard**

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.
You can enable this by passing `DebuggerHookConfig` and `TensorBoardOutputConfig` objects to an estimator.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container's local path (the default path is `/opt/ml/output/tensors`) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

**To save TensorBoard compatible output tensor files using Debugger**

1. Set up a `tensorboard_output_config` configuration object to save TensorBoard output using the Debugger `TensorBoardOutputConfig` class. For the `s3_output_path` parameter, specify the default S3 bucket of the current SageMaker session or a preferred S3 bucket. This example does not add the `container_local_output_path` parameter; instead, it is set to the default local path `/opt/ml/output/tensors`.

   ```python
   import sagemaker
   from sagemaker.debugger import TensorBoardOutputConfig

   bucket = sagemaker.Session().default_bucket()
   tensorboard_output_config = TensorBoardOutputConfig(
       s3_output_path='s3://{}'.format(bucket)
   )
   ```

   For additional information, see the Debugger `TensorBoardOutputConfig` API in the Amazon SageMaker Python SDK.

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the weights parameters every 500 steps (the default `save_interval` value for saving tensor collections is 500), and the bias parameters every 10 global steps until the global step reaches 500.

   ```python
   from sagemaker.debugger import CollectionConfig, DebuggerHookConfig
   
   hook_config = DebuggerHookConfig(
       hook_parameters={
           "train.save_interval": "100",
           "eval.save_interval": "10"
       },
   )
   ```
Visualize Debugger Output Tensors in TensorBoard

```python
collection_configs=[
    CollectionConfig("weights"),
    CollectionConfig(
        name="biases",
        parameters={
            "save_interval": "10",
            "end_step": "500",
            "save_histogram": "True"
        }
    ),
]
```

For more information about the Debugger configuration APIs, see the Debugger `CollectionConfig` and `DebuggerHookConfig` APIs in the Amazon SageMaker Python SDK.

3. Construct a SageMaker estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker estimator. You can replace `estimator` and `Estimator` with other SageMaker frameworks' estimator parent classes and estimator classes. Available SageMaker framework estimators for this functionality are `TensorFlow`, `PyTorch`, and `MXNet`.

```python
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...
    # Debugger parameters
d_debugger_hook_config=hook_config,
    tensorboard_output_config=tensorboard_output_config
)
estimator.fit()
```

The `estimator.fit()` method starts a training job, and Debugger writes the output tensor files in real time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:

- For the Debugger S3 output path, use `estimator.latest_job_debugger_artifacts_path()`.
- For the TensorBoard S3 output path, use `estimator.latest_job_tensorboard_artifacts_path()`.

4. After the training has completed, check the names of saved output tensors:

```python
from smdebug.trials import create_trial

trial = create_trial(estimator.latest_job_debugger_artifacts_path())
trial.tensor_names()
```

5. Check the TensorBoard output data in Amazon S3:

```bash
tensorboard_output_path=estimator.latest_job_tensorboard_artifacts_path()
print(tensorboard_output_path)
!aws s3 ls {tensorboard_output_path}/
```

6. Download the TensorBoard output data to your notebook instance. For example, the following AWS CLI command downloads the TensorBoard files to `/logs/fit` under the current working directory of your notebook instance.

```bash
!aws s3 cp --recursive {tensorboard_output_path} ./logs/fit
```

7. Compress the file directory to a TAR file to download to your local machine.
Best Practices for Amazon SageMaker Debugger

Use the following guidelines when you run training jobs with Debugger.

Topics
- Choose a Machine Learning Framework (p. 1786)
- Use Studio Debugger Insights Dashboard (p. 1786)
- Download Debugger Reports and Gain More Insights (p. 1786)
- Capture Data from Your Training Job and Save Data to Amazon S3 (p. 1787)
- Analyze the Data with a Fleet of Debugger Built-in Rules (p. 1787)
- Take Actions Based on the Built-in Rule Status (p. 1787)
- Dive Deep into the Data Using the SMDebug Client Library (p. 1787)
- Monitor and Analyze Training Job Metrics (p. 1787)
- Monitoring System Utilization and Detect Bottlenecks (p. 1788)
- Profiling Framework Operations (p. 1788)
- Debugging Model Output Tensors (p. 1788)

Choose a Machine Learning Framework

You can choose a machine learning framework and use SageMaker pre-built training containers or your own containers. Use Debugger to detect training and performance issues, and analyze training progress of your training job in SageMaker. SageMaker provides you options to use pre-built containers that are prepared for a number of machine learning framework environments to train your model on Amazon EC2. Any training job can be adapted to run in AWS Deep Learning Containers, SageMaker training containers, and custom containers. To learn more, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1644) and Use Debugger with Custom Training Containers (p. 1723).

Use Studio Debugger Insights Dashboard

With Studio Debugger insights dashboard, you are in control of your training jobs. Use the Studio Debugger dashboards to keep your model performance on Amazon EC2 instances in control and optimized. For any SageMaker training jobs running on Amazon EC2 instance, Debugger monitors resource utilization and basic model output data (loss and accuracy values). Through the Studio Debugger dashboards, gain insights into your training jobs and improve your model training performance. To learn more, see SageMaker Debugger on Studio (p. 1736).

Download Debugger Reports and Gain More Insights

You can view aggregated results and gain insights in Debugger reports. Debugger aggregates training and profiling results collected from the built-in rule analysis into a report per training job. You can find
more detailed information about your training results through the Debugger reports. To learn more, see SageMaker Debugger Interactive Reports (p. 1751).

**Capture Data from Your Training Job and Save Data to Amazon S3**

You can use a Debugger hook to save output tensors. After you choose a container and a framework that fit your training script, use a Debugger hook to configure which tensors to save and to which directory to save them, such as a Amazon S3 bucket. A Debugger hook helps you to build the configuration and to keep it in your account to use in subsequent analyses, where it is secured for use with the most privacy-sensitive applications. To learn more, see Configure Debugger Hook to Save Tensors (p. 1653).

**Analyze the Data with a Fleet of Debugger Built-in Rules**

You can use Debugger built-in rules to inspect tensors in parallel with a training job. To analyze the training performance data, Debugger provides built-in rules that watch for abnormal training process behaviors. For example, a Debugger rule detects issues when the training process suffers from system bottleneck issues or training issues, such as vanishing gradients, exploding tensors, overfitting, or overtraining. If necessary, you can also build customized rules by creating a rule definition with your own criteria to define a training issue. To learn more about the Debugger rules, see Configure Debugger Built-in Rules (p. 1659) for detailed instructions of using the Amazon SageMaker Python SDK. For a full list of the Debugger built-in rules, see List of Debugger Built-in Rules (p. 1677). If you want to create a custom rule, see Create Debugger Custom Rules for Training Job Analysis (p. 1721).

**Take Actions Based on the Built-in Rule Status**

You can use Debugger with Amazon CloudWatch Events and AWS Lambda. You can automate actions based on the rule status, such as stopping training jobs early and setting up notifications through email or text. When the Debugger rules detect problems and triggers an "IssuesFound" evaluation status, CloudWatch Events detects the rule status changes and invokes the Lambda function to take actions. To configure automated actions to your training issues, see Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 1731).

**Dive Deep into the Data Using the SMDebug Client Library**

You can use the SMDebug tools to access and analyze training data collected by Debugger. The TrainingJob and create_trial classes load the metrics and tensors saved by Debugger. These classes provide extended class methods to analyze the data in real time or after the training has finished. The SMDebug library also provides visualization tools: merge timelines of framework metrics to aggregate different profiling, line charts and heatmap to track the system utilization, and histograms to find step duration outliers. To learn more about the SMDebug library tools, see Analyze Data Using the SMDebug Client Library (p. 1775).

**Monitor and Analyze Training Job Metrics**

Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see GetMetricStatistics in the Amazon CloudWatch API Reference.

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as
CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors).

SageMaker Debugger also provides visualizations through Studio and its profiling report. Unlike CloudWatch metrics, which accumulates resource utilization rates of CPU and GPU cores and averages those out across multiple instances, Debugger tracks the utilization rate of each core. This enables you to identify unbalanced usage of hardware resources as you scale up to larger compute clusters. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

Monitoring System Utilization and Detect Bottlenecks

With Amazon SageMaker Debugger monitoring, you can measure hardware system resource utilization of Amazon EC2 instances. Monitoring is available for any SageMaker training job constructed with the SageMaker framework estimators (TensorFlow, PyTorch, and MXNet) and the generic SageMaker estimator (SageMaker built-in algorithms and your own custom containers). Debugger built-in rules for monitoring detect system bottleneck issues and notify you when they detect the bottleneck issues.

To learn how to enable Debugger system monitoring, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1644) and then Configure Debugger Monitoring Hardware System Resource Utilization (p. 1649).

For a full list of available built-in rules for monitoring, see Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics) (p. 1677).

Profiling Framework Operations

With Amazon SageMaker Debugger profiling you can profile deep learning frameworks operations. You can profile your model training with the SageMaker TensorFlow training containers, the SageMaker PyTorch framework containers, and your own training containers. Using the profiling feature of Debugger, you can drill down into the Python operators and functions that are executed to perform the training job. Debugger supports detailed profiling, Python profiling, data loader profiling, and Horovod distributed training profiling. You can merge the profiled timelines to correlate with the system bottlenecks. Debugger built-in rules for profiling watch framework operation related issues, including excessive training initialization time due to data downloading before training starts and step duration outliers in training loops.

To learn how to configure Debugger for framework profiling, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1644) and then Configure Debugger Framework Profiling (p. 1649).

For a complete list of available built-in rules for profiling, see Debugger Built-in Rules for Profiling Framework Metrics (p. 1677).

Debugging Model Output Tensors

Debugging is available for deep learning frameworks using AWS Deep Learning Containers and the SageMaker training containers. For fully supported framework versions (see the versions at Supported Frameworks and Algorithms (p. 1632)), Debugger automatically registers hooks to collect output tensors, and you can directly run your training script. For the versions with one asterisk sign, you need to manually register the hooks to collect tensors. Debugger provides preconfigured tensor collections with generalized names that you can utilize across the different frameworks. If you want to customize output tensor configuration, you can also use the CollectionConfig and DebuggerHookConfig API operations and the Amazon SageMaker Python SDK to configure your own tensor collections. Debugger built-in rules for debugging analyze the output tensors and identifies model optimization problems that blocks your model from minimizing the loss function. For example, the rules identify overfitting, overtraining, loss not decreasing, exploding tensors, and vanishing gradients.
To learn how to configure Debugger for debugging output tensors, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1644) and then Configure Debugger Hook to Save Tensors (p. 1653).

For a full list of available built-in rules for debugging, see Debugger Built-in Rules for Debugging Model Training Data (Output Tensors) (p. 1678).

Amazon SageMaker Debugger Advanced Topics and Reference Documentation

The following sections contain advanced topics, reference documentation for the API operations, exceptions, and known limitations for Debugger.

Topics
- Amazon SageMaker Debugger API Operations (p. 1789)
- Use Debugger Docker Images for Built-in or Custom Rules (p. 1790)
- Amazon SageMaker Debugger Exceptions (p. 1792)
- Considerations for Amazon SageMaker Debugger (p. 1793)
- Amazon SageMaker Debugger Usage Statistics (p. 1795)

Amazon SageMaker Debugger API Operations

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source SMDebug Python library at awslabs/sagemaker-debugger that is used to configure built-in rules, define custom rules, and register hooks to collect output tensor data from training jobs.

The Amazon SageMaker Python SDK is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the SMDebug Python library to monitor and analyze these tensors using SageMaker estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- CreateTrainingJob and UpdateTrainingJob use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - CollectionConfiguration
  - DebugHookConfig
  - DebugRuleConfiguration
  - TensorBoardOutputConfig
  - ProfilerConfig
  - ProfilerRuleConfiguration
- DescribeTrainingJob provides a full description of a training job, including the following Debugger configurations and rule evaluation statuses:
  - DebugHookConfig
  - DebugRuleConfiguration
  - DebugRuleEvaluationStatus
  - ProfilerConfig
  - ProfilerRuleConfiguration
• ProfilerRuleEvaluationStatus

The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see Process Data (p. 706).

Use Debugger Docker Images for Built-in or Custom Rules

Amazon SageMaker provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the Amazon SageMaker Python SDK, you can simply use SageMaker high-level Debugger API operations with SageMaker Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the ConfigureTrainingJob API.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry URL of the image using the CreateTrainingJob API. SageMaker uses the following URL patterns for the Debugger rule container image registry address.

<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>

For the account ID in each AWS Region, Amazon ECR repository name, and tag value, see the following topics.

Topics
• Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators (p. 1790)
• Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1791)

Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators

Use the following values for the components of the registry URLs for the images that provide built-in rules for Amazon SageMaker Debugger. For account IDs, see the following table.

ECR Repository Name: sagemaker-debugger-rules
Tag: latest

Example of a full registry URL:
904829902805.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rules:latest

**Amazon SageMaker Debugger Exceptions**

Amazon SageMaker Debugger is designed to be aware that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the `smdebug.exceptions` module. You can import them as follows:

```python
from smdebug.exceptions import *
```

The following exceptions are available:

- `TensorUnavailableForStep` – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.
• TensorUnavailable – This tensor is not being saved or has not been saved by the `smdebug` API. This means that this tensor is never seen for any step in `smdebug`.
• StepUnavailable – The step was not saved and Debugger has no data from the step.
• StepNotYetAvailable – The step has not yet been seen by `smdebug`. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.
• NoMoreData – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.
• IndexReaderException – The index reader is not valid.
• InvalidWorker – A worker was invoked that was not valid.
• RuleEvaluationConditionMet – Evaluation of the rule at the step resulted in the condition being met.
• InsufficientInformationForRuleInvocation – Insufficient information was provided to invoke the rule.

Considerations for Amazon SageMaker Debugger

Consider the following when using Amazon SageMaker Debugger.

Considerations for Distributed Training

The following list shows the scope of validity and considerations for using Debugger on training jobs with deep learning frameworks and various distributed training options.

• Horovod

Scope of validity of using Debugger for training jobs with Horovod

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

* Debugger does not support framework profiling for TensorFlow 2.x.

** SageMaker distributed data parallel does not support TensorFlow 2.x with Keras implementation.

- **SageMaker distributed model parallel** – Debugger does not support SageMaker distributed model parallel training.

- **Distributed training with SageMaker checkpoints** – Debugger is not available for training jobs when both the distributed training option and SageMaker checkpoints are enabled. You might see an error that looks like the following:

  `SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled`

To use Debugger for training jobs with distributed training options, you need to disable SageMaker checkpointing and add manual checkpointing functions to your training script. For more information about using Debugger with distributed training options and checkpoints, see Considerations for Using SageMaker Distributed Data Parallel with SageMaker Debugger and Checkpoints (p. 1848) and Saving Checkpoints (p. 1871).

- **Parameter Server** – Debugger does not support parameter server-based distributed training.

- Profiling distributed training framework operations, such as the `AllReduced` operation of SageMaker distributed data parallel and Horovod operations, is not available.

### Considerations for Monitoring System Bottlenecks and Profiling Framework Operations

- For AWS TensorFlow, data loader metrics cannot be collected using the default `local_path` setting of the `FrameworkProfile` class. The path has to be manually configured and end in "/". For example:

  ```python
  FrameworkProfile(local_path="/opt/ml/output/profiler/")
  ```

- For AWS TensorFlow, the data loader profiling configuration cannot be updated while a training job is running.

- For AWS TensorFlow, a `NoneType` error might occur when you use analysis tools and notebook examples with TensorFlow 2.3 training jobs and the detailed profiling option.

- Python profiling and detailed profiling are only supported for Keras API.

- To access the deep profiling feature for TensorFlow and PyTorch, currently you must specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI in the TensorFlow and PyTorch estimator as follows:

  - **For TensorFlow**

    ```python
    image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"
    ```

  - **For PyTorch**

    ```python
    image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04"
    ```
Considerations for Debugging Model Output Tensors

- Avoid using functional API operations. Debugger cannot collect model output tensors from PyTorch and MXNet training scripts composed of functional API operations.
- Debugger cannot collect model output tensors from the `torch.nn.functional` API operations. When you write a PyTorch training script, it is recommended to use the `torch.nn` modules instead.
- Debugger cannot collect model output tensors from MXNet functional objects in hybrid blocks. For example, the ReLu activation (`F.relu`) outputs cannot be collected from the following example of `mxnet.gluon.HybridBlock` with `F` in the `hybrid_forward` function.

```python
import mxnet as mx
from mxnet.gluon import HybridBlock, nn

class Model(HybridBlock):
    def __init__(self, **kwargs):
        super(Model, self).__init__(**kwargs)
        # use name_scope to give child Blocks appropriate names.
        with self.name_scope():
            self.dense0 = nn.Dense(20)
            self.dense1 = nn.Dense(20)

    def hybrid_forward(self, F, x):
        x = F.relu(self.dense0(x))
        return F.relu(self.dense1(x))

model = Model()
model.initialize(ctx=mx.cpu(0))
model.hybridize()
model(mx.nd.zeros((10, 10), ctx=mx.cpu(0)))
```

Amazon SageMaker Debugger Usage Statistics

Consider the following when using autogenerated reports by Amazon SageMaker Debugger.

Debugger Profiling Report Usage

Debugger collects profiling report usage statistics by including code in the Jupyter notebook that collects the unique `ProfilerReport` rule's processing job ARN if the user opens the final `profiler-report.html` file.

Debugger only collects information about whether a user opens the final HTML report. It **DOES NOT** collect any information from training jobs, training data, training scripts, processing jobs, logs, or the content of the profiling report itself.

You can opt out of the collection of usage statistics using either of the following options.

(Recommended) Option 1: Opt Out before Running a Training Job

To opt out, you need to add the following Debugger `ProfilerReport` rule configuration to your training job request.

SageMaker Python SDK

```python
estimator=estimator.Estimator()
```
Option 2: Opt Out after a Training Job Has Completed

To opt out after training has completed, you need to modify the profiler-report.ipynb file.

**Note**

HTML reports autogenerated without Option 1 already added to your training job request still report the usage statistics even after you opt out using Option 2.

1. Follow the instructions on downloading the Debugger profiling report files in the Download a Debugger Profiling Report (p. 1752) page.
2. In the /ProfilerReport-1234567890/profiler-output directory, open profiler-report.ipynb.
3. Add `opt_out=True` to the `setup_profiler_report()` function in the fifth code cell as shown in the following example code:

```python
setup_profiler_report(processing_job_arn, opt_out=True)
```
4. Run the code cell to finish opting out.
Perform Automatic Model Tuning with SageMaker

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose.

For example, suppose that you want to solve a binary classification problem on a marketing dataset. Your goal is to maximize the area under the curve (auc) metric of the algorithm by training an XGBoost Algorithm (p. 1568) model. You don't know which values of the eta, alpha, min_child_weight, and max_depth hyperparameters to use to train the best model. To find the best values for these hyperparameters, you can specify ranges of values that SageMaker hyperparameter tuning searches to find the combination of values that results in the training job that performs the best as measured by the objective metric that you chose. Hyperparameter tuning launches training jobs that use hyperparameter values in the ranges that you specified, and returns the training job with highest auc.

You can use SageMaker automatic model tuning with built-in algorithms, custom algorithms, and SageMaker pre-built containers for machine learning frameworks.

Amazon SageMaker automatic model tuning can use Amazon EC2 Spot instance to optimize costs when running training jobs. For more information on managed spot training, see Managed Spot Training in Amazon SageMaker (p. 1914).

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

- A dataset
- An understanding of the type of algorithm you need to train
- A clear understanding of how you measure success

You should also prepare your dataset and algorithm so that they work in SageMaker and successfully run a training job at least once. For information about setting up and running a training job, see Get Started with Amazon SageMaker (p. 33).

How Hyperparameter Tuning Works

Random Search

In a random search, hyperparameter tuning chooses a random combination of values from within the ranges that you specify for hyperparameters for each training job it launches. Because the choice of hyperparameter values doesn't depend on the results of previous training jobs, you can run the maximum number of concurrent training jobs without affecting the performance of the search.
For an example notebook that uses random search, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb.

Bayesian Search

Bayesian search treats hyperparameter tuning like a [regression] problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose. To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results, and runs training jobs to test these values. After testing the first set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.

Hyperparameter tuning uses a Amazon SageMaker implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to exploit the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not well understood. The explore/exploit trade-off is common in many machine learning problems.

For more information about Bayesian optimization, see the following:

Note

Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions, and, as such, should be considered part of the scientific development process.

When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate
your productivity by trying many variations of a model, focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you need to choose the right ranges to explore. Because the algorithm itself is stochastic, it's possible that the hyperparameter tuning model will fail to converge on the best answer, even if the best possible combination of values is within the ranges that you choose.

**Define Metrics**

When you use one of the Amazon SageMaker built-in algorithms, you don't need to define metrics. Built-in algorithms automatically send metrics to hyperparameter tuning. You do need to choose one of the metrics that the built-in algorithm emits as the objective metric for the tuning job. For a list of metrics that a built-in algorithm emits, see the *Metrics* table for the algorithm in *Use Amazon SageMaker Built-in Algorithms* (p. 762).

To optimize hyperparameters for a machine learning model, a tuning job evaluates the training jobs it launches by using a metric that the training algorithm writes to logs. Amazon SageMaker hyperparameter tuning parses your algorithm's `stdout` and `stderr` streams to find algorithm metrics, such as loss or validation-accuracy, that show how well the model is performing on the dataset.

**Note**

These are the same metrics that SageMaker sends to CloudWatch Logs. For more information, see *Log Amazon SageMaker Events with Amazon CloudWatch* (p. 2635).

If you use your own algorithm for hyperparameter tuning, make sure that your algorithm emits at least one metric by writing evaluation data to `stderr` or `stdout`.

**Note**

Hyperparameter tuning sends an additional hyperparameter, `_tuning_objective_metric` to the training algorithm. This hyperparameter specifies the objective metric being used for the hyperparameter tuning job, so that your algorithm can use that information during training.

You can define up to 20 metrics for your tuning job to monitor. You choose one of those metrics to be the objective metric, which hyperparameter tuning uses to evaluate the training jobs. The hyperparameter tuning job returns the training job that returned the best value for the objective metric as the best training job.

You define metrics for a tuning job by specifying a name and a regular expression for each metric that your tuning job monitors. Design the regular expressions to capture the values of metrics that your algorithm emits. You pass these metrics to the `CreateHyperParameterTuningJob` operation in the `TrainingJobDefinition` parameter as the `MetricDefinitions` field of the `AlgorithmSpecification` field.

The following example defines 4 metrics:

```json
[
    {
        "Name": "loss",
        "Regex": "Loss = (.*?);",
    },
    {
        "Name": "ganloss",
        "Regex": "GAN_loss=(.*?);",
    },
    {
        "Name": "discloss",
        "Regex": "disc_train_loss=(.*?);",
    },
    {
        "Name": "disc-combined",
        "Regex": "disc-combined=(.*?);",
    }
]"
The following is an example of the log that the algorithm writes:

```
GAN_loss=0.138318; Scaled_reg=2.654134; disc:[-0.017371,0.102429] real 93.3% gen 0.0%
disc-combined=0.000000; disc_train_loss=1.374587; Loss = 16.020744; Iteration 0 took
0.704s; Elapsed=0s
```

Use the regular expression (regex) to match the algorithm's log output and capture the numeric values of metrics. For example, in the regex for the loss metric defined above, the first part of the regex finds the exact text "Loss = ", and the expression (.*?); captures zero or more of any character until the first semicolon character. In this expression, the parenthesis tell the regex to capture what is inside them, * means any character, ? means capture only until the first instance of the ; character.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the API, specify the value of the name key in the HyperParameterTuningJobObjective field of the HyperParameterTuningJobConfig parameter that you send to the CreateHyperParameterTuningJob operation.

**Define Hyperparameter Ranges**

Hyperparameter tuning finds the best hyperparameter values for your model by searching over a set of values that you specify for each of the hyperparameters that are tunable. Choosing hyperparameters and ranges significantly affects the performance of your tuning job. For guidance on choosing hyperparameters and ranges, see Best Practices for Hyperparameter Tuning (p. 1822).

To define hyperparameter ranges by using the low-level API, you specify the names of hyperparameters and ranges of values in the ParameterRanges field of the HyperParameterTuningJobConfig parameter that you pass to the CreateHyperParameterTuningJob operation. The ParameterRanges field has three subfields, one for each of the categorical, integer, and continuous hyperparameter ranges. You can define up to 20 hyperparameters to search over. Each value of a categorical hyperparameter range counts as a hyperparameter against the limit. Hyperparameter ranges have the following structure:

```json
"ParameterRanges": {
    "CategoricalParameterRanges": [
    {
        "Name": "tree_method",
        "Values": ["auto", "exact", "approx", "hist"]
    }
    ],
    "ContinuousParameterRanges": [
    {
        "Name": "eta",
        "MaxValue": "0.5",
        "MinValue": "0",
        "ScalingType": "Auto"
    }
    ],
    "IntegerParameterRanges": [
    {
        "Name": "max_depth",
        "MaxValue": "10",
        "MinValue": "1",
        "ScalingType": "Auto"
    }
    ]
}
```
Hyperparameter Scaling

For integer and continuous hyperparameter ranges, you can choose the scale you want hyperparameter tuning to use to search the range of values by specifying a value for the ScalingType field of the hyperparameter range. You can choose from the following scaling types:

Auto

SageMaker hyperparameter tuning chooses the best scale for the hyperparameter.

Linear

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude), because uniformly searching values from the range will give you a reasonable exploration of the entire range.

Logarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale. Logarithmic scaling works only for ranges that have only values greater than 0.

Choose logarithmic scaling when you are searching a range that spans several orders of magnitude. For example, if you are tuning a Tune a linear learner model (p. 1486) model, and you specify a range of values between .0001 and 1.0 for the learning_rate hyperparameter, searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would, because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between .1 and 1.0, leaving only 10 percent of your training budget for the values between .0001 and .1.

ReverseLogarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Reverse logarithmic scaling works only for ranges that are entirely within the range 0<=x<1.0.

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

For an example notebook that uses hyperparameter scaling, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb.

Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model

To create a new hyperparameter optimization (HPO) job with Amazon SageMaker that tunes multiple algorithms, you must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources you want to use for the tuning job.

- The job settings to configure include warm starting, early stopping, and the tuning strategy. Warm starting and early stopping are available only when tuning a single algorithm.
- The training job definition to specify the name, algorithm source, objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job. It
configures the channels for data inputs, data output locations, and any checkpoint storage locations for each training job. The definition also configures the resources to deploy for each training job, including instance types and counts, managed spot training, and stopping conditions.

- **The tuning job resources**: to deploy, including the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently and the maximum number of training jobs that the hyperparameter tuning job can run.

### Get Started

You can create a new hyperparameter tuning job, clone a job, add or edit tags to a job from the console. You can also use the search feature to find jobs by their name, creation time, or status. Alternatively, you can also hyperparameter tuning jobs with the SageMaker API.

- **In the console**: To create a new job, open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/, choose Hyperparameter tuning jobs from the Training, menu, and then choose Create hyperparameter tuning job. Then following the configuration steps to create a training job for each algorithm that you want to use. These steps are documented in the Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) (p. 1802) topic.

  **Note**
  When you start the configuration steps, note that the warm start and early stopping features are not available to use with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.

- **With the API**: For instructions on using the SageMaker API to create a hyperparameter tuning job, see Example: Hyperparameter Tuning Job. When you call CreateHyperParameterTuningJob to tune multiple algorithms, you must provide a list of training definitions using TrainingJobDefinitions instead of specifying a single TrainingJobDefinition. You must choose just one of these definition types depending on the number of algorithms being tuned.

### Topics
- Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) (p. 1802)
- Manage Hyperparameter Tuning and Training Jobs (p. 1806)

### Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)

To create a new hyperparameter optimization (HPO) tuning job for one or more algorithms, you need to define the settings for the tuning job, create training job definitions for each algorithm being tuned, and configure the resources for the tuning job.

### Define job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when tuning a single algorithm. After you define the job settings you will create individual training definitions for each algorithm or variation you want to tune.
Warm Start

If you cloned this job, you can choose to use the results from a previous tuning job to improve the performance of this new tuning job. This is the warm start feature and it is only available when tuning a single algorithm. When you choose this option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

**Note**

Warm start is compatible only with tuning jobs created after October 1, 2018. For more information, see [Run a warm start job](#).

Early Stopping

To reduce compute time and avoid overfitting your model, training jobs can be stopped early when they are unlikely to improve the current best objective metric of the hyperparameter tuning job. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it's disabled by default. For more information on how early stopping works, the algorithms that support it, and how to use it with your own algorithms, see [Stop Training Jobs Early](#).

Tuning Strategy

Tuning strategy can be either random or Bayesian. It specifies how the automatic tuning searches over specified hyperparameter ranges. You specify the ranges in a later step. Random search chooses random combinations of values from the specified ranges and can be run concurrently. Bayesian search chooses values based on what is likely to get the best result given what is known about the history of previous selections. For more information search strategies, see [How Hyperparameter Tuning Works](#).

**Tags**

You enter tags as key-value pairs to assign metadata to tuning jobs to help you manage them. Values are not required. You can use just the key. To see the keys associated with a job, choose the Tags tab on the details page for tuning job. For more information about using tags for tuning jobs, see [Manage Hyperparameter Tuning and Training Jobs](#).

Create Training Job Definitions

To create a training job definition, you need to configure the algorithm and parameters, define the data input and output, and configure resources. You must provide at least one TrainingJobDefinition for each HPO tuning job. Each training definition specifies the configuration for an algorithm. To create several definitions for your training job you can clone a job definition. Cloning a job can save time as it copies all of the job settings, including data channels, S3 storage locations for output artifacts. You can then edit the cloned job just for changes needed to configure the algorithm options.

**Topics**

- Configure algorithm and parameters (p. 1803)
- Define Data Input and Output (p. 1804)
- Configure Training Job Resources (p. 1805)
- Add or Clone a Training Job (p. 1805)

Configure algorithm and parameters

Each training job definition for a tuning job requires a name, permission to access services, and the specification of algorithm options, an objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job.

**Name**
Provide a unique name for the training definition.

Permissions

Amazon SageMaker requires permissions to call other services on your behalf. Choose an IAM role or let AWS create a role that has the AmazonSageMakerFullAccess IAM policy attached.

Optional Security Settings

The network isolation setting prevents the container from making any outbound network calls. This is required for AWS Marketplace machine learning offerings.

You can also choose to use a private VPC.

Note

Inter-container encryption is only available when creating job definitions from the API.

Algorithm Options

You can choose one of the built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from AWS Marketplace.

- If you choose a built-in algorithm, it has the ECR image information prepopulated.
- If you choose your own container, you must specify the ECR image information. You can select the input mode for the algorithm as file or pipe.
- If you plan to supply your data using a .CSV file from Amazon S3, you should select the file.

Metrics

When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you need to define your metrics. You can define up to 20 metrics for your tuning job to monitor, one of which must be chosen as the objective metric. For more information on how to define a metric for a tuning job, see Define Metrics (p. 1799).

Objective Metric

To find the best training job, set an objective metric and whether to maximize or minimize it. After the training job is complete, you can view the tuning job detail page for a summary of the best training job found using this objective metric.

Hyperparameter Configuration

When you choose a built-in algorithm, the default values for its hyperparameters are set for you, using ranges that are optimized for the algorithm being tuned. You can change these values as you see fit. For example, instead of a range, you can set a fixed value for a hyperparameter by setting the parameter's type to static. Each algorithm has different required and optional parameters. For more information, see Best Practices for Hyperparameter Tuning and Define Hyperparameter Ranges.

Define Data Input and Output

Each training job definition for a tuning job must configures the channels for data inputs, data output locations, and optionally any checkpoint storage locations for each training job.

Input Data Configuration

Input data is defined by channels, each with their own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the
algorithm you chose supports multiple input channels, you can specify those too. For example, when using the XGBoost churn prediction notebook, you could add two channels: train and validation.

**Checkpoint Configuration**

Checkpoints are periodically generated during training. You must choose an Amazon S3 location for the checkpoints to be saved. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs. For more information, see Use Checkpoints in Amazon SageMaker (p. 1915).

**Output Data Configuration**

You must define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an AWS Key Management Service (AWS KMS) key.

**Configure Training Job Resources**

Each training job definition for a tuning job must configure the resources to deploy, including instance types and counts, managed spot training, and stopping conditions.

**Resource Configuration**

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

**Managed spot training**

You can save computer costs for jobs if you have flexibility in start and end times by allowing SageMaker to use spare capacity to run jobs. For more information, see Managed Spot Training in Amazon SageMaker (p. 1914).

**Stopping condition**

The stopping condition specifies the maximum duration allowed per training job.

**Add or Clone a Training Job**

Once you have created a training job definition for a tuning job, you are returned to the Training Job Definition(s) panel where you can create additional training job definitions to train additional algorithms. You can select the Add training job definition and work through the steps to define a training job again or choose Clone from the Action menu to replicate an existing training job definition and edit it for the new algorithm. The clone option can save time as it copies all of the job's settings, including the data channels, S3 storage locations. For more information on cloning, see Manage Hyperparameter Tuning and Training Jobs (p. 1806)

**Configure Tuning Job Resources**

**Resource Limits**

You can specify the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently (10 at most) and the maximum number of training jobs that the hyperparameter tuning job can run (500 at most). The number of parallel jobs should not exceed the number of nodes you have requested across all of your training definitions. The total number of jobs can't exceed the number of jobs that your definitions are expected to run.

**Review and Create HPO Tuning Job**

Review the job settings, the training job definition(s), and resource limits. Then select Create hyperparameter tuning job.
Manage Hyperparameter Tuning and Training Jobs

A tuning job can contain many training jobs and creating and managing these jobs and their definitions can become a complex and onerous task. SageMaker provides tools to help facilitate the management of these jobs. Tuning jobs you have run can be accessed from the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/. Select **Hyperparameter tuning job** from the **Training** menu to see the list. This page is also where you start the procedure to create a new tuning job by selecting **Create hyperparameter tuning job**.

To see the training jobs run a part of a tuning job, select one of the hyperparameter tuning jobs from the list. The tabs on the tuning job page allow you to inspect the training jobs, their definitions, the tags and configuration used for the tuning job, and the best training job found during tuning. You can select the best training job or any of the other training jobs that belong to the tuning job to see all of their settings. From here you can create a model that uses the hyperparameter values found by a training job by selecting **Create Model** or you can clone the training job by selecting **Clone**.

Cloning

You can save time by cloning a training job that belongs to a hyperparameter tuning job. Cloning copies all of the job's settings, including data channels, S3 storage locations for output artifacts. You can do this for training jobs you have already run from the the tuning job page, as just described, or when you are creating additional training job definitions while creating a hyperparameter tuning job, as described in **Add or Clone a Training Job** step of that procedure.

Tagging

Automatic Model Tuning launches multiple training jobs within a single parent tuning job to discover the ideal weighting of model hyperparameters. Tags can be added to the parent tuning job as described in the **Define job settings** section and these tags are then propagated to the individual training jobs underneath. Customers can use these tags for purposes such as cost allocation or access control. To add tags using the SageMaker SDK, use **AddTags** API. For more information about using tagging for AWS resources, see **Tagging AWS resources**.

Example: Hyperparameter Tuning Job

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the XGBoost Algorithm to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level AWS SDK for Python (Boto) to configure and launch the hyperparameter tuning job, and the AWS Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker high-level Amazon SageMaker Python SDK to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see https://github.com/aws/sagemaker-python-sdk.

Prerequisites

To run the code in this example, you need

- An AWS account and an administrator user (p. 33)
- An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
- A running SageMaker notebook instance (p. 43)

Topics

- Create a Notebook (p. 1807)
• Get the Amazon SageMaker Boto 3 Client (p. 1807)
• Get the SageMaker Execution Role (p. 1808)
• Specify a S3 Bucket to Upload Training Datasets and Store Output Data (p. 1808)
• Download, Prepare, and Upload Training Data (p. 1808)
• Configure and Launch a Hyperparameter Tuning Job (p. 1809)
• Monitor the Progress of a Hyperparameter Tuning Job (p. 1813)
• Clean up (p. 1815)

Create a Notebook

Create a Jupyter notebook that contains a pre-installed environment with the default Anaconda installation and Python3.

To create a Jupyter notebook

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Open a running notebook instance, by choosing Open next to its name. The Jupyter notebook server page appears:

3. To create a notebook, choose Files, New, and conda_python3.
4. Name the notebook.

Next Step

Get the Amazon SageMaker Boto 3 Client (p. 1807)

Get the Amazon SageMaker Boto 3 Client

Import Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```python
import sagemaker
import boto3
import numpy as np                                # For performing matrix operations and numerical processing
import pandas as pd                               # For manipulating tabular data
from time import gmtime, strftime
import os
region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')
```

The preceding code cell defines region and smclient objects that you will use to call the built-in XGBoost algorithm and set the SageMaker hyperparameter tuning job.
Next Step

Get the SageMaker Execution Role (p. 1808)

Get the SageMaker Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance. You pass the role to the tuning job.

```python
from sagemaker import get_execution_role
role = get_execution_role()
print(role)
```

Next Step

Specify a S3 Bucket to Upload Training Datasets and Store Output Data (p. 1808)

Specify a S3 Bucket to Upload Training Datasets and Store Output Data

Set up a S3 bucket to upload training datasets and save training output data.

To use a default S3 bucket

Use the following code to specify the default S3 bucket allocated for your SageMaker session. `prefix` is the path within the bucket where SageMaker stores the data for the current training job.

```python
sess = sagemaker.Session()
bucket = sess.default_bucket()              # Set a default S3 bucket
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

(Optional) To use a specific S3 bucket

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain `sagemaker`, and be globally unique. The bucket must be in the same AWS Region as the notebook instance that you use for this example.

```python
bucket = "sagemaker-your-preferred-s3-bucket"
```

Note

The name of the bucket doesn't need to contain `sagemaker` if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the `S3FullAccess` permission.

Next Step

Download, Prepare, and Upload Training Data (p. 1808)

Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.
For more information about the dataset and the data transformation that the example performs, see the hpo_xgboost_direct_marketing_sagemaker_APIs notebook in the Hyperparameter Tuning section of the SageMaker Examples tab in your notebook instance.

Download and Explore the Training Dataset

To download and explore the dataset, run the following code in your notebook:

```bash
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500)     # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)         # Keep the output on one page
data
```

Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```python
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0)  # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired', 'unemployed']), 1, 0)  # Indicator for individuals not actively employed
model_data = pd.get_dummies(data)  
# Convert categorical variables to sets of indicators
model_data
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx', 'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)
train_data, validation_data, test_data = np.split(model_data.sample(frac=1, random_state=1729), [int(0.7 * len(model_data)), int(0.9*len(model_data))])
pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('test.csv', index=False, header=False)
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/validation.csv')).upload_file('validation.csv')
```

Next Step

Configure and Launch a Hyperparameter Tuning Job (p. 1809)

Configure and Launch a Hyperparameter Tuning Job

To configure and launch a hyperparameter tuning job, complete the following steps.

Topics
- Specify the Hyperparameter Tuning Job Settings (p. 1810)
- Configure the Training Jobs (p. 1811)
Example: Hyperparameter Tuning Job

• Name and Launch the Hyperparameter Tuning Job (p. 1813)
• Next Step (p. 1813)

Specify the Hyperparameter Tuning Job Settings

To specify settings for the hyperparameter tuning job, you define a JSON object. You pass the object as the value of the `HyperParameterTuningJobConfig` parameter to `CreateHyperParameterTuningJob` when you create the tuning job.

In this JSON object, you specify:

• The ranges of hyperparameters that you want to tune. For more information, see Define Hyperparameter Ranges (p. 1800)
• The limits of the resource that the hyperparameter tuning job can consume.
• The objective metric for the hyperparameter tuning job. An objective metric is the metric that the hyperparameter tuning job uses to evaluate the training job that it launches.

Note
To use your own algorithm for hyperparameter tuning, you need to define metrics for your algorithm. For information, see Define Metrics (p. 1799).

The hyperparameter tuning job defines ranges for the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters of the XGBoost Algorithm (p. 1568) built-in algorithm. The objective metric for the hyperparameter tuning job maximizes the `validation:auc` metric that the algorithm sends to CloudWatch Logs.

tuning_job_config = {
    "ParameterRanges": {
        "CategoricalParameterRanges": [],
        "ContinuousParameterRanges": [
            {
                "MaxValue": "1",
                "MinValue": "0",
                "Name": "eta"
            },
            {
                "MaxValue": "2",
                "MinValue": "0",
                "Name": "alpha"
            },
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "min_child_weight"
            }
        ],
        "IntegerParameterRanges": [
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "max_depth"
            }
        ]
    },
    "ResourceLimits": {
        "MaxNumberOfTrainingJobs": 20,
        "MaxParallelTrainingJobs": 3
    },
    "Strategy": "Bayesian",
    "HyperParameterTuningJobObjective": {
        "MetricName": "validation:auc",
        "Type": "Maximize"
    }
}
Configure the Training Jobs

To configure the training jobs that the tuning job launches, define a JSON object that you pass as the value of the `TrainingJobDefinition` parameter of the `CreateHyperParameterTuningJob` call.

In this JSON object, you specify:

- Optional—Metrics that the training jobs emit.

  **Note**  
  Define metrics only when you use a custom training algorithm. Because this example uses a built-in algorithm, you don't specify metrics. For information about defining metrics, see Define Metrics (p. 1799).

- The container image that specifies the training algorithm.

- The input configuration for your training and test data.

- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.

- The values of algorithm hyperparameters that are not tuned in the tuning job.

- The type of instance to use for the training jobs.

- The stopping condition for the training jobs. This is the maximum duration for each training job.

In this example, we set static values for the `eval_metric`, `num_round`, `objective`, `rate_drop`, and `tweedie_variance_power` parameters of the XGBoost Algorithm (p. 1568) built-in algorithm.

```
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')

s3_input_train = 's3://{}/{}'.format(bucket, prefix)
s3_input_validation = 's3://{}/{}'.format(bucket, prefix)

training_job_definition = {  
    "AlgorithmSpecification": {  
        "TrainingImage": training_image,  
        "TrainingInputMode": "File"  
    },  
    "InputDataConfig": [  
        {  
            "ChannelName": "train",  
            "CompressionType": "None",  
            "ContentType": "csv",  
            "DataSource": {  
                "S3DataSource": {  
                    "S3DataDistributionType": "FullyReplicated",  
                    "S3DataType": "S3Prefix",  
                    "S3Uri": s3_input_train  
                }  
            }  
        },  
        {  
            "ChannelName": "validation",  
            "CompressionType": "None",  
            "ContentType": "csv",  
```
"DataSource": {
    "S3DataSource": {
        "S3DataDistributionType": "FullyReplicated",
        "S3DataType": "S3Prefix",
        "S3Uri": s3_input_validation
    }
},
"OutputDataConfig": {
    "S3OutputPath": "s3://{{}}/output".format(bucket, prefix)
},
"ResourceConfig": {
    "InstanceCount": 2,
    "InstanceType": "ml.c4.2xlarge",
    "VolumeSizeInGB": 10
},
"RoleArn": role,
"StaticHyperParameters": {
    "eval_metric": "auc",
    "num_round": "100",
    "objective": "binary:logistic",
    "rate_drop": "0.3",
    "tweedie_variance_power": "1.4"
},
"StoppingCondition": {
    "MaxRuntimeInSeconds": 43200
}
}

SageMaker Python SDK v2

training_image = sagemaker.image_uris.retrieve('xgboost', region, '1.0-1')
s3_input_train = 's3://{{}}/train'.format(bucket, prefix)
s3_input_validation = 's3://{{}}/validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
    {
        "ChannelName": "train",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_train
        }
    },
    {
        "ChannelName": "validation",
        "CompressionType": "None",
        "ContentType": "csv",
        "DataSource": {
            "S3DataDistributionType": "FullyReplicated",
            "S3DataType": "S3Prefix",
            "S3Uri": s3_input_validation
        }
    }
]
Example: Hyperparameter Tuning Job

```json
{
    "OutputDataConfig": {
        "S3OutputPath": "s3://{}/{}\output\format(bucket, prefix)"
    },
    "ResourceConfig": {
        "InstanceCount": 2,
        "InstanceType": "ml.c4.2xlarge",
        "VolumeSizeInGB": 10
    },
    "RoleArn": role,
    "StaticHyperParameters": {
        "eval_metric": "auc",
        "num_round": "100",

    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 43200
    }
}
```

Name and Launch the Hyperparameter Tuning Job

Now you can provide a name for the hyperparameter tuning job and then launch it by calling the `CreateHyperParameterTuningJob` API. Pass `tuning_job_config` and `training_job_definition` that you created in previous steps as the values of the parameters.

```
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = tuning_job_name, 
    HyperParameterTuningJobConfig = tuning_job_config, 
    TrainingJobDefinition = training_job_definition)
```

Next Step

Monitor the Progress of a Hyperparameter Tuning Job (p. 1813)

Monitor the Progress of a Hyperparameter Tuning Job

To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker console.

Topics

- View the Status of the Hyperparameter Tuning Job (p. 1813)
- View the Status of the Training Jobs (p. 1814)
- View the Best Training Job (p. 1815)

View the Status of the Hyperparameter Tuning Job

To view the status of the hyperparameter tuning job

2. Choose **Hyperparameter tuning jobs**.
3. In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:

- **Completed**—The hyperparameter tuning job successfully completed.
- **InProgress**—The hyperparameter tuning job is in progress. One or more training jobs are still running.
- **Failed**—The hyperparameter tuning job failed.
- **Stopped**—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
- **Stopping**—The hyperparameter tuning job is in the process of stopping.

**View the Status of the Training Jobs**

To view the status of the training jobs that the hyperparameter tuning job launched

1. In the list of hyperparameter tuning jobs, choose the job that you launched.
2. Choose **Training jobs**.

3. View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.
A training job can be:

- **Completed**—The training job successfully completed.
- **InProgress**—The training job is in progress.
- **Stopped**—The training job was manually stopped before it completed.
- **Failed (Retryable)**—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
- **Failed (Non-retryable)**—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.

**View the Best Training Job**

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose **Best training job**.

![Image of Best training job](image)

To deploy the best training job as a model that you can host at a SageMaker endpoint, choose **Create model**.

**Next Step**

**Clean up (p. 1815)**

**Clean up**

To avoid incurring unnecessary charges, when you are done with the example, use the AWS Management Console to delete the resources that you created for it.

**Note**

If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.
1. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and delete the notebook instance. Stop the instance before deleting it.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/ and delete the bucket that you created to store model artifacts and the training dataset.
3. Open the IAM console at https://console.aws.amazon.com/iam/ and delete the IAM role. If you created permission policies, you can delete them, too.
4. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/ and delete all of the log groups that have names starting with /aws/sagemaker/.

Stop Training Jobs Early

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the AWS SDK for Python (Boto 3), set the TrainingJobEarlyStoppingType field of the HyperParameterTuningJobConfig object that you use to configure the tuning job to AUTO.
- If you are using the Amazon SageMaker Python SDK, set the early_stopping_type parameter of the HyperParameterTuner object to Auto.
- In the Amazon SageMaker console, in the Create hyperparameter tuning job workflow, under Early stopping, choose Auto.

For a sample notebook that demonstrates how to use early stopping, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb or open the hpo_image_classification_early_stopping.ipynb notebook in the Hyperparameter Tuning section of the SageMaker Examples in a notebook instance. For information about using sample notebooks in a notebook instance, see Example Notebooks (p. 152).

How Early Stopping Works

When you enable early stopping for a hyperparameter tuning job, SageMaker evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.
- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker stops the current training job.

Algorithms That Support Early Stopping

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker algorithms support early stopping:

- Linear Learner Algorithm (p. 1486)—Supported only if you use objective_loss as the objective metric.
- XGBoost Algorithm (p. 1568)
- Image Classification Algorithm (p. 1443)
Note
This list of built-in algorithms that support early stopping is current as of December 13, 2018. Other built-in algorithms might support early stopping in the future. If an algorithm emits a metric that can be used as an objective metric for a hyperparameter tuning job (preferably a validation metric), then it supports early stopping.

To use early stopping with your own algorithm, you must write your algorithms such that it emits the value of the objective metric after each epoch. The following list shows how you can do that in different frameworks:

TensorFlow
Use the `tf.keras.callbacks.ProgbarLogger` class. For information, see https://www.tensorflow.org/api_docs/python/tf/keras/callbacks/ProgbarLogger.

MXNet
Use the `mxnet.callback.LogValidationMetricsCallback`. For information, see https://mxnet.apache.org/api/python/callback/callback.html.

Chainer
Extend chainer by using the `extensions.Evaluator` class. For information, see https://docs.chainer.org/en/v1.24.0/reference/extensions.html#evaluator.

PyTorch and Spark
There is no high-level support. You must explicitly write your training code so that it computes objective metrics and writes them to logs after each epoch.

Run a Warm Start Hyperparameter Tuning Job

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see How Hyperparameter Tuning Works (p. 1797). Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

Note
Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

Reasons you might want to consider warm start include:

- You want to gradually increase the number of training jobs over several tuning jobs based on the results you see after each iteration.
- You get new data, and want to tune a model using the new data.
- You want to change the ranges of hyperparameters that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.
- You stopped a previous hyperparameter job early or it stopped unexpectedly.
Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

**IDENTICAL_DATA_AND_ALGORITHM**

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run a warm start tuning job of type **IDENTICAL_DATA_AND_ALGORITHM**, there is an additional field in the response to `DescribeHyperParameterTuningJob` named `OverallBestTrainingJob`. The value of this field is the `TrainingJobSummary` for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

**TRANSFER_LEARNING**

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

- A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (Completed, Stopped, or Failed) before you start the new tuning job.
- The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
- The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.
- The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.
Run a Warm Start Hyperparameter Tuning Job

- The number of total changes from tunable hyperparameters in the parent jobs to static hyperparameters in the new tuning job, plus the number of changes in the values of static hyperparameters cannot be more than 10. Each value in a categorical hyperparameter counts against this limit. For example, if the parent job has a tunable categorical hyperparameter with the possible values red and blue, you change that hyperparameter to static in the new tuning job, that counts as 2 changes against the allowed total of 10. If the same hyperparameter had a static value of red in the parent job, and you change the static value to blue in the new tuning job, it also counts as 2 changes.

- Warm start tuning is not recursive. For example, if you create MyTuningJob3 as a warm start tuning job with MyTuningJob2 as a parent job, and MyTuningJob2 is itself an warm start tuning job with a parent job MyTuningJob1, the information that was learned when running MyTuningJob1 is not used for MyTuningJob3. If you want to use the information from MyTuningJob1, you must explicitly add it as a parent for MyTuningJob3.

- The training jobs launched by every parent job in a warm start tuning job count against the 500 maximum training jobs for a tuning job.

- Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm start tuning jobs.

Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/hpo_image_classification_warmstart.ipynb. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Example Notebooks (p. 152). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The warm start tuning example notebook is located in the Hyperparameter tuning section, and is named hpo_image_classification_warmstart.ipynb. To open a notebook, click on its Use tab and select Create copy.

Create a Warm Start Tuning Job

You can use either the low-level AWS SDK for Python (Boto 3) or the high-level SageMaker Python SDK to create a warm start tuning job.

Topics

- Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3)) (p. 1819)
- Create a Warm Start Tuning Job (SageMaker Python SDK) (p. 1820)

Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3))

To use warm start tuning, you specify the values of a HyperParameterTuningJobWarmStartConfig object, and pass that as the WarmStartConfig field in a call to CreateHyperParameterTuningJob.

The following code shows how to create a HyperParameterTuningJobWarmStartConfig object and pass it to CreateHyperParameterTuningJob job by using the low-level SageMaker API for Python (Boto 3).

Create the HyperParameterTuningJobWarmStartConfig object:

```python
warm_start_config = {
    "ParentHyperParameterTuningJobs" : [
        {"HyperParameterTuningJobName" : 'MyParentTuningJob'},
    ],
    "WarmStartType" : "IdenticalDataAndAlgorithm"
}
```
Create the warm start tuning job:

```python
smclient = boto3.Session().client('sagemaker')
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName =
    'MyWarmStartTuningJob',
    HyperParameterTuningJobConfig = tuning_job_config, # See notebook for tuning
    configuration
    TrainingJobDefinition = training_job_definition, # See notebook for job definition
    WarmStartConfig = warm_start_config)
```

Create a Warm Start Tuning Job (SageMaker Python SDK)

To use the Amazon SageMaker Python SDK to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a `WarmStartConfig` object.
- Pass the `WarmStartConfig` object as the value of the `warm_start_config` argument of a `HyperparameterTuner` object.
- Call the `fit` method of the `HyperparameterTuner` object.

For more information about using the Amazon SageMaker Python SDK for hyperparameter tuning, see [https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning](https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning).

This example uses an estimator that uses the Image Classification Algorithm (p. 1443) algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see Define Hyperparameter Ranges (p. 1800).

```python
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                        'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a `WarmStartConfig` object.

```python
from sagemaker.tuner import WarmStartConfig,

parent_tuning_job_name = "MyParentTuningJob"
warm_start_config = WarmStartConfig(type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM,
                                     parents=(parent_tuning_job_name))
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, `imageclassification` is an estimator that was created previously.

```python
imageclassification.set_hyperparameters(num_layers=18,
                                         image_shape='3,224,224',
                                         num_classes=257,
                                         num_training_samples=15420,
                                         mini_batch_size=128,
                                         epochs=30,
                                         optimizer='sgd',
                                         top_k='2',
                                         precision_dtype='float32',
                                         augmentation_type='crop')
```

Now create the `HyperparameterTuner` object and pass the `WarmStartConfig` object that you previously created as the `warm_start_config` argument.

```python
tuner_warm_start = HyperparameterTuner(imageclassification,

```
Finally, call the `fit` method of the `HyperparameterTuner` object to launch the warm start tuning job.

```
    tuner_warm_start.fit(
      {'train': s3_input_train, 'validation': s3_input_validation},
      include_cls_metadata=False)
```

## Resource Limits for Automatic Model Tuning

SageMaker sets the following default limits for resources used by automatic model tuning:

- Number of parallel (concurrent) hyperparameter tuning jobs: 100
- Number of hyperparameters that can be searched: 20

  **Note**
  Every possible value in a categorical hyperparameter counts against this limit.

- Number of metrics defined per hyperparameter tuning job: 20
- Number of parallel (concurrent) training jobs per hyperparameter tuning job: 10

  **Note**
  This can be increased to one hundred.

- [Bayesian search strategy] Number of training jobs per hyperparameter tuning job: 500
- [Random search strategy] Number of training jobs per hyperparameter tuning job: 500

  **Note**
  This can be increased up to ten thousand.

- Maximum run time for a hyperparameter tuning job: 30 days

When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker training jobs, see SageMaker Limits. Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one `ml.m4.xlarge` instance. The following limits apply:

- Number of concurrent hyperparameter tuning jobs: You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- Number of training jobs per hyperparameter tuning job: You don't need to increase the limit, because 100 training jobs is below the limit of 500.
- Number of concurrent training jobs per hyperparameter tuning job: You need to request a limit increase to 20, because the default limit is 10.
- SageMaker training `ml.m4.xlarge` instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
- SageMaker training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
To request a quota increase:

1. Open the AWS Support Center page, sign in if necessary, and then choose Create case.
2. On the Create case page, choose Service limit increase.
3. On the Case details panel, select SageMaker Automatic Model Tuning [Hyperparameter Optimization] for the Limit type
4. On the Requests panel for Request 1, select the Region, the resource Limit to increase and the New Limit value you are requesting. Select Add another request if you have additional requests for quota increases.
5. In the Case description panel, provide a description of your use case.
6. In the Contact options panel, select your preferred Contact methods (Web, Chat or Phone) and then choose Submit.

Best Practices for Hyperparameter Tuning

Hyperparameter optimization is not a fully-automated process. To improve optimization, use the following guidelines when you create hyperparameters.

Topics
- Choosing the Number of Hyperparameters (p. 1823)
- Choosing Hyperparameter Ranges (p. 1823)
- Using Logarithmic Scales for Hyperparameters (p. 1823)
- Choosing the Best Number of Concurrent Training Jobs (p. 1823)
- Running Training Jobs on Multiple Instances (p. 1823)
Choosing the Number of Hyperparameters

The computational complexity of a hyperparameter tuning job depends primarily on the number of hyperparameters whose range of values Amazon SageMaker has to search through during optimization. Although you can simultaneously specify up to 20 hyperparameters to optimize for a tuning job, limiting your search to a much smaller number is likely to give you better results.

Choosing Hyperparameter Ranges

The range of values for hyperparameters that you choose to search can significantly affect the success of hyperparameter optimization. Although you might want to specify a very large range that covers every possible value for a hyperparameter, you get better results by limiting your search to a small range of values. If you know that you get the best metric values within a subset of the possible range, consider limiting the range to that subset.

Using Logarithmic Scales for Hyperparameters

During hyperparameter tuning, SageMaker attempts to figure out if your hyperparameters are log-scaled or linear-scaled. Initially, it assumes that hyperparameters are linear-scaled. If they are in fact log-scaled, it might take some time for SageMaker to discover that fact. If you know that a hyperparameter is log-scaled and can convert it yourself, doing so could improve hyperparameter optimization.

Choosing the Best Number of Concurrent Training Jobs

When setting the resource limit `MaxParallelTrainingJobs` for the maximum number of concurrent training jobs that a hyperparameter tuning job can launch, consider the following tradeoff. Running more hyperparameter tuning jobs concurrently gets more work done quickly, but a tuning job improves only through successive rounds of experiments. Typically, running one training job at a time achieves the best results with the least amount of compute time.

Running Training Jobs on Multiple Instances

When a training job runs on multiple instances, hyperparameter tuning uses the last-reported objective metric value from all instances of that training job as the value of the objective metric for that training job. Design distributed training jobs so that the objective metric reported is the one that you want.

Amazon SageMaker Distributed Training Libraries

SageMaker provides distributed training libraries for data parallelism and model parallelism. The libraries are optimized for the SageMaker training environment, help adapt your distributed training jobs to SageMaker, and improve training speed and throughput.

Topics

- Get Started with Distributed Training (p. 1824)
- Basic Distributed Training Concepts (p. 1824)
- Advanced Concepts (p. 1825)
- Strategies (p. 1826)

- Scenarios (p. 1828)
- SageMaker Built-In Distributed Training Features (p. 1831)
• SageMaker’s Distributed Data Parallel Library (p. 1831)
• SageMaker’s Distributed Model Parallel (p. 1849)
• Amazon SageMaker Distributed Training Notebook Examples (p. 1873)

Get Started with Distributed Training

If you’re familiar with distributed training, follow one of the links to your preferred strategy or framework to get started. Otherwise, continue on to the next section to learn some distributed training concepts.

SageMaker distributed training libraries:

• SageMaker's Distributed Data Parallel Library (p. 1831)
• SageMaker's Distributed Model Parallel (p. 1849)

Note
The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Basic Distributed Training Concepts

SageMaker’s distributed training libraries use the following distributed training terms and features.

Datasets and Batches

• **Training Dataset**: All of the data you use to train the model.
• **Global batch size**: The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: \( \text{global batch size} = (\text{the number of model replicas}) \times (\text{per-replica batch size}) \). A single batch of global batch size is often referred to as the *mini-batch* in machine learning literature.
• **Per-replica batch size**: When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.
• **Micro-batch**: A subset of the mini-batch or, if hybrid model and data parallelism is used, it is a subset of the per-replica sized batch. When you use SageMaker’s distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an execution schedule defined by the library’s runtime.

Training

• **Epoch**: One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.
• **Iteration**: A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the global batch size and the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.
• **Learning rate**: A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model's ability to converge as well as the speed and optimality of convergence.

**Instances and GPUs**

- **Instances**: An AWS machine learning compute instance. These are also referred to as *nodes*.
- **Cluster size**: When using SageMaker's distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise, communication between the nodes can add overhead and lead to slower training times. The SageMaker distributed training library is designed to optimize communication between AWS ML compute instances, leading to higher device utilization and faster training times.

**Distributed Training Solutions**

- **Data parallelism**: A strategy in distributed training where a training dataset is split up across multiple processing nodes (such as AWS ML Instances), and each processing node contains a *replica* of the model. Each node receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.

- **Model parallelism**: A strategy in distributed training where the model partitioned across multiple processing nodes (such as AWS ML Instances). The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single node. Each node carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.

- **Pipeline Execution Schedule (Pipelining)**: The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see Pipeline Execution Schedule.

**Example**

The following example demonstrates how these terms might be used to describe a training job that uses hybrid model and data parallelism:

A 2-way data parallelism and 4-way model parallelism training job is launched with a global batch size of 64 images. This training job requires a total of 8 GPUs. Each of the two model replicas processes a per-replica batch of size 32. During the forward and backward pass, a per-replica batch is further divided up into micro-batches. These micro-batches are processed in an interleaved fashion using a pipelined execution schedule.

The training dataset includes 640 images, and so a single epoch takes 10 iterations.

**Advanced Concepts**

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: *scaling model size* and *scaling training data*. While model size and complexity can result in better accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.
Not all models handle training data scaling equally well. Some algorithms need to ingest all the training data in memory for training. They only scale vertically, and to bigger and bigger instance types. Some algorithms have the disadvantage of scaling super-linearly with dataset size. For example, the computational load of a nearest-neighbor search for all records of an N-rows dataset scales in N squared. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD). In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called mini-batches. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an epoch. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called data parallel distributed training, and is the most commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called allreduce that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware subtracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing devices, like a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called model-parallel distributed training.

### Strategies

Distributed training is usually split by two approaches: data parallel and model parallel. Data parallel is the most common approach to distributed training: You have a lot of data, batch it up, and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A model parallel approach is used with large models that won’t fit in a node’s memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms network and model are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading the model back onto the network with all your pre-trained parameters and their weights loads a large model into memory. When you break apart a model to split it across nodes, you’re also breaking apart the underlying network. A network consists of layers, and to split up the network, you put layers on different nodes that are spread across multiple compute devices.

A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is inherently sequential in both forward and backward passes, and at a given time, only one GPU can actively compute, while the others wait on the activations to be sent. Modern model parallel libraries solve this problem by using pipeline execution schedules to improve device utilization. However, only the Amazon SageMaker’s distributed model parallel library includes automatic model splitting. The two core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the
process of implementing model parallelism by making automated decisions that lead to efficient device utilization.

Train with Data Parallel and Model Parallel

If you are training with a large dataset, start with a data parallel approach. If you run out of memory during training, you may want to switch to a model parallel approach, or try hybrid model and data parallelism. You can also try the following to improve performance with data parallel:

- Change your model's hyperparameters.
- Reduce the batch size.
- Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory, then you should try model-parallel training.

Try gradient compression (FP16, INT8):

- On NVIDIA TensorCore-equipped hardware, using mixed precision training creates both speed-up and memory consumption reduction.
- SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:
  - Frameworks - PyTorch in the NVIDIA Deep Learning Performance documentation
  - Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
  - Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
  - Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the PyTorch Blog
  - TensorFlow mixed precision APIs in the TensorFlow documentation

Try reducing the input size:

- Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down, or adjust the GPUs up to spread the batch.
- Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error rate thereby disrupting the model from converging. For example, if you prototyped your network on a single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a single node.

Start with model-parallel training when:

- Your model does not fit on a single device.
- Due to your model size, you're facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.

To learn more about the SageMaker distributed libraries, see the following:

- PyTorch distributed training
- TensorFlow distributed training

Batch Size

SageMaker distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

**Tip**
Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.

A number of techniques have been developed to maintain good model convergence when batch is increased.

Mini-Batch Size

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

Scenarios

The following sections cover scenarios in which you may want to scale up training, and how you can do so using AWS resources.
Scaling from a Single GPU to Many GPUs

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer than you are willing to wait. Sometimes, the training doesn’t work at all because the model or the training data is too large. One solution is to increase the number of GPUs you use for training. On an instance with multiple GPUs, like a `p3.16xlarge` that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on `p3.2xlarge` with one GPU.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>GPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p3.2xlarge</code></td>
<td>1</td>
</tr>
<tr>
<td><code>p3.8xlarge</code></td>
<td>4</td>
</tr>
<tr>
<td><code>p3.16xlarge</code></td>
<td>8</td>
</tr>
<tr>
<td><code>p3dn.24xlarge</code></td>
<td>8</td>
</tr>
</tbody>
</table>

**Note**

The ml instance types used by SageMaker training have the same number of GPUs as the corresponding `p3` instance types. For example, `ml.p3.8xlarge` has the same number of GPUs as `p3.8xlarge - 4`.

Scaling from a Single Instance to Multiple Instances

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each `p3` instance type.

If you have made the jump from a single GPU on a `p3.2xlarge` to four GPUs on a `p3.8xlarge`, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a `p3.16xlarge` before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker Python SDK’s `estimator` function by setting your `instance_count`. For example, you can set `instance_type = p3.16xlarge` and `instance_count = 2`. Instead of the eight GPUs on a single `p3.16xlarge`, you have 16 GPUs across two identical instances. The following chart shows scaling and throughput starting with eight GPUs on a single instance and increasing to 64 instances for a total of 256 GPUs.
Availability Zones and Network Backplane

With multiple instances, it's important to understand the network that connects the instances, how they read the training data, and how they share information between themselves (for example, communication between the nodes in the cluster when doing an AllReduce operation).

First, your instances need to be in the same Region and same Availability Zone. For example, instances in us-west-2 must all be in us-west-2a. When you use the SageMaker Python SDK, this is handled for you. If you use Amazon EC2 and orchestrate your own training clusters, you need to be aware of this, or your training speeds suffer.

Your training data should also be in the same Availability Zone. When you use a SageMaker estimator, you pass in the Region and the S3 bucket, and if the data is not in the Region you set, you get an error.

Optimized GPU, Network, and Storage

The p3dn.24xlarge instance type was designed for fast local storage and a fast network backplane with up to 100 gigabits, and we highly recommend it as the most performant option for distributed training. SageMaker supports streaming data modes from S3, referred to as pipe mode. For HPC loads like distributed training, we recommend Amazon Fsx for your file storage.

Custom Training Scripts

While SageMaker makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker's container guide for Deep Learning Containers, and various example notebooks that demonstrate implementations.

SageMaker Built-In Distributed Training Features

The SageMaker built-in libraries of algorithms consists of 18 popular machine learning algorithms. Many of them were rewritten from scratch to be scalable and distributed out of the box. If you want to use distributed deep learning training code, we recommend Amazon SageMaker's distributed training libraries. SageMaker's distributed training libraries make it easier for you to write highly scalable and cost-effective custom data parallel and model parallel deep learning training jobs.

SageMaker distributed training libraries offer both data parallel and model parallel training strategies. It combines software and hardware technologies to improve inter-GPU and inter-node communications. It extends SageMaker's training capabilities with built-in options that require only small code changes to your training scripts.

- SageMaker's Distributed Data Parallel Library (p. 1831)
- SageMaker's Distributed Model Parallel (p. 1849)

SageMaker's Distributed Data Parallel Library

Important
To use new features with an existing notebook instance or Studio application, restart the notebook instance or Studio application to get the latest updates.
SageMaker's distributed data parallel library extends SageMaker's training capabilities on deep learning models with near-linear scaling efficiency, achieving fast time-to-train with minimal code changes.

- The library optimizes your training job for AWS network infrastructure and Amazon EC2 instance topology.
- The library takes advantage of gradient updates to communicate between nodes with a custom AllReduce algorithm.

When training a model on a large amount of data, machine learning practitioners often turn to distributed training to reduce the time to train. In some cases, where time is of the essence, the business requirement is to finish training as quickly as possible or at least within a constrained time period. Then, distributed training is scaled to use a cluster of multiple nodes—not just multiple GPUs in a computing instance, but multiple instances with multiple GPUs. As the cluster size increases, so does the significant drop in performance. This drop in performance is primarily caused by the communications overhead between nodes in a cluster.

SageMaker's distributed library offers two options for distributed training: model parallel and data parallel. This guide focuses on how to train models using a data parallel strategy. For more information on training with a model-parallel strategy, refer to SageMaker's Distributed Model Parallel (p. 1849).

Introduction to SageMaker's Distributed Data Parallel Library

Why Use SageMaker Distributed Data Parallel Library?

SageMaker's distributed data parallel library addresses communications overhead in two ways:

1. The library performs AllReduce, a key operation during distributed training that is responsible for a large portion of communication overhead.
2. The library performs optimized node-to-node communication by fully utilizing AWS's network infrastructure and Amazon EC2 instance topology.

Use this data parallel library to increase speed by up to 25% in training models such as BERT. While implementations like Horovod offer sub-linear performance at scale, this library offers near-linear performance at scale. This means that you get a faster training time and a lower cost to train a model.

Note

The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Training Benchmarks

PyTorch with SageMaker's data parallel library
Using instance type `p3dn.24xlarge` and on 2, 4, and 8 node clusters:

- **BERT**: When used with PyTorch, the SageMaker library is 41%, 52%, and 13% faster than PyTorch-DDP.
- **MaskRCNN**: When used with PyTorch, the SageMaker library is 4%, 19%, and 15% faster than PyTorch-DDP.

These benchmarks were run on PyTorch v1.6 using `ml.p3dn.24xlarge` instances. You can find the training code on the [SageMaker examples website](https://sagemaker-examples.github.io/). The examples website also has benchmark training code for these models using TensorFlow 2.3.

**Optimal Bandwidth Use with Balanced Fusion Buffer**

SageMaker’s distributed data parallel library uses a communication pattern similar to parameter servers to reduce the amount of data transferred and the number of steps involved in averaging gradients from multiple GPUs. It also uses a new technique called balanced fusion buffers to make optimal use of the bandwidth available across all nodes in the cluster.

One key disadvantage of traditional parameter servers is their suboptimal use of available network bandwidth. Parameter servers treat variables as atomic units and place each variable on one server. Since gradients become available sequentially during the backward pass, at any given instant, there is imbalance in the volume of data being sent and received from different servers. Some servers are receiving and sending more data, some less, and some none. This problem becomes worse as the number of parameter servers increases.

The library addresses these problems by introducing **balanced fusion buffers**. A balanced fusion buffer is a buffer in the GPU that holds the gradients until the size of the buffer exceeds a threshold. In a setup with N parameter servers, when the buffer exceeds the threshold, the balanced fusion buffer is copied to CPU memory, sharded into N parts, and the ith part is sent to the ith parameter server. Each server receives exactly the same number of bytes from a balanced fusion buffer. The ith server receives the ith partition of the balanced fusion buffer from all workers, sums them up, and sends the results back to all workers. Since all the servers participate equally in averaging each balanced fusion buffer, server bandwidth is efficiently utilized.

**Optimal GPU Usage with Efficient AllReduce Overlapping with a Backward Pass**

SageMaker’s distributed data parallel library achieves optimal overlapping of the **AllReduce** operation with the backward pass, significantly improving the GPU utilization, and achieves near-linear scaling efficiency and faster time to train by optimizing tasks between CPUs and GPUs. The library performs **AllReduce** in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library faster.
• **Leverages CPUs**: The library uses CPUs to AllReduce gradients, offloading this task from the GPUs.
• **Improved GPU usage**: The cluster’s GPUs focus on computing gradients, improving their utilization throughout training.

## SageMaker Distributed Data Parallel Architecture

The library supports larger compute instances that have 8 GPUs per node: `ml.p3.16xlarge`, `ml.p3dn.24xlarge`, and `ml.p4d.24xlarge`. The high-level workflow of the SageMaker distributed data parallel library is as following:

1. The library assigns ranks to GPUs (workers).
2. At each iteration, the library divides each global batch by the total number of workers (world size) and assigns small batches (batch shards) to the workers.
   - The size of the global batch is `(number of nodes in a cluster) * (number of GPUs per node) * (per batch shard)`.
   - A batch shard (small batch) is a subset of dataset assigned to each GPU (worker) per iteration.
3. The library launches a training script on each worker.
4. The library manages copies of model weights and gradients from the workers at the end of every iteration.
5. The library synchronizes model weights and gradients across the workers to aggregate a single trained model.

The following architecture diagram shows an example of how the library sets up data parallelism for a cluster of 3 nodes.
To start using the SageMaker distributed data parallel library, see Run a SageMaker Distributed Data Parallel Training Job (p. 1840) to set up a SageMaker estimator through Amazon SageMaker Python SDK, and Modify Your Training Script Using the SageMaker Data Parallel Library (p. 1835) to adapt your training script using the SageMaker distributed data parallel library.

Modify Your Training Script Using the SageMaker Data Parallel Library

Script Modification Overview

SageMaker’s distributed data parallel library (the library) APIs are designed for ease of use, and to provide seamless integration with existing distributed training toolkits.

- **SageMaker Python SDK with the library API**: In most cases, all you have to change in your training script is the Horovod or other data parallel library import statements. Swap these out with the SageMaker data parallel library equivalents.
- **Focus on your model training without infrastructure management**: When training a deep learning model with the library on SageMaker, you can focus on your model training, while SageMaker does cluster management: brings up the nodes and creates the cluster, completes the training, then tears down the cluster.

To customize your own training script, you need to do the following:

- You must provide TensorFlow/PyTorch training scripts that are adapted to use the library. The following sections provide example code for this.
- Your input data must be in an S3 bucket or in FSx in the AWS Region that you will use to launch your training job. If you use the Jupyter Notebooks provided, create a SageMaker notebook instance in the same Region as the bucket that contains your input data. For more information about storing your training data, refer to the SageMaker Python SDK data inputs documentation.

**Tip**
Consider using FSx instead of Amazon S3 to increase training performance. It has higher throughput and lower latency than Amazon S3.

Use the following sections to see examples of adapting the library to your TensorFlow or PyTorch training scripts. Once you have launched a training job, you can monitor system utilization and model performance using Amazon SageMaker Debugger (p. 1630) or Amazon CloudWatch.

**Topics**
- Modify a TensorFlow Training Script (p. 1835)
- Modify a PyTorch Training Script (p. 1838)

Modify a TensorFlow Training Script

The following steps show you how to convert a TensorFlow training script to utilize SageMaker’s distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. Refer to the SageMaker distributed data parallel TensorFlow API documentation for additional details on each API that the library offers for TensorFlow.

**Note**
SageMaker distributed data parallel is adaptable to TensorFlow training scripts composed of tf core modules except tf.keras modules. SageMaker distributed data parallel does not support TensorFlow with Keras implementation.
Note
SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- **Frameworks - TensorFlow** in the NVIDIA Deep Learning Performance documentation
- **Automatic Mixed Precision for Deep Learning** in the NVIDIA Developer Docs
- **TensorFlow mixed precision APIs** in the TensorFlow documentation

1. Import the library's TensorFlow client and initialize it:

   ```python
   import smdistributed.dataparallel.tensorflow as sdp
   sdp.init()
   ```

2. Pin each GPU to a single `smdistributed.dataparallel` process with `local_rank`—this refers to the relative rank of the process within a given node. The `sdp.tensorflow.local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the next code block as `sdp.local_rank()`.

   ```python
   gpus = tf.config.experimental.list_physical_devices('GPU')
   for gpu in gpus:
     tf.config.experimental.set_memory_growth(gpu, True)
   if gpus:
     tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')
   ```

3. Scale the learning rate by the number of workers. The `sdp.tensorflow.size()` API provides you the number of workers in the cluster. This is invoked in the next code block as `sdp.size()`.

   ```python
   learning_rate = learning_rate * sdp.size()
   ```

4. Use the library's `DistributedGradientTape` to optimize `AllReduce` operations during training. This wraps `tf.GradientTape`.

   ```python
   with tf.GradientTape() as tape:
     output = model(input)
     loss_value = loss(label, output)
   # SageMaker data parallel: Wrap tf.GradientTape with the library's DistributedGradientTape
tape = sdp.DistributedGradientTape(tape)
   ```

5. Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. For this, you use the `sdp.tensorflow.broadcast_variables` API after the model and optimizer variables are initialized. This is invoked in the next code block as `sdp.broadcast_variables()`.

   ```python
   sdp.broadcast_variables(model.variables, root_rank=0)
sdp.broadcast_variables(opt.variables(), root_rank=0)
   ```

6. Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

   ```python
   if sdp.rank() == 0:
   ```
The following is an example TensorFlow2 training script for distributed training with the library:

```python
import tensorflow as tf
# SageMaker data parallel: Import the library TF API
import smdistributed.dataparallel.tensorflow as sdp
# SageMaker data parallel: Initialize the library
sdp.init()

gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    # SageMaker data parallel: Pin GPUs to a single library process
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)

# Define Model
mnist_model = tf.keras.Sequential(...)
loss = tf.losses.SparseCategoricalCrossentropy()

# SageMaker data parallel: Scale Learning Rate
# LR for 8 node run : 0.000125
# LR for single node run : 0.001
opt = tf.optimizers.Adam(0.000125 * sdp.size())

@tf.function
def training_step(images, labels, first_batch):
    with tf.GradientTape() as tape:
        probs = mnist_model(images, training=True)
        loss_value = loss(labels, probs)

        # SageMaker data parallel: Wrap tf.GradientTape with the library's
        # DistributedGradientTape
        tape = sdp.DistributedGradientTape(tape)

        grads = tape.gradient(loss_value, mnist_model.trainable_variables)
        opt.apply_gradients(zip(grads, mnist_model.trainable_variables))

    if first_batch:
        # SageMaker data parallel: Broadcast model and optimizer variables
        sdp.broadcast_variables(mnist_model.variables, root_rank=0)
        sdp.broadcast_variables(opt.variables(), root_rank=0)

        return loss_value

...  

# SageMaker data parallel: Save checkpoints only from master node.
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

For more advanced usage, refer to SageMaker Distributed Data Parallel TensorFlow API documentation.

After you have completed adapting your training script, move on to the next topic: Run a SageMaker Distributed Data Parallel Training Job (p. 1840) using the SageMaker Python SDK.
Modify a PyTorch Training Script

The following steps show you how to convert a PyTorch training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to PyTorch Distributed Data Parallel (DDP) APIs. For additional details on each data parallel API offered for PyTorch, see the SageMaker distributed data parallel PyTorch API documentation.

Note
SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - PyTorch in the NVIDIA Deep Learning Performance documentation
- Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
- Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the PyTorch Blog

1. Import the library's PyTorch client and initialize it, then import the module for distributed training.

   ```python
   import smdistributed.dataparallel.torch.distributed as dist
   from smdistributed.dataparallel.torch.parallel.distributed import DistributedDataParallel as DDP
   dist.init_process_group()
   ```

2. After parsing arguments and defining a batch size parameter (for example, `batch_size=args.batch_size`), add a 2-line of code to resize the batch size per worker (GPU). PyTorch's DataLoader operation does not automatically handle the batch resizing for distributed training.

   ```python
   batch_size //= dist.get_world_size()
   batch_size = max(batch_size, 1)
   ```

3. Pin each GPU to a single SageMaker data parallel library process with `local_rank`—this refers to the relative rank of the process within a given node.

   The `smdistributed.dataparallel.torch.get_local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the next code block as `dist.get_local_rank()`.

   ```python
   torch.cuda.set_device(dist.get_local_rank())
   ```

4. Wrap the PyTorch model with the library's DDP.

   ```python
   model = ...
   # Wrap model with the library's DistributedDataParallel
   model = DDP(model)
   ```

5. Modify the torch.utils.data.distributed.DistributedSampler to include the cluster's information. Set `num_replicas` to the total number of GPUs participating in training across all the nodes in the cluster. This is called `world_size`. You can get `world_size` with the `smdistributed.dataparallel.torch.get_world_size()` API. This is invoked in the following code as `dist.get_world_size()`. Also supply the node rank using `smdistributed.dataparallel.torch.get_rank()`. This is invoked as `dist.get_rank()`.
train_sampler = DistributedSampler(train_dataset, num_replicas=dist.get_world_size(), rank=dist.get_rank())

6. Modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

The following is an example PyTorch training script for distributed training with the library:

```python
# SageMaker data parallel: Import the library PyTorch API
import smdistributed.dataparallel.torch.distributed as dist

# SageMaker data parallel: Import the library PyTorch DDP
from smdistributed.dataparallel.torch.parallel.distributed import DistributedDataParallel as DDP

# SageMaker data parallel: Initialize the library
dist.init_process_group()

class Net(nn.Module):
    ...
    # Define model

def train(...):
    ...
    # Model training

def test(...):
    ...
    # Model evaluation

def main():
    # SageMaker data parallel: Scale batch size by world size
    batch_size //= dist.get_world_size()
    batch_size = max(batch_size, 1)

    # Prepare dataset
    train_dataset = torchvision.datasets.MNIST(...)

    # SageMaker data parallel: Set num_replicas and rank in DistributedSampler
    train_sampler = torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=dist.get_world_size(),
        rank=dist.get_rank())

    train_loader = torch.utils.data.DataLoader(..)

    # SageMaker data parallel: Wrap the PyTorch model with the library’s DDP
    model = DDP(Net().to(device))

    # SageMaker data parallel: Pin each GPU to a single library process.
    torch.cuda.set_device(local_rank)
    model.cuda(local_rank)

    # Train
    optimizer = optim.Adadelta(...)
    scheduler = StepLR(...)
    for epoch in range(1, args.epochs + 1):
        train(...)
        if rank == 0:
            test(...)```
# SageMaker data parallel: Save model on master node.
if dist.get_rank() == 0:
    torch.save(...)
if __name__ == '__main__':
    main()

For more advanced usage, see the SageMaker distributed data parallel PyTorch API documentation.

After you have completed adapting your training script, move on to the next topic: Run a SageMaker Distributed Data Parallel Training Job (p. 1840) using the SageMaker Python SDK.

Run a SageMaker Distributed Data Parallel Training Job

Learn how to run a distributed data parallel training job using the SageMaker Python SDK and your adapted training script with SageMaker's distributed data parallel library. For API specifications, refer to distributed data parallel in the SageMaker Python SDK documentation.

Use SageMaker's Distributed Data Parallel Library

To use SageMaker's distributed data parallel library, you start with a training script. Just as with any training job on SageMaker, you use your training script to launch a SageMaker training job. To get started, we recommend that you use the SageMaker data parallel library in the following ways:

- Using a SageMaker notebook instance
- Using SageMaker Studio

With either option, you can then use the Amazon SageMaker Distributed Training Notebook Examples (p. 1873) provided with this documentation to get started.

Use the Data Parallel Library with SageMaker's Python SDK

To use SageMaker's distributed data parallel library, you must create a training script for one of the supported frameworks and launch the training job using the SageMaker Python SDK. To learn how you can incorporate the library into a training script, see Modify Your Training Script Using SageMaker's Distributed Model Parallel Library (p. 1855). The library API documentation is located in the SageMaker Python SDK. See SageMaker's data parallel API documentation.

SageMaker supports the following training environment configurations:

- You can use a prebuilt TensorFlow or PyTorch container.
- You can customize SageMaker prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

To extend a pre-built container, or adapt your own container to use the library, you must use one of the PyTorch or TensorFlow GPU general framework base-images. The distributed data parallel library is included in all CUDA 11 (cu11x) TensorFlow 2.3.x and PyTorch 1.6.x versioned images and later. See Available Deep Learning Containers Images for a list of available images.

Important
It is recommended that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up to date version of the SageMaker distributed data parallel library. All images that include TensorFlow 2.4.1 and PyTorch 1.8.1 versions and later support EFA instance types (ml.p3dn.24xlarge, ml.p4d.24xlarge).
For example, if you are using PyTorch 1.8.1, your Dockerfile should contain a FROM statement similar to the following:

```bash
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.8.1-gpu-py36-cu11-ubuntu18.04

ENV PATH="/opt/ml/code:${PATH}"
# this environment variable is used by the SageMaker PyTorch container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py
# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM cifar10.py
```

- You can adapt your own Docker container to work with SageMaker using the SageMaker Training toolkit. For an example, see Adapting Your Own Training Container.

In all cases, you launch your job using a SageMaker Python SDK Estimator.

If you are using the SageMaker pre-built PyTorch or TensorFlow containers, see the following section to learn how configure an Estimator to use the library.

If you bring your own container or extend a pre-built container, you can create an instance of the Estimator class with the desired Docker image.

**TensorFlow Estimator**

You can use SageMaker’s distributed data parallel library API by specifying `smdistributed dataparallel` as the distribution strategy in the SageMaker TensorFlow Estimator API. Refer to SageMaker TensorFlow Estimator API documentation for full details about the API.

```python
class sagemaker.tensorflow.estimator.TensorFlow(py_version=None, framework_version=None, model_dir=None, image_uri=None, distribution=None, **kwargs)
```

The following two parameters of the SageMaker Python SDK TensorFlow estimator are required to use `smdistributed.dataparallel` with TensorFlow.

**distribution(dict)(optional):** A dictionary with information on how to run distributed training (default: None).

- To use `smdistributed.dataparallel` as a distribution strategy, use the following option:

  ```python
distribution = { "smdistributed": { "dataparallel": { "enabled": True } } }
  ```

- **custom_mpi_options (str)(optional):** Custom MPI options. The following is an example of how you can use this parameter when defining distribution. To learn more, see Custom MPI Options (p. 1845).

  ```python
distribution = {
    "smdistributed": {
      "dataparallel": {
        "enabled": True,
        "custom_mpi_options": "-x NCCL_DEBUG=VERSION"
      }
    }
  }
  ```
**train_instance_type (str)** *(required)*: A type of Amazon EC2 instance to use.

- If the `smdistributed.dataparallel` distribution strategy is used, the allowed instance types are: `ml.p4d.24xlarge`, `ml.p3dn.24xlarge`, and `ml.p3.16xlarge`. For best performance, it is recommended that you use an EFA supported instance, `ml.p3dn.24xlarge` or `ml.p4d.24xlarge`, with the latest supported version of TensorFlow.

**Example**

```python
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name = "training_job_name_prefix",
    entry_point="tf-train.py",
    role="SageMakerRole",
    framework_version="2.4.1",
    py_version="py37",
    instance_count=2,
    instance_type="ml.p3.16xlarge",
    distribution={"smdistributed": {"dataparallel": {"enabled": True}}}
)

tf_estimator.fit("s3://bucket/path/to/training/data")
```

**Note**

If you are using the SageMaker Python SDK 1.x, you need to use hyperparameters to specify to use `smdistributed dataparallel` as the distributed training strategy.

```python
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    ...,
    hyperparameters={"sagemaker_distributed_dataparallel_enabled": True},
    ...,
)

tf_estimator.fit("s3://bucket/path/to/training/data")
```

**PyTorch Estimator**

You can use SageMaker's `distributed data parallel library API` by specifying `smdistributed dataparallel` as the distribution strategy in SageMaker PyTorch Estimator API. Refer to the [SageMaker PyTorch Estimator API specification](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#SageMaker.Client) for full details of the API.

```python
class sagemaker.pytorch.estimator.PyTorch(py_version=None, framework_version=None, model_dir=None, image_uri=None, hyperparameters=None, distribution=None, **kwargs)
```

The following two parameters of the SageMaker PyTorch Estimator are necessary for using `smdistributed.dataparallel` on SageMaker with PyTorch.
distribution (dict)(optional): A dictionary with information on how to run distributed training (default: None).

- To use smdistributed.dataparallel as a distribution strategy, use the following option:

```python
distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
```

- custom_mpi_options (str)(optional): Custom MPI options. The following is an example of how you can use this parameter when defining distribution. To learn more, see Custom MPI Options (p. 1845).

```python
distribution = {
    "smdistributed": {
        "dataparallel": {
            "enabled": True,
            "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
        }
    }
}
```

train_instance_type (str)(required): A type of Amazon EC2 instance to use.

- If the smdistributed.dataparallel distribution strategy is used, the allowed instance types are: ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge. For best performance, it is recommended that you use an EFA supported instance, ml.p3dn.24xlarge or ml.p4d.24xlarge, with the latest supported version of PyTorch.

Example

```python
from sagemaker.pytorch import PyTorch
pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    entry_point="pt-train.py",
    role="SageMakerRole",
    py_version="py36",
    framework_version="1.8.1",
    instance_count=2,
    instance_type="ml.p3.16xlarge",
    distribution={"smdistributed": {"dataparallel": {"enabled": True}}}"
)
pt_estimator.fit("s3://bucket/path/to/training/data")
```

**Note**

If you are using SageMaker Python SDK 1.x, you need to use hyperparameters to specify smdistributed.dataparallel as the distributed training strategy.

```python
from sagemaker.pytorch import PyTorch
pt_estimator = PyTorch(
    ...,
    # Training using smdistributed.dataparallel Distributed Training Framework
)
```
SageMaker Distributed Data Parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using SageMaker’s distributed data parallel library. This list includes tips that are applicable across frameworks.

Topics

- Data Preprocessing (p. 1844)
- Single Versus Multiple Nodes (p. 1844)
- Debug Scaling Efficiency with Debugger (p. 1844)
- Batch Size (p. 1844)
- Custom MPI Options (p. 1845)
- Use Amazon FSx and set up an optimal storage and throughput capacity (p. 1845)

Data Preprocessing

If you preprocess data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker distributed data parallel uses the CPU for AllReduce operations. You may be able to improve training time by moving preprocessing steps to a library that uses GPUs or by completing all preprocessing before training.

Single Versus Multiple Nodes

We recommend that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs); however, when you use two or more nodes, the library’s AllReduce operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node AllReduce efficiency.

Debug Scaling Efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization and other metrics of interest during training. You can use Debugger built-in rules to monitor computational performance issues, such as CPU Bottleneck, Load Balancing, and Low GPU Utilization. You can specify these rules with Debugger configurations when you define an Amazon SageMaker Python SDK estimator. If you use AWS CLI and AWS Boto3 for training on SageMaker, you can enable Debugger as shown in Configure Debugger Using Amazon SageMaker API.

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook examples in the SageMaker Notebook Examples GitHub repository. To learn more about Debugger, see Amazon SageMaker Debugger.

Batch Size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.
One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a Linear Scaling Rule where each time the mini-batch size is multiplied by k, the learning rate is also multiplied by k. To learn more about this technique, see the research paper, Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Sections 2 and 3.

Custom MPI Options

The SageMaker distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA’s NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or Pytorch Estimator, the respective container sets up the MPI environment and executes the mpirun command to start jobs on the cluster nodes.

You can set custom MPI operations using the custom_mpi_options parameter in the Estimator. Any mpirun flags passed in this field are added to the mpirun command and executed by SageMaker for training. For example, you may define the distribution parameter of an Estimator using the following to use the NCCL_DEBUG variable to print the NCCL version at the start of the program:

```
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"}}}
```

Use Amazon FSx and set up an optimal storage and throughput capacity

When training a model on multiple nodes with distributed data parallelism, it is highly recommended to use FSx for Lustre. Amazon FSx is a scalable and high-performance storage service that supports shared file storage with a faster throughput. Using Amazon FSx storage at scale, you can achieve a faster data loading speed across the compute nodes.

Typically, with distributed data parallelism, you would expect that the total training throughput scales near-linearly with the number of GPUs. However, if you use suboptimal Amazon FSx storage, the training performance might slow down due to a low Amazon FSx throughput.

For example, if you use the SCRATCH_2 deployment type of Amazon FSx file system with the minimum 1.2 TiB storage capacity, the I/O throughput capacity is 240 MB/s. Amazon FSx storage works in a way that you can assign physical storage devices, and the more devices assigned, the larger throughput you get. The smallest storage increment for the SCRATCH_2 type is 1.2 TiB, and the corresponding throughput gain is 240 MB/s.

Assume that you have a model to train on a 4-node cluster over a 100 GB data set. With a given batch size that’s optimized to the cluster, assume that the model can complete one epoch in about 30 seconds. In this case, the minimum required I/O speed is approximately 3 GB/s (100 GB / 30 s). This is apparently a much higher throughput requirement than 240 MB/s. With such a limited Amazon FSx capacity, scaling your distributed training job up to larger clusters might aggravate I/O bottleneck problems; model training throughput might improve in later epochs as cache builds up, but Amazon FSx throughput can still be a bottleneck.

To alleviate such I/O bottleneck problems, you should increase the Amazon FSx storage size to obtain a higher throughput capacity. Typically, to find an optimal I/O throughput, you may experiment with different Amazon FSx throughput capacities, assigning an equal to or slightly lower throughput than your estimate, until you find that it is sufficient to resolve the I/O bottleneck problems. In case of the aforementioned example, Amazon FSx storage with 2.4 GB/s throughput and 67 GB RAM cache would be sufficient. If the file system has an optimal throughput, the model training throughput should reach maximum either immediately or after the first epoch as cache has built up.

To learn more about how to increase Amazon FSx storage and deployment types, see the following pages in the Amazon FSx for Lustre documentation:
Data Parallel Library FAQ

Use the following to find answers to commonly asked questions about SageMaker's data parallelism library.

Q: When using the library, how are the allreduce-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker service create extra C5s for jobs that use the library?

The library uses the CPUs available with GPU instances. No additional C5 or CPU instances are launched; if your SageMaker training job is 8 node ml.p3dn.24xlarge clusters, only 8 ml.p3dn.24xlarge instances are used. No additional instances are provisioned.

Q: I have a training job taking 5 days on a single ml.p3.24xlarge instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is enabling SDP and using a 5x bigger cluster enough to experience an approximate 5x speedup? Or will I have to revisit its training hyperparameters after enabling SDP?

Enabling the library would change the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

Q: Does the library support Spot?

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You enable save and restore checkpoints in their training script as mentioned in the last step of the section called “Script Modification Overview” (p. 1835).

Q: What is the difference between the library's balanced fusion buffers and PyTorch Distributed Data Parallel (DDP) “Gradient Buckets”?

The primary difference is that DDP's fusion buffer is used for AllReduce and the library's balanced fusion buffer is used for parameter server style synchronization. The library is the first framework to shard fusion buffers in parameter server-based gradient synchronization.

From the PyTorch DDP documentation: “To improve communication efficiency, the Reducer organizes parameter gradients into buckets, and reduces one bucket at a time. Bucket size can be configured by setting the bucket_cap_mb argument in DDP constructor. The mapping from parameter gradients to buckets is determined at the construction time, based on the bucket size limit and parameter sizes. Model parameters are allocated into buckets in (roughly) the reverse order of Model.parameters() from the given model. The reason for using the reverse order is because DDP expects gradients to become ready during the backward pass in approximately that order.”

Q: Is the library relevant in single-host, multi-device setup?

The library can be used with a single-host, multi-device setup. However, in two or more nodes, the library's AllReduce operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node AllReduce efficiency.

Q: Can the library be used with PyTorch Lightning?

No. However, with the library's DDP for PyTorch, you can write custom DDP to achieve the functionality.

Q: Where should the training dataset be stored?
The training dataset can be stored in an Amazon S3 bucket or on an Amazon FSx drive. See this document for various supported input filesystem for a training job.

Q: When using the library, is it mandatory to have training data in FSx for Lustre? Can Amazon EFS and Amazon S3 be used?

We recommend using Amazon FSx to cut down the time to kickstart the training. It is not mandatory.

Q: Can the library be used with CPU nodes?

No. The library supports ml.p3.16xlarge, ml.p3dn.24xlarge, and ml.p4d.24xlarge instances at this time.

Q: What frameworks and framework versions are currently supported by the library at launch?

The library currently supports PyTorch v1.6.0 or later and Tensorflow v2.3.0 or later. It doesn't support Tensorflow 1.x. For more information about which version of the library is packaged within AWS deep learning containers, see Release Notes for Deep Learning Containers.

Q: Does the library support AMP?

Yes, SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- **Frameworks - PyTorch** in the NVIDIA Deep Learning Performance documentation
- **Frameworks - TensorFlow** in the NVIDIA Deep Learning Performance documentation
- **Automatic Mixed Precision for Deep Learning** in the NVIDIA Developer Docs
- **Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs** in the PyTorch Blog
- **TensorFlow mixed precision APIs** in the TensorFlow documentation

Q: How do I identify if my distributed training job is slowed down due to I/O bottleneck?

With a larger cluster, the training job requires more I/O throughput, and therefore the training throughput might take longer (more epochs) to ramp up to the maximum performance. This indicates that I/O is being bottlenecked and cache is harder to build up as you scale nodes up (higher throughput requirement, more complex network topology). For more information about monitoring the Amazon FSx throughput on CloudWatch, see Monitoring FSx for Lustre in the FSx for Lustre User Guide.

Q: How do I resolve I/O bottlenecks when running a distributed training job with data parallelism?

It is highly recommended to use Amazon FSx as your data channel if you are using Amazon S3. If you are already using Amazon FSx but still having I/O bottleneck problems, you might have set up your Amazon FSx file system with a low I/O throughput and a small storage capacity. For more information about how to estimate and choose the right size of I/O throughput capacity, see Use Amazon FSx and set up sufficient storage and throughput capacity.

**Data Parallel Troubleshooting**

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact AWS Support.

**Topics**
Considerations for Using SageMaker Distributed Data Parallel with SageMaker Debugger and Checkpoints

To monitor system bottlenecks, profile framework operations, and debug model output tensors for training jobs with SageMaker distributed data parallel, you use SageMaker Debugger. However, when you use SageMaker Debugger, SageMaker distributed data parallel, and SageMaker checkpoints, you might see an error that looks like the following:

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled
```

This is due to an internal error between Debugger and checkpoints, which occurs when you enable SageMaker Distributed.

- If you enable all three features, SageMaker Python SDK automatically turns off Debugger by passing `debugger_hook_config=False`, which is equivalent to the following framework `estimator` example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3:///{bucket}/{base_job_name}/{checkpoint_in_bucket}"

estimator = TensorFlow(
    ...  
    distribution={"smdistributed": { "dataparallel": { "enabled": True }},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False,
)
```

- If you want to keep using both SageMaker distributed data parallel and SageMaker Debugger, a workaround is manually adding checkpointing functions to your training script instead of specifying the `checkpoint_s3_uri` and `checkpoint_local_path` parameters from the estimator. For more information about setting up manual checkpointing in a training script, see Saving Checkpoints (p. 1871).

An Unexpected Prefix (`model` for example) Is Attached to state_dict keys (model parameters) from a PyTorch Distributed Training Job

The SageMaker data parallel library does not directly alter or prepend any model parameter names when PyTorch training jobs save model artifacts. The PyTorch's distributed training changes the names in the `state_dict` to go over the network, prepending the prefix. If you encounter any model failure problem due to the different parameter names while you are using the SageMaker data parallel library and checkpointing for PyTorch training, adapt the following example code to remove the prefix at the step you load checkpoints in your training script:

```
state_dict = {k.partition('model.')[2]: state_dict[k] for k in state_dict.keys()}
```
This takes each `state_dict` key as a string value, separates the string at the first occurrence of `'model.'`, and takes the third list item (with index 2) of the partitioned string.

For more information about the prefix issue, see a discussion thread at Prefix parameter names in saved model if trained by multi-GPU? in the PyTorch discussion forum.

For more information about the PyTorch methods for saving and loading models, see Saving & Loading Model Across Devices in the PyTorch documentation.

## SageMaker's Distributed Model Parallel

**Important**

To use new features with an existing notebook instance or Studio app, restart it to get the latest updates.

Amazon SageMaker's distributed model parallel library (the library) can be used to training large deep learning models that were previously difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances and coordinates model training, allowing you to increase prediction accuracy by creating larger models with more parameters.

You can use the library to automatically partition your existing TensorFlow and PyTorch workloads across multiple GPUs with minimal code changes. You can access the library's API through the SageMaker SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library's API documentation is located in the SageMaker Python SDK under Distributed Training APIs. To see the latest updates to the library, refer to the release notes.

### Introduction to Model Parallelism

**Model parallelism** is the process of splitting a model up between multiple devices or nodes (such as GPU-equipped instances) and creating an efficient pipeline to train the model across these devices to maximize GPU utilization.

Use the sections on this page to learn more about model parallelism, including how it can be used to overcome issues that arise when training large ML models, and important considerations when integrating it into your ML training script.

#### What is Model Parallelism?

Increasing deep learning model size (layers and parameters) can result in better accuracy, however there is a limit to the maximum model size you can fit in a single GPU. When training deep learning models, GPU memory limitations can be a bottleneck in the following ways:

- They can limit the size of the model you train. Given that larger models tend to achieve higher accuracy, this directly translates to trained model accuracy.
- They can limit the batch size you train with, leading to lower GPU utilization and slower training.
To overcome the limitations associated with training a model on a single GPU, you can use model parallelism to distribute and train your model on multiple computing devices.

**Important Considerations when Using Model Parallelism**

When you use model parallelism, you must consider the following:

- **How you split your model across devices**: The computational graph of your model, sizes of model parameters and activations, and your resource constraints (for example, time vs. memory) determine the best partitioning strategy.

  To reduce the time and effort required to efficiently split your model, you can use automated model splitting features offered by Amazon SageMaker's distributed model parallel library.

- **Achieving parallelization**: Model training—that is, forward computations and backward propagation—is inherently sequential, where each operation must wait for its inputs to be computed by another operation. For this reason, forward and backward pass stages of deep learning training are not easily parallelizable, and naively splitting a model across multiple GPUs may lead to poor device utilization. For example, a layer on GPU $i+1$ has to wait for the output from a layer on GPU $i$, and so GPU $i+1$ remains idle during this waiting period.

  The model parallel library can achieve true parallelization by implementing pipelined execution by building an efficient computation schedule where different devices can work on forward and backward passes for different data samples at the same time.

To learn how you can use the library to efficiently split your model across devices and improve device utilization during training, see [Core Features of SageMaker Distributed Model Parallel (p. 1850)](#).

**Core Features of SageMaker Distributed Model Parallel**

Amazon SageMaker’s distributed model parallel makes model parallelism more accessible by providing automated model splitting and sophisticated pipeline execution scheduling. The model splitting algorithms can optimize for speed or memory consumption. The library also supports manual partitioning. When you use the library, training is executed in a pipelined fashion over microbatches to maximize GPU usage.

You can configure these features using a few lines of code when you create your training script and define your SageMaker PyTorch or TensorFlow Estimator. Use the following sections to learn more about these core features of the library.

**Note**

The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

**Automated Model Splitting**

When you use SageMaker’s model parallel library, you can take advantage of **automated model splitting**, also referred to as **automated model partitioning**. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.
How It Works

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for AWS infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The following section reviews the specifics of the design in each framework.

**Automated Model Splitting with PyTorch**

During the first training step, the model parallel library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After this tracing step, the library constructs a tree, which consists of the nested `nn.Module` objects in the model, as well as additional data gathered from tracing, such as the amount of stored `nn.Parameters`, and execution time for each `nn.Module`.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each `nn.Module` to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored `nn.Parameter` size and activations). If multiple `nn.Modules` share the same `nn.Parameter`, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.

**Automated Model Splitting with TensorFlow**

The model parallel library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
- Balancing the number of operations executed in each device

If you specify `speed for optimize` in the model parallel parameters in the Python SDK, the library tries to balance the number of operations and `tf.Variable` objects in each device. Otherwise, it tries to balance the total size of `tf.Variables`.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same `tf.Variable` and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a `tf.Variable`, then all operations that are part of these layers are placed on a single device.

**Comparison of Automated Model Splitting Between Frameworks**

In TensorFlow, the fundamental unit of computation is a `tf.Operation`, and TensorFlow represents the model as a directed acyclic graph (DAG) of `tf.Operations`, and therefore model parallel library
partitions this DAG so that each node goes to one device. Crucially, `tf.Operation` objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an `nn.Module`, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

**Manual Model Splitting**

If you want to manually specify how your model is partitioned across devices, you can use manual model splitting by using `smp.partition` context managers.

To use this option, set `auto_partition` to `False`, and define a `default_partition` in the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the `smp.partition` context manager is executed on the `default_partition`. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallel library creates a pipelined execution schedule automatically.

**Pipeline Execution Schedule**

A core feature of SageMaker’s distributed model parallel library is *pipelined execution*, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation.

Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A *microbatch* is a smaller subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by which device for every time slot.

For example, depending on the pipeline schedule and the model partition, GPU $i$ might perform (forward or backward) computation on microbatch $b$ while GPU $i+1$ performs computation on microbatch $b+1$, thereby keeping both GPUs active at the same time. During a single forward or backward pass, execution flow for a single microbatch might visit the same device multiple times, depending on the partitioning decision. For instance, an operation that is at the beginning of the model might be placed on the same device as an operation at the end of the model, while the operations in between are on different devices, which means this device is visited twice.

The library offers two different pipeline schedules, *simple* and *interleaved*, which can be configured using the `pipeline` parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve better performance by utilizing the GPUs more efficiently.

**Interleaved Pipeline**

In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This allows quicker release of the memory used for activations, using memory more efficiently. It also allows for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each device alternates between running forward and backward passes. This means that the backward pass of one microbatch may run before the forward pass of another microbatch finishes.
The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs. In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass for microbatch 1. **Update** represents the optimizer update of the parameters. GPU0 always prioritizes backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of the memory used for activations earlier.

**Simple Pipeline**

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting the backward pass. This means that it only pipelines the forward pass and backward pass stages within themselves. The following figure illustrates an example of how this works, over 2 GPUs.

**Pipelining Execution in Specific Frameworks**

Use the following sections to learn about the framework-specific pipeline scheduling decisions SageMaker’s distributed model parallel library makes for TensorFlow and PyTorch.

**Pipeline Execution with TensorFlow**

The following image is an example of a TensorFlow graph partitioned by the model parallel library, using automated model splitting. When a graph is split, each resulting subgraph is replicated B times (except for the variables), where B is the number of microbatches. In this figure, each subgraph is replicated 2 times (B=2). An **SMPInput** operation is inserted at each input of a subgraph, and an **SMPOutput** operation is inserted at each output. These operations communicate with the library backend to transfer tensors to and from each other.

The following image is an example of 2 subgraphs split with B=2 with gradient operations added. The gradient of a **SMPInput** op is a **SMPOutput** op, and vice versa. This enables the gradients to flow backwards during back-propagation.
This GIF demonstrates an example interleaved pipeline execution schedule with $B=2$ microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As $B$ grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue `SMPInput` operations to start executing.

Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

**Pipeline Execution with PyTorch**

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallel library's PyTorch feature uses a more dynamic pipelining paradigm.

As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch which the current device can actively work on. The prioritization of microbatches is determined by the chosen...
pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

**Modify Your Training Script Using SageMaker's Distributed Model Parallel Library**

Use this section to learn how to customize your training script with Amazon SageMaker's distributed model parallel library-specific API functions and parameters. We recommend you use this documentation alongside the model parallel library API documentation.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end to end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed model parallel library, see Amazon SageMaker Distributed Training Notebook Examples (p. 1873).

**Topics**
- Modify a TensorFlow Training Script (p. 1855)
- Modify a PyTorch Training Script (p. 1860)

**Modify a TensorFlow Training Script**

The following are examples of training scripts that you can use to configure the SageMaker distributed model parallel library with TensorFlow versions 2.3.1 and 2.4.1 with auto-partitioning and manual partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism. We recommend that you review Unsupported Framework Features (p. 1855) before creating a training script.

The required modifications you must make to your training script to use the library are listed in TensorFlow (p. 1856).

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see TensorFlow with Horovod (p. 1857).

If you want to use manual partitioning, also review Manual partitioning with TensorFlow (p. 1859).

**Tip**
For end to end, runnable notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker distributed model parallel library, see TensorFlow Examples (p. 1874).

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following example scripts use auto-partitioning.

**Topics**
- Unsupported Framework Features (p. 1855)
- TensorFlow (p. 1856)
- TensorFlow with Horovod (p. 1857)
- Manual partitioning with TensorFlow (p. 1859)

**Unsupported Framework Features**

The following TensorFlow features are unsupported by the library:

- `tf.GradientTape()` is currently not supported. You can use `Optimizer.get_gradients()` or `Optimizer.compute_gradients()` instead to compute gradients.
• The `tf.train.Checkpoint.restore()` API is currently not supported. For checkpointing, use `smp.CheckpointManager` instead, which provides the same API and functionality. Note that checkpoint restores with `smp.CheckpointManager` should take place after the first step.

**TensorFlow**

The following training script changes are required to run a TensorFlow model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.

2. Define Keras model by inheriting from `smp.DistributedModel` instead of Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.

3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.

4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.

5. Put the forward and backward logic in a step function and decorate it with `smp.step`.

6. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`. The `smp.step` function must have a return value that depends on the output of `smp.DistributedModel`.

7. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput API`.

To learn more about the SageMaker’s distributed model parallel library API, refer to the API documentation.

```python
import tensorflow as tf

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data("MNIST-data-%d" % smp.rank())

x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = tf.data.Dataset.from_tensor_slices((x_train, y_train))

   .shuffle(10000, seed=smp.dp_rank())

   .batch(256, drop_remainder=True)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
```
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return the model output

    model = MyModel()

    loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
    optimizer = tf.keras.optimizers.Adam()
    train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

    @smp.step
    def get_grads(images, labels):
        predictions = model(images, training=True)
        loss = loss_object(labels, predictions)
        grads = optimizer.get_gradients(loss, model.trainable_variables)
        return grads, loss, predictions

    @tf.function
    def train_step(images, labels):
        gradients, loss, predictions = get_grads(images, labels)

        # smpdistributed: Accumulate the gradients across microbatches
        gradients = [g.accumulate() for g in gradients]
        optimizer.apply_gradients(zip(gradients, model.trainable_variables))

        # smpdistributed: Merge predictions and average losses across microbatches
        train_accuracy(labels, predictions.merge())
        return loss.reduce_mean()

    for epoch in range(5):
        # Reset the metrics at the start of the next epoch
        train_accuracy.reset_states()
        for images, labels in train_ds:
            loss = train_step(images, labels)
            accuracy = train_accuracy.result()

---

**TensorFlow with Horovod**

The SageMaker distributed model parallel library can be used with Horovod for hybrid model and data parallelism. In this case, the total number of GPUs must be divisible by the number of partitions. The quotient is inferred to be the number of model replicas or data parallelism degree. For instance, if a training job is launched with 8 processes (which corresponds to 8 GPUs), and partitions is 2, then the library applies 2-way model parallelism and 4-way data parallelism over the 8 GPUs.

To access the data parallel rank and model parallel rank of a process, you can use `smp.dp_rank()` and `smp.mp_rank()`, respectively. To see all MPI primitives the library exposes, see [MPI Basics](#) in the API documentation.

If you are using Horovod, you should not directly call `hvd.init`. Instead, set "horovod" to `True` in the SageMaker Python SDK `modelparallel` parameters, and the library internally initializes Horovod. This is because Horovod must be initialized based on the device assignments of model partitions, and calling `hvd.init()` directly results in problems.

Furthermore, using `hvd.DistributedOptimizer` directly results in poor performance or hangs, since this implicitly places the AllReduce operation inside `smp.step`. The recommended way to use the model
parallel library with Horovod is by directly calling `hvd.allreduce` after calling `accumulate()` or `reduce_mean()` on the gradients returned from `smp.step`, as seen in the following example.

The four main changes needed in the script are:

- Adding `hvd.allreduce`
- Broadcasting variables after the first batch, as required by Horovod
- Setting the "horovod" parameter to `True` in the `modelparallel` dict in the Python SDK
- Seeding shuffling and/or sharding operations in the data pipeline with `smp.dp_rank()`.

To learn more about the SageMaker’s distributed model parallel library API, refer to the API documentation.

```python
import tensorflow as tf
import horovod.tensorflow as hvd
# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train)).shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return model outputs

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)
```

1858
grads = optimizer.get_gradients(loss, model.trainable_variables)
return grads, loss, predictions

@tf.function
def train_step(images, labels, first_batch):
    gradients, loss, predictions = get_grads(images, labels)
    # smdistributed: Accumulate the gradients across microbatches
    # Horovod: Allreduce the accumulated gradients
    gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # Horovod: Broadcast the variables after first batch
    if first_batch:
        hvd.broadcast_variables(model.variables, root_rank=0)
        hvd.broadcast_variables(optimizer.variables(), root_rank=0)
    # smdistributed: Merge predictions across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for batch, (images, labels) in enumerate(train_ds):
        loss = train_step(images, labels, tf.constant(batch == 0))

Manual partitioning with TensorFlow

Use sm.partition context managers to place operations in specific partition. Any operation not placed in any sm.partition contexts is placed in the default_partition. To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

import tensorflow as tf
# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp
# smdistributed: Initialize
smp.init()
# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data("MNIST-data-%d" % smp.rank())
x_train, x_test = x_train / 255.0, x_test / 255.0
# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]
# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)
# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
```python
class MyModel(smp.DistributedModel):
    def __init__(self):
        # define layers

def call(self, x):
    with smp.partition(0):
        x = self.layer0(x)
    with smp.partition(1):
        return self.layer1(x)

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smpdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    # smpdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # smpdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
        accuracy = train_accuracy.result()
```

### Modify a PyTorch Training Script

The following are examples of training scripts that you can use to configure SageMaker's model parallel library with PyTorch versions 1.7.1 and 1.6.0, with auto-partitioning and manual partitioning. We recommend that you review the Important Considerations (p. 1861) and Unsupported Framework Features (p. 1863) before creating a training script.

The required modifications you must make to your training script to use the library are listed in PyTorch (p. 1863).

If you want to use manual partitioning, also review Manual Partitioning with PyTorch (p. 1865).

**Tip**

For end to end, runnable notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker distributed model parallel library, see PyTorch Examples (p. 1873).
Note that auto-partitioning is enabled by default. Unless otherwise specified, the following scripts use auto-partitioning.

**Topics**
- Important Considerations (p. 1861)
- Unsupported Framework Features (p. 1863)
- PyTorch (p. 1863)
- Manual Partitioning with PyTorch (p. 1865)

**Important Considerations**

When you configure a PyTorch training script using SageMaker's distributed model parallel library, you should be aware of the following:

- If you are using an optimization technique that relies on global gradient norms, for example gradient norm from the entire model, such as some variants of LAMB optimizer or global gradient clipping, you need to gather all the norms across the model partitions for correctness. You can use the library’s communication basic data types to do this.

- All `torch.Tensor` arguments to the forward methods of the `nn.Module` in your model must be used in the computation of the module output. In other words, the library does not support the case where there is a `torch.Tensor` argument to a module on which the module output does not depend.

- The argument to the `smp.DistributedModel.backward()` call must depend on all model outputs. In other words, there cannot be an output from the `smp.DistributedModel.forward` call that is not used in the computation of the tensor that is fed into the `smp.DistributedModel.backward` call.

- If there are `torch.cuda.synchronize()` calls in your code, you might need to call `torch.cuda.set_device(smp.local_rank())` immediately before the synchronize call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.

- Since the library places `nn.Module` on different devices, the modules in the model must not depend on any global state that is modified inside `smp.step`. Any state that remains fixed throughout training, or that is modified outside `smp.step` in a way that is visible to all processes, is allowed.

- You don't need to move the model to GPU (for example, using `model.to(device)`) when using the library. If you try to move the model to GPU before the model is partitioned (before the first `smp.step` call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don't move the model to CPU and use it, as it won't have correct parameters for modules not assigned to the partition held by the process. If you want to retrain a model or use it for inference without the library after it was trained using the model parallel library, the recommended way is to save the full model using our checkpointing API and load it back to a regular PyTorch Module.

- If you have a list of modules such that output of one feeds into another, replacing that list with `nn.Sequential` can significantly improve performance.

- The weight update (`optimizer.step()`) needs to happen outside of `smp.step` because that is when the entire backward pass is done and gradients are ready. When using a hybrid model with model and data parallelism, at this point, Allreduce of gradients is also guaranteed to finish.

- When using the library in combination with data parallelism, make sure that the number of batches on all data parallel ranks is the same so that Allreduce does not hang waiting for a rank which is not participating in the step.

- If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), you must set the data loader variable `num_workers=0`. For example, you may define your `DataLoader` as follows:

```python
  dataloader = torch.utils.data.DataLoader(  
    data,  
    batch_size=batch_size,  
```
• The inputs to `smp.step` must be the model inputs generated by `DataLoader`. This is because `smp.step` internally splits the input tensors along the batch dimension and pipelines them. This means that passing `DataLoader` itself to the `smp.step` function to generate the model inputs inside does not work.

For example, if you define a `DataLoader` as follows:

```python
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

You should access the model inputs generated by `train_loader` and pass those to an `smp.step` decorated function. Do not pass `train_loader` directly to the `smp.step` function.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        ...
        _, loss_mb = train_step(model, data, target)
        ...
    @smp.step
    def train_step(model, data, target):
        ...
        return output, loss
```

• The input tensors to `smp.step` must be moved to the current device using `.to()` API, which must take place after the `torch.cuda.set_device(local_rank())` call.

For example, you may define the `train` function as follows. This function adds `data` and `target` to the current device using `.to()` API before using those input tensors to call `train_step`.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)
        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()
```

The input tensors to this `smp.set` decorated function have been moved to the current device in the `train` function above. The model does not need to be moved to the current device. The library automatically moves the part of the model assigned to a rank to its GPU.

```python
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
```
Unsupported Framework Features

The following PyTorch features are unsupported by SageMaker's distributed model parallel library:

- If you use data parallelism with the native PyTorch DDP, the `torch.nn.parallel.DistributedDataParallel` wrapper module is not supported by the library. The library internally manages integrating with PyTorch DDP, including parameter broadcast and gradient AllReduce. When using the library, module buffers are only broadcast once at the start of training. If your model has module buffers that need to be synchronized across data parallel groups at each step, you can do so through the `torch.distributed` API, using the process group that can be obtained via `smp.get_dp_process_group()`.

- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using `smp.amp.GradScaler` instead of the implementation in torch.

- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `smp.DistributedModel`.

- `apex`: FusedLayerNorm, FusedAdam, FusedLAMB, and FusedNovoGrad from apex are not supported. You can use the library implementations of these through `smp.optimizers` and `smp.nn` APIs instead.

PyTorch

The following training script changes are required to run a PyTorch model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.
2. Wrap the model with `smp.DistributedModel`. Be mindful that any tensors returned from the `forward` method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Wrap the optimizer with `smp.DistributedOptimizer`.
4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).
9. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`.
10. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput API`.
11. Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.
import torch.nn as nn

        }
        dataset = SplitDataset(dataset, partitions=partitions_dict)
        dataset.select(f"{smp.dp_rank()}")

    # smdistributed: Set drop_last=True to ensure that batch size is always divisible
    # by the number of microbatches
    train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

    model = GroupedNet()
    optimizer = optim.Adadelta(model.parameters(), lr=4.0)
Model Parallel Training

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

Manual Partitioning with PyTorch

Use smp.partition context managers to place modules in specific devices. Any module not placed
in any smp.partition contexts is placed in the default_partition. The default_partition
needs to be provided if auto_partition is set to False. The modules that are created within a specific
smp.partition context are placed on the corresponding partition.

To learn more about the SageMaker's distributed model parallel library API, refer to the API
documentation.

Run a SageMaker Distributed Model Parallel Training Job

Learn how to run a distributed model parallel training job using the SageMaker Python SDK and your adapted training script with SageMaker's distributed model parallel library.

SageMaker supports the following training environment configurations.

1. You can use a prebuilt TensorFlow or PyTorch container. This option is recommended for new users of  
   the model parallel library, and is demonstrated in the example MNIST with PyTorch 1.6 and Amazon  
   SageMaker's distributed model parallel library.

2. You can extend SageMaker prebuilt containers to handle any additional functional requirements  
   for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. To see an  
   example of how you can extend a pre-built container, see Extend a Prebuilt Container.

3. You can adapt your own Docker container to work with SageMaker using the SageMaker Training  
   toolkit. For an example, see Adapting Your Own Training Container.

For options 2 and 3 in the preceding list, refer to Extend or Adapt A Docker Container that Contains  
SageMaker's Distributed Model Parallel Library (p. 1869) to learn how to install the model parallel  
library in an extended or customized Docker container.

In all cases, you launch your job using a SageMaker Python SDK TensorFlow or PyTorch Estimator to  
initialize the library and launch a training job. To learn more, see the following section, Launch a Training  
Job with the SageMaker Python SDK (p. 1867).
Launch a Training Job with the SageMaker Python SDK

The SageMaker Python SDK supports managed training of TensorFlow and PyTorch models. To launch a training job using one of these frameworks, you can define a TensorFlow Estimator or a PyTorch Estimator.

The TensorFlow and PyTorch Estimator object contains a distribution parameter, which is used to enable and specify parameters for the initialization of SageMaker's distributed model parallel library. The library internally uses MPI, so in order to use model parallelism, MPI must be enabled using the distribution parameter.

The following is an example of how you can launch a new PyTorch training job with the library.

```python
import sagemaker
sagemaker_session = sagemaker.session.Session(boto_session=session)

smp_options = {
    "enabled": True,
    "parameters": {
        "partitions": 2,
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "ddp": True,
    }
}

mpi_options = {
    "enabled": True,
    "processes_per_host": 8,
    # "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py",  # Specify your train script
    source_dir="location_to_your_script",
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.8.1',
    # You must set py_version to py36
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options,
                         "mpi": mpi_options
                      },
        "base_job_name": "SMD-MP-demo",
    }
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

To enable the library, you need to pass dictionaries for the "mpi" and "smdistributed" keys to the distribution argument of the estimator constructors in SageMaker Python SDK.

- For the "smdistributed" key, pass a dictionary with the "modelparallel" key and the following inner dictionaries.

  **Note**

  Using "modelparallel" and "dataparallel" in one training job is not supported.

- "enabled" (required) – To enable model parallelism, set "enabled": True.
Model Parallel Training

- "parameters" (required) – Specify a set of parameters for model parallelism listed in `smdistributed Parameters`. Among the parameters, the "partitions" key is required to specify how many model partitions need to be requested for a training job.

- For the "mpi" key, pass a dictionary that contains the following:
  - "enabled" (required) – True to launch the training job with MPI.
  - "processes_per_host" (required) – Specify the number of processes MPI should launch on each host. In SageMaker a host is a single Amazon EC2 ml instance. The SageMaker Python SDK maintains a one-to-one mapping between processes and GPUs across model and data parallelism. This means that SageMaker schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`. To learn more, see PyTorch (p. 1863).

    **Important**
    
    process_per_host must not be greater than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

    For example, if you use one instance with 4-way model parallelism and 2-way data parallelism, then processes_per_host should be 2 x 4 = 8. Therefore, you must choose an instance that has at least 8 GPUs, such as an mlp3.16xlarge.

    The following image illustrates how 2-way data parallelism and 4-way model parallelism is distributed across 8 GPUs: the models is partitioned across 4 GPUs, and each partition is added to 2 GPUs.

- "custom_mpi_options" (optional) – Use this key to pass any custom MPI options you might need. If you do not pass any MPI custom options to the key, the MPI option is set by default to the following flag.

    ```
    --mca btl_vader_single_copy_mechanism none
    ```

    **Note**
    
    You do not need to explicitly specify this default flag to the key. If you explicitly specify it, your distributed model parallel training job might fail with the following error:

    The following MCA parameter has been listed multiple times on the command line:
    MCA param: btl_vader_single_copy_mechanism MCA parameters can only be listed once on a command line to ensure there is no ambiguity as to its value. Please correct the situation and try again.

    **Tip**
    
    If you launch a training job using an EFA-enabled instance type, such as ml.p4d.24xlarge and ml.p3dn.24xlarge, use the following flag for best performance:

    ```
    -x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa -x RDMAV_FORK_SAFE=1
    ```

    To launch the training job using SageMaker model parallel configured training script, you use the `Estimator.fit()` function. You can launch a SageMaker training job using a SageMaker notebook instance, or locally.

    - Using a SageMaker notebook instance is recommended for new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see Amazon SageMaker Distributed Training Notebook Examples (p. 1873).

    - You can launch locally if you have set up your AWS credentials and Region for development.
Use the following resources to learn more about using the SageMaker Python SDK with these frameworks:

- Use TensorFlow with the SageMaker Python SDK
- Use PyTorch with the SageMaker Python SDK

**Extend or Adapt A Docker Container that Contains SageMaker's Distributed Model Parallel Library**

To extend a pre-built container, or adapt your own container to use SageMaker's distributed model parallel library, you must use one of the PyTorch or TensorFlow GPU general framework base-images. The distributed model parallel library is included in all CUDA 11 (cu11x) TensorFlow 2.3.x and PyTorch 1.6.x versioned images and later. See Available Deep Learning Containers Images for a list of available images.

**Tip**

It is recommended that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up to date version of the SageMaker distributed model parallel library.

For example, if you are using PyTorch 1.8.1, your Dockerfile should contain a FROM statement similar to the following:

```bash
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.8.1-gpu-py36-cu111-ubuntu18.04

# Add your dependencies here
RUN ...

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker PyTorch container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py
```

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the entry_point for your training script. This should be the same path identified with ENV SAGEMAKER_SUBMIT_DIRECTORY in your Dockerfile.

You must push this docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (image_uri) to define an estimator. See Extend a Prebuilt Container for more information.

For example, if your Dockerfile was defined using the preceding code block and used name and tag to push it to Amazon ECR, you would define a PyTorch estimator as follows. This example assumes you have already defined smp_options and mpi_options.

```python
smd_mp_estimator = PyTorch(  
    entry_point='/opt/ml/code/pt_mnist.py',  
    source_dir='utils',  
    role=role,  
    instance_type='ml.p3.16xlarge',  
    sagemaker_session=sagemaker_session,  
    image_uri='aws_account_id.dkr.ecr.region.amazonaws.com/name:tag'  
    instance_count=1,  
    distribution={
```
Review the following tips and pitfalls before using Amazon SageMaker's distributed model parallel library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see Modify a TensorFlow Training Script (p. 1855) and Modify a PyTorch Training Script (p. 1860), respectively.

**Batch Size and Number of Microbatches**

- The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.

- Choosing a number of microbatches that is too small or too large can hurt performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.

- Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it is not, you can set `drop_remainder=True` in the `tf.Dataset.batch()` call (in TensorFlow), or set `drop_last=True` in `DataLoader` (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

**Manual Partitioning**

- If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.

**Data Preparation**

- If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with `smp.dp_rank()`. If the dataset is being deterministically sharded across data parallel devices, make sure that the shard is indexed by `smp.dp_rank()`. This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

**Returning Tensors from smp.DistributedModel**

- Any tensor that is returned from the `smp.DistributedModel.call` (for TensorFlow) or `smp.DistributedModel.forward` (for PyTorch) function is broadcast to all other ranks, from the
rank that computed that particular tensor. As a result, any tensor that is not needed outside the call and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

The @smp.step Decorator

- If an smp.step-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the non_split_inputs list when calling smp.step. This prevents the library from attempting to split the tensor into microbatches. For more information see smp.step in the API documentation.

Model Parallel Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact AWS Support.

Topics

- Considerations for Using SageMaker Debugger with SageMaker Distributed Model Parallel (p. 1871)
- Saving Checkpoints (p. 1871)
- Convergence Using Model Parallel and TensorFlow (p. 1873)

Considerations for Using SageMaker Debugger with SageMaker Distributed Model Parallel

SageMaker Debugger is not available for SageMaker distributed model parallel. Debugger is enabled by default for all SageMaker TensorFlow and PyTorch training jobs, and you might see an error that looks like the following:

```python
FileNotFoundError: [Errno 2] No such file or directory: '/opt/ml/checkpoints/metadata.json.sagemaker-uploading'
```

To fix this issue, disable Debugger by passing debugger_hook_config=False when creating a framework estimator as shown in the following example.

```python
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"
# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/*/{}").format(bucket, base_job_name, checkpoint_in_bucket)
estimator = TensorFlow(
    ...
    distribution="smdistributed": {"modelparallel": {"enabled": True }},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)
```

Saving Checkpoints

You might run into the following error when saving checkpoints of a large model on SageMaker:

```python
InternalServerError: We encountered an internal error. Please try again
```
This could be caused by a SageMaker limitation while uploading the local checkpoint to Amazon S3 during training. To disable checkpointing in SageMaker, use the following example to explicitly upload the checkpoints.

If you run into the preceding error, do not use checkpoint_s3_uri with the SageMaker estimator call. While saving checkpoints for larger models, we recommend saving checkpoints to a custom directory and passing the same to the helper function (as a local_path argument).

```python
import os

def aws_s3_sync(source, destination):
    """aws s3 sync in quiet mode and time profile""
    import time, subprocess
    cmd = ['aws', 's3', 'sync', '--quiet', source, destination]
    print(f"Syncing files from {source} to {destination}"
    start_time = time.time()
    p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.PIPE)
    p.wait()
    end_time = time.time()
    print("Time Taken to Sync: ", (end_time-start_time))
    return

def sync_local_checkpoints_to_s3(local_path="/opt/ml/checkpoints",
                               s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """ sample function to sync checkpoints from local path to s3 ""
    import boto3
    #check if local path exists
    if not os.path.exists(local_path):
        raise RuntimeError("Provided local path {local_path} does not exist. Please check")
    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError("Provided s3 uri {s3_uri} is not valid.")
    s3_bucket = s3_uri.replace('s3://','').split('/')[0]
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(local_path, s3_uri)
    return

def sync_s3_checkpoints_to_local(local_path="/opt/ml/checkpoints",
                                 s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """ sample function to sync checkpoints from s3 to local path ""
    import boto3
    #try to create local path if it does not exist
    if not os.path.exists(local_path):
        print(f"Provided local path {local_path} does not exist. Creating...")
        try:
            os.makedirs(local_path)
        except Exception as e:
            raise RuntimeError(f"Failed to create {local_path}"
    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")
    s3_bucket = s3_uri.replace('s3://','').split('/')[0]
```
print(f"S3 Bucket: {s3_bucket}")
try:
    s3.meta.client.head_bucket(Bucket=s3_bucket)
except Exception as e:
    raise e
aws_s3_sync(s3_uri, local_path)
return

Usage of helper functions:

#base_s3_uri - user input s3 uri or save to model directory (default)
#curr_host - to save checkpoints of current host
#iteration - current step/epoch during which checkpoint is saved

# save checkpoints on every node using local_rank
if smp.local_rank() == 0:
    base_s3_uri = os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))

Convergence Using Model Parallel and TensorFlow

When you use SageMaker multi-node training with TensorFlow and distributed model parallel, the loss may not converge as expected because the order of training input files may be different on each node. This may cause different ranks in the same model parallel group to work on different input files, causing inconsistencies. To prevent this, ensure the input files are ordered the same way in all the ranks before they get converted to TensorFlow datasets. One way to achieve this is to sort the input file names in the training script.

Amazon SageMaker Distributed Training Notebook Examples

The following case studies and notebooks provide examples of implementing the SageMaker distributed training libraries for the supported deep learning frameworks (PyTorch, TensorFlow, and HuggingFace) and models, such as CNN and MaskRCNN for vision, and BERT for natural language processing.

These notebooks are provided in the SageMaker examples GitHub repository. You can also browse them on the SageMaker examples website.

The examples are set up to use p3.16xlarge instances for the worker nodes, but you may choose ml.p3dn.24xlarge or ml.p4d.24xlarge instance types for which the SageMaker distributed training libraries are optimized. You can test the notebooks using a cluster of a single node; however, to see a performance improvement as shown in the Training Benchmarks section, use a cluster of multiple nodes (two or more). The examples call out the section in which you modify this configuration.

Blogs and Case Studies

The following blogs discuss case studies about using the SageMaker distributed training libraries.

- Hyundai reduces ML model training time for autonomous driving models using Amazon SageMaker
- Distributed Training: Train BART/T5 for Summarization using Transformers and Amazon SageMaker in the HuggingFace documentation

PyTorch Examples

SageMaker Distributed Data Parallel
SageMaker Distributed Model Parallel

- CNN with PyTorch 1.6 and SageMaker Model Parallel
- BERT with PyTorch 1.6 and SageMaker Model Parallel

TensorFlow Examples

SageMaker Distributed Data Parallel

- CNN with TensorFlow 2.3.1 and SageMaker Data Parallel
- MaskRCNN with TensorFlow 2.3.1 and SageMaker Data Parallel
- BERT with TensorFlow 2.3.1 and SageMaker Data Parallel

SageMaker Distributed Model Parallel

- CNN with TensorFlow 2.3.1 and SageMaker Model Parallel

HuggingFace Examples

The following HuggingFace on SageMaker examples are available in the HuggingFace notebooks repository.

How to Access or Download the SageMaker Distributed Training Notebook Examples

Follow instructions to access or download the SageMaker distributed training example notebooks.

Option 1: Use a SageMaker notebook instance

To use the aforementioned examples, we recommend that you use an Amazon SageMaker notebook instance. A notebook instance runs Jupyter Notebook and JupyterServer apps on Amazon EC2 instances, which are optimized for machine learning. If you do not have an active notebook instance, follow the instructions in Create a Notebook Instance (p. 141) in the SageMaker developer guide to create one.
Detect Posttraining Data and Model Bias

After you have created an instance, in the **Notebook instances** page of the SageMaker console, do the following:

1. Open **JupyterLab**.
2. Select the examples icon ( ) in the left tray.
3. Browse the examples for **Training** and look for notebooks titled *Distributed Data Parallel* or *Distributed Model Parallel*.

**Option 2: Clone the SageMaker example repository to SageMaker Studio or notebook instance**

To download and use the aforementioned example notebooks, do the following to clone the example GitHub repositories:

1. Open a terminal.
2. In the command line, navigate to the SageMaker folder.
   ```bash
   $ cd SageMaker
   ```
3. Clone the SageMaker examples GitHub repository.
   ```bash
   git clone https://github.com/aws/amazon-sagemaker-examples.git
   ```

   **Note**
   To download the **HuggingFace** example notebooks (p. 1874), clone the **HuggingFace** notebooks GitHub repository:
   ```bash
   git clone https://github.com/huggingface/notebooks huggingface-notebooks
   ```
4. In the JupyterLab interface, navigate into the `amazon-sagemaker-examples` folder.
5. In the `training/distributed_training` folder, there are folders for frameworks, and in each of these, there are folders for `data_parallel` and `model_parallel`. Choose the example of your choice and follow the instructions to launch distributed training with a SageMaker distributed training library.

**Detect Posttraining Data and Model Bias**

Posttraining bias analysis can help reveal biases that might have emanated from biases in the data, or from biases introduced by the classification and prediction algorithms. These analyses take into consideration the data, including the labels, and the predictions of a model. You assess performance by analyzing predicted labels or by comparing the predictions with the observed target values in the data with respect to groups with different attributes. There are different notions of fairness, each requiring different bias metrics to measure.

There are legal concepts of fairness that might not be easy to capture because they are hard to detect. For example, the US concept of disparate impact that occurs when a group, referred to as a less favored facet \( d \), experiences an adverse effect even when the approach taken appears to be fair. This type of bias might not be due to a machine learning model, but might still be detectable by posttraining bias analysis.

Amazon SageMaker Clarify tries to ensure a consistent use of terminology. For a list of terms and their definitions, see Amazon SageMaker Clarify Terms for Bias and Fairness (p. 590).
For additional information about posttraining bias metrics, see Fairness Measures for Machine Learning in Finance.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection:

- **Explainability and bias detection with Amazon SageMaker Clarify** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 70). If you're prompted to choose a kernel, choose Python 3 (Data Science).

**Topics**

- Measure Posttraining Data and Model Bias (p. 1876)
- Configure an Amazon SageMaker Clarify Processing Jobs for Fairness and Explainability (p. 1894)
- Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability (p. 1901)
- Troubleshoot SageMaker Clarify Processing Jobs (p. 1905)

Measure Posttraining Data and Model Bias

Amazon SageMaker Clarify provides eleven posttraining data and model bias metrics to help quantify various conceptions of fairness. These concepts cannot all be satisfied simultaneously and the selection depends on specifics of the cases involving potential bias being analyzed. Most of these metrics are a combination of the numbers taken from the binary classification confusion matrices for the different demographic groups. Because fairness and bias can be defined by a wide range of metrics, human judgment is required to understand and choose which metrics are relevant to the individual use case, and customers should consult with appropriate stakeholders to determine the appropriate measure of fairness for their application.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multiclassification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet $a$ and for a disfavored facet $d$. These labels $y$ are referred to as observed labels to distinguish them from the predicted labels $y'$ that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions $P_a(y)$ and $P_d(y)$ for their respective facet outcomes.

- **labels:**
  - $y$ represents the $n$ observed labels for event outcomes in a training dataset.
  - $y'$ represents the predicted labels for the $n$ observed labels in the dataset by a trained model.

- **outcomes:**
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
    - $n^{(1)}$ is the number of observed labels for positive outcomes (acceptances).
    - $n'_{(1)}$ is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
    - $n^{(0)}$ is the number of observed labels for negative outcomes (rejections).
    - $n'_{(0)}$ is the number of predicted labels for negative outcomes (rejections).

- **facet values:**
• facet \( a \) – The feature value that defines a demographic that bias favors.
  
  • \( n_a \) is the number of observed labels for the favored facet value: \( n_a = n_a^{(1)} + n_a^{(0)} \) the sum of the positive and negative observed labels for the facet value \( a \).

  • \( n'_a \) is the number of predicted labels for the favored facet value: \( n'_a = n'_a^{(1)} + n'_a^{(0)} \) the sum of the positive and negative predicted outcome labels for the facet value \( a \). Note that \( n'_a = n_a \).

• facet \( d \) – The feature value that defines a demographic that bias disfavors.

  • \( n_d \) is the number of observed labels for the disfavored facet value: \( n_d = n_d^{(1)} + n_d^{(0)} \) the sum of the positive and negative observed labels for the facet value \( d \).

  • \( n'_d \) is the number of predicted labels for the disfavored facet value: \( n'_d = n'_d^{(1)} + n'_d^{(0)} \) the sum of the positive and negative predicted labels for the facet value \( d \). Note that \( n'_d = n_d \).

• probability distributions for outcomes of the labeled facet data outcomes:

  • \( P_a(y) \) is the probability distribution of the observed labels for facet \( a \). For binary labeled data, this distribution is given by the ratio of the number of samples in facet \( a \) labeled with positive outcomes to the total number, \( P_a(y^{(1)}) = n_a^{(1)}/n_a \), and the ratio of the number of samples with negative outcomes to the total number, \( P_a(y^{(0)}) = n_a^{(0)}/n_a \).

  • \( P_d(y) \) is the probability distribution of the observed labels for facet \( d \). For binary labeled data, this distribution is given by the number of samples in facet \( d \) labeled with positive outcomes to the total number, \( P_d(y^{(1)}) = n_d^{(1)}/n_d \), and the ratio of the number of samples with negative outcomes to the total number, \( P_d(y^{(0)}) = n_d^{(0)}/n_d \).

The following table contains a cheat sheet for quick guidance and links to the posttraining bias metrics.

### Posttraining Bias Metrics

<table>
<thead>
<tr>
<th>Posttraining Bias Metric</th>
<th>Description</th>
<th>Example Question</th>
<th>Interpreting Metric Values</th>
</tr>
</thead>
</table>
| Difference in Positive Proportions in Predicted Labels (DPPL) (p. 1884) | Measures the difference in the proportion of positive predictions between the favored facet \( a \) and the disfavored facet \( d \). | Has there been an imbalance across demographic groups in the predicted positive outcomes that might indicate bias? | Range for normalized binary & multicategory facet labels: [-1, +1] Range for continuous labels: (-\( \infty \), +\( \infty \)) Interpretation:  
  
  • Positive values indicate that the favored facet \( a \) has a higher proportion of predicted positive outcomes.  
  
  • Values near zero indicate a more equal proportion of predicted positive outcomes between facets.  
  
  • Negative values indicate the disfavored facet \( d \) has a higher proportion of predicted positive outcomes. |
<table>
<thead>
<tr>
<th>Posttraining Bias Metric</th>
<th>Description</th>
<th>Example Question</th>
<th>Interpreting Metric Values</th>
</tr>
</thead>
</table>
| Disparate Impact (DI) (p. 1885) | Measures the ratio of proportions of the predicted labels for the favored facet $a$ and the disfavored facet $d$. | Has there been an imbalance across demographic groups in the predicted positive outcomes that might indicate bias? | Range for normalized binary, multicategory facet, and continuous labels: $[0, \infty)$  
Interpretation:  
- Values greater than 1 indicate the favored facet $a$ has a higher proportion of predicted positive outcomes.  
- A value of 1 indicates that we have demographic parity.  
- Values less than 1 indicate the disfavored facet $d$ has a higher proportion of predicted positive outcomes. |
| Difference in Conditional Acceptance (DCAcc) (p. 1885) | Compares the observed labels to the labels predicted by a model and assesses whether this is the same across facets for predicted positive outcomes (acceptances). | Are there more or less acceptances for loan applications than predicted for one age group as compared to another based on qualifications? | The range for binary, multicategory facet, and continuous labels: $(-\infty, +\infty)$.  
- Positive values indicate a possible bias against the qualified applicants from the disfavored facet $d$.  
- Values near zero indicate that qualified applicants from both facets are being accepted in a similar way.  
- Negative values indicate a possible bias against the qualified applicants from the favored facet $a$. |

Difference in Positive Proportions in Predicted Labels (DPPL)

The difference in positive proportions in predicted labels (DPPL) metric determines whether the model predicts outcomes differently for each facet. It is defined as the difference between the proportion of positive predictions \( y' = 1 \) for facet \( a \) and the proportion of positive predictions \( y' = 1 \) for facet \( d \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% other age groups (facet \( d \)), it might be biased against facet \( d \). In this example, you need to determine whether the 10% difference is material to a case for bias. A comparison of DPL with DPPL assesses whether bias initially present in the dataset increases or decreases in the model predictions after training.

The formula for the difference in proportions of predicted labels:

\[
DPPL = q_a' - q_d'
\]

Where:

- \( q_a' = n_a^{(1)}/n_a \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n_a^{(1)} \) represents the number of members of facet \( a \) who get a positive predicted outcome of value 1 and \( n_a \) the number of members of facet \( a \).
- \( q_d' = n_d^{(1)}/n_d \) is the predicted proportion of facet \( d \) who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n_d^{(1)} \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the number of members of facet \( d \).

If DPPL is close enough to 0, it means that posttraining demographic parity has been achieved.

For binary and multicategory facet labels, the normalized DPL values range over the interval \([-1, 1]\). For continuous labels, the values vary over the interval \((-\infty, +\infty)\).

- Positive DPPL values indicate that facet \( a \) has a higher proportion of predicted positive outcomes when compared with facet \( d \).
  
  This is referred to as positive bias.

- Values of DPPL near zero indicate a more equal proportion of predicted positive outcomes between facets \( a \) and \( d \) and a value of zero indicates perfect demographic parity.

- Negative DPPL values indicate that facet \( d \) has a higher proportion of predicted positive outcomes when compared with facet \( a \). This is referred to as negative bias.
Disparate Impact (DI)

The difference in positive proportions in the predicted labels metric can be assessed in the form of a ratio.

The comparison of positive proportions in predicted labels metric can be assessed in the form of a ratio instead of as a difference, as it is with the Difference in Positive Proportions in Predicted Labels (DPPL) (p. 1884). The disparate impact (DI) metric is defined as the ratio of the proportion of positive predictions ($y' = 1$) for facet $a$ over the proportion of positive predictions ($y' = 1$) for facet $d$. For example, if the model predictions grant loans to 60% of a middle-aged group (facet $a$) and 50% other age groups (facet $d$), then $\text{DI} = .5/.6 = 0.8$, which indicates a positive bias and an adverse impact on facet $d$.

The formula for the ratio of proportions of the predicted labels:

$$\text{DI} = q'_d / q'_a$$

Where:

- $q'_a = n'_a (1) / n_a$ is the predicted proportion of facet $a$ who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here $n'_a (1)$ represents the number of members of facet $a$ who get a positive predicted outcome and $n_a$ is the number of members of facet $a$.
- $q'_d = n'_d (1) / n_d$ is the predicted proportion of facet $d$ who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here $n'_d (1)$ represents the number of members of facet $d$ who get a positive predicted outcome and $n_d$ is the number of members of facet $d$.

For binary, multicategory facet, and continuous labels, the DI values range over the interval $[0, \infty)$.

- Values less than 1 indicate that facet $a$ has a higher proportion of predicted positive outcomes than facet $d$. This is referred to as positive bias.
- A value of 1 indicates demographic parity.
- Values greater than 1 indicate that facet $d$ has a higher proportion of predicted positive outcomes than facet $a$. This is referred to as negative bias.

Difference in Conditional Acceptance (DCAcc)

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for predicted positive outcomes. This metric comes close to mimicking human bias in that it quantifies how many more positive outcomes a model predicted (labels $y'$) for a certain facet as compared to what was observed in the training dataset (labels $y$). For example, if there were more acceptances (a positive outcome) for loan applications for a middle-aged group (facet $a$) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet $d$), this might indicate potential bias in the way loans were approved.

The formula for the difference in conditional acceptance:

$$\text{DCAcc} = c_a - c_d$$

Where:

- $c_a = n_a (1) / n'_a (1)$ is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet $a$ to the predicted number of positive outcome (acceptances) for facet $a$.
- $c_d = n_d (1) / n'_d (1)$ is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet $d$ to the predicted number of predicted positive outcomes (acceptances) for facet $d$. 

1885
The DCAcc metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan acceptances.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 70 from facet $a$ and 20 from facet $d$ were granted loans. In other words, the model granted loans to 17% more from the middle aged facet than the observed labels in the training data suggested ($70/60 = 1.17$) and granted loans to 33% less from other age groups than the observed labels suggested ($20/30 = 0.67$). The calculation of the DCAcc value quantifies this difference between +17% and -33%. The calculation of the DCAcc value gives the following:

$$\text{DCAcc} = \frac{70}{60} - \frac{20}{30} = \frac{1}{2}$$

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 50 from facet $a$ and 40 from facet $d$ were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested ($50/60 = 0.83$), and granted loans to 33% more from other age groups than the observed labels suggested ($40/30 = 1.33$). The calculation of the DCAcc value quantifies this difference between -17% and +33%. The calculation of the DCAcc value gives the following:

$$\text{DCAcc} = \frac{50}{60} - \frac{40}{30} = -\frac{1}{2}$$

Note that you can use DCAcc to help you detect potential (unintentional) biases by humans overseeing the model predictions in a human-in-the-loop setting. Assume, for example, that the predictions $y'$ by the model were unbiased, but the eventual decision is made by a human (possibly with access to additional features) who can alter the model predictions to generate a new and final version of $y'$. The additional processing by the human may unintentionally deny loans to a disproportionate number from one facet. DCAcc can help detect such potential biases.

The range of values for differences in conditional acceptance for binary, multicategory facet, and continuous labels is $(-\infty, +\infty)$.

- Positive values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is higher than the same ratio for facet $d$. These values indicate a possible bias against the qualified applicants from facet $d$. The larger the difference of the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is the similar to the ratio for facet $d$. These values indicate that predicted acceptance rates are consistent with the observed values in the labeled data and that qualified applicants from both facets are being accepted in a similar way.
- Negative values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is less than that ratio for facet $d$. These values indicate a possible bias against the qualified applicants from facet $a$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Conditional Rejection (DCR)**

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for negative outcomes (rejections). This metric comes close to mimicking human bias, in that it quantifies how many more negative outcomes a model granted (predicted labels
y') to a certain facet as compared to what was suggested by the labels in the training dataset (observed labels y). For example, if there were more rejections (a negative outcome) for loan applications for a middle-aged group (facet a) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet d), this might indicate potential bias in the way loans were rejected.

The formula for the difference in conditional acceptance:

$$DCR = r_d - r_a$$

Where:

- $$r_d = n_d^{(0)} / n_d^{(0)}$$ is the ratio of the observed number of negative outcomes of value 1 (rejections) of facet d to the predicted number of negative outcome (rejections) for facet d.
- $$r_a = n_a^{(0)} / n_a^{(0)}$$ is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet a to the predicted number of negative outcome of value 0 (rejections) for facet a.

The DCR metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan rejections.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet a) and 50 people from other age groups (facet d) who applied for loans, where the model recommended that 60 from facet a and 30 from facet d be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 50 from facet a and 40 from facet d were rejected. In other words, the model rejected loans for 17% fewer from the middle aged facet than the observed labels in the training data suggested (50/60 = 0.83), and rejected loans for 33% more from other age groups than the observed labels suggested (40/30 = 1.33). The calculation of the DCR value quantifies this difference between -17% and +33%.

$$DCR = 40/30 - 50/60 = 1/2$$

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet a) and 50 people from other age groups (facet d) who applied for loans, where the model recommended that 60 from facet a and 30 from facet d be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 70 from facet a and 20 from facet d were rejected. In other words, the model rejected loans for 17% more from the middle aged facet than the observed labels in the training data suggested (70/60 = 1.17), and rejected loans for 33% fewer from other age groups than the observed labels suggested (20/30 = 0.67). The calculation of the DCR value quantifies this difference between 17% and -33%.

$$DCR = 20/30 - 70/60 = -1/2$$

The range of values for differences in conditional rejection for binary, multicategory facet, and continuous labels is $$(-\infty, +\infty)$$.

- Positive values occur when the ratio of the observed number of rejections compared to predicted rejections for facet d is greater than that ratio for facet a. These values indicate a possible bias against the qualified applicants from facet d. The larger the value of DCR metric, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of rejections compared to predicted acceptances for facet a is the similar to the ratio for facet d. These values indicate that predicted rejections rates are consistent with the observed values in the labeled data and that the qualified applicants from both facets are being rejected in a similar way.
• Negative values occur when the ratio of the observed number of rejections compared to predicted rejections for facet $d$ is less than that ratio facet $a$. These values indicate a possible bias against the qualified applicants from facet $a$. The larger magnitude of the negative DCR metric, the more extreme the apparent bias.

### Recall Difference (RD)

The recall difference (RD) metric is the difference in recall of the model between the favored facet $a$ and disfavored facet $d$. Any difference in these recalls is a potential form of bias. Recall is the true positive rate (TPR), which measures how often the model correctly predicts the cases that should receive a positive outcome. Recall is perfect for a facet if all of the $y=1$ cases are correctly predicted as $y'=1$ for that facet. Recall is greater when the model minimizes false negatives known as the Type II error. For example, how many of the people in two different groups (facets $a$ and $d$) that should qualify for loans are detected correctly by the model? If the recall rate is high for lending to facet $a$, but low for lending to facet $d$, the difference provides a measure of this bias against the group belonging to facet $d$.

The formula for difference in the recall rates for facets $a$ and $d$:

$$RD = \frac{TP_a}{TP_a + FN_a} - \frac{TP_d}{TP_d + FN_d} = TPR_a - TPR_d$$

Where:

- $TP_a$ are the true positives predicted for facet $a$.
- $FN_a$ are the false negatives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TPR_a = \frac{TP_a}{TP_a + FN_a}$ is the recall for facet $a$. or its true positive rate.
- $TPR_d = \frac{TP_d}{TP_d + FN_d}$ is the recall for facet $d$. or its true positive rate.

For example, consider the following confusion matrices for facets $a$ and $d$.

#### Confusion Matrix for the Favored Facet $a$

<table>
<thead>
<tr>
<th>Class $a$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

#### Confusion Matrix for the Disfavored Facet $d$

<table>
<thead>
<tr>
<th>Class $d$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the recall difference is $RD = \frac{65}{70} - \frac{20}{27} = 0.93 - 0.74 = 0.19$ which indicates a bias against facet $d$. 

1888
The range of values for the recall difference between facets $a$ and $d$ for binary and multicategory classification is $[-1, +1]$. This metric is not available for the case of continuous labels.

- Positive values are obtained when there is higher recall for facet $a$ than for facet $d$. This suggests that the model finds more of the true positives for facet $a$ than for facet $d$, which is a form of bias.
- Values near zero indicate that the recall for facets being compared is similar. This suggests that the model finds about the same number of true positives in both of these facets and is not biased.
- Negative values are obtained when there is higher recall for facet $d$ than for facet $a$. This suggests that the model finds more of the true positives for facet $d$ than for facet $a$, which is a form of bias.

### Difference in Acceptance Rates (DAR)

The difference in acceptance rates (DAR) metric is the difference in the ratios of the true positive (TP) predictions to the observed positives (TP + FP) for facets $a$ and $d$. This metric measures the difference in the precision of the model for predicting acceptances from these two facets. Precision measures the fraction of qualified candidates from the pool of qualified candidates that are identified as such by the model. If the model precision for predicting qualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DAR.

The formula for difference in acceptance rates between facets $a$ and $d$:

$$
\text{DAR} = \frac{\text{TP}_a}{\text{TP}_a + \text{FP}_a} - \frac{\text{TP}_d}{\text{TP}_d + \text{FP}_d}
$$

Where:
- $\text{TP}_a$ are the true positives predicted for facet $a$.
- $\text{FP}_a$ are the false positives predicted for facet $a$.
- $\text{TP}_d$ are the true positives predicted for facet $d$.
- $\text{FP}_d$ are the false positives predicted for facet $d$.

For example, suppose the model accepts 70 middle-aged applicants (facet $a$) for a loan (predicted positive labels) of whom only 35 are actually accepted (observed positive labels). Also suppose the model accepts 100 applicants from other age demographics (facet $d$) for a loan (predicted positive labels) of whom only 40 are actually accepted (observed positive labels). Then $\text{DAR} = 35/70 - 40/100 = 0.10$, which indicates a potential bias against qualified people from the second age group (facet $d$).

The range of values for DAR for binary, multicategory facet, and continuous labels is $[-1, +1]$.

- Positive values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet $a$ is larger than the same ratio for facet $d$. These values indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false positives in facet $d$. The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facets $a$ and $d$ have similar values indicating the observed labels for positive outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet $d$ is larger than the ratio facet $a$. These values indicate a possible bias against the favored facet $a$ caused by the occurrence of relatively more false positives in facet $a$. The more negative the difference in the ratios, the more extreme the apparent bias.

### Difference in Rejection Rates (DRR)

The difference in rejection rates (DRR) metric is the difference in the ratios of the true negative (TN) predictions to the observed negatives (TN + FN) for facets $a$ and $d$. This metric measures the difference
in the precision of the model for predicting rejections from these two facets. Precision measures the fraction of unqualified candidates from the pool of unqualified candidates that are identified as such by the model. If the model precision for predicting unqualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DRR.

The formula for difference in rejection rates between facets $a$ and $d$:

$$\text{DRR} = \frac{\text{TN}_d}{(\text{TN}_d + \text{FN}_d)} - \frac{\text{TN}_a}{(\text{TN}_a + \text{FN}_a)}$$

Where:

- $\text{TN}_d$ are the true negatives predicted for facet $d$.
- $\text{FN}_d$ are the false negatives predicted for facet $d$.
- $\text{TP}_a$ are the true negatives predicted for facet $a$.
- $\text{FN}_a$ are the false negatives predicted for facet $a$.

For example, suppose the model rejects 100 middle-aged applicants (facet $a$) for a loan (predicted negative labels) of whom 80 are actually unqualified (observed negative labels). Also suppose the model accepts 50 applicants from other age demographics (facet $d$) for a loan (predicted negative labels) of whom only 40 are actually unqualified (observed negative labels). Then DRR = 40/50 - 80/100 = 0, so no bias is indicated.

The range of values for DRR for binary, multicategory facet, and continuous labels is $[-1, +1]$.
- Positive values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet $d$ is larger than the same ratio for facet $a$. These values indicate a possible bias against the favored facet $a$ caused by the occurrence of relatively more false negatives in facet $a$. The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facets $a$ and $d$ have similar values, indicating the observed labels for negative outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet $a$ is larger than the ratio facet $d$. These values indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false positives in facet $d$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Accuracy Difference (AD)**

Accuracy difference (AD) metric is the difference between the prediction accuracy for different facets. This metric determines whether the classification by the model is more accurate for one facet than the other. AD indicates whether one facet incurs a greater proportion of Type I and Type II errors. But it cannot differentiate between Type I and Type II errors. For example, the model may have equal accuracy for different age demographics, but the errors may be mostly false positives (Type I errors) for one age-based group and mostly false negatives (Type II errors) for the other.

Also, if loan approvals are made with much higher accuracy for a middle-aged demographic (facet $a$) than for another age-based demographic (facet $d$), either a greater proportion of qualified applicants in the second group are denied a loan (FN) or a greater proportion of unqualified applicants from that group get a loan (FP) or both. This can lead to within group unfairness for the second group, even if the proportion of loans granted is nearly the same for both age-based groups, which is indicated by a DPPL value that is close to zero.

The formula for AD metric is the difference between the prediction accuracy for facet $a$, $\text{ACC}_a$, minus that for facet $d$, $\text{ACC}_d$:

$$\text{AD} = \text{ACC}_a - \text{ACC}_d$$
Measure Posttraining Data and Model Bias

Where:

- \( ACC_a = \frac{(TP_a + TN_a)}{(TP_a + TN_a + FP_a + FN_a)} \)
  - \( TP_a \) are the true positives predicted for facet \( a \)
  - \( TN_a \) are the true negatives predicted for facet \( a \)
  - \( FP_a \) are the false positives predicted for facet \( a \)
  - \( FN_a \) are the false negatives predicted for facet \( a \)

- \( ACC_d = \frac{(TP_d + TN_d)}{(TP_d + TN_d + FP_d + FN_d)} \)
  - \( TP_d \) are the true positives predicted for facet \( d \)
  - \( TN_d \) are the true negatives predicted for facet \( d \)
  - \( FP_d \) are the false positives predicted for facet \( d \)
  - \( FN_d \) are the false negatives predicted for facet \( d \)

For example, suppose a model approves loans to 70 applicants from facet \( a \) of 100 and rejected the other 30. 10 should not have been offered the loan (\( FP_a \)) and 60 were approved that should have been (\( TP_a \)). 20 of the rejections should have been approved (\( FN_a \)) and 10 were correctly rejected (\( TN_a \)). The accuracy for facet \( a \) is as follows:

\[
ACC_a = \frac{(60 + 10)}{(60 + 10 + 20 + 10)} = 0.7
\]

Next, suppose a model approves loans to 50 applicants from facet \( d \) of 100 and rejected the other 50. 10 should not have been offered the loan (\( FP_d \)) and 40 were approved that should have been (\( TP_d \)). 40 of the rejections should have been approved (\( FN_d \)) and 10 were correctly rejected (\( TN_d \)). The accuracy for facet \( a \) is determined as follows:

\[
ACC_d = \frac{(40 + 10)}{(40 + 10 + 40 + 10)} = 0.5
\]

The accuracy difference is thus \( AD = ACC_a - ACC_d = 0.7 - 0.5 = 0.2 \). This indicates there is a bias against facet \( d \) as the metric is positive.

The range of values for \( AD \) for binary and multicategory facet labels is \([-1, +1]\).

- Positive values occur when the prediction accuracy for facet \( a \) is greater than that for facet \( d \). It means that facet \( d \) suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet \( d \).
- Values near zero occur when the prediction accuracy for facet \( a \) is similar to that for facet \( d \).
- Negative values occur when the prediction accuracy for facet \( d \) is greater than that for facet \( a \). It means that facet \( a \) suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means the is a bias against the favored facet \( a \).

### Treatment Equality (TE)

The treatment equality (TE) is the difference in the ratio of false positives to false negatives between facets \( a \) and \( d \). The main idea of this metric is to assess whether, even if the accuracy across groups is the same, is it the case that errors are more harmful to one group than another? Error rate comes from the total of false positives and false negatives, but the breakdown of these two maybe very different across facets. \( TE \) measures whether errors are compensating in the similar or different ways across facets.

The formula for the treatment equality:

\[
TE = \frac{FP_a}{FN_a} - \frac{FP_d}{FN_d}
\]

Where:

- \( FP_a \) are the false positives predicted for facet \( a \).
• FNₐ are the false negatives predicted for facet a.
• FPₐ are the false positives predicted for facet d.
• FN₃ are the false negatives predicted for facet d.

Note the metric becomes unbounded if FNₐ or FN₃ is zero.

For example, suppose that there are 100 loan applicants from facet a and 50 from facet d. For facet a, 8 were wrongly denied a loan (FNₐ) and another 6 were wrongly approved (FPₐ). The remaining predictions were true, so TPₐ + TNₐ = 86. For facet d, 5 were wrongly denied (FN₃) and 2 were wrongly approved (FP₃). The remaining predictions were true, so TP₃ + TN₃ = 43. The ratio of false positives to false negatives equals 6/8 = 0.75 for facet a and 2/5 = 0.40 for facet d. Hence TE = 0.75 - 0.40 = 0.35, even though both facets have the same accuracy:

ACCₐ = (86)/(68 + 8 + 6) = 0.86
ACC₃ = (43)/(43 + 5 + 2) = 0.86

The range of values for differences in conditional rejection for binary and multicategory facet labels is (-∞, +∞). The TE metric is not defined for continuous labels. The interpretation of this metric depends on the relative important of false positives (Type I error) and false negatives (Type II error).

• Positive values occur when the ratio of false positives to false negatives for facet a is greater than that for facet d.
• Values near zero occur when the ratio of false positives to false negatives for facet a is similar to that for facet d.
• Negative values occur when the ratio of false positives to false negatives for facet a is less than that for facet d.

Conditional Demographic Disparity in Predicted Labels (CDDPL)

The demographic disparity metric (DDPL) determines whether facet d has a larger proportion of the predicted rejected labels than of the predicted accepted labels. It enables a comparison of difference in predicted rejection proportion and predicted acceptance proportion across facets. This metric is exactly the same as the pretraining CDD metric except that it is computed off the predicted labels instead of the observed ones. This metric lies in the range (-1, +1).

The formula for the demographic disparity predictions for labels of facet d is as follows:

\[
\text{DDPL}_d = \frac{n'_d(0)}{n'(0)} - \frac{n'_d(1)}{n'(1)} = \frac{\text{P}_d^R(y'_0)}{\text{P}_d^A(y'_1)} - \frac{\text{P}_d^A(y'_0)}{\text{P}_d^R(y'_1)}
\]

Where:

• \(n'_d(0) = n'_a(0) + n'_d(0)\) is the number of predicted rejected labels for facets a and d.
• \(n'_d(1) = n'_a(1) + n'_d(1)\) is the number of predicted accepted labels for facets a and d.
• \(\text{P}_d^R(y'_0)\) is the proportion of predicted rejected labels (value 0) in facet d.
• \(\text{P}_d^A(y'_1)\) is the proportion of predicted accepted labels (value 1) in facet d.

A conditional demographic disparity in predicted labels (CDDPL) metric that conditions DDPL on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson’s paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. But when departmental subgroups were examined, women were shown to have higher admission rates than men by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgroup acceptance rates
revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDDPL metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities in predicted labels (DDPL) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations in contains. The formula for the conditional demographic disparity in predicted labels is as follows:

$$CDDPL = \frac{1}{n} \sum_{i} n_i \cdot DDPL_i$$

Where:
- $\sum_{i} n_i = n$ is the total number of observations and $n_i$ is the number of observations for each subgroup.
- $DDPL_i = \frac{n_i^{(0)}}{n^{(0)}} - \frac{n_i^{(1)}}{n^{(1)}} = P_i^R(y^0) - P_i^A(y^1)$ is the demographic disparity in predicted labels for the subgroup.

So the demographic disparity for a subgroup in predicted labels (DDPL$_i$) are the difference between the proportion of predicted rejected labels and the proportion of predicted accepted labels for each subgroup.

The range of DDPL values for binary, multicategory, and continuous outcomes is [-1,+1].

- +1: when there are no predicted rejection labels for facet $a$ or subgroup and no predicted acceptances for facet $d$ or subgroup.
- Positive values indicate there is a demographic disparity in predicted labels as facet $d$ or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The higher the value the greater the disparity.
- Values near zero indicate there is no demographic disparity on average.
- Negative values indicate there is a demographic disparity in predicted labels as facet $a$ or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The lower the value the greater the disparity.
- -1: when there are no predicted rejection labels for facet $d$ or subgroup and no predicted acceptances for facet $a$ or subgroup.

**Counterfactual Fliptest (FT)**

The fliptest is an approach that looks at each member of facet $d$ and assesses whether similar members of facet $a$ have different model predictions. The members of facet $a$ are chosen to be k-nearest neighbors of the observation from facet $d$. We assess how many nearest neighbors of the opposite group receive a different prediction, where the flipped prediction can go from positive to negative and vice versa.

The formula for the counterfactual fliptest is the difference in the cardinality of two sets divided by the number of members of facet $d$:

$$FT = (F^+ - F^-)/n_d$$

Where:
- $F^+$ is the number of disfavored facet $d$ members with an unfavorable outcome whose nearest neighbors in favored facet $a$ received a favorable outcome.
- $F^-$ is the number of disfavored facet $d$ members with a favorable outcome whose nearest neighbors in favored facet $a$ received an unfavorable outcome.
- $n_d$ is the sample size of facet $d$. 

1893
The range of values for the counterfactual flippstest for binary and multicategory facet labels is \([-1, +1]\). For continuous labels, we set a threshold to collapse the labels to binary.

- Positive values occur when the number of unfavorable counterfactual flippstest decisions for the disfavored facet \(d\) exceeds the favorable ones.
- Values near zero occur when the number of unfavorable and favorable counterfactual flippstest decisions balance out.
- Negative values occur when the number of unfavorable counterfactual flippstest decisions for the disfavored facet \(d\) is less than the favorable ones.

**Configure an Amazon SageMaker Clarify Processing Jobs for Fairness and Explainability**

This topic describes how to configure an Amazon SageMaker Clarify processing job capable of computing bias metrics and feature attributions for explainability. It is implemented using a specialized SageMaker Clarify container image. Instructions are provided for how to locate and download one of these container images. A brief overview of how SageMaker Clarify works is sketched. The parameters needed to configure the processing job and type of analysis are described. Prerequisites are outlined and some advice about compute resources consumed by SageMaker Clarify processing job is provided.

**Topics**

- Prerequisites (p. 1894)
- Getting Started with a SageMaker Clarify Container (p. 1894)
- How It Works (p. 1896)
- Configure a Processing Job Container’s Input and Output Parameters (p. 1897)
- Configure the Analysis (p. 1897)

**Prerequisites**

Before you begin, you need to meet the following prerequisites:

- You need to provide an input dataset as tabular files in CSV or JSONLines format. The input dataset must include a label column for bias analysis. The dataset should be prepared for machine learning with any pre-processing needed, such as data cleaning or feature engineering, already completed.
- You need to provide a model artifact that supports either the CSV or JSONLines file format as one of its content type inputs. For posttraining bias metrics and explainability, we use the dataset to make inferences with the model artifact. Each row minus the label column must be ready to be used as payload for inferences.
- When creating processing jobs with the SageMaker container image, you need the following:
  - Network isolation must be disabled for the processing job.
  - If the model is in a VPC, the processing job must be in the same VPC as the model.
  - The IAM user/role of the caller must have permissions for SageMaker APIs. We recommend that you use the “arn:aws:iam::aws:policy/AmazonSageMakerFullAccess” managed policy.

**Getting Started with a SageMaker Clarify Container**

Amazon SageMaker provides prebuilt SageMaker Clarify container images that include the libraries and other dependencies needed to compute bias metrics and feature attributions for explainability. This image has been enabled to run SageMaker Process Data (p. 706) in your account.

The image URIs for the containers are in the following form:
Configure SageMaker Clarify processing jobs

For example:

```
205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0
```

The following table lists the addresses by AWS Region.

### How It Works

A SageMaker processing job used the SageMaker Clarify container at several stages in the lifecycle of the machine learning workflow. You can use the SageMaker Clarify container with your datasets and models to compute the following types of analysis:

- pretraining bias metrics
- posttraining bias metrics
- SHAP values for explainability

You can control which of these analyses are computed when you configure the processing job. For pretraining bias metrics, you need to provide the dataset. You can compute posttraining bias metrics and explainability after your model has been trained by providing the dataset and model name. You must configure the necessary parameters in the form of a JSON configuration file and provide this as an input to the processing job.

After the processing job completes, the result of the analyses is saved in the output location specified in the `ProcessingOutput` parameters of the processing job. You can then download it from there and view the outputs or you can view the results in Studio if you have run a notebook there.

In order to compute posttraining bias metrics and SHAP values, the computation needs to get inferences for the model name provided. To accomplish this, the processing job creates an ephemeral endpoint with the model name, known as a *shadow endpoint*. The processing job deletes the shadow endpoint after the computations are completed.

At a high level, the processing job completes the following steps:

1. Validate inputs and parameters.
2. Create the shadow endpoint.
3. Compute pretraining bias metrics.
5. Compute local and global feature attributions.
6. Delete shadow endpoint.
7. Generate output files.
Configure a Processing Job Container's Input and Output Parameters

The Processing Job requires that you specify the following input parameters: a dataset files with input name "dataset" as S3 object or prefix, and an analysis configuration file with input name "analysis_config" as an S3 object. The job also requires an output parameter: the output location as an S3 prefix.

You can create and run a processing job with SageMaker CreateProcessingJob API using the AWS SDK or CLI or SageMaker Python SDK.

Using SageMaker Python SDK, create a Processor using the SageMaker Clarify container image URI:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
    instance_count=1,
    instance_type='ml.c5.xlarge',
    max_runtime_in_seconds=1200,
    volume_size_in_gb=100)
```

Then, you must also provide the input and output parameters for the SageMakerClarifyProcessor. If you provide the "dataset_uri", the dataset input is optional.

```python
dataset_path = "s3://my_bucket/my_folder/train.csv"
analysis_config_path = "s3://my_bucket/my_folder/analysis_config.json"
analysis_result_path = "s3://my_bucket/my_folder/output"

analysis_config_input = ProcessingInput(
    input_name="analysis_config",
    source=analysis_config_path,
    destination="/opt/ml/processing/input/config",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None")

dataset_input = ProcessingInput(
    input_name="dataset",
    source=dataset_path,
    destination="/opt/ml/processing/input/data",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None")

analysis_result_output = ProcessingOutput(
    source="/opt/ml/processing/output",
    destination=analysis_result_path,
    output_name="analysis_result",
    s3_upload_mode="EndOfJob")
```

Configure the Analysis

Parameters for the analysis configuration must be provided in a JSON file named "analysis_config.json". The path must be provided in the ProcessingInput parameter named "analysis_config". Examples of analysis configuration files are provided below. In this JSON configuration file, you specify the following parameters:

- "version" – (Optional) Schema version of the configuration file. The latest supported version is used if not provided.
- "dataset_type" – Format of the dataset. Valid values are "text/csv" for CSV and "application/jsonlines" for JSON Lines.
- "dataset_uri" – (Optional) Dataset S3 prefix/object URI (if not given as ProcessingInput). If it is a prefix, then processing job recursively collects all S3 files under the prefix.
- "headers" – (Optional) A list of column names in the dataset. If the dataset_type is "application/jsonlines" and "label" is specified, then the last header shall be the header of label column.
- "label" – (Optional) Target attribute for the model to be used for bias metrics specified as a column name or index if the dataset format is CSV or as JSONPath if the dataset format is JSONLines.
- "probability_threshold" – (Optional) A float value to indicate the threshold to select the binary label in the case of binary classification. The default value is 0.5.
- "features" – (Optional) JSONPath for locating the feature columns for bias metrics if the dataset format is JSONLines.
- "label_values_or_threshold" – (Optional) List of label values or threshold to indicate positive outcome used for bias metrics.
- "facet" – (Optional) A list of features that are sensitive attributes, referred to as facets, to be used for bias metrics in the form of pairs to include the following:
  - "name_or_index" – Facet column name or index.
  - "value_or_threshold" – (Optional) List of values or threshold that the facet column can take which indicates the sensitive group, i.e. the group that is used to measure bias against. If not provided, bias metrics are computed as one group versus all for every unique value. If the facet column is numeric this threshold value is applied as the lower bound to select the sensitive group.
- "group_variable" – (Optional) A column name or index to indicate group variable to be used for the bias metric Conditional Demographic Disparity.
- "methods" – A list of methods and their parameters for the analyses and reports. If any section is omitted then it is not computed.
  - "pre_training_bias" – (Optional) Section on pretraining bias metrics.
    - "methods" – A list of pretraining metrics to be computed.
  - "post_training_bias" – (Optional) Section on posttraining bias metrics.
    - "methods" – A list of posttraining metrics to be computed.
- "shap" – (Optional) Section on SHAP value computation.
  - "baseline" – A list of rows (at least one) or S3 object URI to be used as the baseline dataset (also known as a background dataset) in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns/values and omit the label column/values
  - "num_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
  - "agg_method" – Aggregation method for global SHAP values. Valid values are as follows:
    - "mean_abs" – Mean of absolute SHAP values for all instances.
    - "median" – Median of SHAP values for all instances.
    - "mean_sq" – Mean of squared SHAP values for all instances.
  - "use_logit" – (Optional) Boolean value to indicate if logit function is to be applied to the model predictions. The default value is "false". If "use_logit" is "true" then the SHAP values have log-odds units.
  - "save_local_shap_values" – (Optional) Boolean value to indicate if local SHAP values are to be saved in the output location. Default is false.
- "predictor" – (Optional) Section on model parameters, required if "shap" and "post_training_bias" sections are present.
  - "model_name" – Model name (as created by CreateModel API with container mode as SingleModel.
  - "instance_type" – Instance type for the shadow endpoint.
  - "initial_instance_count" – Instance count for the shadow endpoint.
• "content_type" – (Optional) The model input format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV and "application/jsonlines". The default value is the same as dataset format.

• "accept_type" – (Optional) The model output format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV and "application/jsonlines". The default value is the same as content_type.

• "label" – (Optional) Index or JSONPath location in the model output for the target attribute to be used bias metrics. In CSV accept_type case, if it is not provided then assume that the model output is a single numeric value corresponding to score or probability.

• "probability" – (Optional) Index or JSONPath location in the model output for probabilities or scores to be used for explainability. For example, if the model output is JSONLines with a list of labels and probabilities, then for bias methods, the label that corresponds to the maximum probability is selected for bias computations. For explainability method, currently all probabilities are explained.

• "label_headers" – (Optional) A list of values that the "label" takes in the dataset that describe which label value each of the scores returned by the model endpoint correspond to. It is used to extract the label value with the highest score as predicted label for bias computations.

• "content_template" – (Optional) A template string to be used to construct the model input from dataset instances. It is only used when "content_type" is "application/jsonlines". The template should have one and only one placeholder, $features, which is replaced by features list at runtime. For example, given "content_template" : "{"myfeatures":$features}", if an instance (no label) is 1,2,3 then model input becomes JSONline '{"myfeatures":[1,2,3]}'.

• "report" – (Optional) Section on report parameters. A report is generated if this section is present.

• "name" – (Optional) Filename prefix for the report notebook and PDF file. The default name is "report".

• "title" – (Optional) Title string for the report notebook and PDF file. The default title is "SageMaker Analysis Report".

Example Analysis Configuration JSON File for a CSV Dataset

```json
{
    "dataset_type": "text/csv",
    "headers": [
        "feature_0",
        "feature_1",
        "feature_2",
        "feature_3",
        "target"
    ],
    "label": "target",
    "label_values_or_threshold": [1],
    "probability_threshold": 0.7,
    "facet": [
        {
            "name_or_index": "feature_1",
            "value_or_threshold": [1]
        },
        {
            "name_or_index": "feature_2",
            "value_or_threshold": [0.7]
        }
    ],
    "group_variable": "feature_3",
    "methods": {
        "shap": {
            "baseline": [
```
Model output as CSV is as follows:

```plaintext
Current,"[0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860035]
```

Corresponding predictor configuration is as follows:

```json
"predictor": {
  "instance_type": "ml.m5.xlarge",
  "content_type": "text/csv",
  "accept_type": "text/csv",
  "label": 0,
  "probability": 1,
  ...
}
```

### Example Analysis Configuration JSON File for a JSONLines Dataset

```json
{
  "dataset_type": "application/jsonlines",
  "dataset_uri": "s3://my_bucket/my_folder/dataset.jsonl",
  "headers": ["Label", "Feature1", "Feature2"],
  "label": "data.label",
  "features": "data.features.values",
  "facet": [
    {"name_or_index": "Feature1", "value_or_threshold": [1, 5]
    }
  ]
}
```
"name_or_index": "Feature2",
"value_or_threshold": [2, 6]
},
"methods": {
"shap": {
"baseline": [
{
"data": {
"features": {
"values": [9, 10]
},
"label": 0
}
},
{
"data": {
"features": {
"values": [11, 12]
},
"label": 1
}
}
],
"predictor": {
"model_name": "my_jsonl_model",
"instance_type": "ml.m5.xlarge",
"initial_instance_count": 1
}
}
}

Dataset as S3 prefix is as follows:

```
"dataset_uri": "s3://my_bucket/my_folder"
```

Dataset as S3 object is as follows:

```
"dataset_uri": "s3://my_bucket/my_folder/train.csv"
```

Baseline as S3 object is as follows:

```
"baseline": "s3://my_bucket/my_folder/baseline.csv"
```

Model output as JSONLines is as follows:

```
{"predicted_label": "Current", "score": [0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860035]}
```

Corresponding predictor configuration is as follows:

```
"predictor": {
...
"accept_type": "application/jsonlines",
"label": "predicted_label",
"probability": "score",
...
}
```

Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability

You use SageMaker Clarify processing jobs to analyze potential sources of bias in your training data and to check your trained model for bias. For the procedure to analyze the data in SageMaker Studio, see Generate Reports for Bias in Pretraining Data in SageMaker Studio (p. 601). The focus here is on posttraining bias metric and SHAP values for explainability. Model predictions can be a source of bias (for example, if they make predictions that more frequently produce a negative result for one group than another). SageMaker Clarify is integrated with SageMaker Experiments so that after a model has been
trained, you can identify attributes you would like to check for bias (for example, income). SageMaker runs a set of algorithms to check the trained model and provides you with a visual report on the different types of bias for each attribute, such as whether high-income earners receive more positive predictions compared to low-income earners.

### Topics
- Compute Resources Required for SageMaker Clarify Processing Jobs (p. 1902)
- Run the Clarify Processing Job (p. 1902)
- Run the Clarify Processing Job with Spark (p. 1903)
- Get the Analysis Results (p. 1903)

### Compute Resources Required for SageMaker Clarify Processing Jobs

Take the following into consideration when determining the compute resources you need to run SageMaker Clarify processing jobs:

- Processing jobs can take several minutes or more to complete.
- Computing explanations can be more time intensive than the actual inference. This includes the time to launch compute resources.
- Computing explanations can be more compute intensive than the actual inference. Review and monitor the charges you may incur from using SageMaker resources. For more information, see Amazon SageMaker Pricing.

### Run the Clarify Processing Job

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio to detect posttraining model bias, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 70). The following code samples are taken from the example notebook listed previously.

After you have trained your model, instantiate the SageMaker Clarify processor using the following command:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
                                                      instance_count=1,
                                                      instance_type='ml.c4.xlarge',
                                                      sagemaker_session=session)
```

Next, configure the input dataset, where to store the output, the label column targeted with a `DataConfig` object, specify information about your trained model with `ModelConfig`, and provide information about the formats of your predictions with `ModelPredictedLabelConfig`.

```python
bias_report_output_path = 's3://{}/clarify-bias'.format(bucket, prefix)
bias_data_config = clarify.DataConfig(s3_data_input_path=train_uri,
                                      s3_output_path=bias_report_output_path,
                                      label='Target',
                                      headers=training_data.columns.to_list(),
                                      dataset_type='text/csv')
model_config = clarify.ModelConfig(model_name=model_name,
                                    ...)
```
instance_type='ml.c5.xlarge',
instance_count=1,
accept_type='text/csv')

predictions_config = clarify.ModelPredictedLabelConfig(probability_threshold=0.8)

Use `BiasConfig` to provide information on which columns contain the facets (sensitive groups, Sex), what the sensitive features (`facet_values_or_threshold`) might be, and what the desirable outcomes are (`label_values_or_threshold`).

```python
bias_config = clarify.BiasConfig(label_values_or_threshold=[1],
                                facet_name='Sex',
                                facet_values_or_threshold=[0])
```

You can run both the pretraining and posttraining analysis in the processing job at the same time with `run_bias()`.

```python
clarify_processor.run_bias(data_config=bias_data_config,
                          bias_config=bias_config,
                          model_config=model_config,
                          model_predicted_label_config=predictions_config,
                          pre_training_methods='all',
                          post_training_methods='all')
```

View the results in Studio or download them from the `bias_report_output_path` S3 bucket.

## Run the Clarify Processing Job with Spark

`Apache Spark` is a unified analytics engine for large-scale data processing. When working with large datasets, you can use the Spark processing capabilities of SageMaker Clarify to enable your Clarify processing jobs to run faster. To use Spark processing for Clarify jobs, set the instance count to a number greater than one. Clarify uses Spark distributed computing when there is more than once instance per Clarify processor.

The following example shows how to use `SageMakerClarifyProcessor` to create a Clarify processor with 5 instances.

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
                                                      instance_count=5,
                                                      instance_type='ml.c5.xlarge',
                                                      max_runtime_in_seconds=1200,
                                                      volume_size_in_gb=100)
```

If you configure a Clarify job to save local SHAP values in the `SHAPConfig` class, Spark saves the local SHAP value as multiple part files in parallel.

If you add more instances, we recommend that you also increase the number of instances in the model configuration `ModelConfig` for the shadow endpoint. This is to prevent the processing instances from being bottlenecked by the shadow endpoint. Specifically, we recommend that you use a one-to-one ratio of endpoint to processing instances.

## Get the Analysis Results

After the processing job is finished, you can download the output files to inspect or visualize the results in Studio. The output directory contains the following files:
• analysis.json – Bias metrics and SHAP values in JSON format.
• report.ipynb – Static notebook to visualize the bias metrics and SHAP values.
• explanations_shap/out.csv – Local (per-instance) SHAP values for each row in the dataset in the same format as input dataset. On each row, the output file contains SHAP values for each feature and the predicted label.

In the analysis JSON file, the bias metrics and SHAP values are organized into three separate sections.

```json
{
  "explanations": { . . . }
  "pre_training_bias_metrics": { . . . }
  "post_training_bias_metrics": { . . . }
}
```

SHAP values are in the “explanations” section. Values correspond to the global SHAP value for each feature column.

```json
"explanations": {
  "kernel_shap": {
    "label0": {
      "global_shap_values": {
        "feature_0": 0.022486410860333206,
        "feature_1": 0.007381025261958729,
        "feature_2": 0.006843906804137847
      },
      "expected_value": 0.508233428001
    }
  }
}
```

The bias metrics are in the pretraining and posttraining bias metrics sections.

```json
{
  "post_training_bias_metrics": {
    "label": "target",
    "label_value_or_threshold": "1",
    "facets": {
      "feature_2": [
        {"value_or_threshold": "1",
         "metrics": [
           {"name": "DI",
            "description": "Disparate Impact (DI)",
            "value": 0.71340206185567
          },
          {"name": "DCR",
           "description": "Difference in Conditional Rejections (DCR)",
           "value": -0.34782608695652184
         }
        ]
      }
    }
  }
}
```
For more information on bias metrics and SHAP values and how to interpret them, see the Amazon AI Fairness and Explainability Whitepaper.

A bar chart of top SHAP values and tables with the bias metrics are provided in the report notebook.

**Troubleshoot SageMaker Clarify Processing Jobs**

If you encounter failures with SageMaker Clarify processing jobs, consult the following scenarios to help identify the issue.

**Note**
The failure reason and exit message are intended to contain descriptive messages and exceptions, if encountered, during the run. One common reason is invalid or missing parameters. If you encounter unclear, confusing, or misleading messages or are unable to find a solution, submit feedback.

**Topics**
- Processing job fails to finish (p. 1905)
- Processing job finishes without results and you get a CloudWatch warning message (p. 1905)
- Error message for invalid analysis configuration (p. 1906)
- Bias metric computation fails for several or all metrics (p. 1906)
- Mismatch between analysis config and dataset/model input/output (p. 1906)
- Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error (p. 1906)
- Execution role is invalid (p. 1907)
- Failed to download data (p. 1907)
- Could not connect to SageMaker (p. 1907)

**Processing job fails to finish**

If the processing job fails to finish, you can try the following:

- Inspect the job logs directly in the notebook where you ran the job in. The job logs are located in the output of the notebook cell where you initiated the run.
- Inspect the job logs in CloudWatch.
- Add the following line in your notebook to describe the last processing job and look for the failure reason and exit message:
  ```python
  clarify_processor.jobs[-1].describe()
  ```
- Execute the following AWS CLI command to describe the processing job and look for the failure reason and exit message:
  ```bash
  aws sagemaker describe-processing-job --processing-job-name <processing-job-id>
  ```

**Processing job finishes without results and you get a CloudWatch warning message**

If the processing job finishes but no results are found and a warning message is found in the CloudWatch logs that says "Signal 15 received, cleaning up", this is an indication that the job was stopped either due to a customer request that called the StopProcessingJob API or that the job ran out of time.
allotted for its completion. In the later case, check the maximum runtime in the job configuration (max_runtime_in_seconds) and increase it as needed.

Error message for invalid analysis configuration

- If you get the error message "Unable to load analysis configuration as JSON.", this means that the analysis configuration input file for the processing job does not contain a valid JSON object. Check the validity of the JSON object using a JSON linter.
- If you get the error message "Analysis configuration schema validation error.", this means that the analysis configuration input file for the processing job contains unknown fields or invalid types for some field values. Review the configuration parameters in the file and cross-check them with the parameters listed in the configuration specification file.

Bias metric computation fails for several or all metrics

If your receive one of the following error messages "No Label values are present in the predicted Label Column, Positive Predicted Index Series contains all False values." or "Predicted Label Column series datatype is not the same as Label Column series.", try the following:

- Check that the correct dataset is being used.
- Check whether the dataset size is too small; whether, for example, it contains only a few rows. This may cause the model outputs to have the same value or the data type is inferred incorrectly.
- Check if the label or facet is treated as continuous or categorical. SageMaker Clarify uses heuristics to determine the DataType. For post-training bias metrics, the data type returned by the model may not match what is in the dataset or SageMaker Clarify may not be able to transform it correctly.
- In the bias report, you should see a single value for categorical columns or an interval for continuous columns.
- For example, if a column has values 0.0 and 1.0 as floats, it will be treated as continuous even if there are too few unique values.

Mismatch between analysis config and dataset/model input/output

- Check that the baseline format in the analysis config is the same as dataset format.
- If your receive the error message "Could not convert string to float.", check that the format is correctly specified. It could also indicate that the model predictions have a different format than the label column or it could indicate that the configuration for the label or probabilities is incorrect.
- If your receive the error message "Unable to locate the facet." or "Headers must contain label." or "Headers in config do not match with the number of columns in the dataset." or "Feature names not found.", check that the headers match the columns.
- If your receive the error message "Data must contain features.", check the content template for JSONLines and compare it with the dataset sample if available.

Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error

If you receive the error message "Fallback to per-record prediction because of model error.", this could indicate that model cannot handle the batch size, or be throttled, or just does not accept the input passed by the container due to serialization problems. You should review the CloudWatch logs for the SageMaker endpoint and look for error messages or tracebacks. For model throttling cases, it may help to use a different instance type or increasing the number of instances for the endpoint.
Execution role is invalid

This indicates that the role provided is incorrect or missing required permissions. Check the role and its permissions that were used to configure the processing job and verify the permission and trust policy for the role.

Failed to download data

This indicates that job inputs could not be downloaded for the job to start. Check the bucket name and permissions for the dataset and the configuration inputs.

Could not connect to SageMaker

This indicates that the job could not reach SageMaker service endpoints. Check the network configuration settings for the processing job and verify VPC configuration.

Model Explainability

Amazon SageMaker Clarify provides tools to help explain how machine learning (ML) models make predictions. These tools can help ML modelers and developers and other internal stakeholders understand model characteristics as a whole prior to deployment and to debug predictions provided by the model after it's deployed. Transparency about how ML models arrive at their predictions is also critical to consumers and regulators who need to trust the model predictions if they are going to accept the decisions based on them. SageMaker Clarify uses a model-agnostic feature attribution approach, which you can used to understand why a model made a prediction after training and to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of SHAP, based on the concept of a Shapley value from the field of cooperative game theory that assigns each feature an importance value for a particular prediction.

What is the function of an explanation in the machine learning context? An explanation can be thought of as the answer to a Why question that helps humans understand the cause of a prediction. In the context of an ML model, you might be interested in answering questions such as:

- "Why did the model predict a negative outcome such as a loan rejection for a given applicant?"
- "How does the model make predictions?"
- "Why did the model make an incorrect prediction?"
- "Which features have the largest influence on the behavior of the model?"

You can use explanations for auditing and meeting regulatory requirements, building trust in the model and supporting human decision-making, and debugging and improving model performance.

The need to satisfy the demands for human understanding about the nature and outcomes of ML inference is key to the sort of explanation needed. Research from philosophy and cognitive science disciplines has shown that people care especially about contrastive explanations, or explanations of why an event X happened instead of some other event Y that did not occur. Here, X could be an unexpected or surprising event that happened and Y corresponds to an expectation based on their existing mental model referred to as a baseline. Note that for the same event X, different people might seek different explanations depending on their point of view or mental model Y. In the context of explainable AI, you can think of X as the example being explained and Y as a baseline that is typically chosen to represent an uninformative or average example in the dataset. Sometimes, the baseline might be implicit as with an image with all pixels of the same color in the case of ML models for images.

Topics
- Feature Attributions that Use Shapley Values (p. 1908)
Feature Attributions that Use Shapley Values

SageMaker Clarify provides feature attributions based on the concept of Shapley value. You can use Shapley values to determine the contribution that each feature made to model predictions. These attributions can be provided for specific predictions and at a global level for the model as a whole. For example, if you used an ML model for college admissions, the explanations could help determine whether the GPA or the SAT score was the feature most responsible for the model’s predictions, and then you can determine how responsible each feature was for determining an admission decision about a particular student.

SageMaker Clarify has taken the concept of Shapley values from game theory and deployed it in a machine learning context. The Shapley value provides a way to quantify the contribution of each player to a game, and hence the means to distribute the total gain generated by a game to its players based on their contributions. In this machine learning context, SageMaker Clarify treats the prediction of the model on a given instance as the game and the features included in the model as the players. For a first approximation, you might be tempted to determine the marginal contribution or effect of each feature by quantifying the result of either dropping that feature from the model or dropping all other features from the model. However, this approach does not take into account that features included in a model are often not independent from each other. For example, if two features are highly correlated, dropping either one of the features might not alter the model prediction significantly.

To address these potential dependencies, the Shapley value requires that the outcome of each possible combination (or coalition) of features must be considered to determine the importance of each feature. Given $d$ features, there are $2^d$ such possible feature combinations, each corresponding to a potential model. To determine the attribution for a given feature $f$, consider the marginal contribution of including $f$ in all feature combinations (and associated models) that do not contain $f$, and take the average. It can be shown that Shapley value is the unique way of assigning the contribution or importance of each feature that satisfies certain desirable properties. In particular, the sum of Shapley values of each feature corresponds to the difference between the predictions of the model and a dummy model with no features. However, even for reasonable values of $d$, say 50 features, it is computationally prohibitive and impractical to train $2^d$ possible models. As a result, SageMaker Clarify needs to make use of various approximation techniques. For this purpose, SageMaker Clarify uses SHapley Additive exPlanations (SHAP), which incorporates such approximations and devised a scalable and efficient implementation of the Kernel SHAP algorithm through additional optimizations.

For additional information on Shapley values, see A Unified Approach to Interpreting Model Predictions.

SHAP Baselines for Explainability

As noted earlier, explanations are typically contrastive (that is, they account for deviations from a baseline). As a result, for the same model prediction, you can expect to get different explanations with respect to different baselines so your choice of a baseline is crucial. In an ML context, the baseline corresponds to a hypothetical instance that can be either uninformative or informative. During the computation of Shapley values, SageMaker Clarify generates several new instances between the baseline and the given instance, in which the absence of a feature is modeled by setting the feature value to that of the baseline and the presence of a feature is modeled by setting the feature value to that of the given instance. Thus, the absence of all features corresponds to the baseline and the presence of all features corresponds to the given instance.

How can you choose good baselines? Often it is desirable to select a baseline with very low information content. For example, you can construct an average instance from the training dataset by taking either the median or average for numerical features and the mode for categorical features. For the college admissions example, you might be interested in explaining why a particular applicant was accepted.
as compared to a baseline acceptances based on an average applicant. If not provided, a baseline is calculated automatically by SageMaker Clarify using K-means or K-prototypes in the input dataset.

Alternatively, you can choose to generate explanations with respect to informative baselines. For the college admissions scenario, you might want to explain why a particular applicant was rejected when compared with other applicants from similar demographic backgrounds. In this case, you can choose a baseline that represents the applicants of interest, namely those from a similar demographic background. Thus, you can use informative baselines to concentrate the analysis on the specific aspects of a particular model prediction. You can isolate the features for assessment by setting demographic attributes and other features that you can't act on to the same value as in the given instance.

Create Feature Attribute Baselines and Explainability Reports

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio that creates explanations for its predictions relative to a baseline, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 70). The following code examples are taken from the example notebook listed previously. This section discusses the code related to the use of Shapley values to provide reports that compare the relative contributions each feature made the predictions.

Use SHAPConfig to create the baseline. In this example, the mean_abs is the mean of absolute SHAP values for all instances, specified as the baseline. You use DataConfig to configure the target variable, data input and output paths, and their formats.

```python
shap_config = clarify.SHAPConfig(baseline=test_features.iloc[0].values.tolist(),
                                num_samples=15,
                                agg_method='mean_abs')

explainability_output_path = 's3://{}/clarify-explainability'.format(bucket, prefix)
explainability_data_config = clarify.DataConfig(s3_data_input_path=train_uri,
                                                s3_output_path=explainability_output_path,
                                                label='Target',
                                                headers=training_data.columns.to_list(),
                                                dataset_type='text/csv')
```

Note

Kernel SHAP in SageMaker Clarify supports omitting the "baseline" parameter. In this case, a baseline based on clustering the input dataset is generated automatically.

Then run the explainability job.

```python
clarify_processor.run_explainability(data_config=explainability_data_config,
                                     model_config=model_config,
                                     explainability_config=shap_config)
```

View the results in Studio or download them from the explainability_output_path S3 bucket.

Incremental Training in Amazon SageMaker

Over time, you might find that a model generates inference that are not as good as they were in the past. With incremental training, you can use the artifacts from an existing model and use an expanded dataset to train a new model. Incremental training saves both time and resources.
Use incremental training to:

- Train a new model using an expanded dataset that contains an underlying pattern that was not accounted for in the previous training and which resulted in poor model performance.
- Use the model artifacts or a portion of the model artifacts from a popular publicly available model in a training job. You don’t need to train a new model from scratch.
- Resume a training job that was stopped.
- Train several variants of a model, either with different hyperparameter settings or using different datasets.

For more information about training jobs, see Train a Model with Amazon SageMaker (p. 8).

You can train incrementally using the SageMaker console or the Amazon SageMaker Python SDK.

Important
Only three built-in algorithms currently support incremental training: Object Detection Algorithm (p. 1523), Image Classification Algorithm (p. 1443), and Semantic Segmentation Algorithm (p. 1546).

Topics
• Perform Incremental Training (Console) (p. 1910)
• Perform Incremental Training (API) (p. 1912)

Perform Incremental Training (Console)

To complete this procedure, you need:

- The Amazon Simple Storage Service (Amazon S3) bucket URI where you’ve stored the training data.
- The S3 bucket URI where you want to store the output of the job.
- The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code (p. 769).
- The URL of the S3 bucket where you’ve stored the model artifacts that you want to use in incremental training. To find the URL for the model artifacts, see the details page of the training job used to create the model. To find the details page, in the SageMaker console, choose Inference, choose Models, and then choose the model.

To restart a stopped training job, use the URL to the model artifacts that are stored in the details page as you would with a model or a completed training job.

To perform incremental training (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. The training job name must have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and : + @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about algorithms, see Use Amazon SageMaker Built-in Algorithms (p. 762).
6. (Optional) For Resource configuration, either leave the default values or increase the resource consumption to reduce computation time.
a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, **ml.m4.xlarge** is sufficient.

b. For **Instance count**, use the default, 1.

c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.

7. Provide information about the input data for the training dataset.

   a. For **Channel name**, either leave the default (train) or enter a more meaningful name for the training dataset, such as `expanded-training-dataset`.
   
   b. For **InputMode**, choose File. For incremental training, you need to use file input mode.
   
   c. For **S3 data distribution type**, choose **FullyReplicated**. This causes each ML compute instance to use a full replicate of the expanded dataset when training incrementally.
   
   d. If the expanded dataset is uncompressed, set the **Compression type** to None. If the expanded dataset is compressed using Gzip, set it to Gzip.
   
   e. (Optional) If you are using File input mode, leave **Content type** empty. For Pipe input mode, specify the appropriate MIME type. **Content type** is the multipurpose internet mail extension (MIME) type of the data.
   
   f. For **Record wrapper**, if the dataset is saved in RecordIO format, choose RecordIO. If your dataset is not saved as a RecordIO formatted file, choose None.
   
   g. For **S3 data type**, if the dataset is stored as a single file, choose **S3Prefix**. If the dataset is stored as several files in a folder, choose Manifest.
   
   h. For **S3 location**, provide the URL to the path where you stored the expanded dataset.
   
   i. Choose Done.

8. To use model artifacts in a training job, you need to add a new channel and provide the needed information about the model artifacts.

   a. For **Input data configuration**, choose Add channel.
   
   b. For **Channel name**, enter model to identify this channel as the source of the model artifacts.
   
   c. For **InputMode**, choose File. Model artifacts are stored as files.
   
   d. For **S3 data distribution type**, choose **FullyReplicated**. This indicates that each ML compute instance should use all of the model artifacts for training.
   
   e. For **Compression type**, choose None because we are using a model for the channel.
   
   f. Leave **Content type** empty. Content type is the multipurpose internet mail extension (MIME) type of the data. For model artifacts, we leave it empty.
   
   g. Set **Record wrapper** to None because model artifacts are not stored in RecordIO format.
   
   h. For **S3 data type**, if you are using a built-in algorithm or an algorithm that stores the model as a single file, choose **S3Prefix**. If you are using an algorithm that stores the model as several files, choose Manifest.
   
   i. For **S3 location**, provide the URL to the path where you stored the model artifacts. Typically, the model is stored with the name `model.tar.gz`. To find the URL for the model artifacts, in the navigation pane, choose **Inference**, then choose **Models**. From the list of models, choose a model to display its details page. The URL for the model artifacts is listed under **Primary container**.
   
   j. Choose Done.

9. For **Output data configuration**, provide the following information:

   a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.
   
   b. (Optional) For **Encryption key**, you can add your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. Provide the key ID or its Amazon Resource Number (ARN). For more information, see [KMS-Managed Encryption Keys](#).
10. (Optional) For **Tags**, add one or more tags to the training job. A *tag* is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **Project** as a key and a value referring to a project that is related to the training job, such as **Home value forecasts**.

11. Choose **Create training job**. SageMaker creates and runs training job.

After the training job has completed, the newly trained model artifacts are stored under the **S3 output path** that you provided in the **Output data configuration** field. To deploy the model to get predictions, see **Step 5: Deploy the Model to Amazon EC2** (p. 53).

### Perform Incremental Training (API)

This example shows how to use SageMaker APIs to train a model using the SageMaker image classification algorithm and the **Caltech 256 Image Dataset**, then train a new model using the first one. It uses Amazon S3 for input and output sources. Please see the **incremental training sample notebook** for more details on using incremental training.

**Note**

In this example we used the original datasets in the incremental training, however you can use different datasets, such as ones that contain newly added samples. Upload the new datasets to S3 and make adjustments to the **data_channels** variable used to train the new model.

Get an AWS Identity and Access Management (IAM) role that grants required permissions and initialize environment variables:

```python
import sagemaker
from sagemaker import get_execution_role

role = get_execution_role()
print(role)

sess = sagemaker.Session()

bucket=sess.default_bucket()
print(bucket)

prefix = 'ic-inr-training'
```

Get the training image for the image classification algorithm:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri

training_image = get_image_uri(sess.boto_region_name, 'image-classification',
repo_version="latest")

#Display the training image
print (training_image)
```

Download the training and validation datasets, then upload them to Amazon Simple Storage Service (Amazon S3):

```python
import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split("/")[1]
```
if not os.path.exists(filename):
    urllib.request.urlretrieve(url, filename)

# Download the caltech-256 training and validation datasets
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-train.rec')
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-val.rec')

# Create four channels: train, validation, train_lst, and validation_lst
s3train = 's3://{}//{}//training'.format(bucket, prefix)
s3validation = 's3://{}//{}//validation'.format(bucket, prefix)

# Upload the first files to the train and validation channels
!aws s3 cp caltech-256-60-train.rec $s3train --quiet
!aws s3 cp caltech-256-60-val.rec $s3validation --quiet

Define the training hyperparameters:

# Define hyperparameters for the estimator
hyperparams = { "num_layers": "18",
"resize": "32",
"num_training_samples": "50000",
"num_classes": "10",
"image_shape": "3,28,28",
"mini_batch_size": "128",
"epochs": "3",
"learning_rate": "0.1",
"lr_scheduler_step": "2,3",
"lr_scheduler_factor": "0.1",
"augmentation_type": "crop_color",
"optimizer": "sgd",
"momentum": "0.9",
"weight_decay": "0.0001",
"beta_1": "0.9",
"beta_2": "0.999",
"gamma": "0.9",
"eps": "1e-8",
"top_k": "5",
"checkpoint_frequency": "1",
"use_pretrained_model": "0",
"model_prefix": "" }

Create an estimator object and train the first model using the training and validation datasets:

# Fit the base estimator
s3_output_location = 's3://{}//{}//output'.format(bucket, prefix)
ic = sagemaker.estimator.Estimator(training_image,
role,
instance_count=1,
instance_type='ml.p2.xlarge',
volume_size=50,
max_run=360000,
input_mode='File',
output_path=s3_output_location,
sagemaker_session=sess,
hyperparameters=hyperparams)

train_data = sagemaker.inputs.TrainingInput(s3train, distribution='FullyReplicated',
content_type='application/x-recordio',
s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3validation,
distribution='FullyReplicated',
content_type='application/x-recordio',
s3_data_type='S3Prefix')
To use the model to incrementally train another model, create a new estimator object and use the model artifacts (ic.model_data, in this example) for the model_uri input argument:

```python
# Given the base estimator, create a new one for incremental training
incr_ic = sagemaker.estimator.Estimator(training_image,
                                          role,
                                          instance_count=1,
                                          instance_type='ml.p2.xlarge',
                                          max_run=360000,
                                          input_mode='File',
                                          output_path=s3_output_location,
                                          sagemaker_session=sess,
                                          hyperparameters=hyperparams,
                                          model_uri=ic.model_data)  # This parameter will
                                          # ingest the previous job’s model as a new channel
incr_ic.fit(inputs=data_channels, logs=True)
```

After the training job has completed, the newly trained model artifacts are stored under the S3 output path that you provided in Output_path. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 53).

### Managed Spot Training in Amazon SageMaker

Amazon SageMaker makes it easy to train machine learning models using managed Amazon EC2 Spot instances. Managed spot training can optimize the cost of training models up to 90% over on-demand instances. SageMaker manages the Spot interruptions on your behalf.

Managed Spot Training uses Amazon EC2 Spot instance to run training jobs instead of on-demand instances. You can specify which training jobs use spot instances and a stopping condition that specifies how long SageMaker waits for a job to run using Amazon EC2 Spot instances. Metrics and logs generated during training runs are available in CloudWatch.

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, can use managed spot training. For more information on automatic model training, see Perform Automatic Model Tuning with SageMaker (p. 1797).

Spot instances can be interrupted, causing jobs to take longer to start or finish. You can configure your managed spot training job to use checkpoints. SageMaker copies checkpoint data from a local path to Amazon S3. When the job is restarted, SageMaker copies the data from Amazon S3 back into the local path. The training job can then resume from the last checkpoint instead of restarting. For more information about checkpointing, see Use Checkpoints in Amazon SageMaker (p. 1915).

**Note**

Unless your training job will complete quickly, we recommend you use checkpointing with managed spot training. SageMaker built-in algorithms and marketplace algorithms that do not checkpoint are currently limited to a MaxWaitTimeInSeconds of 3600 seconds (60 minutes).

**Topics**

- Using Managed Spot Training (p. 1915)
- Managed Spot Training Lifecycle (p. 1915)
Using Managed Spot Training

To use managed spot training, create a training job. Set `EnableManagedSpotTraining` to `True` and specify the `MaxWaitTimeInSeconds`. `MaxWaitTimeInSeconds` must be larger than `MaxRuntimeInSeconds`. For more information about creating a training job, see `DescribeTrainingJob`.

You can calculate the savings from using managed spot training using the formula \(1 - \left(\frac{BillableTimeInSeconds}{TrainingTimeInSeconds}\right) * 100\). For example, if `BillableTimeInSeconds` is 100 and `TrainingTimeInSeconds` is 500, the savings is 80%.

To learn how to run training jobs on Amazon SageMaker spot instances and how managed spot training works and reduces the billable time, see the following example notebooks:

- Managed Spot Training with TensorFlow
- Managed Spot Training with XGBoost
- Managed Spot Training with MXNet

Managed Spot Training Lifecycle

You can monitor a training job using `TrainingJobStatus` and `SecondaryStatus` returned by `DescribeTrainingJob`. The list below shows how `TrainingJobStatus` and `SecondaryStatus` values change depending on the training scenario:

- **Spot instances acquired with no interruption during training**
  1. `InProgress`: `Starting` → `Downloading` → `Training` → `Uploading`

- **Spot instances interrupted once. Later, enough spot instances were acquired to finish the training job.**
  1. `InProgress`: `Starting` → `Downloading` → `Training` → `Interrupted` → `Starting` → `Downloading` → `Training` → `Uploading`

- **Spot instances interrupted twice and `MaxWaitTimeInSeconds` exceeded.**
  1. `InProgress`: `Starting` → `Downloading` → `Training` → `Interrupted` → `Starting` → `Downloading` → `Training` → `Interrupted` → `Uploading` → `Interrupted` → `Uploading`

- **Stopping**
  2. `Stopping`

- **Stopped: `MaxWaitTimeExceeded`**
  3. `Stopped: MaxWaitTimeExceeded`

- **Spot instances were never launched.**
  1. `InProgress`: `Starting`
  2. `Stopping`: `Stopping`
  3. `Stopped: MaxWaitTimeExceeded`

Use Checkpoints in Amazon SageMaker

Use checkpoints in Amazon SageMaker to save the state of machine learning (ML) models during training. Checkpoints are snapshots of the model and can be configured by the callback functions of ML frameworks. You can use the saved checkpoints to restart a training job from the last saved checkpoint.

The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers. SageMaker provides functionality to copy the checkpoints from the local path to Amazon S3. Using checkpoints, you can do the following:

- Save your model snapshots under training due to an unexpected interruption to the training job or instance.
Resume training the model in the future from a checkpoint.
Analyze the model at intermediate stages of training.
Use checkpoints with SageMaker managed spot training to save on training costs.

If you are using checkpoints with SageMaker managed spot training, SageMaker manages checkpointing your model training on a spot instance and resuming the training job on the next spot instance. With SageMaker managed spot training, you can significantly reduce the billable time for training ML models. For more information, see Managed Spot Training in Amazon SageMaker (p. 1914).

Topics
- Enable Checkpointing (p. 1917)
- Browse Checkpoint Files (p. 1918)
- Resume Training From a Checkpoint (p. 1918)
- Considerations for Checkpointing (p. 1919)

Checkpoints for Frameworks and Algorithms in SageMaker

Use checkpoints to save snapshots of ML models built on your preferred frameworks within SageMaker.

SageMaker frameworks and algorithms that support checkpointing

SageMaker supports checkpointing for Deep Learning Containers and a subset of built-in algorithms without requiring training script changes. SageMaker saves the checkpoints to the default local path `/opt/ml/checkpoints` and copies them to Amazon S3.

- Deep Learning Containers: TensorFlow, PyTorch, MXNet, and HuggingFace
  
  **Note**
  If you are using the HuggingFace framework estimator, you need to specify a checkpoint output path through hyperparameters. For more information, see Run training on Amazon SageMaker in the HuggingFace documentation.

- Built-in algorithms: Image Classification, Object Detection, Semantic Segmentation, and XGBoost (0.90-1 or later)
  
  **Note**
  If you are using the XGBoost algorithm in framework mode (script mode), you need to bring an XGBoost training script with checkpointing that's manually configured. For more information about the XGBoost training methods to save model snapshots, see Training XGBoost in the XGBoost Python SDK documentation.

If a pre-built algorithm that does not support checkpointing is used in a managed spot training job, SageMaker does not allow a maximum wait time greater than an hour for the job in order to limit wasted training time from interrupts.

For custom training containers and other frameworks

If you are using your own training containers, training scripts, or other frameworks not listed in the previous section, you must properly set up your training script using callbacks or training APIs to save checkpoints to the local path (`'/opt/ml/checkpoints'`) and load from the local path in your training script. SageMaker estimators can sync up with the local path and save the checkpoints to Amazon S3.
Enable Checkpointing

After you enable checkpointing, SageMaker saves checkpoints to Amazon S3 and syncs your training job with the checkpoint S3 bucket.

The following example shows how to configure checkpoint paths when you construct a SageMaker estimator. To enable checkpointing, add the `checkpoint_s3_uri` and `checkpoint_local_path` parameters to your estimator.

The following example template shows how to create a generic SageMaker estimator and enable checkpointing. You can use this template for the supported algorithms by specifying the `image_uri` parameter. To find Docker image URIs for algorithms with checkpointing supported by SageMaker, see Docker Registry Paths and Example Code (p. 769). You can also replace `estimator` and `Estimator` with other SageMaker frameworks' estimator parent classes and estimator classes, such as `TensorFlow`, `PyTorch`, `MXNet`, `HuggingFace` and `XGBoost`.

```python
import sagemaker
from sagemaker.estimator import Estimator

bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket=s3://{}/{}#/{}".format(bucket, base_job_name, checkpoint_in_bucket)

# The local path where the model will save its checkpoints in the training container
checkpoint_local_path="/opt/ml/checkpoints"

estimator = Estimator(  
    ...  
    image_uri="<ecr_path>/<algorithm-name>:<tag>" # Specify to use built-in algorithms  
    output_path=bucket,  
    base_job_name=base_job_name,  
    checkpoint_s3_uri=checkpoint_s3_bucket,  
    checkpoint_local_path=checkpoint_local_path  
)
```

The following two parameters specify paths for checkpointing:

- `checkpoint_local_path` – Specify the local path where the model saves the checkpoints periodically in a training container. The default path is set to `'/opt/ml/checkpoints'`. If you are using other frameworks or bringing your own training container, ensure that your training script's checkpoint configuration specifies the path to `'/opt/ml/checkpoints'`.  

Note
We recommend specifying the local paths as '/opt/ml/checkpoints' to be consistent with the default SageMaker checkpoint settings. If you prefer to specify your own local path, make sure you match the checkpoint saving path in your training script and the checkpoint_local_path parameter of the SageMaker estimators.

- checkpoint_s3_uri – The URI to an S3 bucket where the checkpoints are stored in real time.

To find a complete list of SageMaker estimator parameters, see the Estimator API in the Amazon SageMaker Python SDK documentation.

Browse Checkpoint Files

Locate checkpoint files using the SageMaker Python SDK and the Amazon S3 console.

To find the checkpoint files programmatically

To retrieve the S3 bucket URI where the checkpoints are saved, check the following estimator attribute:

```python
estimator.checkpoint_s3_uri
```

This returns the Amazon S3 output path for checkpoints configured while requesting the CreateTrainingJob request. To find the saved checkpoint files using the Amazon S3 console, use the following procedure.

To find the checkpoint files from the Amazon S3 console

2. In the left navigation pane, choose Training jobs.
3. Choose the link to the training job with checkpointing enabled to open Job settings.
4. On the Job settings page of the training job, locate the Checkpoint configuration section.
   
   Checkpoint configuration

   
<table>
<thead>
<tr>
<th>S3 output path</th>
<th>Local path</th>
</tr>
</thead>
<tbody>
<tr>
<td>s3://path-to-your-checkpoint</td>
<td>/opt/ml/checkpoints/</td>
</tr>
</tbody>
</table>

5. Use the link to the S3 bucket to access the checkpoint files.

Resume Training From a Checkpoint

To resume a training job from a checkpoint, run a new estimator with the same checkpoint_s3_uri that you created in the Enable Checkpointing (p. 1917) section. Once the training has resumed, the checkpoints from this S3 bucket are restored to checkpoint_local_path in each instance of the new training job. Ensure that the S3 bucket is in the same Region as that of the current SageMaker session.
Considerations for Checkpointing

Consider the following when using checkpoints in SageMaker.

- To avoid overwrites in distributed training with multiple instances, you must manually configure the checkpoint file names and paths in your training script. The high-level SageMaker checkpoint configuration specifies a single Amazon S3 location without additional suffixes or prefixes to tag checkpoints from multiple instances.

- The SageMaker Python SDK does not support high-level configuration for checkpointing frequency. To control the checkpointing frequency, modify your training script using the framework's model save functions or checkpoint callbacks.

- If you use SageMaker checkpoints with SageMaker Debugger and SageMaker distributed and are facing issues, see the following pages for troubleshooting and considerations.
  - Considerations for Amazon SageMaker Debugger (p. 1793)
  - Data Parallel Troubleshooting (p. 1847)
  - Model Parallel Troubleshooting (p. 1871)

Provide Dataset Metadata to Training Jobs with an Augmented Manifest File

To include metadata with your dataset in a training job, use an augmented manifest file. When using an augmented manifest file, your dataset must be stored in Amazon Simple Storage Service (Amazon S3) and you must configure your training job to use dataset stored there. You specify the location and format of this dataset for one or more Channel. Augmented manifests can only support Pipe input mode. See the section, InputMode in Channel to learn more about pipe input mode.

When specifying a channel's parameters, you specify a path to the file, called a S3Uri. Amazon SageMaker interprets this URI based on the specified S3DataType in S3DataSource. The AugmentedManifestFile option defines a manifest format that includes metadata with the input data. Using an augmented manifest file is an alternative to preprocessing when you have labeled data. For training jobs using labeled data, you typically need to preprocess the dataset to combine input data with metadata before training. If your training dataset is large, preprocessing can be time consuming and expensive.

Augmented Manifest File Format

An augmented manifest file must be formatted in JSON Lines format. In JSON Lines format, each line in the file is a complete JSON object followed by a newline separator.
During training, SageMaker parses each JSON line and sends some or all of its attributes on to the training algorithm. You specify which attribute contents to pass and the order in which to pass them with the AttributeNames parameter of the CreateTrainingJob API. The AttributeNames parameter is an ordered list of attribute names that SageMaker looks for in the JSON object to use as training input.

For example, if you list ["line", "book"] for AttributeNames, the input data must include the attribute names of line and book in the specified order. For this example, the following augmented manifest file content is valid:

```
{"author": "Herman Melville", "line": "Call me Ishmael", "book": "Moby Dick"}
{"line": "It was love at first sight.", "author": "Joseph Heller", "book": "Catch-22"}
```

SageMaker ignores unlisted attribute names even if they precede, follow, or are in between listed attributes.

When using augmented manifest files, observe the following guidelines:

- The order of the attributes listed in the AttributeNames parameter determines the order of the attributes passed to the algorithm in the training job.
- The listed AttributeNames can be a subset of all of the attributes in the JSON line. SageMaker ignores unlisted attributes in the file.
- You can specify any type of data allowed by the JSON format in AttributeNames, including text, numerical, data arrays, or objects.
- To include an S3 URI as an attribute name, add the suffix -ref to it.

If an attribute name contains the suffix -ref, the attribute's value must be an S3 URI to a data file that is accessible to the training job. For example, if AttributeNames contains ["image-ref", "is-a-cat"], a valid augmented manifest file might contain these lines:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "is-a-cat": 1}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "is-a-cat": 0}
```

For the first line of this manifest, SageMaker retrieves the contents of the S3 object s3://mybucket/ foo/image1.jpg and streams it to the algorithm for training. The second line is the string representation of the is-a-cat attribute "1", which is followed by the contents of the second line.

To create an augmented manifest file, use Amazon SageMaker Ground Truth to create a labeling job. For more information, see Output Data (p. 433).

### Stream Augmented Manifest File Data

Augmented manifest format enables you to do training in Pipe mode using files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Augmented manifest files are supported only for channels using Pipe input mode. For each channel, the data is extracted from its augmented manifest file and streamed (in order) to the algorithm through the channel’s named pipe. Pipe mode uses the first in first out (FIFO) method, so records are processed in the order in which they are queued. For information about Pipe input mode, see Input Mode.

Attribute names with a "-ref" suffix point to preformatted binary data. In some cases, the algorithm knows how to parse the data. In other cases, you might need to wrap the data so that records are delimited for the algorithm. If the algorithm is compatible with RecordIO-formatted data, specifying RecordIO for RecordWrapperType solves this issue. If the algorithm is not compatible with RecordIO format, specify None for RecordWrapperType and make sure that your data is parsed correctly for your algorithm.
Using the ["image-ref", "is-a-cat"] example, if you use RecordIO wrapping, the following stream of data is sent to the queue:

```
recordio_formatted(s3://mybucket/foo/image1.jpg)recordio_formatted("1")recordio_formatted(s3://mybucket/bar/image2.jpg)recordio_formatted("0")
```

Images that are not wrapped with RecordIO format, are streamed with the corresponding is-a-cat attribute value as one record. This can cause a problem because the algorithm might not delimit the images and attributes correctly. For more information about using augmented manifest files for image classification, see Train with Augmented Manifest Image Format.

With augmented manifest files and Pipe mode in general, size limits of the EBS volume do not apply. This includes settings that otherwise must be within the EBS volume size limit such as S3DataDistributionType. For more information about Pipe mode and how to use it, see Using Your Own Training Algorithms - Input Data Configuration.

**Use an Augmented Manifest File (Console)**

To complete this procedure, you need:

- The URL of the S3 bucket where you’ve stored the augmented manifest file.
- To store the data that is listed in the augmented manifest file in an S3 bucket.
- The URL of the S3 bucket where you want to store the output of the job.

**To use an augmented manifest file in a training job (console)**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Training**, then choose **Training jobs**.
3. Choose **Create training job**.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. It can have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and . : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about supported built-in algorithms, see Use Amazon SageMaker Built-in Algorithms (p. 762). If you want to use a custom algorithm, make sure that it is compatible with Pipe mode.
6. (Optional) For **Resource configuration**, either accept the default values or, to reduce computation time, increase the resource consumption.
   a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, **ml.m4.xlarge** is sufficient.
   b. For **Instance count**, use the default, 1.
   c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
   a. For **Channel name**, either accept the default (train) or enter a more meaningful name, such as **training-augmented-manifest-file**.
   b. For **InputMode**, choose **Pipe**.
   c. For **S3 data distribution type**, choose **FullyReplicated**. When training incrementally, fully replicating causes each ML compute instance to use a complete copy of the expanded dataset. For neural-based algorithms, such as Neural Topic Model (NTM) Algorithm (p. 1501), choose **ShardedByS3Key**.
d. If the data specified in the augmented manifest file is uncompressed, set the **Compression type** to **None**. If the data is compressed using gzip, set it to **Gzip**.

e. **Optional** For **Content type**, specify the appropriate MIME type. Content type is the multipurpose internet mail extension (MIME) type of the data.

f. For **Record wrapper**, if the dataset specified in the augmented manifest file is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO-formatted file, choose **None**.

g. For **S3 data type**, choose **AugmentedManifestFile**.

h. For **S3 location**, provide the path to the bucket where you stored the augmented manifest file.

i. For **AugmentedManifestFile attribute names**, specify the name of an attribute that you want to use. The attribute name must be present within the augmented manifest file, and is case-sensitive.

j. **Optional** To add more attribute names, choose **Add row** and specify another attribute name for each attribute.

k. **Optional** To adjust the order of attribute names, choose the up or down buttons next to the names. When using an augmented manifest file, the order of the specified attribute names is important.

l. Choose **Done**.

8. For **Output data configuration**, provide the following information:

a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.

b. **Optional** You can use your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. For **Encryption key**, provide the key ID or its Amazon Resource Number (ARN). For more information, see **KMS-Managed Encryption Keys**.

9. **Optional** For **Tags**, add one or more tags to the training job. A **tag** is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **Project** as a key and a value that refers to a project that is related to the training job, such as **Home value forecasts**.

10. Choose **Create training job**. SageMaker creates and runs the training job.

After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 53).

### Use an Augmented Manifest File (API)

The following shows how to train a model with an augmented manifest file using the SageMaker high-level Python library:

```python
# Create a model object set to using "Pipe" mode.
model = sagemaker.estimator.Estimator(training_image, role, instance_count=1, instance_type='ml.p3.2xlarge', volume_size = 50, max_run = 360000, input_mode = 'Pipe', output_path=s3_output_location, sagemaker_session=session)

# Create a train data channel with S3_data_type as 'AugmentedManifestFile' and attribute names.
train_data = sagemaker.session.s3_input(your_augmented_manifest_file, distribution='FullyReplicated',
```

1922
Monitor and Analyze Using CloudWatch Metrics

An Amazon SageMaker training job is an iterative process that teaches a model to make predictions by presenting examples from a training dataset. Typically, a training algorithm computes several metrics, such as training error and prediction accuracy. These metrics help diagnose whether the model is learning well and will generalize well for making predictions on unseen data. The training algorithm writes the values of these metrics to logs, which SageMaker monitors and sends to Amazon CloudWatch in real time. To analyze the performance of your training job, you can view graphs of these metrics in CloudWatch. When a training job has completed, you can also get a list of the metric values that it computes in its final iteration by calling the `DescribeTrainingJob` operation.

**Note**
Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see `GetMetricStatistics` in the *Amazon CloudWatch API Reference*.

**Tip**
If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker Debugger also provides visualizations through Studio and its profiling report. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

**Topics**
- Defining Training Metrics (p. 1923)
- Monitoring Training Job Metrics (CloudWatch Console) (p. 1926)
- Monitoring Training Job Metrics (SageMaker Console) (p. 1926)
- Example: Viewing a Training and Validation Curve (p. 1928)

**Defining Training Metrics**

SageMaker automatically parses training job logs and sends training metrics to CloudWatch. By default, SageMaker sends system resource utilization metrics listed in *SageMaker Jobs and Endpoint Metrics*. If
you want SageMaker to parse logs and send custom metrics from a training job of your own algorithm to CloudWatch, you need to specify metrics definitions by passing the name of metrics and regular expressions when you configure a SageMaker training job request.

You can specify the metrics that you want to track using the SageMaker console, the SageMaker Python SDK, or the low-level SageMaker API.

If you are using your own algorithm, do the following:

- Make sure that the algorithm writes the metrics that you want to capture to logs.
- Define a regular expression that accurately searches the logs to capture the values of the metrics that you want to send to CloudWatch.

For example, suppose your algorithm emits the following metrics for training error and validation error:

```
Train_error=0.138318;  Valid_error=0.324557;
```

If you want to monitor both of those metrics in CloudWatch, the dictionary for the metric definitions should look like the following example:

```
[
  {
    "Name": "train:error",
    "Regex": "Train_error=(.*?);"
  },
  {
    "Name": "validation:error",
    "Regex": "Valid_error=(.*?);"
  }
]
```

In the regex for the `train:error` metric defined in the preceding example, the first part of the regex finds the exact text "Train_error=" and the expression ".*?"; captures any characters until the first semicolon character appears. In this expression, the parenthesis tell the regex to capture what is inside them, . means any character, * means zero or more, and ? means capture only until the first instance of the ; character.

**Define Metrics Using the SageMaker Python SDK**

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions as the `metric_definitions` argument when you initialize an `Estimator` object. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `Estimator` initialization would look like the following example:

```
import sagemaker
from sagemaker.estimator import Estimator

estimator = Estimator(
    image_uri="your-own-image-uri",
    role=sagemaker.get_execution_role(),
    sagemaker_session=sagemaker.Session(),
    instance_count=1,
    instance_type='ml.c4.xlarge',
    metric_definitions=[
        {'Name': 'train:error', 'Regex': 'Train_error=(.*?);'},
        {'Name': 'validation:error', 'Regex': 'Valid_error=(.*?);'}
    ]
```
For more information about training by using Amazon SageMaker Python SDK estimators, see Sagemaker Python SDK on GitHub.

Define Metrics Using the SageMaker Console

If you choose the **Your own algorithm container in ECR** option as your algorithm source in the SageMaker console when you create a training job, add the metric definitions in the **Metrics** section. The following screenshot shows how it should look after you add the example metric names and the corresponding regular expressions.

Define Metrics Using the Low-level SageMaker API

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions in the **MetricDefinitions** field of the **AlgorithmSpecification** input parameter that you pass to the **CreateTrainingJob** operation. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your **AlgorithmSpecification** would look like the following example:

```json
"AlgorithmSpecification": {
  "TrainingImage": "your-own-image-url",
  "TrainingInputMode": "File",
  "MetricDefinitions" : [
    {
      "Name": "train:error",
      "Regex": "Train_error=(.*?);"
    },
    {
      "Name": "validation:error",
      "Regex": "Valid_error=(.*?);"
    }
  ]
}
```
Monitoring Training Job Metrics (CloudWatch Console)

You can monitor the metrics that a training job emits in real time in the CloudWatch console.

To monitor training job metrics (CloudWatch console)
2. Choose Metrics, then choose /aws/sagemaker/TrainingJobs.
3. Choose TrainingJobName.
4. On the All metrics tab, choose the names of the training metrics that you want to monitor.
5. On the Graphed metrics tab, configure the graph options. For more information about using CloudWatch graphs, see Graph Metrics in the Amazon CloudWatch User Guide.

Monitoring Training Job Metrics (SageMaker Console)

You can monitor the metrics that a training job emits in real time by using the SageMaker console.

To monitor training job metrics (SageMaker console)
2. Choose Training jobs, then choose the training job whose metrics you want to see.
3. Choose TrainingJobName.
4. In the Monitor section, you can review the graphs of instance utilization and algorithm metrics.
Example: Viewing a Training and Validation Curve

Typically, you split the data on which you train your model into training and validation datasets. You use the training set to train the model parameters that are used to make predictions on the training dataset. Then you test how well the model makes predictions by calculating predictions for the validation set. To analyze the performance of a training job, you commonly plot a training curve against a validation curve.

Viewing a graph that shows the accuracy for both the training and validation sets over time can help you to improve the performance of your model. For example, if training accuracy continues to increase over time, but, at some point, validation accuracy starts to decrease, you are likely overfitting your model. To address this, you can make adjustments to your model, such as increasing regularization.

For this example, you can use the `Image-classification-full-training` example in the `Example notebooks` section of your SageMaker notebook instance. If you don't have a SageMaker notebook instance, create one by following the instructions at Step 1: Create an Amazon SageMaker Notebook Instance (p. 43). If you prefer, you can follow along with the End-to-End Multiclass Image Classification Example in the example notebook on GitHub. You also need an Amazon S3 bucket to store the training data and for the model output.

**To view training and validation error curves**

2. Choose **Notebooks**, and then choose **Notebook instances**.
3. Choose the notebook instance that you want to use, and then choose **Open**.
4. On the dashboard for your notebook instance, choose **SageMaker Examples**.
5. Expand the **Introduction to Amazon Algorithms** section, and then choose Use next to `Image-classification-fulltraining.ipynb`.
6. Choose **Create copy**. SageMaker creates an editable copy of the `Image-classification-fulltraining.ipynb` notebook in your notebook instance.
7. Run all of the cells in the notebook up to the **Inference** section. You don't need to deploy an endpoint or get inference for this example.
8. After the training job starts, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch.
10. Choose **TrainingJobName**.
11. On the **All metrics** tab, choose the `train:accuracy` and `validation:accuracy` metrics for the training job that you created in the notebook.
12. On the graph, choose an area that the metric's values to zoom in. You should see something like the following example.
Example: Viewing a Training and Validation Curve

![Graph of training and validation curves](https://example.com/graph.png)

- All metrics
- Graphed metrics (2)
- Graph options

All > /aws/sagemaker/TrainingJobs > TrainingJobName

TrainingJobName (10)

- DEMO-imageclassification-2018-10-27-00-05-40
Deploy Models for Inference

After you build and train your models, you can deploy them to get predictions in one of two ways:

- To set up a persistent endpoint to get predictions from your models, use Amazon SageMaker hosting services. For an overview on deploying a single model or multiple models with SageMaker hosting services, see Deploy a Model on SageMaker Hosting Services (p. 10).

  For an example of how to deploy a model to the SageMaker hosting service, see Deploy the Model to SageMaker Hosting Services (p. 53).

  Or, if you prefer, watch the following video tutorial:

  Deploy Your ML Models to Production at Scale with Amazon SageMaker

- To get predictions for an entire dataset, use SageMaker batch transform. For an overview on deploying a model with SageMaker batch transform, see Get Inferences for an Entire Dataset with Batch Transform (p. 11).

  For an example of how to deploy a model with batch transform, see (Optional) Make Prediction with Batch Transform (p. 54).

  Or, if you prefer, watch the following video tutorial:

  Deploy Your ML Models to Production at Scale with Amazon SageMaker

Prerequisites

These topics assume that you have built and trained one or more machine learning models and are ready to deploy them. If you are new to SageMaker and have not completed these prerequisite tasks, work through the steps in the Get Started with Amazon SageMaker (p. 33) tutorial to familiarize yourself with an example of how SageMaker manages the data science process and how it handles model deployment. For more information about training a model, see Train Models (p. 757).

What do you want to do?

SageMaker provides features to manage resources and optimize inference performance when deploying machine learning models. For guidance on using inference pipelines, compiling and deploying models with Neo, Elastic Inference, and automatic model scaling, see the following topics.

- To manage data processing and real-time predictions or to process batch transforms in a pipeline, see Deploy an Inference Pipeline (p. 1990).

- If you want to deploy a model on inf1 instances, see Compile and Deploy Models with Neo (p. 2094).

- To train TensorFlow, Apache MXNet, PyTorch, ONNX, and XGBoost models once and optimize them to deploy on ARM, Intel, and Nvidia processors, see Compile and Deploy Models with Neo (p. 2094).

- To preprocess entire datasets quickly or to get inferences from a trained model for large datasets when you don't need a persistent endpoint, see Use Batch Transform (p. 1960).

- To speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as SageMaker hosted models using a GPU instance for your endpoint, see Use Amazon SageMaker Elastic Inference (EI) (p. 1935).
• To dynamically adjust the number of instances provisioned in response to changes in your workload, see Automatically Scale Amazon SageMaker Models (p. 2004).
• To create an endpoint that can host multiple models using a shared serving container, see Host Multiple Models with Multi-Model Endpoints (p. 1968).
• To test multiple models in production, see Test models in production (p. 2019).

Manage Model Deployments

For guidance on managing model deployments, including monitoring, troubleshooting, and best practices, and for information on storage associated with inference hosting instances:

• For tools that can be used to monitor model deployments, see Monitor Amazon SageMaker (p. 2624).
• For troubleshooting model deployments, see Troubleshoot Amazon SageMaker Model Deployments (p. 2027).
• For model deployment best practices, see Deployment Best Practices (p. 2028).
• For information about the size of storage volumes provided for different sizes of hosting instances, see Host Instance Storage Volumes (p. 2019).

Deploy Your Own Inference Code

For developers that need more advanced guidance on how to run your own inference code:

• To run your own inference code hosting services, see Use Your Own Inference Code with Hosting Services (p. 2245).
• To run your own inference code for batch transforms, see Use Your Own Inference Code with Batch Transform (p. 2251).

Guide to SageMaker

What Is Amazon SageMaker? (p. 1)

Real-time Inference

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. You can deploy your model to SageMaker hosting services and get an endpoint that can be used for inference. These endpoints are fully managed, support autoscaling (see Automatically Scale Amazon SageMaker Models (p. 2004)), and can be deployed in multiple Availability Zones (p. 2648).

Deploy Your Model

Deploying a model using SageMaker hosting services is a three-step process:

1. **Create a model in SageMaker**—By creating a model, you tell SageMaker where it can find the model components. This includes the S3 path where the model artifacts are stored and the Docker registry path for the image that contains the inference code. In subsequent deployment steps, you specify the model by name. For more information, see the CreateModel API.
Note
The S3 bucket where the model artifacts are stored must be in the same region as the model that you are creating.

2. Create an endpoint configuration for an HTTPS endpoint—You specify the name of one or more models in production variants and the ML compute instances that you want SageMaker to launch to host each production variant.

Note
SageMaker supports running (a) multiple models, (b) multiple variants of a model, or (c) combinations of models and variants on the same endpoint. Model variants can reference the same model inference container (i.e. run the same algorithm), but use different model artifacts (e.g., different model weight values based on other hyper-parameter configurations). In contrast, two different models may use the same algorithm, but focus on different business problems or underlying goals and may operate on different data sets.

When hosting models in production, you can configure the endpoint to elastically scale the deployed ML compute instances. For each production variant, you specify the number of ML compute instances that you want to deploy. When you specify two or more instances, SageMaker launches them in multiple Availability Zones. This ensures continuous availability. SageMaker manages deploying the instances. For more information, see the CreateEndpointConfig API.

3. Create an HTTPS endpoint—Provide the endpoint configuration to SageMaker. The service launches the ML compute instances and deploys the model or models as specified in the configuration. For more information, see the CreateEndpoint API. To get inferences from the model, client applications send requests to the SageMaker Runtime HTTPS endpoint. For more information about the API, see the InvokeEndpoint API.

Note
Endpoints are scoped to an individual AWS account, and are not public. The URL does not contain the account ID, but SageMaker determines the account ID from the authentication token that is supplied by the caller.

For an example of how to use Amazon API Gateway and AWS Lambda to set up and deploy a web service that you can call from a client application that is not within the scope of your account, see Call a SageMaker model endpoint using Amazon API Gateway and AWS Lambda in the AWS Machine Learning Blog.

Note
When you create an endpoint, SageMaker attaches an Amazon EBS storage volume to each ML compute instance that hosts the endpoint. The size of the storage volume depends on the instance type. For a list of instance types that SageMaker hosting service supports, see AWS Service Limits. For a list of the sizes of the storage volumes that SageMaker attaches to each instance, see Host Instance Storage Volumes (p. 2019).

To increase a model's accuracy, you might choose to save the user's input data and ground truth, if available, as part of the training data. You can then retrain the model periodically with a larger, improved training dataset.

Test Endpoints

After you deploy your model using SageMaker hosting services, you can test your model on that endpoint by sending it test data. You can test your endpoints using Amazon SageMaker Studio, the AWS CLI, or AWS SDKs.

Test Your Endpoint Using Amazon SageMaker Studio

After you deploy your model to an endpoint (see Deploy Your Model (p. 1931)) you can check that endpoint with Amazon SageMaker Studio.
Note
Note: SageMaker only supports endpoint testing with Amazon SageMaker Studio for real-time endpoints.

1. Launch Amazon SageMaker Studio.
2. Select the SageMaker Components and registries icon on the left sidebar.
3. From the dropdown, choose Endpoints.
4. Search for your endpoint by name and double-click on the name of your endpoint. The endpoint names listed within the SageMaker resources panel are defined when you deploy a model. You can deploy your model in several ways:
   - The SageMaker Python SDK Model Class `sagemaker.model.Model.deploy`.
   - The AWS SDK for Python (Boto3) SageMaker Service Client API `CreateEndpoint`.
   - The SageMaker console. Select Inference in the left panel and then select Endpoint configuration. Provide an endpoint name within the Endpoint name field.
5. A new tab will populate in the Studio workspace. Select the Test inference tab.
6. Send a request to your endpoint by providing sample data in JSON format. Use the JSON editor to submit a request to your endpoint.
7. Select Send Request.
8. When you send the request an Inference output card will appear on the right-hand side of the console.

The top of the card will display the type of request that was sent to the endpoint (currently only JSON is accepted). Within the card there are four main fields: Status, Execution Length, Request Time, and Result Time.

- **Status**: displays the request status. There are three types of statuses:
  - Complete - If the request is successful, the status will display Complete and the execution length will is calculated by tracking the request time.
  - Failed - If the request fails for any reason. A failure response will appear within the Failure Reason accordion.
  - Pending - A spinning, circular icon will appear while the inference request is pending.
- **Execution Length**: How long the invocation takes (end time minus the start time) in milliseconds.
- **Request Time**: How many minutes have passed since the request was sent.
- **Result Time**: How many minutes have passed since the result was returned.

Test Your Endpoint Using AWS SDKs

After you deploy your model to an endpoint (see Deploy Your Model (p. )) you can check your endpoint with the `InvokeEndpoint` API using one of the AWS SDKs. If the invocation is successful, SageMaker will return an HTTP 200 response. You can index the returned response dictionary object to find out more about the response headers. For more information, see `InvokeEndpoint`.

The following demonstrates how to use `InvokeEndpoint` to check the status of your endpoint using the AWS SDK for Python (Boto3). Provide the name of your endpoint. This is the name you specified for EndpointName when you created your endpoint with `CreateEndpoint`.

Provide input data in the Body field for SageMaker to pass to the model. The data must be in the same format that was used for training.

```python
import boto3
```
Once you have the response object (in the aforementioned example it is stored in a variable called `response`) you can index it to check the HTTP status, the name of the deployed model (`InvokedProductionVariant`), and other fields.

The proceeding code snippet prints the `HTTPStatusCode` stored in the `response` variable:

```python
print(response['HTTPStatusCode'])
```

For more information, see `InvokeEndpoint` in the SageMaker API Reference Guide.

**Test Your Endpoint Using the AWS CLI**

The following demonstrates how to use `InvokeEndpoint` to check the status of your endpoint using the AWS CLI. Provide the name of your endpoint. This is the name you specified for `EndpointName` when you created your endpoint with `CreateEndpoint`.

Provide input data in the `Body` field for SageMaker to pass to the model. The data must be in the same format that was used for training. The example code template shows how to send binary data to your endpoint.

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name endpoint_name \
  --body fileb://$file_name \
  output_file.txt
```

For more information on when to use `file://` over `fileb://` when passing contents of a file to a parameter of the AWS CLI, see Best Practices for Local File Parameters.

See `invoke-endpoint` in the AWS CLI Command Reference guide for more information on additional parameters you can pass.

If the above invocation shows a snippet such as following, it means the command executed successfully. Otherwise, check whether input payload is in correct format.

```
{
  "ContentType": "<content_type>; charset=utf-8",
  "InvokedProductionVariant": "<Variant>"
}
```
Best Practices for Deploying Models on SageMaker Hosting Services

When hosting models using SageMaker hosting services, consider the following:

- Typically, a client application sends requests to the SageMaker HTTPS endpoint to obtain inferences from a deployed model. You can also send requests to this endpoint from your Jupyter notebook during testing.
- You can deploy a model trained with SageMaker to your own deployment target. To do that, you need to know the algorithm-specific format of the model artifacts that were generated by model training. For more information about output formats, see the section corresponding to the algorithm you are using in Common Data Formats for Training (p. 1398).
- You can deploy multiple variants of a model to the same SageMaker HTTPS endpoint. This is useful for testing variations of a model in production. For example, suppose that you’ve deployed a model into production. You want to test a variation of the model by directing a small amount of traffic, say 5%, to the new model. To do this, create an endpoint configuration that describes both variants of the model. You specify the ProductionVariant in your request to the CreateEndPointConfig. For more information, see ProductionVariant.
- You can configure a ProductionVariant to use Application Auto Scaling. For information about configuring automatic scaling, see Automatically Scale Amazon SageMaker Models (p. 2004).
- You can modify an endpoint without taking models that are already deployed into production out of service. For example, you can add new model variants, update the ML Compute instance configurations of existing model variants, or change the distribution of traffic among model variants. To modify an endpoint, you provide a new endpoint configuration. SageMaker implements the changes without any downtime. For more information see, UpdateEndpoint and UpdateEndPointWeightsAndCapacities.
- Changing or deleting model artifacts or changing inference code after deploying a model produces unpredictable results. If you need to change or delete model artifacts or change inference code, modify the endpoint by providing a new endpoint configuration. Once you provide the new endpoint configuration, you can change or delete the model artifacts corresponding to the old endpoint configuration.
- If you want to get inferences on entire datasets, consider using batch transform as an alternative to hosting services. For information, see Get Inferences for an Entire Dataset with Batch Transform (p. 11)

Use Amazon SageMaker Elastic Inference (EI)

By using Amazon Elastic Inference (EI), you can speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as Amazon SageMaker hosted models, but at a fraction of the cost of using a GPU instance for your endpoint. EI allows you to add inference acceleration to a hosted endpoint for a fraction of the cost of using a full GPU instance. Add an EI accelerator in one of the available sizes to a deployable model in addition to a CPU instance type, and then add that model as a production variant to an endpoint configuration that you use to deploy a hosted endpoint. You can also add an EI accelerator to a SageMaker notebook instance so that you can test and evaluate inference performance when you are building your models.

Elastic Inference is supported in EI-enabled versions of TensorFlow, Apache MXNet, and PyTorch. To use any other deep learning framework, export your model by using ONNX, and then import your model into
MXNet. You can then use your model with EI as an MXNet model. For information about importing an ONNX model into MXNet, see Importing an ONNX model into MXNet.

**Topics**
- How EI Works (p. 1936)
- Choose an EI Accelerator Type (p. 1936)
- Use EI in a SageMaker Notebook Instance (p. 1937)
- Use EI on a Hosted Endpoint (p. 1937)
- Frameworks that Support EI (p. 1937)
- Use EI with SageMaker Built-in Algorithms (p. 1938)
- EI Sample Notebooks (p. 1938)
- Set Up to Use EI (p. 1938)
- Attach EI to a Notebook Instance (p. 1941)
- Use EI on Amazon SageMaker Hosted Endpoints (p. 1943)

**How EI Works**

Amazon Elastic Inference accelerators are network attached devices that work along with SageMaker instances in your endpoint to accelerate your inference calls. Elastic Inference accelerates inference by allowing you to attach fractional GPUs to any SageMaker instance. You can select the client instance to run your application and attach an Elastic Inference accelerator to use the right amount of GPU acceleration for your inference needs. Elastic Inference helps you lower your cost when not fully utilizing your GPU instance for inference. We recommend trying Elastic Inference with your model using different CPU instances and accelerator sizes.

The following EI accelerator types are available. You can configure your endpoints or notebook instances with any EI accelerator type.

In the table, the throughput in teraflops (TFLOPS) is listed for both single-precision floating-point (F32) and half-precision floating-point (F16) operations. The memory in GB is also listed.

<table>
<thead>
<tr>
<th>Accelerator Type</th>
<th>F32 Throughput in TFLOPS</th>
<th>F16 Throughput in TFLOPS</th>
<th>Memory in GB</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.eia2.medium</td>
<td>1</td>

<td>16</td>
<td>2</td>
</tr>
<tr>
<td>ml.eia1.xlarge</td>
<td>4</td>
<td>32</td>
<td>4</td>
</tr>
</tbody>
</table>

**Choose an EI Accelerator Type**

Consider the following factors when choosing an accelerator type for a hosted model:

- Models, input tensors and batch sizes influence the amount of accelerator memory you need. Start with an accelerator type that provides at least as much memory as the file size of your trained model. Factor in that a model might use significantly more memory than the file size at runtime.
• Demands on CPU compute resources, main system memory, and GPU-based acceleration and accelerator memory vary significantly between different kinds of deep learning models. The latency and throughput requirements of the application also determine the amount of compute and acceleration you need. Thoroughly test different configurations of instance types and EI accelerator sizes to make sure you choose the configuration that best fits the performance needs of your application.

For more information on selecting an EI accelerator, see:

• Amazon Elastic Inference Overview
• Choosing an Instance and Accelerator Type for Your Model
• Optimizing costs in Amazon Elastic Inference with TensorFlow

Use EI in a SageMaker Notebook Instance

Typically, you build and test machine learning models in a SageMaker notebook before you deploy them for production. You can attach EI to your notebook instance when you create the notebook instance. You can set up an endpoint that is hosted locally on the notebook instance by using the local mode supported by TensorFlow, MXNet, and PyTorch estimators and models in the Amazon SageMaker Python SDK to test inference performance. Elastic Inference enabled PyTorch is not currently supported on notebook instances. For instructions on how to attach EI to a notebook instance and set up a local endpoint for inference, see Attach EI to a Notebook Instance (p. 1941). There are also Elastic Inference-enabled SageMaker Notebook Jupyter kernels for Elastic Inference-enabled versions of TensorFlow and Apache MXNet. For information about using SageMaker notebook instances, see Use Amazon SageMaker Notebook Instances

Use EI on a Hosted Endpoint

When you are ready to deploy your model for production to provide inferences, you create a SageMaker hosted endpoint. You can attach EI to the instance where your endpoint is hosted to increase its performance at providing inferences. For instructions on how to attach EI to a hosted endpoint instance, see Use EI on Amazon SageMaker Hosted Endpoints (p. 1943).

Frameworks that Support EI

Amazon Elastic Inference is designed to be used with AWS enhanced versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks. These enhanced versions of the frameworks are automatically built into containers when you use the Amazon SageMaker Python SDK, or you can download them as binary files and import them in your own Docker containers.

You can download the EI-enabled TensorFlow binary files from the public amazonei-tensorflow Amazon S3 bucket to the TensorFlow serving containers. For more information about building a container that uses the EI-enabled version of TensorFlow, see Amazon Elastic Inference with TensorFlow in SageMaker.

You can download the EI-enabled MXNet binary files from the public amazonei-apachemxnet Amazon S3 bucket to the MXNet serving containers. For more information about building a container that uses the EI-enabled version of MXNet, see Amazon Elastic Inference with MXNet in SageMaker.

You can download the EI-enabled PyTorch binary files from the public amazonei-pytorch Amazon S3 bucket to the PyTorch serving containers. For more information about building a container that uses the EI-enabled version of PyTorch, see Amazon Elastic Inference with PyTorch in SageMaker.

To use Elastic Inference in a hosted endpoint, you can choose any of the following frameworks depending on your needs.
Use EI with SageMaker Built-in Algorithms

Currently, the Image Classification Algorithm (p. 1443) and Object Detection Algorithm (p. 1523) built-in algorithms support EI. For an example that uses the Image Classification algorithm with EI, see End-to-End Multiclass Image Classification Example.

EI Sample Notebooks

The following Sample notebooks provide examples of using EI in SageMaker:

- Using Amazon Elastic Inference with MXNet on Amazon SageMaker
- Using Amazon Elastic Inference with MXNet on an Amazon SageMaker Notebook Instance
- Using Amazon Elastic Inference with Neo-compiled TensorFlow model on SageMaker
- Using Amazon Elastic Inference with a pre-trained TensorFlow Serving model on SageMaker

Set Up to Use EI

Use the instructions in this topic only if one of the following applies to you:

- You want to use a customized role or permission policy.
- You want to use a VPC for your hosted model or notebook instance.

**Note**

If you already have an execution role that has the AmazonSageMakerFullAccess managed policy attached (this is true for any IAM role that you create when you create a notebook instance, training job, or model in the console) and you are not connecting to an EI model or notebook instance in a VPC, you do not need to make any of these changes to use EI in Amazon SageMaker.

Topics

- Set Up Required Permissions (p. 1938)
- Use a Custom VPC to Connect to EI (p. 1941)

Set Up Required Permissions

To use EI in SageMaker, the role that you use to open a notebook instance or create a deployable model must have a policy with the required permissions attached. You can attach the AmazonSageMakerFullAccess managed policy, which contains the required permissions, to the role, or you can add a custom policy that has the required permissions. For information about creating an IAM role, see [Creating a Role for an AWS Service (Console)] in the AWS Identity and Access Management User Guide. For information about attaching a policy to a role, see [Adding and Removing IAM Policies](#).
Add these permissions specifically for connecting EI in an IAM policy.

```
{
  "Effect": "Allow",
  "Action": [
    "elastic-inference:Connect",
    "ec2:DescribeVpcEndpoints"
  ],
  "Resource": "*"
}
```

The following IAM policy is the complete list of required permissions to use EI in SageMaker.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elastic-inference:Connect",
        "ec2:DescribeVpcEndpoints"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:*"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ecr:GetAuthorizationToken",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage",
        "ecr:BatchCheckLayerAvailability",
        "cloudwatch:PutMetricData",
        "cloudwatch:PutMetricAlarm",
        "cloudwatch:DescribeAlarms",
        "cloudwatch:DeleteAlarms",

      "iam:PassedToService": "sagemaker.amazonaws.com"
    }
  }
}
}```
Use a Custom VPC to Connect to EI

To use EI with SageMaker in a VPC, you need to create and configure two security groups, and set up a PrivateLink VPC interface endpoint. EI uses VPC interface endpoint to communicate with SageMaker endpoints in your VPC. The security groups you create are used to connect to the VPC interface endpoint.

Set up Security Groups to Connect to EI

To use EI within a VPC, you need to create two security groups:

- A security group to control access to the VPC interface endpoint that you will set up for EI.
- A security group that allows SageMaker to call into the first security group.

To configure the two security groups

1. Create a security group with no outbound connections. You will attach this to the VPC endpoint interface you create in the next section.
2. Create a second security group with no inbound connections, but with an outbound connection to the first security group.
3. Edit the first security group to allow inbound connections only to the second security group and all outbound connections.

For more information about VPC security groups, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

Set up a VPC Interface Endpoint to Connect to EI

To use EI with SageMaker in a custom VPC, you need to set up a VPC interface endpoint (PrivateLink) for the EI service.

- Set up a VPC interface endpoint (PrivateLink) for the EI. Follow the instructions at Creating an Interface Endpoint. In the list of services, choose com.amazonaws.<region>.elastic-inference.runtime. For Security group, make sure you select the first security group you created in the previous section to the endpoint.
- When you set up the interface endpoint, choose all of the Availability Zones where EI is available. EI fails if you do not set up at least two Availability Zones. For information about VPC subnets, see VPCs and Subnets.

Attach EI to a Notebook Instance

To test and evaluate inference performance using EI, you can attach EI to a notebook instance when you create or update a notebook instance. You can then use EI in local mode to host a model at an endpoint hosted on the notebook instance. You should test various sizes of notebook instances and EI accelerators to evaluate the configuration that works best for your use case.

Set Up to Use EI

To use EI locally in a notebook instance, create a notebook instance with an EI instance.

To create a notebook instance with an EI instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Notebook instances**.
3. Choose **Create notebook instance**.
4. For **Notebook instance name**, provide a unique name for your notebook instance.
5. For **notebook instance type**, choose a CPU instance such as ml.t2.medium.
6. For **Elastic Inference (EI)**, choose an instance from the list, such as **ml.eia2.medium**.
7. For **IAM role**, choose an IAM role that has the required permissions to use SageMaker and EI.
8. (Optional) For **VPC - Optional**, if you want the notebook instance to use a VPC, choose one from the available list. Otherwise, leave it as **No VPC**. If you use a VPC follow the instructions at Use a Custom VPC to Connect to EI (p. 1941).
9. (Optional) For **Lifecycle configuration - optional**, either leave it as **No configuration** or choose a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 145).
10. (Optional) For **Encryption key - optional**, if you want SageMaker to use an AWS Key Management Service (AWS KMS) key to encrypt data in the ML storage volume attached to the notebook instance, specify the key.
11. (Optional) For **Volume Size In GB - optional**, leave the default value of 5.
12. (Optional) For **Tags**, add tags to the notebook instance. A tag is a label you assign to help manage your notebook instances. A tag consists of a key and a value, both of which you define.
13. Choose **Create Notebook Instance**.

After you create your notebook instance with EI attached, you can create a Jupyter notebook and set up an EI endpoint that is hosted locally on the notebook instance.

**Topics**
- Use EI in Local Mode in SageMaker (p. 1942)

**Use EI in Local Mode in SageMaker**

To use EI locally in an endpoint hosted on a notebook instance, use local mode with the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch estimators or models. For more information about local mode support in the SageMaker Python SDK, see https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview.

**Topics**
- Use EI in Local Mode with SageMaker TensorFlow Estimators and Models (p. 1942)
- Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models (p. 1943)
- Use EI in Local Mode with SageMaker PyTorch Estimators and Models (p. 1943)

**Use EI in Local Mode with SageMaker TensorFlow Estimators and Models**

To use EI with TensorFlow in local mode, specify **local** for **instance_type** and **local_sagemaker_notebook** for **accelerator_type** when you call the **deploy** method of an estimator or a model object. For more information about Amazon SageMaker Python SDK TensorFlow estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/tensorflow/index.html.

The following code shows how to use local mode with an estimator object. To call the **deploy** method, you must have previously either:

- Trained the model by calling the **fit** method of an estimator.
- Pass a model artifact when you initialize the model object.
Endpoints with Elastic Inference

Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models

The following code shows how to use local mode with an estimator object. You must have previously called the fit method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
mxnet_predictor = mxnet_estimator.deploy(initial_instance_count=1,
instance_type='local',
accelerator_type='local_sagemaker_notebook')
```

Use EI in Local Mode with SageMaker PyTorch Estimators and Models

To use EI with PyTorch in local mode, when you call the deploy method of an estimator or a model object, specify local for instance_type and local_sagemaker_notebook for accelerator_type. For more information about Amazon SageMaker Python SDK PyTorch estimators and models, see [SageMaker PyTorch Estimators and Models](https://sagemaker.readthedocs.io/en/stable/). The following code shows how to use local mode with an estimator object. You must have previously called the fit method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
pytorch_predictor = pytorch_estimator.deploy(initial_instance_count=1,
instance_type='local',
accelerator_type='local_sagemaker_notebook')
```

Use EI on Amazon SageMaker Hosted Endpoints

To use Elastic Inference (EI) in Amazon SageMaker with a hosted endpoint for real-time inference, specify an EI accelerator when you create the deployable model to be hosted at that endpoint. You can do this in one of the following ways:

- Use the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch and the SageMaker pre-built containers for TensorFlow, MXNet, and PyTorch
- Build your own container, and use the low-level SageMaker API (Boto 3). You will need to import the EI-enabled version of either TensorFlow, MXNet, or PyTorch from the provided Amazon S3 locations into your container, and use one of those versions to write your training script.
- Use either the [Image Classification Algorithm](https://docs.aws.amazon.com/sagemaker/latest/dg/classification.html) or [Object Detection Algorithm](https://docs.aws.amazon.com/sagemaker/latest/dg/detection.html) build-in algorithms, and use the AWS SDK for Python (Boto3) to run your training job and create your deployable model and hosted endpoint.

Topics
- [Use EI with a SageMaker TensorFlow Container](https://docs.aws.amazon.com/sagemaker/latest/dg/tf-elastic-inference.html)
Use EI with a SageMaker TensorFlow Container

SageMaker provides default model training and inference code for your convenience. For custom file formats, you might need to implement custom model training and inference code.

**Use an Estimator Object**

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

**Use a Model Object**

To use a model object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

Use EI with a SageMaker MXNet Container

To use MXNet with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using MXNet in the Amazon SageMaker Python SDK, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html.

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

**Use an Estimator Object**

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```
Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                         instance_type='ml.m4.xlarge',
                         accelerator_type='ml.eia2.medium')
```

For a complete example of using EI with MXNet in SageMaker, see the sample notebook at https://github.com/awslabs/amazon-sagemaker-examples/blob/master/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference.ipynb

Use EI with a SageMaker PyTorch Container

To use PyTorch with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using PyTorch in the Amazon SageMaker Python SDK, see SageMaker PyTorch Estimators and Models.

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in this example code.

```
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                              instance_type='ml.m4.xlarge',
                              accelerator_type='ml.eia2.medium')
```

Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The model returns a predictor object, which we call its deploy method, as shown in this example code.

```
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                         instance_type='ml.m4.xlarge',
                         accelerator_type='ml.eia2.medium')
```

Use EI with Your Own Container

To use EI with a model in a custom container that you build, use the low-level AWS SDK for Python (Boto 3). download and import the AWS EI-enabled versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks, and write your training script using those frameworks.

Import the EI Version of TensorFlow, MXNet, or PyTorch into Your Docker Container

To use EI with your own container, you need to import either the Amazon EI TensorFlow Serving library, the Amazon EI Apache MXNet library, or the Elastic Inference enabled PyTorch library into
Asynchronous Inference

Amazon SageMaker Asynchronous Inference is a new capability in SageMaker that queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes up
to 1GB, long processing times, and near real-time latency requirements. Asynchronous Inference enables you to save on costs by autoscaling the instance count to zero when there are no requests to process, so you only pay when your endpoint is processing requests.

How It Works

Creating an asynchronous inference endpoint is similar to creating real-time inference endpoints. You can use your existing SageMaker models and only need to specify the AsyncInferenceConfig object while creating your endpoint configuration with the EndpointConfig field in the CreateEndpointConfig API. To invoke this endpoint, you need to place the request payload in Amazon S3 and provide a pointer to this payload as a part of the InvokeEndpointAsync request. Upon invocation, SageMaker queues the request for processing and returns an identifier and output location as a response. Upon processing, SageMaker places the result in the Amazon S3 location. You can optionally choose to receive success or error notifications with Amazon SNS. For more information about how to set up asynchronous notifications, see Check Prediction Results (p. 1957).

Note

The presence of an asynchronous inference configuration (AsyncInferenceConfig) object in the endpoint configuration implies that the endpoint can only receive asynchronous invocations.

How Do I Get Started?

If you are a first-time user of Amazon SageMaker Asynchronous Inference, we recommend that you do the following:

- Read Create, Invoke, and Update an Asynchronous Endpoint (p. 1947) for information on how to create, invoke, update, and delete an asynchronous endpoint.
- Explore the Asynchronous Inference example notebook in the aws/amazon-sagemaker-examples GitHub repository.

Create, Invoke, and Update an Asynchronous Endpoint

This guide demonstrates the prerequisites you must satisfy to create an asynchronous endpoint, along with how to create, invoke, and delete your asynchronous endpoints. You can create, update, delete, and invoke asynchronous endpoints with any AWS SDK.

Topics

- Prerequisites (p. 1947)
- Create an Asynchronous Inference Endpoint (p. 1950)
- Invoke an Asynchronous Endpoint (p. 1953)
- Update an Asynchronous Endpoint (p. 1954)
- Delete an Asynchronous Endpoint (p. 1954)

Prerequisites

To use asynchronous endpoints, first make sure you have met these prerequisites.

1. **Create an IAM role for Amazon SageMaker.**

   Asynchronous Inference needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3 and Amazon SNS. Using this
role, SageMaker can run under your account and access your Amazon S3 bucket and Amazon SNS topics.

You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
c. For Select type of trusted entity, choose AWS service.
d. Choose the service that you want to allow to assume this role. In this case, choose SageMaker. Then choose Next: Permissions.
   • This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.
e. Choose Next: Tags.
f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.
g. Choose Next: Review.
h. Type in a Role name.
i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
j. (Optional) For Role description, type a description for the new role.
k. Review the role and then choose Create role.

Note the SageMaker role ARN. To find the role ARN using the console, do the following:
   i. Go to the IAM console: https://console.aws.amazon.com/iam/
   ii. Select Roles.
   iii. Search for the role you just created by typing in the name of the role in the search field.
   iv. Select the role.
   v. The role ARN is at the top of the Summary page.

2. Add Amazon SageMaker, Amazon S3 and Amazon SNS Permissions to your IAM Role.

Once the role is created, grant SageMaker, Amazon S3, and optionally Amazon SNS permissions to your IAM role.

Choose Roles in the IAM console. Search for the role you created by typing in your role name in the Search field.

a. Choose your role.
b. Next, choose Attach Policies.
c. Amazon SageMaker Asynchronous Inference needs permission to perform the following actions: "sagemaker:CreateModel", "sagemaker:CreateEndpointConfig", "sagemaker:CreateEndpoint", and "sagemaker:InvokeEndpointAsync".

   These actions are included in the AmazonSageMakerFullAccess policy. Add this policy to your IAM role. Search for AmazonSageMakerFullAccess in the Search field. Select AmazonSageMakerFullAccess.
d. Choose Attach policy.
e. Next, choose Attach Policies to add Amazon S3 permissions.
f. Select **Create policy**.
g. Select the **JSON** tab.
h. Add the following policy statement:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:AbortMultipartUpload",
        "s3:ListBucket"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::bucket_name/*"
    }
  ]
}
```
i. Choose **Next: Tags**.
j. Type in a **Policy name**.
k. Choose **Create policy**.
l. Repeat the same steps you completed to add Amazon S3 permissions in order to add Amazon SNS permissions. For the policy statement, attach the following:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "sns:Publish"
      ],
      "Effect": "Allow",
    }
  ]
}
```

3. **Upload your inference data (e.g., machine learning model, sample data) to Amazon S3.**

4. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**

   SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see Available Deep Learning Containers Images.

   If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. See Use Your Own Inference Code (p. 2245) for information on how to create your Docker image.

5. **Create an Amazon SNS topic (optional)**

   Create an Amazon Simple Notification Service (Amazon SNS) topic that sends notifications about requests that have completed processing. Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. You can specify Amazon SNS topics when you create an EndpointConfig object when you specify AsyncInferenceConfig using the EndpointConfig API.
Follow the steps to create and subscribe to an Amazon SNS topic.

a. Using Amazon SNS console, create a topic. For instructions, see Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

b. Subscribe to the topic. For instructions, see Subscribing to an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

c. When you receive email requesting that you confirm your subscription to the topic, confirm the subscription.

d. Note the topic Amazon Resource Name (ARN). The Amazon SNS topic you created is another resource in your AWS account, and it has a unique ARN. The ARN is in the following format:

```
arn:aws:sns:aws-region:account-id:topic-name
```

For more information about Amazon SNS, see the Amazon SNS Developer Guide.

Create an Asynchronous Inference Endpoint

Create an asynchronous endpoint the same way you would create an endpoint using SageMaker hosting services:

- Create a model in SageMaker with CreateModel.
- Create an endpoint configuration with CreateEndpointConfig.
- Create an HTTPS endpoint with CreateEndpoint.

To create an endpoint, you first create a model with CreateModel, where you point to the model artifact and a Docker registry path (Image). You then create a configuration using CreateEndpointConfig where you specify one or more models that were created using the CreateModel API to deploy and the resources that you want SageMaker to provision. Create your endpoint with CreateEndpoint using the endpoint configuration specified in the request. You can update an asynchronous endpoint with the UpdateEndpoint API. Send and receive inference requests from the model hosted at the endpoint with InvokeEndpointAsync. You can delete your endpoints with the DeleteEndpoint API.

For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. See Use Your Own Inference Code (p. 2245) for information on how to create your Docker image.

Create a Model

The following example shows how to create a model using the AWS SDK for Python (Boto3). The first few lines define:

- sagemaker_client: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- sagemaker_role: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- aws_region: A string variable with the name of your AWS region.

```
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Create a low-level SageMaker service client.
```
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Role to give SageMaker permission to access AWS services.
sagemaker_role = "arn:aws:iam::<account>:role/*"

Next, specify the location of the pre-trained model stored in Amazon S3. In this example, we use a pre-trained XGBoost model named demo-xgboost-model.tar.gz. The full Amazon S3 URI is stored in a string variable model_url:

#Create a variable w/ the model S3 URI
s3_bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
bucket_prefix='saved_models'
model_s3_key = f"{bucket_prefix}/demo-xgboost-model.tar.gz"

#Specify S3 bucket w/ model
model_url = f"s3://{s3_bucket}/{model_s3_key}"

Specify a primary container. For the primary container, you specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

In this example, we specify an XGBoost built-in algorithm container image:

from sagemaker.amazon.amazon_estimator import get_image_uri

# Specify an AWS container image.
container = get_image_uri(region=aws_region, framework='xgboost', version='0.90-1')

Create a model in Amazon SageMaker with CreateModel. Specify the following:

- **ModelName:** A name for your model (in this example it is stored as a string variable called model_name).
- **ExecutionRoleArn:** The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- **PrimaryContainer:** The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

model_name = '<The_name_of_the_model>'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    })

Create an Endpoint Configuration

Once you have a model, create an endpoint configuration with CreateEndpointConfig. Amazon SageMaker hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using CreateModel, to deploy the resources that you want Amazon SageMaker to provision. Specify the AsyncInferenceConfig object and provide an output Amazon

1951
S3 location for `OutputConfig`. You can optionally specify Amazon SNS topics on which to send notifications about prediction results. For more information about Amazon SNS topics, see Configuring Amazon SNS.

The following example shows how to create an endpoint configuration using AWS SDK for Python (Boto3):

```python
import datetime
from time import gmtime, strftime

# Create an endpoint config name. Here we create one based on the date
# so it we can search endpoints based on creation time.
endpoint_config_name = f"XGBoostEndpointConfig-{strftime('%Y-%m-%d-%H-%M-%S', gmtime())}"

# The name of the model that you want to host. This is the name that you specified when creating the model.
model_name='<The_name_of_your_model>'

create_endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,  # You will specify this name in a CreateEndpoint request.
    # List of ProductionVariant objects, one for each model that you want to host at this endpoint.
    ProductionVariants=[
        {
            "VariantName": "variant1",  # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": "ml.m5.xlarge",  # Specify the compute instance type.
            "InitialInstanceCount": 1  # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig=
        "OutputConfig": {
            # Location to upload response outputs when no location is provided in the request.
            "S3OutputPath": f"s3://{s3_bucket}/{bucket_prefix}/output"
            # (Optional) specify Amazon SNS topics
            "NotificationConfig": {
            }
        },
        "ClientConfig": {
            # (Optional) Specify the max number of inflight invocations per instance
            # If no value is provided, Amazon SageMaker will choose an optimal value for you
            "MaxConcurrentInvocationsPerInstance": 4
        }
    )

print(f"Created EndpointConfig: {create_endpoint_config_response["EndpointConfigArn"]}")
```

In the aforementioned example, you specify the following keys for `OutputConfig` for the `AsyncInferenceConfig` field:

- **S3OutputPath**: Location to upload response outputs when no location is provided in the request.
- **NotificationConfig**: (Optional) SNS topics that post notifications to you when an inference request is successful (`SuccessTopic`) or if it fails (`ErrorTopic`).

You can also specify the following optional argument for `ClientConfig` in the `AsyncInferenceConfig` field:
Create, Invoke, and Update an Asynchronous Endpoint

- MaxConcurrentInvocationsPerInstance: (Optional) The maximum number of concurrent requests sent by the SageMaker client to the model container.

Create Endpoint

Once you have your model and endpoint configuration, use the CreateEndpoint API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name = '<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(  
    EndpointName=endpoint_name,  
    EndpointConfigName=endpoint_config_name)
```

When you call the CreateEndpoint API, Amazon SageMaker Asynchronous Inference sends a test notification to check that you have configured an Amazon SNS topic. This lets SageMaker check that you have the required permissions. The notification can simply be ignored. The test notification has the following form:

```json
{
    "eventVersion": "1.0",
    "eventSource": "aws:sagemaker",
    "eventName": "TestNotification"
}
```

Invoke an Asynchronous Endpoint

Get inferences from the model hosted at your asynchronous endpoint with InvokeEndpointAsync.

**Note**
If you have not done so already, upload your inference data (e.g., machine learning model, sample data) to Amazon S3.

Specify the location of your inference data in the InputLocation field and the name of your endpoint for EndpointName:

```python
# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the location of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# After you deploy a model into production using SageMaker hosting services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint_async(  
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
```
You receive a response as a JSON string with your request ID and the name of the Amazon S3 bucket that will have the response to the API call after it is processed.

## Update an Asynchronous Endpoint

Update an asynchronous endpoint with the `UpdateEndpoint` API. When you update an endpoint, SageMaker first switches to the new endpoint you specify before it deletes the resources that were provisioned in the previous endpoint configuration. Do not delete an `EndpointConfig` with an endpoint that is live or while the `UpdateEndpoint` or `CreateEndpoint` operations are being performed on the endpoint.

```python
sagemaker_client.update_endpoint(
    EndpointConfigName=endpoint_config_name,
    EndpointName=endpoint_name
)
```

When Amazon SageMaker receives the request, it sets the endpoint status to **Updating**. After updating the asynchronous endpoint, it sets the status to **InService**. To check the status of an endpoint, use the `DescribeEndpoint` API. For a full list of parameters you can specify when updating an endpoint, see the `UpdateEndpoint` API.

## Delete an Asynchronous Endpoint

Delete an asynchronous endpoint in a similar manner to how you would delete a SageMaker hosted endpoint with the `DeleteEndpoint` API. Specify the name of the asynchronous endpoint you want to delete. When you delete an endpoint, SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

Delete your SageMaker model with the `DeleteModel` API or with the SageMaker console.

### Boto3

```python
import boto3

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.delete_endpoint(EndpointName='<endpoint-name>')
```

### SageMaker console

2. Expand the **Inference** dropdown list.
3. Select **Endpoints**.
4. Search for endpoint in the **Search endpoints** search bar.
5. Select your endpoint.
6. Choose **Delete**.
In addition to deleting the asynchronous endpoint, you might want to clear up other resources that were used to create the endpoint, such as the Amazon ECR repository (if you created a custom inference image), the SageMaker model, and the asynchronous endpoint configuration itself.

## Monitor Asynchronous Endpoint

You can monitor SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. With Amazon CloudWatch, you can access historical information and gain a better perspective on how your web application or service is performing. For more information about Amazon CloudWatch, see What is Amazon CloudWatch?

### Monitoring with CloudWatch

The metrics below are an exhaustive list of metrics for asynchronous endpoints. Any metric not listed below is not published if the endpoint is enabled for asynchronous inference. Such metrics include (but are not limited to):

- OverheadLatency
- Invocations
- InvocationsPerInstance

### Common Endpoint Metrics

These metrics are the same as the metrics published for real-time endpoints today. For more information about other metrics in Amazon CloudWatch, see Monitor SageMaker with Amazon CloudWatch.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
</table>
| Invocation4XXErrors    | The number of requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent. | Units: None
|                        |                                                                             | Valid statistics: Average, Sum |
| Invocation5XXErrors    | The number of InvokeEndpoint requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent. | Units: None
|                        |                                                                             | Valid statistics: Average, Sum |
| ModelLatency           | The interval of time taken by a model to respond as viewed from SageMaker. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container. | Units: Microseconds
|                        |                                                                             | Valid statistics: Average, Sum, Min, Max, Sample Count |

### Asynchronous Inference Endpoint Metrics

These metrics are published for endpoints enabled for asynchronous inference. The following metrics are published with the EndpointName dimension:
## Monitor Asynchronous Endpoint

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ApproximateBacklogSize</strong></td>
<td>The number of items in the queue for an endpoint that are currently being processed or yet to be processed.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td><strong>ApproximateBacklogSizePerInstance</strong></td>
<td>Number of items in the queue divided by the number of instances behind an endpoint. This metric is primarily used for setting up application autoscaling for an async-enabled endpoint.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td><strong>ApproximateAgeOfOldestRequest</strong></td>
<td>Age of the oldest request in the queue.</td>
<td>Units: Seconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
</tbody>
</table>

The following metrics are published with the `EndpointName` and `VariantName` dimensions:

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RequestDownloadFailures</strong></td>
<td>When an inference failure occurs due to an issue downloading the request from Amazon S3.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>

<tr>
<td><strong>InvocationsProcessed</strong></td>
<td>Number of async invocations processed by the endpoint.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
</tbody>
</table>
## Check Prediction Results

There are several ways you can check predictions results from your asynchronous endpoint. Some options are:

1. Amazon SNS topics.
2. Check for outputs in your Amazon S3 bucket.

### Amazon SNS Topics

Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. Amazon SageMaker Asynchronous Inference posts notifications when you create an endpoint with `CreateEndpointConfig` and specify an Amazon SNS topic.

**Note**

In order to receive Amazon SNS notifications, your IAM role must have `sns:Publish` permissions. See the [LINK TO PREREQS.](#) for information on requirements you must satisfy to use Asynchronous Inference.

---

### Metric Name | Description | Unit/Stats
---|---|---
TimeInBacklog | Total time the request was queued before being processed. This does not include the actual processing time (i.e. downloading time, uploading time, model latency). | Units: Microseconds
Valid statistics: Average, Sum, Min, Max, Sample Count
TotalProcessingTime | Time the inference request was received by SageMaker to the time the request finished processing. This includes time in backlog and time to upload and send response notifications, if any. | Units: Milliseconds
Valid statistics: Average, Sum, Min, Max, Sample Count

Amazon SageMaker Asynchronous Inference also includes host-level metrics. For information on host-level metrics, see [SageMaker Jobs and Endpoint Metrics](#).

### Logs

In addition to the Model container logs that are published to Amazon CloudWatch in your account, you also get a new platform log for tracing and debugging inference requests.

The new logs are published under the Endpoint Log Group:

/aws/sagemaker/Endpoints/[EndpointName]

The log stream name consists of:

[production-variant-name]/[instance-id]/data-log.

Log lines contain the request's inference ID so that errors can be easily mapped to a particular request.
To use Amazon SNS to check prediction results from your asynchronous endpoint, you first need to create a topic, subscribe to the topic, confirm your subscription to the topic, and note the Amazon Resource Name (ARN) of that topic. For detailed information on how to create, subscribe, and find the Amazon ARN of an Amazon SNS topic, see Configuring Amazon SNS.

Provide the Amazon SNS topic ARN(s) in the AsyncInferenceConfig field when you create an endpoint configuration with CreateEndpointConfig. You can specify both an Amazon SNS ErrorTopic and a SuccessTopic.

```python
import boto3
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.create_endpoint_config(
    EndpointConfigName=<endpoint_config_name>, # You specify this name in a CreateEndpoint request.
    # List of ProductionVariant objects, one for each model that you want to host at this endpoint.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": "model_name",
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {
            # Location to upload response outputs when no location is provided in the request.
            "S3OutputPath": "s3://<bucket>/<output_directory>"
        }
    }
)
```

Check Your S3 Bucket

When you invoke an endpoint with InvokeEndpointAsync, it returns a response object. You can use the response object to get the Amazon S3 URI where your output is stored. With the output location, you can use a SageMaker Python SDK SageMaker session class to programmatically check for an output.

The following stores the output dictionary of InvokeEndpointAsync as a variable named response. With the response variable, you then get the Amazon S3 output URI and store it as a string variable called output_location.

```python
import uuid
import boto3
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the S3 URI of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

response = sagemaker_runtime.invoke_endpoint_async(
    EndpointName='<endpoint-name>',
    InputLocation=input_location,
    InferenceId=str(uuid.uuid4()),
)
```
Autoscale an Asynchronous Endpoint

Amazon SageMaker supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models Amazon SageMaker supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up.

To autoscale your asynchronous endpoint you must at a minimum:

- Register a deployed model (production variant).
- Define a scaling policy.
- Apply the autoscaling policy.

Before you can use autoscaling, you must have already created a SageMaker model deployment. Deployed models are referred to as a production variant. See Deploy the Model to SageMaker Hosting Services for more information about deploying a model endpoint. To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. For information on how to define a scaling policy, see Define a scaling policy. After registering your model and defining a scaling policy, apply the scaling policy to the registered model. For information on how to apply the scaling policy, see Apply a scaling policy.
For details on other prerequisites and components used with autoscaling, see the Prerequisites section in the SageMaker autoscaling documentation.

**Define a Scaling Policy**

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. Define the scaling policy as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

For asynchronous endpoints SageMaker strongly recommends that you create a policy configuration for target-tracking scaling for a variant. In this configuration example, we use a custom metric, CustomizedMetricSpecification, called ApproximateBacklogSizePerInstance.

```json
TargetTrackingScalingPolicyConfiguration={
    'TargetValue': 5.0, # The target value for the metric. Here the metric is:
    'SageMakerVariantInvocationsPerInstance',
    'CustomizedMetricSpecification': {
        'MetricName': 'ApproximateBacklogSizePerInstance',
        'Namespace': 'AWS/SageMaker',
        'Dimensions': [
            {'Name': 'EndpointName', 'Value': <endpoint_name>}
        ],
        'Statistic': 'Average',
    }
}
```

**Define a Scaling Policy that Scales to 0**

The following shows you how to both define and register your endpoint variant with application autoscaling using the AWS SDK for Python (Boto3). After defining a low-level client object representing application autoscaling with Boto3, we use the RegisterScalableTarget method to register the production variant. We set MinCapacity to 0 because Asynchronous Inference enables you to autoscale to 0 when there are no requests to process.

```python
# Common class representing application autoscaling for SageMaker
client = boto3.client('application-autoscaling')

# This is the format in which application autoscaling references the endpoint
resource_id='endpoint/' + <endpoint_name> + '/variant/' + <variant1>

# Define and register your endpoint variant
response = client.register_scalable_target(
    ServiceNamespace='sagemaker',
    ResourceId=resource_id,
    ScalableDimension='sagemaker:variant:DesiredInstanceCount', # The number of EC2 instances for your Amazon SageMaker model endpoint variant.
    MinCapacity=0,
    MaxCapacity=5
)
```

For detailed description about the Application Autoscaling API, see the Application Scaling Boto3 documentation.

**Use Batch Transform**

Use batch transform when you need to do the following:
Use Batch Transform to Get Inferences from Large Datasets

Batch transform automatically manages the processing of large datasets within the limits of specified parameters. For example, suppose that you have a dataset file, input1.csv, stored in an S3 bucket. The content of the input file might look like the following:

Record1-Attribute1, Record1-Attribute2, Record1-Attribute3, ..., Record1-AttributeM
Record2-Attribute1, Record2-Attribute2, Record2-Attribute3, ..., Record2-AttributeM
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
...
RecordN-Attribute1, RecordN-Attribute2, RecordN-Attribute3, ..., RecordN-AttributeM

When a batch transform job starts, SageMaker initializes compute instances and distributes the inference or preprocessing workload between them. Batch Transform partitions the Amazon S3 objects in the input by key and maps Amazon S3 objects to instances. When you have multiples files, one instance might process input1.csv, and another instance might process the file named input2.csv.

To keep large payloads below the MaxPayloadInMB limit, you can split an input file into several mini-batches. For example, you might create a mini-batch from input1.csv by including only two of the records.

Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
Record4-Attribute1, Record4-Attribute2, Record4-Attribute3, ..., Record4-AttributeM

Note
SageMaker processes each input file separately. It doesn't combine mini-batches from different input files to comply with the MaxPayloadInMB limit.
To split input files into mini-batches, when you create a batch transform job, set the SplitType parameter value to Line. If SplitType is set to None or if an input file can't be split into mini-batches, SageMaker uses the entire input file in a single request.

If the batch transform job successfully processes all of the records in an input file, it creates an output file with the same name and the .out file extension. For multiple input files, such as input1.csv and input2.csv, the output files are named input1.csv.out and input2.csv.out. The batch transform job stores the output files in the specified location in Amazon S3, such as s3://awsexamplebucket/output/.

The predictions in an output file are listed in the same order as the corresponding records in the input file. The output file input1.csv.out, based on the input file shown earlier, would look like the following.

```
Inference1-Attribute1, Inference1-Attribute2, Inference1-Attribute3, ..., Inference1-AttributeM
Inference2-Attribute1, Inference2-Attribute2, Inference2-Attribute3, ..., Inference2-AttributeM
Inference3-Attribute1, Inference3-Attribute2, Inference3-Attribute3, ..., Inference3-AttributeM
...  
InferenceN-Attribute1, InferenceN-Attribute2, InferenceN-Attribute3, ..., InferenceN-AttributeM
```

To combine the results of multiple output files into a single output file, set the AssembleWith parameter to Line.

When the input data is very large and is transmitted using HTTP chunked encoding, to stream the data to the algorithm, set MaxPayloadInMB to 0. Amazon SageMaker built-in algorithms don't support this feature.

For information about using the API to create a batch transform job, see the CreateTransformJob API. For more information about the correlation between batch transform input and output objects, see OutputDataConfig. For an example of how to use batch transform, see (Optional) Make Prediction with Batch Transform (p. 54).

**Speed up a Batch Transform Job**

If you are using the CreateTransformJob API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as MaxPayloadInMB, MaxConcurrentTransforms, or BatchStrategy. If you are using the SageMaker console, you can specify these optimal parameter values in the Additional configuration section of the Batch transform job configuration page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

**Use Batch Transform to Test Production Variants**

To test different models or various hyperparameter settings, create a separate transform job for each new model variant and use a validation dataset. For each transform job, specify a unique model name and location in Amazon S3 for the output file. To analyze the results, use Inference Pipeline Logs and Metrics (p. 1997).

**Batch Transform Errors**

SageMaker uses the Amazon S3 Multipart Upload API to upload results from a batch transform job to Amazon S3. If an error occurs, the uploaded results are removed from Amazon S3. In some cases, such
as when a network outage occurs, an incomplete multipart upload might remain in Amazon S3. To avoid incurring storage charges, we recommend that you add the S3 bucket policy to the S3 bucket lifecycle rules. This policy deletes incomplete multipart uploads that might be stored in the S3 bucket. For more information, see Object Lifecycle Management.

If a batch transform job fails to process an input file because of a problem with the dataset, SageMaker marks the job as failed. If an input file contains a bad record, the transform job doesn't create an output file for that input file because doing so prevents it from maintaining the same order in the transformed data as in the input file. When your dataset has multiple input files, a transform job continues to process input files even if it fails to process one. The processed files still generate useable results.

Exceeding the MaxPayloadInMB limit causes an error. This might happen with a large dataset if it can't be split, the SplitType parameter is set to none, or individual records within the dataset exceed the limit.

If you are using your own algorithms, you can use placeholder text, such as ERROR, when the algorithm finds a bad record in an input file. For example, if the last record in a dataset is bad, the algorithm places the placeholder text for that record in the output file.

Batch Transform Sample Notebooks

For a sample notebook that uses batch transform with a principal component analysis (PCA) model to reduce data in a user-item review matrix, followed by the application of a density-based spatial clustering of applications with noise (DBSCAN) algorithm to cluster movies, see Batch Transform with PCA and DBSCAN Movie Clusters. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the NTM algorithms are located in the Advanced functionality section. To open a notebook, choose its Use tab, then choose Create copy.

Associate Prediction Results with Input Records

When making predictions on a large dataset, you can exclude attributes that aren't needed for prediction. After the predictions have been made, you can associate some of the excluded attributes with those predictions or with other input data in your report. By using batch transform to perform these data processing steps, you can often eliminate additional preprocessing or postprocessing. You can use input files in JSON and CSV format only.

Topics
- Workflow for Associating Inferences with Input Records (p. 1963)
- Use Data Processing in Batch Transform Jobs (p. 1964)
- Supported JSONPath Operators (p. 1965)
- Batch Transform Examples (p. 1965)

Workflow for Associating Inferences with Input Records

The following diagram shows the workflow for associating inferences with input records.
To associate inferences with input data, there are three main steps:

1. Filter the input data that is not needed for inference before passing the input data to the batch transform job. Use the `InputFilter` parameter to determine which attributes to use as input for the model.
2. Associate the input data with the inference results. Use the `JoinSource` parameter to combine the input data with the inference.
3. Filter the joined data to retain the inputs that are needed to provide context for interpreting the predictions in the reports. Use `OutputFilter` to store the specified portion of the joined dataset in the output file.

**Use Data Processing in Batch Transform Jobs**

When creating a batch transform job with `CreateTransformJob` to process data:

1. Specify the portion of the input to pass to the model with the `InputFilter` parameter in the `DataProcessing` data structure.
2. Join the raw input data with the transformed data with the `JoinSource` parameter.
3. Specify which portion of the joined input and transformed data from the batch transform job to include in the output file with the `OutputFilter` parameter.
4. Choose either JSON- or CSV-formatted files for input:
   - For JSON- or JSON Lines-formatted input files, SageMaker either adds the `SageMakerOutput` attribute to the input file or creates a new JSON output file with the `SageMakerInput` and `SageMakerOutput` attributes. For more information, see `DataProcessing`.
   - For CSV-formatted input files, the joined input data is followed by the transformed data and the output is a CSV file.

If you use an algorithm with the `DataProcessing` structure, it must support your chosen format for both input and output files. For example, with the `TransformOutput` field of the
CreateTransformJob API, you must set both the Content Type and Accept parameters to one of the following values: text/csv, application/json, or application/jsonlines. The syntax for specifying columns in a CSV file and specifying attributes in a JSON file are different. Using the wrong syntax causes an error. For more information, see Batch Transform Examples (p. 1965). For more information about input and output file formats for built-in algorithms, see Use Amazon SageMaker Built-in Algorithms (p. 762).

The record delimiters for the input and output must also be consistent with your chosen file input. The SplitType parameter indicates how to split the records in the input dataset. The AssembleWith parameter indicates how to reassemble the records for the output. If you set input and output formats to text/csv, you must also set the SplitType and AssemblyType parameters to line. If you set the input and output formats to application/jsonlines, you can set both SplitType and AssemblyType to line.

For JSON files, the attribute name SageMakerOutput is reserved for output. The JSON input file can't have an attribute with this name. If it does, the data in the input file might be overwritten.

### Supported JSONPath Operators

To filter and join the input data and inference, use a JSONPath subexpression. SageMaker supports only a subset of the defined JSONPath operators. The following table lists the supported JSONPath operators. For CSV data, each row is taken as a JSON array, so only index based JSONPaths can be applied, e.g. $[0], $[1:,]. CSV data should also follow RFC format.

<table>
<thead>
<tr>
<th>JSONPath Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>The root element to a query. This operator is required at the beginning of all path expressions.</td>
<td>$</td>
</tr>
<tr>
<td>.&lt;name&gt;</td>
<td>A dot-notated child element.</td>
<td>$.id</td>
</tr>
<tr>
<td>*</td>
<td>A wildcard. Use in place of an attribute name or numeric value.</td>
<td>$.id.*</td>
</tr>
<tr>
<td>['&lt;name&gt;','&lt;name&gt;']</td>
<td>A bracket-notated element or multiple child elements.</td>
<td>$['id','SageMakerOutput']</td>
</tr>
<tr>
<td>[&lt;number&gt;,&lt;number&gt;]</td>
<td>An index or array of indexes. Negative index values are also supported. A -1 index refers to the last element in an array.</td>
<td>$[1],$[1,3,5]</td>
</tr>
<tr>
<td>[&lt;start&gt;:&lt;end&gt;]</td>
<td>An array slice operator. The array slice() method extracts a section of an array and returns a new array. If you omit &lt;start&gt;, SageMaker uses the first element of the array. If you omit &lt;end&gt;, SageMaker uses the last element of the array.</td>
<td>$[2:5],$[:5],$[2:]</td>
</tr>
</tbody>
</table>

When using the bracket-notation to specify multiple child elements of a given field, additional nesting of children within brackets is not supported. For example, $.field1.['child1','child2'] is supported while $.field1.['child1','child2.grandchild'] is not.

For more information about JSONPath operators, see JsonPath on GitHub.

### Batch Transform Examples

The following examples show some common ways to join input data with prediction results.
Amazon SageMaker Developer Guide
Associate Prediction Results with Input

Topics
• Example: Output Only Inferences (p. 1966)
• Example: Output Input Data and Inferences (p. 1966)
• Example: Output an ID Column with Results and Exclude the ID Column from the Input
(CSV) (p. 1967)
• Example: Output an ID Attribute with Results and Exclude the ID Attribute from the Input
(JSON) (p. 1967)

Example: Output Only Inferences
By default, the DataProcessing parameter doesn't join inference results with input. It outputs only
the inference results.
If you want to explicitly specify to not join results with input, use the Amazon SageMaker Python SDK
and specify the following settings in a transformer call.
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$", join_source= "None", output_filter="$")

To output inferences using the AWS SDK for Python, add the following code to your CreateTransformJob
request. The following code mimics the default behavior.
{

}

"DataProcessing": {
"InputFilter": "$",
"JoinSource": "None",
"OutputFilter": "$"
}

Example: Output Input Data and Inferences
If you're using the Amazon SageMaker Python SDK, to combine the input data with the inferences in the
output ﬁle, specify "Input" for the JoinSource parameter in a transformer call.
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, join_source= "Input")

If you're using the AWS SDK for Python (Boto 3), join all input data with the inference by adding the
following code to your CreateTransformJob request.
{

}

"DataProcessing":
{
"JoinSource": "Input"
}

For JSON or JSON Lines input ﬁles, the results are in the SageMakerOutput key in the input JSON ﬁle.
For example, if the input is a JSON ﬁle that contains the key-value pair {"key":1}, the data transform
result might be {"label":1}.
SageMaker stores both in the input ﬁle in the SageMakerInput key.

1966


Note
The joined result for JSON must be a key-value pair object. If the input isn't a key-value pair object, SageMaker creates a new JSON file. In the new JSON file, the input data is stored in the SageMakerInput key and the results are stored as the SageMakerOutput value.

For a CSV file, for example, if the record is [1, 2, 3], and the label result is [1], then the output file would contain [1, 2, 3, 1].

Example: Output an ID Column with Results and Exclude the ID Column from the Input (CSV)

If you are using the Amazon SageMaker Python SDK, to include results or an ID column in the output, specify indexes of the joined dataset in a transformer call. For example, if your data includes five columns and the first one is the ID column, use the following transformer request.

```python
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$[1:]", join_source= "Input", output_filter="$")
```

If you are using the AWS SDK for Python (Boto 3), add the following code to your CreateTransformJob request.

```json
{  
  "DataProcessing": {  
    "InputFilter": "$[1:]",
    "JoinSource": "Input",
    "OutputFilter": "$"
  }
}
```

To specify columns in SageMaker, use the index of the array elements. The first column is index 0, the second column is index 1, and the sixth column is index 5.

To exclude the first column from the input, set InputFilter to "$[1:]". The colon (:) tells SageMaker to include all of the elements between two values, inclusive. For example, $[1:4] specifies the second through fifth columns.

If you omit the number after the colon, for example, [5:], the subset includes all columns from the 6th column through the last column. If you omit the number before the colon, for example, [:5], the subset includes all columns from the first column (index 0) through the sixth column.

Example: Output an ID Attribute with Results and Exclude the ID Attribute from the Input (JSON)

If you are using the Amazon SageMaker Python SDK, include results of an ID attribute in the output by specifying it in a transformer call. For example, if you store data in the features attribute and the record ID in the ID attribute, you would use the following transformer request.

```python
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$.features", join_source= "Input", output_filter="$['id','SageMakerOutput']")
```
If you are using the AWS SDK for Python (Boto 3), join all input data with the inference by adding the following code to your `CreateTransformJob` request.

```json
{
  "DataProcessing": {
    "InputFilter": "$.features",
    "JoinSource": "Input",
    "OutputFilter": "#['id','SageMakerOutput']"
  }
}
```

**Warning**

If you are using a JSON-formatted input file, the file can't contain the attribute name `SageMakerOutput`. This attribute name is reserved for the output file. If your JSON-formatted input file contains an attribute with this name, values in the input file might be overwritten with the inference.

**Host Multiple Models with Multi-Model Endpoints**

To create an endpoint that can host multiple models, use multi-model endpoints. Multi-model endpoints provide a scalable and cost-effective solution to deploying large numbers of models. They use a shared serving container that is enabled to host multiple models. This reduces hosting costs by improving endpoint utilization compared with using single-model endpoints. It also reduces deployment overhead because Amazon SageMaker manages loading models in memory and scaling them based on the traffic patterns to them.

Multi-model endpoints also enable time-sharing of memory resources across your models. This works best when the models are fairly similar in size and invocation latency. When this is the case, multi-model endpoints can effectively use instances across all models. If you have models that have significantly higher transactions per second (TPS) or latency requirements, we recommend hosting them on dedicated endpoints. Multi-model endpoints are also well suited to scenarios that can tolerate occasional cold-start-related latency penalties that occur when invoking infrequently used models.

Multi-model endpoints support A/B testing. They work with Auto Scaling and AWS PrivateLink. You can use multi-model-enabled containers with serial inference pipelines, but only one multi-model-enabled container can be included in an inference pipeline. You can't use multi-model-enabled containers with Amazon Elastic Inference.

You can use the AWS SDK for Python (Boto) or the SageMaker console to create a multi-model endpoint. You can use multi-model endpoints with custom-built containers by integrating the Multi Model Server library.

**Topics**

- Supported Algorithms and Frameworks (p. 1969)
- Sample Notebooks for Multi-Model Endpoints (p. 1969)
- Setting SageMaker Multi-Model Endpoint Model Caching Behavior (p. 1970)
- Instance Recommendations for Multi-Model Endpoint Deployments (p. 1970)

- Multi-Model Endpoint Security (p. 1982)
Supported Algorithms and Frameworks

The inference containers for the following algorithms and frameworks support multi-model endpoints:

- XGBoost Algorithm (p. 1568)
- K-Nearest Neighbors (k-NN) Algorithm (p. 1472)
- Linear Learner Algorithm (p. 1486)
- Random Cut Forest (RCF) Algorithm (p. 1538)
- Use TensorFlow with Amazon SageMaker (p. 30)
- Use Scikit-learn with Amazon SageMaker (p. 29)
- Use Apache MXNet with Amazon SageMaker (p. 14)
- Use PyTorch with Amazon SageMaker (p. 26)

To use any other framework or algorithm, use the SageMaker inference toolkit to build a container that supports multi-model endpoints. For information, see Build Your Own Container with Multi Model Server (p. 1977).

Sample Notebooks for Multi-Model Endpoints

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see the Multi-Model Endpoint XGBoost Sample Notebook. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the Multi-Model Endpoint BYOC Sample Notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 139). After you've created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. The Multi-Model Endpoint notebook is located in the ADVANCED FUNCTIONALITY section. To open a notebook, choose its Use tab and choose Create copy.

How Multi-Model Endpoints Work

SageMaker manages the lifecycle of models hosted on multi-model endpoints in the container's memory. Instead of downloading all of the models from an Amazon S3 bucket to the container when you create the endpoint, SageMaker dynamically loads them when you invoke them. When SageMaker receives an invocation request for a particular model, it does the following:

1. Routes the request to an instance behind the endpoint.
2. Downloads the model from the S3 bucket to that instance's storage volume.
3. Loads the model to the container's memory on that instance. If the model is already loaded in the container's memory, invocation is faster because SageMaker doesn't need to download and load it.

SageMaker continues to route requests for a model to the instance where the model is already loaded. However, if the model receives many invocation requests, and there are additional instances for the multi-model endpoint, SageMaker routes some requests to another instance to accommodate the traffic. If the model isn't already loaded on the second instance, the model is downloaded to that instance's storage volume and loaded into the container's memory.

When an instance's memory utilization is high and SageMaker needs to load another model into memory, it unloads unused models from that instance's container to ensure that there is enough
memory to load the model. Models that are unloaded remain on the instance's storage volume and can be loaded into the container's memory later without being downloaded again from the S3 bucket. If the instance's storage volume reaches its capacity, SageMaker deletes any unused models from the storage volume.

To delete a model, stop sending requests and delete it from the S3 bucket. SageMaker provides multi-model endpoint capability in a serving container. Adding models to, and deleting them from, a multi-model endpoint doesn't require updating the endpoint itself. To add a model, you upload it to the S3 bucket and invoke it. You don't need code changes to use it.

When you update a multi-model endpoint, invocation requests on the endpoint might experience higher latencies as traffic is directed to the instances in the updated endpoint.

Setting SageMaker Multi-Model Endpoint Model Caching Behavior

By default, multi-model endpoints cache frequently used models in memory and on disk to provide low latency inference. The cached models are unloaded and/or deleted from disk only when a container runs out of memory or disk space to accommodate a newly targeted model.

You can change the caching behavior of a multi-model endpoint and explicitly enable or disable model caching by setting the parameter ModelCacheSetting when you call create_model.

We recommend setting the value of the ModelCacheSetting parameter to Disabled for use cases that do not benefit from model caching. For example, when a large number of models need to be served from the endpoint but each model is invoked only once (or very infrequently). For such use cases, setting the value of the ModelCacheSetting parameter to Disabled allows higher transactions per second (TPS) for invoke_endpoint requests compared to the default caching mode. Higher TPS in these use cases is because SageMaker does the following after the invoke_endpoint request:

- Asynchronously unloads the model from memory and deletes it from disk immediately after it is invoked.
- Provides higher concurrency for downloading and loading models in the inference container. The concurrency is a factor of the number of vCPUs of the container instance.

For guidelines on choosing a SageMaker ML instance type for a multi-model endpoint, see Instance Recommendations for Multi-Model Endpoint Deployments (p. 1970).

Instance Recommendations for Multi-Model Endpoint Deployments

There are several items to consider when selecting a SageMaker ML instance type for a multi-model endpoint. Provision sufficient Amazon Elastic Block Store (Amazon EBS) capacity for all of the models that need to be served. Balance performance (minimize cold starts) and cost (don't over-provision instance capacity). For information about the size of the storage volume that SageMaker attaches for each instance type for an endpoint and for a multi-model endpoint, see Host Instance Storage Volumes (p. 2019). For a container configured to run in MultiModel mode, the storage volume provisioned for its instances has more memory. This allows more models to be cached on the instance storage volume.

When choosing a SageMaker ML instance type, consider the following:

- Multi-model endpoints are not supported on GPU instance types.
• The traffic distribution (access patterns) to the models that you want to host behind the multi-model endpoint, along with the model size (how many models could be loaded in memory on the instance):
  • Think of the amount of memory on an instance as the cache space for models to be loaded. Think of the number of vCPUs as the concurrency limit to perform inference on the loaded models (assuming that invoking a model is bound to CPU).
  • A higher amount of instance memory enables you to have more models loaded and ready to serve inference requests. You don’t need to waste time loading the model.
  • A higher amount of vCPUs enables you to invoke more unique models concurrently (again assuming that inference is bound to CPU).
  • Have some “slack” memory available so that unused models can be unloaded, and especially for multi-model endpoints with multiple instances. If an instance or an Availability Zone fails, the models on those instances will be rerouted to other instances behind the endpoint.

• Tolerance to loading/downloading times:
  • d instance type families (for example, m5d, c5d, or r5d) come with an NVMe (non-volatile memory express) SSD, which offers high I/O performance and might reduce the time it takes to download models to the storage volume and for the container to load the model from the storage volume.
  • Because d instance types come with an NVMe SSD storage, SageMaker does not attach an Amazon EBS storage volume to these ML compute instances that hosts the multi-model endpoint. Auto scaling works best when the models are similar-sized and homogenous, that is when they have similar inference latency and resource requirements.

In some cases, you might opt to reduce costs by choosing an instance type that can’t hold all of the targeted models in memory at once. SageMaker dynamically unloads models when it runs out of memory to make room for a newly targeted model. For infrequently requested models, you are going to pay a price with the dynamic load latency. In cases with more stringent latency needs, you might opt for larger instance types or more instances. Investing time up front for proper performance testing and analysis will pay great dividends in successful production deployments.

You can use the Average statistic of the ModelCacheHit metric to monitor the ratio of requests where the model is already loaded. You can use the SampleCount statistic for the ModelUnloadingTime metric to monitor the number of unload requests sent to the container during a time period. If models are unloaded too frequently (an indicator of thrashing, where models are being unloaded and loaded again because there is insufficient cache space for the working set of models), consider using a larger instance type with more memory or increasing the number of instances behind the multi-model endpoint. For multi-model endpoints with multiple instances, be aware that a model might be loaded on more than 1 instance.

SageMaker multi-model endpoints fully supports Auto Scaling, which manages replicas of models to ensure models scale based on traffic patterns. We recommend that you configure your multi-model endpoint and the size of your instances by considering all of the above and also set up auto scaling for your endpoint. The invocation rates used to trigger an auto-scale event is based on the aggregate set of predictions across the full set of models served by the endpoint.

Create a Multi-Model Endpoint

You can use AWS SDK for Python (Boto) or Amazon SageMaker to create a multi-model endpoint.

Topics
• Create a Multi-Model Endpoint (Console) (p. 1971)
• Create a Multi-Model Endpoint (AWS SDK for Python (Boto)) (p. 1974)

Create a Multi-Model Endpoint (Console)
To create a multi-model endpoint (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Model, and then from the Inference group, choose Create model.
3. For Model name, enter a name.
4. For IAM role, choose or create an IAM role that has the AmazonSageMakerFullAccess IAM policy attached.
5. In the Container definition section, for Provide model artifacts and inference image options choose Use multiple models.
Create model

To deploy a model to Amazon SageMaker, first create the model by providing the location of model artifacts and inference code. See Deploying a Model on Amazon SageMaker Hosting Services.

Model settings

Model name

mml-test-model

Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an AWS Region.

IAM role

Amazon SageMaker requires permissions to call other services on your behalf. Choose a role or let Amazon SageMaker create a role that has the AmazonSageMakerFullAccess IAM policy attached.

AmazonSageMaker-ExecutionRole- XXXXXXXXXXXXXXXXXXX

Container definition 1

Container input options

Provide model artifacts and inference image location

Provide model artifacts and inference image options

Use multiple models

Use this to host multiple models in this container.

Location of inference code image

Type the registry path where the inference code image is stored in Amazon ECR.

123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage:mytag

Location of model artifacts

Type the URL where model artifacts are stored in S3.

s3://my-bucket/path/to/artifacts/
Create a Multi-Model Endpoint (AWS SDK for Python (Boto))

You create a multi-model endpoint using the Amazon SageMaker create_model, create_endpoint_config, and create_endpoint APIs just as you would create a single model endpoint, but with two changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model.

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see Multi-Model Endpoint XGBoost Sample Notebook.

The following procedure outlines the key steps used in that sample to create a multi-model endpoint.

To deploy the model (AWS SDK for Python (Boto 3))

1. Get a container with an image that supports deploying multi-model endpoints. For a list of built-in algorithms and framework containers that support multi-model endpoints, see Supported Algorithms and Frameworks (p. 1969). For this example, we use the K-Nearest Neighbors (k-NN) Algorithm (p. 1472) built-in algorithm. We call the SageMaker Python SDK utility function image_uris.retrieve() to get the address for the K-Nearest Neighbors built-in algorithm image.

   ```python
   import sagemaker
   region = sagemaker_session.boto_region_name
   image = sagemaker.image_uris.retrieve("knn", region=region)
   container = { 'Image': image,
                 'ModelDataUrl': 's3://<BUCKET_NAME>/PATH_TO_ARTIFACTS',
                 'Mode': 'MultiModel'}
   ```

2. Get a Boto 3 SageMaker client and create the model that uses this container.

   ```python
   import boto3
   sm_client = boto3.client('sagemaker')
   response = sm_client.create_model(
       ModelName = '<MODEL_NAME>',
       ExecutionRoleArn = role,
       Containers = [container])
   ```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of `CreateModel`.

   ```python
   preprocessing_container = { 'Image':
                           '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>:<TAG>'
   } 
   multi_model_container = { 'Image':
                           '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',
                           'ModelDataUrl': 's3://<BUCKET_NAME>/PATH_TO_ARTIFACTS',
                           'Mode': 'MultiModel'}
   response = sm_client.create_model(
       ModelName = '<MODEL_NAME>',
       Containers = [preprocessing_container, multi_model_container])
   ```
4. **(Optional)** If your use case does not benefit from model caching, set the value of the ModelCacheSetting field of the MultiModelConfig parameter to Disabled, and include it in the Container argument of the call to create_model. The value of the ModelCacheSetting field is Enabled by default.

```python
container = {
    'Image': image,
    'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
    'Mode': 'MultiModel'
    'MultiModelConfig': {
        // Default value is 'Enabled'
        'ModelCacheSetting': 'Disabled'
    }
}
```

```python
response = sm_client.create_model(
    ModelName        = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers       = [container])
```

5. Configure the multi-model endpoint for the model. We recommend configuring your endpoints with at least two instances. This allows SageMaker to provide a highly available set of predictions across multiple Availability Zones for the models.

```python
response = sm_client.create_endpoint_config(
    EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
    ProductionVariants=[[
        'InstanceType':       'ml.m4.xlarge',
        'InitialInstanceCount': 2,
        'InitialVariantWeight': 1,
        'ModelName': '<MODEL_NAME>',
        'VariantName': 'AllTraffic']])
```

**Note**

You can use only one multi-model-enabled endpoint in a serial inference pipeline.

6. Create the multi-model endpoint using the EndpointName and EndpointConfigName parameters.

```python
response = sm_client.create_endpoint(
    EndpointName       = '<ENDPOINT_NAME>',
    EndpointConfigName = '<ENDPOINT_CONFIG_NAME>'
)
```

---

## Invoke a Multi-Model Endpoint

To invoke a multi-model endpoint, use the `invoke_endpoint` from the SageMaker Runtime just as you would invoke a single model endpoint, with one change. Pass a new `TargetModel` parameter that specifies which of the models at the endpoint to target. The SageMaker Runtime InvokeEndpoint request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the CreateModel API call with the relative path of the model.

**AWS SDK for Python (Boto 3)**

The following example prediction request uses the AWS SDK for Python (Boto 3) in the sample notebook.
Invoke a Multi-Model Endpoint

```python
response = runtime_sm_client.invoke_endpoint(
    EndpointName = "<ENDPOINT_NAME>",
    ContentType = "text/csv",
    TargetModel = "<MODEL_FILENAME>.tar.gz",
    Body = body)
```

AWS CLI

The following example shows how to make a CSV request with two rows using the AWS Command Line Interface (AWS CLI):

```
aws sagemaker-runtime invoke-endpoint \
    --endpoint-name "<ENDPOINT_NAME>" \ 
    --body "1.0,2.0,5.0"$'
          'n"2.0,3.0,4.0" \ 
    --content-type "text/csv" \ 
    --target-model "<MODEL_NAME>.tar.gz" \ 
    output_file.txt
```

An output_file.txt with information about your inference requests is made if the inference was successful. For more examples on how to make predictions with the AWS CLI, see Making predictions with the AWS CLI in the SageMaker Python SDK documentation.

The multi-model endpoint dynamically loads target models as needed. You can observe this when running the MME Sample Notebook as it iterates through random invocations against multiple target models hosted behind a single endpoint. The first request against a given model takes longer because the model has to be downloaded from Amazon Simple Storage Service (Amazon S3) and loaded into memory. (This is called a cold start.) Subsequent calls finish faster because there's no additional overhead after the model has loaded.

**Retry Requests on ModelNotReadyException Errors**

The first time you call `invoke_endpoint` for a model, the model is downloaded from Amazon Simple Storage Service and loaded into the inference container. This makes the first call take longer to return. Subsequent calls to the same model finish faster, because the model is already loaded.

SageMaker returns a response for a call to `invoke_endpoint` within 60 seconds. Some models are too large to download within 60 seconds. If the model does not finish loading before the 60 second timeout limit, the request to `invoke_endpoint` returns with the error code `ModelNotReadyException`, and the model continues to download and load into the inference container for up to 360 seconds. If you get a `ModelNotReadyException` error code for an `invoke_endpoint` request, retry the request. By default, the AWS SDKs for Python (Boto 3) (using Legacy retry mode) and Java retry `invoke_endpoint` requests that result in `ModelNotReadyException` errors. You can configure the retry strategy to continue retrying the request for up to 360 seconds. If you expect your model to take longer than 60 seconds to download and load into the container, set the SDK socket timeout to 70 seconds. For more information about configuring the retry strategy for Boto 3, see Configuring a retry mode. The following code shows an example that configures the retry strategy to retry calls to `invoke_endpoint` for up to 180 seconds.

```python
import boto3
from botocore.config import Config

# This example retry strategy sets the retry attempts to 2.
# With this setting, the request can attempt to download and/or load the model
# for up to 180 seconds: 1 orginal request (60 seconds) + 2 retries (120 seconds)
config = Config(
    read_timeout=70,
    retries={
```

1976
Add or Remove Models

You can deploy additional models to a multi-model endpoint and invoke them through that endpoint immediately. When adding a new model, you don't need to update or bring down the endpoint, so you avoid the cost of creating and running a separate endpoint for each new model.

SageMaker unloads unused models from the container when the instance is reaching memory capacity and more models need to be downloaded into the container. SageMaker also deletes unused model artifacts from the instance storage volume when the volume is reaching capacity and new models need to be downloaded. The first invocation to a newly added model takes longer because the endpoint takes time to download the model from S3 to the container's memory in instance hosting the endpoint.

With the endpoint already running, copy a new set of model artifacts to the Amazon S3 location there you store your models.

```python
# Add an AdditionalModel to the endpoint and exercise it
aws s3 cp AdditionalModel.tar.gz s3://my-bucket/path/to/artifacts/
```

**Important**

To update a model, proceed as you would when adding a new model. Use a new and unique name. Don't overwrite model artifacts in Amazon S3 because the old version of the model might still be loaded in the containers or on the storage volume of the instances on the endpoint. Invocations to the new model could then invoke the old version of the model.

Client applications can request predictions from the additional target model as soon as it is stored in S3.

```python
response = runtime_sm_client.invoke_endpoint(
    EndpointName='<ENDPOINT_NAME>',
    ContentType='text/csv',
    TargetModel='AdditionalModel.tar.gz',
    Body=body)
```

To delete a model from a multi-model endpoint, stop invoking the model from the clients and remove it from the S3 location where model artifacts are stored.

**Build Your Own Container with Multi Model Server**

Custom Elastic Container Registry (ECR) images deployed in Amazon SageMaker are expected to adhere to the basic contract described in Use Your Own Inference Code with Hosting Services (p. 2245) that govern how SageMaker interacts with a Docker container that runs your own inference code. For a container to be capable of loading and serving multiple models concurrently, there are additional APIs and behaviors that must be followed. This additional contract includes new APIs to load, list, get, and unload models, and a different API to invoke models. There are also different behaviors for error scenarios that the APIs need to abide by. To indicate that the container complies with the additional requirements, you can add the following command to your Docker file:

```dockerfile
LABEL com.amazonaws.sagemaker.capabilities.multi-models=true
```

SageMaker also injects an environment variable into the container

```bash
SAGEMAKER_MULTI_MODEL=true
```
If you are creating a multi-model endpoint for a serial inference pipeline, your Docker file must have the required labels for both multi-models and serial inference pipelines. For more information about serial information pipelines, see Run Real-time Predictions with an Inference Pipeline (p. 1994).

To help you implement these requirements for a custom container, two libraries are available:

- **Multi Model Server** is an open source framework for serving machine learning models that can be installed in containers to provide the front end that fulfills the requirements for the new multi-model endpoint container APIs. It provides the HTTP front end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and performs inference on a specified loaded model. It also provides a pluggable backend that supports a pluggable custom backend handler where you can implement your own algorithm.

- **SageMaker Inference Toolkit** is a library that bootstraps Multi Model Server with a configuration and settings that make it compatible with SageMaker multi-model endpoints. It also allows you to tweak important performance parameters, such as the number of workers per model, depending on the needs of your scenario.

### Use the SageMaker Inference Toolkit

Currently, the only pre-built containers that support multi-model endpoints are the MXNet inference container and the PyTorch inference container. If you want to use any other framework or algorithm, you need to build a container. The easiest way to do this is to use the SageMaker Inference Toolkit to extend an existing pre-built container. The SageMaker inference toolkit is an implementation for the multi-model server (MMS) that creates endpoints that can be deployed in SageMaker. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the Multi-Model Endpoint BYOC Sample Notebook.

**Note**

The SageMaker inference toolkit supports only Python model handlers. If you want to implement your handler in any other language, you must build your own container that implements the additional multi-model endpoint APIs. For information, see Contract for Custom Containers to Serve Multiple Models (p. 1980).

### To extend a container by using the SageMaker inference toolkit

1. Create a model handler. MMS expects a model handler, which is a Python file that implements functions to pre-process, get predictions from the model, and process the output in a model handler. For an example of a model handler, see model_handler.py from the sample notebook.

2. Import the inference toolkit and use its `model_server.start_model_server` function to start MMS. The following example is from the dockerd-entrypoint.py file from the sample notebook. Notice that the call to `model_server.start_model_server` passes the model handler described in the previous step:

```python
import subprocess
import sys
import shlex
import os
from retrying import retry
from subprocess import CalledProcessError
from sagemaker_inference import model_server

def _retry_if_error(exception):
    return isinstance(exception, CalledProcessError or OSError)

@retry(stop_max_delay=1000 * 50,
       retry_on_exception=_retry_if_error)
def _start_mms():
    # Start MMS
    subprocess.run(shlex.split('model_server.start_model_server {model_handler}'))

_start_mms()
```
Bring Your Own Container

# by default the number of workers per model is 1, but we can configure it through
# the
# environment variable below if desired.
# os.environ['SAGEMAKER_MODEL_SERVER_WORKERS'] = '2'
model_server.start_model_server(handler_service='/home/model-server/model_handler.py:handle')

def main():
    if sys.argv[1] == 'serve':
        _start_mms()
    else:
        subprocess.check_call(shlex.split(' '.join(sys.argv[1:])))

    # prevent docker exit
    subprocess.call(['tail', '-f', '/dev/null'])
main()

3. In your Dockerfile, copy the model handler from the first step and specify the Python file from the previous step as the entrypoint in your Dockerfile. The following lines are from the Dockerfile used in the sample notebook:

```bash
COPY model_handler.py /home/model-server/model_handler.py
ENTRYPOINT ["python", "/usr/local/bin/dockerd-entrypoint.py"]
```

4. Build and register your container. The following shell script from the sample notebook builds the container and uploads it to an Amazon Elastic Container Registry repository in your AWS account:

```bash
algorithm_name=demo-sagemaker-multimodel
cd container
account=$(aws sts get-caller-identity --query Account --output text)

region=$(aws configure get region)
region=${region:-us-west-2}
fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $# -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

aws ecr get-login --region ${region} --no-include-email

# Get the login command from ECR and execute it directly
$(aws ecr get-login --region ${region} --no-include-email)

# Build the docker image locally with the image name and then push it to ECR
# with the full name.
docker build -q -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
You can now use this container to deploy multi-model endpoints in SageMaker.

**Topics**
- Contract for Custom Containers to Serve Multiple Models (p. 1980)

**Contract for Custom Containers to Serve Multiple Models**

To handle multiple models, your container must support a set of APIs that enable Amazon SageMaker to communicate with the container for loading, listing, getting, and unloading models as required. The `model_name` is used in the new set of APIs as the key input parameter. The customer container is expected to keep track of the loaded models using `model_name` as the mapping key. Also, the `model_name` is an opaque identifier and is not necessarily the value of the TargetModel parameter passed into the InvokeEndpoint API. The original TargetModel value in the InvokeEndpoint request is passed to container in the APIs as a `X-Amzn-SageMaker-Target-Model` header that can be used for logging purposes.

**Topics**
- Load Model API (p. 1980)
- List Model API (p. 1980)
- Get Model API (p. 1981)
- Unload Model API (p. 1981)
- Invoke Model API (p. 1982)

**Load Model API**

Instructs the container to load a particular model present in the `url` field of the body into the memory of the customer container and to keep track of it with the assigned `model_name`. After a model is loaded, the container should be ready to serve inference requests using this `model_name`.

```plaintext
POST /models HTTP/1.1
Content-Type: application/json
Accept: application/json

{
    "model_name": "{model_name}"
    "url": "/opt/ml/models/{model_name}/model",
}
```

**Note**

If `model_name` is already loaded, this API should return 409. Any time a model cannot be loaded due to lack of memory or to any other resource, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

**List Model API**

Returns the list of models loaded into the memory of the customer container.

```plaintext
GET /models HTTP/1.1
Accept: application/json

Response =
{
    "models": [}
This API also supports pagination.

GET /models HTTP/1.1
Accept: application/json

Response =
{
 "models": [ 
 { 
 "modelName": "{model_name}",
 "modelUrl": "/opt/ml/models/{model_name}/model",
 },
 { 
 "modelName": "{model_name}",
 "modelUrl": "/opt/ml/models/{model_name}/model",
 },
 ....
 ]
}

SageMaker can initially call the List Models API without providing a value for next_page_token.
If a nextPageToken field is returned as part of the response, it will be provided as the value for next_page_token in a subsequent List Models call. If a nextPageToken is not returned, it means that there are no more models to return.

**Get Model API**

This is a simple read API on the model_name entity.

GET /models/{model_name} HTTP/1.1
Accept: application/json

{ 
 "modelName": "{model_name}",
 "modelUrl": "/opt/ml/models/{model_name}/model",
}

**Note**
If model_name is not loaded, this API should return 404.

**Unload Model API**

Instructs the SageMaker platform to instruct the customer container to unload a model from memory.
This initiates the eviction of a candidate model as determined by the platform when starting the process of loading a new model. The resources provisioned to model_name should be reclaimed by the container when this API returns a response.

DELETE /models/{model_name}
Note
If model_name is not loaded, this API should return 404.

Invoke Model API

Makes a prediction request from the particular model_name supplied. The SageMaker Runtime InvokeEndpoint request supports X-Amzn-SageMaker-Target-Model as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the CreateModel API call with the relative path of the model.

POST /models/{model_name}/invoke HTTP/1.1
Content-Type: Content-Type
Accept: Accept
X-Amzn-SageMaker-Custom-Attributes: CustomAttributes
X-Amzn-SageMaker-Target-Model: [relativePath]/{artifactName}.tar.gz

Note
If model_name is not loaded, this API should return 404.

Multi-Model Endpoint Security

Models and data in a multi-model endpoint are co-located on instance storage volume and in container memory. All instances for Amazon SageMaker endpoints run on a single tenant container that you own. Only your models can run on your multi-model endpoint. It's your responsibility to manage the mapping of requests to models and to provide access for users to the correct target models. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify allowed or denied actions and resources and the conditions under which actions are allowed or denied.

By default, an IAM principal with InvokeEndpoint permissions on a multi-model endpoint can invoke any model at the address of the S3 prefix defined in the CreateModel operation, provided that the IAM Execution Role defined in operation has permissions to download the model. If you need to restrict InvokeEndpoint access to a limited set of models in S3, you can do one of the following:

- Restrict InvokeEndpoint calls to specific models hosted at the endpoint by using the sagemaker:TargetModel IAM condition key. For example, the following policy allows InvokeEndpoint requests only when the value of the TargetModel field matches one of the specified regular expressions:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": ["sagemaker:InvokeEndpoint"],
            "Effect": "Allow",
            "Condition": {
                // TargetModel provided must be from this set of values
                "StringLike": {
                    "sagemaker:TargetModel": ["company_a/*", "common/*"]
                }
            }
        }
    ]
}
```
CloudWatch Metrics for Multi-Model Endpoint Deployments

Amazon SageMaker provides metrics for endpoints so you can monitor the cache hit rate, the number of models loaded, and the model wait times for loading, downloading, and uploading at a multi-model endpoint. For information, see Multi-Model Endpoint Model Loading Metrics and Multi-Model Endpoint Model Instance Metrics in Monitor Amazon SageMaker with Amazon CloudWatch (p. 2624). Per-model metrics aren't supported.

Deploy multi-container endpoints

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. The containers can be run in a sequence as an inference pipeline, or each container can be accessed individually by using direct invocation to improve endpoint utilization and optimize costs.

For information about invoking the containers in a multi-container endpoint in sequence, see Deploy an Inference Pipeline (p. 1990).

For information about invoking a specific container in a multi-container endpoint, see Use a multi-container endpoint with direct invocation (p. 1984)

Topics

- Create a multi-container endpoint (Boto 3) (p. 1983)
- Update a multi-container endpoint (p. 1984)
- Delete a multi-container endpoint (p. 1984)
- Use a multi-container endpoint with direct invocation (p. 1984)
- Deploy an Inference Pipeline (p. 1990)

Create a multi-container endpoint (Boto 3)

Create a Multi-container endpoint by calling CreateModel, CreateEndpointConfig, and CreateEndpoint APIs as you would to create any other endpoints. You can run these containers sequentially as an inference pipeline, or run each individual container by using direct invocation. Multi-container endpoints have the following requirements when you call create_model:

- Use the Containers parameter instead of PrimaryContainer, and include more than one container in the Containers parameter.
- The ContainerHostname parameter is required for each container in a multi-container endpoint with direct invocation.
- Set the Mode parameter of the InferenceExecutionConfig field to Direct for direct invocation of each container, or Serial to use containers as an inference pipeline. The default mode is Serial.
Note
Currently there is a limit of up to 15 containers supported on a multi-container endpoint.

The following example creates a multi-container model for direct invocation.

1. Create container elements and `InferenceExecutionConfig` with direct invocation.

   ```python
   container1 = { 'Image':        '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage1:mytag',
                 'ContainerHostname': 'firstContainer'}
   container2 = { 'Image':        '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage2:mytag',
                 'ContainerHostname': 'secondContainer'}
   inferenceExecutionConfig = {'Mode': 'Direct'}
   ```

2. Create the model with the container elements and set the `InferenceExecutionConfig` field.

   ```python
   import boto3
   sm_client = boto3.Session().client('sagemaker')
   response = sm_client.create_model(
       ModelName        = 'my-direct-mode-model-name',
       InferenceExecutionConfig = inferenceExecutionConfig,
       ExecutionRoleArn = role,
       Containers       = [container1, container2])
   ```

   To create an endpoint, you would then call `create_endpoint_config` and `create_endpoint` as you would to create any other endpoint.

Update a multi-container endpoint

To update a multi-container endpoint, complete the following steps.

1. Call `create_model` to create a new model with a new value for the `Mode` parameter in the `InferenceExecutionConfig` field.
2. Call `create_endpoint_config` to create a new endpoint config with a different name by using the new model you created in the previous step.
3. Call `update_endpoint` to update the endpoint with the new endpoint config you created in the previous step.

Delete a multi-container endpoint

To delete an endpoint, call `delete_endpoint`, and provide the name of the endpoint you want to delete as the `EndpointName` parameter.

Use a multi-container endpoint with direct invocation

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. You can host up to 15 different inference containers on a single endpoint. By using direct invocation, you can send a request to a specific inference container hosted on a multi-container endpoint.

Topics
Invoke a multi-container endpoint with direct invocation

To invoke a multi-container endpoint with direct invocation, call `invoke_endpoint` as you would invoke any other endpoint, and specify which container you want to invoke by using the `TargetContainerHostname` parameter.

The following example directly invokes the secondContainer of a multi-container endpoint to get a prediction.

```python
import boto3
runtime_sm_client = boto3.Session().client('sagemaker-runtime')
response = runtime_sm_client.invoke_endpoint(
    EndpointName = 'my-endpoint',
    ContentType = 'text/csv',
    TargetContainerHostname = 'secondContainer',
    Body = body)
```

For each direct invocation request to a multi-container endpoint, only the container with the `TargetContainerHostname` processes the invocation request. You will get validation errors if you do any of the following:

- Specify a `TargetContainerHostname` that does not exist in the endpoint
- Do not specify a value for `TargetContainerHostname` in a request to an endpoint configured for direct invocation
- Specify a value for `TargetContainerHostname` in a request to an endpoint that is not configured for direct invocation.

Security with multi-container endpoints with direct invocation

For multi-container endpoints with direct invocation, there are multiple containers hosted in a single instance by sharing memory and a storage volume. It's your responsibility to use secure containers, maintain the correct mapping of requests to target containers, and provide users with the correct access to target containers. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify whether access to a resource is allowed or denied to that role, and under what conditions. For information about IAM roles, see IAM roles in the AWS Identity and Access Management User Guide. For information about identity-based policies, see Identity-based policies and resource-based policies.

By default, an IAM principal with InvokeEndpoint permissions on a multi-container endpoint with direct invocation can invoke any container inside the endpoint with the endpoint name that you specify when you call `invoke_endpoint`. If you need to restrict `invoke_endpoint` access to a limited set of containers inside a multi-container endpoint, use the `sagemaker:TargetContainerHostname` IAM condition key. The following policies show how to limit calls to specific containers within an endpoint.

The following policy allows `invoke_endpoint` requests only when the value of the `TargetContainerHostname` field matches one of the specified regular expressions.

```json
{
    "Version": "2012-10-17",
```
The following policy denies `invoke_endpoint` requests when the value of the
TargetContainerHostname field matches one of the specified regular expressions in the Deny
statement.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "sagemaker:InvokeEndpoint"
      ],
      "Effect": "Allow",
      "Condition": {
        "StringLike": {
          "sagemaker:TargetContainerHostname": ["customIps*", "common*" ]
        }`)
    },
    {
      "Action": [
        "sagemaker:InvokeEndpoint"
      ],
      "Effect": "Deny",
      "Condition": {
        "StringLike": {
          "sagemaker:TargetContainerHostname": ["special*" ]
        }
      }
    }
  ]
}
```

For information about SageMaker condition keys, see `Condition Keys for SageMaker` in the `AWS Identity and Access Management User Guide`.

### Metrics for multi-container endpoints with direct invocation

In addition to the endpoint metrics that are listed in `Monitor Amazon SageMaker with Amazon CloudWatch (p. 2624)`, SageMaker also provides per-container metrics.

Per-container metrics for multi-container endpoints with direct invocation are located in CloudWatch and categorized into two namespaces: `AWS/SageMaker` and `aws/sagemaker/Endpoints`. The `AWS/SageMaker` namespace includes invocation-related metrics, and the `aws/sagemaker/Endpoints` namespace includes memory and CPU utilization metrics.
The following table lists the per-container metrics for multi-container endpoints with direct invocation. All the metrics use the [EndpointName, VariantName, ContainerName] dimension, which filters metrics at a specific endpoint, for a specific variant and corresponding to a specific container. These metrics share the same metric names as those for inference pipelines, but at a per-container level [EndpointName, VariantName, ContainerName].

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Dimension</th>
<th>NameSpace</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocations</td>
<td>The number of InvokeEndpoint requests sent to a container inside an endpoint. To get the total number of requests sent to that container, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>Invocation4XX Errors</td>
<td>The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for on a specific container. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>Invocation5XX Errors</td>
<td>The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for on a specific container. For each 5xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>ContainerLatency</td>
<td>The time it took for the target container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average,</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead. OverheadLatency is measured from the time that SageMaker receives the request until it returns a response to the client, minus the ModelLatency. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU units that are used by each container running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For endpoints with direct invocation, the number of CPUUtilization metrics equals the number of containers in that endpoint. Units: Percent</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
MemoryUtilization

The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as CPUUtilization, in endpoints with direct invocation, the number of MemoryUtilization metrics equals the number of containers in that endpoint. Units: Percent

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Dimension</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MemoryUtilization</td>
<td>The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as CPUUtilization, in endpoints with direct invocation, the number of MemoryUtilization metrics equals the number of containers in that endpoint. Units: Percent.</td>
<td>[EndpointName, VariantName, ContainerName]</td>
<td>aws/sagemaker/Endpoints</td>
</tr>
</tbody>
</table>

All the metrics in the previous table are specific to multi-container endpoints with direct invocation. Besides these special per-container metrics, there are also metrics at the variant level with dimension [EndpointName, VariantName] for all the metrics in the table except ContainerLatency.

### Autoscale multi-container endpoints

If you want to configure automatic scaling for a multi-container endpoint using the `InvocationsPerInstance` metric, we recommend that the model in each container exhibits similar CPU utilization and latency on each inference request. This is recommended because if traffic to the multi-container endpoint shifts from a high CPU utilization model to a low CPU utilization model, but the overall call volume remains the same, the endpoint does not scale out and there may not be enough instances to handle all the requests to the high CPU utilization model. For information about automatically scaling endpoints, see [Automatically Scale Amazon SageMaker Models](p. 2004).

### Troubleshoot multi-container endpoints

The following sections can help you troubleshoot errors with multi-container endpoints.

#### Ping Health Check Errors

With multiple containers, endpoint memory and CPU are under higher pressure during endpoint creation. Specifically, the MemoryUtilization and CPUUtilization metrics are higher than for single-container endpoints, because utilization pressure is proportional to the number of containers. Because of this, we recommend that you choose instance types with enough memory and CPU to ensure that there is enough memory on the instance to have all the models loaded (the same guidance applies to deploying an inference pipeline). Otherwise, your endpoint creation might fail with an error such as XXX did not pass the ping health check.

#### Missing accept-bind-to-port=true Docker label

The containers in a multi-container endpoints listen on the port specified in the `SAGEMAKER_BIND_TO_PORT` environment variable instead of port 8080. When a container runs in a multi-container endpoint, SageMaker automatically provides this environment variable to the container. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```bash
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```
Otherwise, you will see an error message such as **Your Ecr Image XXX does not contain required com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true Docker label(s).**

If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format `xxxx-yyyy`, where `xxxx` and `yyyy` are multi-digit integers. SageMaker provides this value automatically when you run the container in a multi-container endpoint.

## Deploy an Inference Pipeline

An **inference pipeline** is a Amazon SageMaker model that is composed of a linear sequence of two to fifteen containers that process requests for inferences on data. You use an inference pipeline to define and deploy any combination of pretrained SageMaker built-in algorithms and your own custom algorithms packaged in Docker containers. You can use an inference pipeline to combine preprocessing, predictions, and post-processing data science tasks. Inference pipelines are fully managed.

You can add SageMaker Spark ML Serving and scikit-learn containers that reuse the data transformers developed for training models. The entire assembled inference pipeline can be considered as a SageMaker model that you can use to make either real-time predictions or to process batch transforms directly without any external preprocessing.

Within an inference pipeline model, SageMaker handles invocations as a sequence of HTTP requests. The first container in the pipeline handles the initial request, then the intermediate response is sent as a request to the second container, and so on, for each container in the pipeline. SageMaker returns the final response to the client.

When you deploy the pipeline model, SageMaker installs and runs all of the containers on each Amazon Elastic Compute Cloud (Amazon EC2) instance in the endpoint or transform job. Feature processing and inferences run with low latency because the containers are co-located on the same EC2 instances. You define the containers for a pipeline model using the `CreateModel` operation or from the console. Instead of setting one `PrimaryContainer`, you use the `Containers` parameter to set the containers that make up the pipeline. You also specify the order in which the containers are executed.

A pipeline model is immutable, but you can update an inference pipeline by deploying a new one using the `UpdateEndpoint` operation. This modularity supports greater flexibility during experimentation.

For information on how to create an inference pipeline with the SageMaker model registry, see **Register and Deploy Models with Model Registry** (p. 2075).

There are no additional costs for using this feature. You pay only for the instances running on an endpoint.

**Topics**
- Sample Notebooks for Inference Pipelines (p. 1990)
- Feature Processing with Spark ML and Scikit-learn (p. 1991)
- Create a Pipeline Model (p. 1992)
- Run Real-time Predictions with an Inference Pipeline (p. 1994)
- Run Batch Transforms with Inference Pipelines (p. 1996)
- Inference Pipeline Logs and Metrics (p. 1997)
- Troubleshoot Inference Pipelines (p. 2002)

**Sample Notebooks for Inference Pipelines**

For a sample notebook that uploads and processes a dataset, trains a model, and builds a pipeline model, see the **Inference Pipelines with Spark ML and XGBoost on Abalone** notebook. This notebook
shows how you can build your machine learning pipeline by using Spark feature Transformers and the
SageMaker XGBoost algorithm. After training the model, the sample shows how to deploy the pipeline
(feature Transformer and XGBoost) for real-time predictions and also performs a batch transform job
using the same pipeline.

For an example that shows how to do both pre-processing and post-processing by using an inference
pipeline, see Deploy Apache Spark pre-processing and post-processing with XGBoost for real-time
prediction requests in Amazon SageMaker using Inference Pipelines

For more examples that show how to create and deploy inference pipelines, see the Inference
Pipelines with SparkML and BlazingText on DBPedia and Training using SparkML on EMR and hosting
on SageMaker sample notebooks. For instructions on creating and accessing Jupyter notebook
instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook
instances (p. 139).

To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the
SageMaker Examples tab. There are three inference pipeline notebooks. The first two inference pipeline
notebooks just described are located in the advanced_functionality folder and the third notebook
is in the sagemaker-python-sdk folder. To open a notebook, choose its Use tab, then choose Create
copy.

**Feature Processing with Spark ML and Scikit-learn**

Before training a model with either Amazon SageMaker built-in algorithms or custom algorithms, you
can use Spark and scikit-learn preprocessors to transform your data and engineer features.

**Feature Processing with Spark ML**

You can run Spark ML jobs with AWS Glue, a serverless ETL (extract, transform, load) service, from your
SageMaker notebook. You can also connect to existing EMR clusters to run Spark ML jobs with Amazon
EMR. To do this, you need an AWS Identity and Access Management (IAM) role that grants permission for
making calls from your SageMaker notebook to AWS Glue.

**Note**

To see which Python and Spark versions AWS Glue supports, refer to AWS Glue Release Notes.

After engineering features, you package and serialize Spark ML jobs with MLeap into MLeap containers
that you can add to an inference pipeline. You don't need to use externally managed Spark clusters.
With this approach, you can seamlessly scale from a sample of rows to terabytes of data. The same
transformers work for both training and inference, so you don't need to duplicate preprocessing and
feature engineering logic or develop a one-time solution to make the models persist. With inference
pipelines, you don't need to maintain outside infrastructure, and you can make predictions directly from
data inputs.

When you run a Spark ML job on AWS Glue, a Spark ML pipeline is serialized into MLeap format. Then,
you can use the job with the SparkML Model Serving Container in a SageMaker Inference Pipeline. MLeap
is a serialization format and execution engine for machine learning pipelines. It supports Spark, Scikit-
learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap
Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime
to power real-time API services.

**Feature Processing with Scikit-Learn**

You can run and package scikit-learn jobs into containers directly in Amazon SageMaker. For an example
of Python code for building a scikit-learn featurizer model that trains on Fisher's Iris flower data set and
predicts the species of Iris based on morphological measurements, see IRIS Training and Prediction with
Sagemaker Scikit-learn.
Create a Pipeline Model

To create a pipeline model that can be deployed to an endpoint or used for a batch transform job, use the Amazon SageMaker console or the `CreateModel` operation.

**To create an inference pipeline (console)**

2. Choose **Models**, and then choose **Create models** from the **Inference** group.
3. On the **Create model** page, provide a model name, choose an IAM role, and, if you want to use a private VPC, specify VPC values.

4. To add information about the containers in the inference pipeline, choose **Add container**, then choose **Next**.

5. Complete the fields for each container in the order that you want to execute them, up to the maximum of fifteen. Complete the **Container input options**, **Location of inference code image**, and, optionally, **Location of model artifacts**, **Container host name**, and **Environmental variables** fields.
Container definition 1

Container input options
- Provide model artifacts and inference image.

Provide model artifacts and inference image
- Location of inference code image
  The registry path where the inference code image is stored in Amazon ECR.
  123456789012.dkr.ecr.us-east-2.amazonaws.com/myimagev1
- Location of model artifacts - optional
  The URL for the S3 location where model artifacts are stored.
  s3://bucket/path-to-your-data/
  The path must point to a single gzip-compressed tar archive (*.tar.gz suffix).
- Container host name - optional
  The DNS host name for the container.

Environment variables - optional
- Key: value
  key1: value1
  key2: value2

Container definition 2 - optional

Container input options
- Provide model artifacts and inference image.

Provide model artifacts and inference image
- Location of inference code image
  The registry path where the inference code image is stored in Amazon ECR.
  123456789012.dkr.ecr.us-east-2.amazonaws.com/myimagev1
- Location of model artifacts - optional
  The URL for the S3 location where model artifacts are stored.
  s3://bucket/path-to-your-data/
  The path must point to a single gzip-compressed tar archive (*.tar.gz suffix).
- Container host name - optional
  The DNS host name for the container.

Environment variables - optional
- Key: value
  key3: value3

Container definition 3 - optional

Container input options
- Provide model artifacts and inference image.

Provide model artifacts and inference image
- Location of inference code image
  The registry path where the inference code image is stored in Amazon ECR.
  123456789012.dkr.ecr.us-east-2.amazonaws.com/myimagev1
The **MyInferencePipelineModel** page summarizes the settings for the containers that provide input for the model. If you provided the environment variables in a corresponding container definition, SageMaker shows them in the **Environment variables** field.

### Run Real-time Predictions with an Inference Pipeline

You can use trained models in an inference pipeline to make real-time predictions directly without performing external preprocessing. When you configure the pipeline, you can choose to use the built-in feature transformers already available in Amazon SageMaker. Or, you can implement your own transformation logic using just a few lines of scikit-learn or Spark code.

**MLeap**, a serialization format and execution engine for machine learning pipelines, supports Spark, scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

The containers in a pipeline listen on the port specified in the **SAGEMAKER_BIND_TO_PORT** environment variable (instead of 8080). When running in an inference pipeline, SageMaker automatically provides this environment variable to containers. If this environment variable isn't present, containers default to using 1994.
port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format "XXXX-YYYY", where XXXX and YYYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multicontainer pipeline.

**Note**
To use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (Amazon ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2002).

### Create and Deploy an Inference Pipeline Endpoint

The following code creates and deploys a real-time inference pipeline model with SparkML and XGBoost models in series using the SageMaker SDK.

```python
from sagemaker.model import Model
from sagemaker.pipeline_model import PipelineModel
from sagemaker.sparkml.model import SparkMLModel

sparkml_data = 's3://{}/{}/{}'.format(s3_model_bucket, s3_model_key_prefix, 'model.tar.gz')
sparkml_model = SparkMLModel(model_data=sparkml_data)
xgb_model = Model(model_data=xgb_model.model_data, image=training_image)

model_name = 'serial-inference-' + timestamp_prefix
endpoint_name = 'serial-inference-ep-' + timestamp_prefix
sm_model = PipelineModel(name=model_name, role=role, models=[sparkml_model, xgb_model])
sm_model.deploy(initial_instance_count=1, instance_type='ml.c4.xlarge', endpoint_name=endpoint_name)
```

### Request Real-Time Inference from an Inference Pipeline Endpoint

The following example shows how to make real-time predictions by calling an inference endpoint and passing a request payload in JSON format:

```python
import sagemaker
from sagemaker.predictor import json_serializer, json_deserializer, Predictor

payload = {
    "input": [
    {
        "name": "Pclass",
        "type": "float",
        "val": "1.0"
    },
    {
        "name": "Embarked",
        "type": "string",
        "val": "Q"
    },
    {
        "name": "Age",
        "type": "double",
        "val": "48.0"
    }
]
```

1995
"name": "Fare",
"type": "double",
"val": "100.67"
},
{
"name": "SibSp",
"type": "double",
"val": "1.0"
},
{
"name": "Sex",
"type": "string",
"val": "male"
}
}
"output": {
"name": "features",
"type": "double",
"struct": "vector"
}

predictor = Predictor(endpoint=endpoint_name, sagemaker_session=sagemaker.Session(),
serializer=json_serializer, content_type='text/csv', accept='application/json'
print(predictor.predict(payload))

The response you get from `predictor.predict(payload)` is the model's inference result.

**Realtime inference pipeline example**

You can run this example notebook using the SKLearn predictor that shows how to deploy an endpoint, run an inference request, then deserialize the response. Find this notebook and more examples in the Amazon SageMaker example GitHub repository.

**Run Batch Transforms with Inference Pipelines**

To get inferences on an entire dataset you run a batch transform on a trained model. To run inferences on a full dataset, you can use the same inference pipeline model created and deployed to an endpoint for real-time processing in a batch transform job. To run a batch transform job in a pipeline, you download the input data from Amazon S3 and send it in one or more HTTP requests to the inference pipeline model. For an example that shows how to prepare data for a batch transform, see the "Preparing Data for Batch Transform" section of the ML Pipeline with SparkML and XGBoost - Training and Inference sample notebook. For information about Amazon SageMaker batch transforms, see Get Inferences for an Entire Dataset with Batch Transform (p. 11).

**Note**

To use custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2002).

The following example shows how to run a transform job using the Amazon SageMaker Python SDK. In this example, `model_name` is the inference pipeline that combines SparkML and XGBoost models (created in previous examples). The Amazon S3 location specified by `input_data_path` contains the input data, in CSV format, to be downloaded and sent to the Spark ML model. After the transform job has finished, the Amazon S3 location specified by `output_data_path` contains the output data returned by the XGBoost model in CSV format.

```python
import sagemaker
input_data_path = 's3:////{}/{}'.format(default_bucket, 'key', 'file_name')
```
Inference Pipeline Logs and Metrics

Monitoring is important for maintaining the reliability, availability, and performance of Amazon SageMaker resources. To monitor and troubleshoot inference pipeline performance, use Amazon CloudWatch logs and error messages. For information about the monitoring tools that SageMaker provides, see Monitor Amazon SageMaker (p. 2624).

Use Metrics to Monitor Multi-container Models

To monitor the multi-container models in Inference Pipelines, use Amazon CloudWatch. CloudWatch collects raw data and processes it into readable, near real-time metrics. SageMaker training jobs and endpoints write CloudWatch metrics and logs in the AWS/SageMaker namespace.

The following tables list the metrics and dimensions for the following:

- Endpoint invocations
- Training jobs, batch transform jobs, and endpoint instances

A *dimension* is a name/value pair that uniquely identifies a metric. You can assign up to 10 dimensions to a metric. For more information on monitoring with CloudWatch, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 2624).

Endpoint Invocation Metrics

The AWS/SageMaker namespace includes the following request metrics from calls to `InvokeEndpoint`.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of <code>InvokeEndpoint</code> requests that the model returned a 4xx HTTP response code for. For each 4xx response, SageMaker sends a 1.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Invocation5XXErrors</td>
<td>The number of <code>InvokeEndpoint</code> requests that the model returned a 5xx HTTP response code for. For each 5xx response, SageMaker sends a 1.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
</tbody>
</table>
# Metric Description

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocations</td>
<td>The number of <code>InvokeEndpoint</code> requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count</td>
</tr>
<tr>
<td>InvocationsPerInstance</td>
<td>The number of endpoint invocations sent to a model, normalized by <code>InstanceCount</code> in each <code>ProductionVariant</code>. SageMaker sends 1/<code>numberOfInstances</code> as the value for each request, where <code>numberOfInstances</code> is the number of active instances for the <code>ProductionVariant</code> at the endpoint at the time of the request. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td>ModelLatency</td>
<td>The time the model or models took to respond. This includes the time it took to send the request, to fetch the response from the model container, and to complete the inference in the container. <code>ModelLatency</code> is the total time taken by all containers in an inference pipeline. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead. <code>OverheadLatency</code> is measured from the time that SageMaker receives the request until it returns a response to the client, minus the <code>ModelLatency</code>. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ContainerLatency</td>
<td>The time it took for an Inference Pipelines container to respond as viewed from SageMaker. <code>ContainerLatency</code> includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

## Dimensions for Endpoint Invocation Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName, ContainerName</td>
<td>Filters endpoint invocation metrics for a <code>ProductionVariant</code> at the specified endpoint and for the specified variant.</td>
</tr>
</tbody>
</table>
For an inference pipeline endpoint, CloudWatch lists per-container latency metrics in your account as **Endpoint Container Metrics** and **Endpoint Variant Metrics** in the **SageMaker** namespace, as follows. The **ContainerLatency** metric appears only for inferences pipelines.

For each endpoint and each container, latency metrics display names for the container, endpoint, variant, and metric.

### Training Job, Batch Transform Job, and Endpoint Instance Metrics

The namespaces /aws/sagemaker/TrainingJobs, /aws/sagemaker/TransformJobs, and /aws/sagemaker/Endpoints include the following metrics for training jobs and endpoint instances.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
</table>
| CPUUtilization     | The percentage of CPU units that are used by the containers running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%.

  For training jobs, CPUUtilization is the CPU utilization of the algorithm container running on the instance.

  For batch transform jobs, CPUUtilization is the CPU utilization of the transform container running on the instance.

  For multi-container models, CPUUtilization is the sum of CPU utilization by all containers running on the instance.

  For endpoint variants, CPUUtilization is the sum of CPU utilization by all of the containers running on the instance.

  Units: Percent |
| MemoryUtilization  | The percentage of memory that is used by the containers running on an instance. This value ranges from 0% to 100%.

  For training jobs, MemoryUtilization is the memory used by the algorithm container running on the instance.

  For batch transform jobs, MemoryUtilization is the memory used by the transform container running on the instance.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MemoryUtilization</td>
<td>For multi-container models, MemoryUtilization is the sum of memory used by all containers running on the instance. For endpoint variants, MemoryUtilization is the sum of memory used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>GPUUtilization</td>
<td>The percentage of GPU units that are used by the containers running on an instance. GPUUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, GPUUtilization is the GPU used by the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, GPUUtilization is the GPU used by the transform container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For multi-container models, GPUUtilization is the sum of GPU used by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, GPUUtilization is the sum of GPU used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>GPUMemoryUtilization</td>
<td>The percentage of GPU memory used by the containers running on an instance. GPUMemoryUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUMemoryUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, GPUMemoryUtilization is the GPU memory used by the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, GPUMemoryUtilization is the GPU memory used by the transform container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For multi-container models, GPUMemoryUtilization is sum of GPU used by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, GPUMemoryUtilization is the sum of the GPU memory used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>DiskUtilization</td>
<td>The percentage of disk space used by the containers running on an instance. DiskUtilization ranges from 0% to 100%. This metric is not supported for batch transform jobs.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, DiskUtilization is the disk space used by the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, DiskUtilization is the sum of the disk space used by all of the provided containers running on the instance.</td>
</tr>
<tr>

</table>
Dimensions for Training Job, Batch Transform Job, and Endpoint Instance Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
</table>
| Host      | For training jobs, Host has the format `[training-job-name]/algo-[instance-number-in-cluster]`. Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the `/aws/sagemaker/TrainingJobs` namespace.  
For batch transform jobs, Host has the format `[transform-job-name]/[instance-id]`. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the `/aws/sagemaker/TransformJobs` namespace.  
For endpoints, Host has the format `[endpoint-name]/[production-variant-name]/[instance-id]`. Use this dimension to filter instance metrics for the specified endpoint, variant, and instance. This dimension format is present only in the `/aws/sagemaker/Endpoints` namespace. |

To help you debug your training jobs, endpoints, and notebook instance lifecycle configurations, SageMaker also sends anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to `stdout` or `stderr` to Amazon CloudWatch Logs. You can use this information for debugging and to analyze progress.

Use Logs to Monitor an Inference Pipeline

The following table lists the log groups and log streams SageMaker sends to Amazon CloudWatch.

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

Logs

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Stream Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/sagemaker/</td>
<td>[training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]</td>
</tr>
<tr>
<td>TrainingJobs</td>
<td></td>
</tr>
<tr>
<td>/aws/sagemaker/</td>
<td>[production-variant-name]/[instance-id]</td>
</tr>
<tr>
<td>Endpoints/</td>
<td></td>
</tr>
<tr>
<td>[EndpointName]</td>
<td>[production-variant-name]/[instance-id]</td>
</tr>
<tr>
<td></td>
<td>[production-variant-name]/[instance-id]/[container-name provided in the SageMaker model] (For Inference Pipelines) For Inference Pipelines logs, if you don't provide container names, CloudWatch uses &quot;container-1, container-2&quot;, and so on, in the order that containers are provided in the model.</td>
</tr>
<tr>
<td>/aws/sagemaker/</td>
<td>[notebook-instance-name]/[LifecycleConfigHook]</td>
</tr>
<tr>
<td>NotebookInstances</td>
<td></td>
</tr>
<tr>
<td>/aws/sagemaker/</td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]</td>
</tr>
<tr>
<td>TransformJobs</td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/data-log</td>
</tr>
<tr>
<td>Log Group Name</td>
<td>Log Stream Name</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in the SageMaker model] (For Inference Pipelines)</td>
<td>For Inference Pipelines logs, if you don't provide container names, CloudWatch uses <strong>container-1, container-2</strong>, and so on, in the order that containers are provided in the model.</td>
</tr>
</tbody>
</table>

**Note**

SageMaker creates the /aws/sagemaker/NotebookInstances log group when you create a notebook instance with a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 145).

For more information about SageMaker logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 2635).

**Troubleshoot Inference Pipelines**

To troubleshoot inference pipeline issues, use CloudWatch logs and error messages. If you are using custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you might also encounter permissions problems. To grant the required permissions, create an Amazon Elastic Container Registry (Amazon ECR) policy.

**Topics**

- Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2002)
- Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines (p. 2002)
- Use Error Messages to Troubleshoot Inference Pipelines (p. 2003)

**Troubleshoot Amazon ECR Permissions for Inference Pipelines**

When you use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon ECR policy. The policy allows your Amazon ECR repository to grant permission for SageMaker to pull the image. The policy must add the following permissions:

```json
{
  "Version": "2008-10-17",
  "Statement": [
    {
      "Sid": "allowSageMakerToPull",
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": [
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage",
        "ecr:BatchCheckLayerAvailability"
      ]
    }
  ]
}
```

**Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines**

SageMaker publishes the container logs for endpoints that deploy an inference pipeline to Amazon CloudWatch at the following path for each container.
For example, logs for this endpoint are published to the following log groups and streams:

<table>
<thead>
<tr>
<th>EndpointName: MyInferencePipelinesEndpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variant: MyInferencePipelinesVariant</td>
</tr>
<tr>
<td>InstanceId: i-0179208609ff7e488</td>
</tr>
<tr>
<td>ContainerHostname: MyContainerName1 and MyContainerName2</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>logGroup: /aws/sagemaker/Endpoints/MyInferencePipelinesEndpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName1</td>
</tr>
<tr>
<td>logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName2</td>
</tr>
</tbody>
</table>

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

**To see the log groups and streams**

2. In the navigation page, choose Logs.
3. In Log Groups, filter on MyInferencePipelinesEndpoint:

4. To see the log streams, on the CloudWatch Log Groups page, choose MyInferencePipelinesEndpoint, and then Search Log Group.
